The waste *Manila elemi* oil was subjected to fractional distillation under reduced pressure. Optimum conditions of limonene extraction was obtained at a temperature of 43+5oC and pressure of 15 inHg. IR and GC analyses were performed to determine the qualitative and quantitative properties of the distillates. The IR spectrum of limonene-rich distillate exhibited distinct similarity with commercial limonene isolated from citrus peel. Analysis of the limonene-rich faction using GC showed that the distillate contains 88.5% limonene. Further purification of the limonene-rich fraction was done by passing it through column using hexane as solvent. Hexane was recovered by rotary evaporation under vacuum. The purified limonene was utilized as component of spray-type air freshener. The experimental air freshener had coefficient of volatility similar with the commercial limonene prepared. *Manila elemi* oil is a promising source of limonene which the Philippines has an abundant and steady supply for the last two decades. Importation of orange and lemon oil for medicine and perfumery of 2.5M US $ could be reduced with the utilization of locally available limonene from *Manila elemi* oil, hence help conserve dollar reserves.

Note: An improvement in the process of extraction was conducted as follow-up to the previous study to produce limonene from the resin of higher purity, thus a limonene content of 88.5% was achieved compared with the previous 74%.

Supercritical Extraction of Wood: A New Way to Utilize Wood for High-priced Chemicals or Energy

Xueren Qian, Li Jian
Northeast Forestry University, 238#, 150040 Harbin, China
Email: qwwang@mail.hr.hl.cn

Man is facing a severe challenge with the population explosion, natural resources decreasing day by day and steady increase in society needs for chemicals and energy. Reserves of the fossil resources oil, gas and coal are limited, their exploitation and utilization can cause environmental pollution, and their supply is not reliable because of the influence of world political situation. Therefore, the production of chemicals and energy from renewable resources (e.g. wood) to replace expensive energy and petrochemicals from exhausted reserves of the fossil resources has been a forward and heated subject.

The extraction of wood with supercritical fluids has been receiving considerable attention for conversion of wood, the potential industrial applications are extraction of biomass as a source of organic chemicals or fuels. The extraction of some Chinese woods with sub- and supercritical ethanol or ethanol-water mixtures has been investigated in a semi-continuous apparatus and a batch autoclave apparatus for the purpose of wood conversion to chemicals or energy. In this paper, the following contents will be discussed: (1) the introductory remarks of wood conversion by supercritical fluid extraction; (2) the recent development of wood supercritical extraction; (3) the main engineering problems in the supercritical extraction of wood; (4) conclusion and suggestion.

Stem Oleoresin Yield as Influenced by Needle Characteristics and Effect of Tapping on Growth of Chir Pine (*Pinus roxburghii* Sargent) Trees in Himachal Pradesh

Kulwant Rai Sharma, G. Murtem and A.N. Kaushal
Dr. Y.S. Parmar University of Horticulture and Social Sciences, Department of Forest Products, Post Box # Nauni- 173, 230 Solan, India
Tel: 1792 52495 (o), FAX: +91-1792 52242, Email: fpu@yspuhf.hp.nic.in

The oleoresin industry in Himachal Pradesh (India) is based on suitable and renewable pine resources and the various operations are labour intensive, which offer employment to the rural people. At present, only chir pine (*Pinus roxburghii* Sargent) is being tapped but there is also a great potential to tap other indigenous or exotic pines. The exudation of resin is substantially influenced by various physical and technical factors and a score of scientific experiments have been conducted to develop a suitable approach in the tapping of trees. The need now is the application of the established scientific principles in the field. The fluctuation in oleoresin yield has created shortages in this commodity, which have to be met by imports thereby affecting the balance of trade of the country. India has become a net importer of both rosin and turpentine because of the shortfall in production due to the damage done to the trees by the use of incorrectly applied methods. The availability of an adequate number of mature pine trees is a fundamental requirement for smooth running of the oleoresin tapping work which, in turn, affect the downstream industries. The plantations are to be raised solely for oleoresin production by exploiting the indicators, which determine the natural variability in oleoresin production.

The present investigations were conducted to find out the influence of needle characteristics on the oleoresin yield and also to identify the needle colour markers for high oleoresin yield. The effect of tapping on the growth of trees is also a contentious issue and needs long term experimentation to determine its influence conclusively.

Thirty needles each were collected from bottom, middle and top of the tree crown and their average diameter and length were recorded. In total, 262 trees were tapped. The needle colour was compared with the colour chart of Royal Horticultural Society, Kew and four colour classes viz. Dark Green, Green, Yellow-Green and Yellow were identified. A simple correlation coefficient was worked out between needle diameter, needle length and oleoresin yield. A Chi-Square test was performed to find out the association between needle colour and oleoresin yielding capability (high, medium and low) of the trees. A 't' test was then used to test the significance of difference in subsequent growth rates of the tapped and untapped trees as measured by the incremental increase in diameter.

The diameter and length of needle were found to be positively and significantly correlated with oleoresin yield. The trees with Dark Green, Green and Yellow needle colouration were found to be in the higher resin yielding class than that expected in general. The trees with Yellow-Green needle colour were lower resin yielders than that expected in the high and medium resin yielding classes. It was found that this characteristic produced a greater number of trees in low resin yielding class than expected.

The mean diameter increment during 5-years (1993-1998) of tapping was 5.06cm for tapped trees compared with 7.80cm for untapped trees. The height increment was not found to be significant.

The needle characteristics on oleoresin yield exhibited significant effect. All needle colours except Yellow-Green produced higher oleoresin. The tapping of trees for five years have shown a significant effect on the diameter increment. The tapped trees grew slower than the untapped trees. The height increment showed no correlation possibly might be due to the fact that the trees had already reached the maturity stage.

Bioconversion of Agro-forestry wastes by Gamma Irradiation Treatments and Fungal Fermentations

Le Xuan Tham, Nguyen Duy Hang, Tran Huu Do, Hoang Thi Linh, Nguyen Duy Lam and Tamikazu Kume
Vietnam Atomic Energy Commission, Nuclear Research Institute, Dalat, Vietnam
FAX: 84-63-821107, Email: thamdala@hcm.vnn.vn

Utilizing and upgrading lignocellulosic wastes and by-products into more useful end-products may be one potential solution, necessary to recycle the forestry-agricultural resources and also to reduce the environmental pollutions, due to discarding, incinerating or under-utilizing them. Kume et al. (1998) have outlined. The Bilateral Program Kapan-Malaysia on Upgrading Cellulosic wastes by Radiation Technology and Biotechnology, mainly on conversion of irradiated oil palm fibres into animal feed by fermentation with Oyster mushroom *Pleurotus* spp. In Vietnam, large amounts of lignocellulosic wastes from forestry-agricultural productions were estimated approximately 90 million tons per annum or more, that requires actually to be rationally treated.

Our present studies were carried out on lignocellulosic substrates mixed with some kinds of wastes from fermentic and latex processing industries, irradiated with X rays of ^{60}Co and then fermented with various edible and medicinal mushrooms, able effectively wood-decaying, such as *Ganoderma* spp, *Amauroderma* spp., *Pleurotus spp*., *Auricularia* spp., *Trametes versicolor, Hericium erinaceum, Grifola frondosa, Schizophyllum commune, Lentinus edodes,* etc. Effects of microbial eliminations (initially contaminated bacteria and fungi) were confirmed at wide range of radiation doses (15-30 kGy) for substrates with sawdusts, sugar cane baggasse, rice straw, oil palm fibre and others.

Some changes of main components of basic polysaccharides and nitrogen sources in mixed substrates under irradiation and fungal fermentations have been examined to confirm effective conversions and assimilations of inorganic nitrogen into protein, particularly using ^{15}N tracer techniques. Biomass obtained by fungal fermentations would be used for animal feed production and spent composts were useful for biofertilizer production. Fruitful cultivations of wood-decaying mushrooms were promising and a Project for applications at large scales was suggested to contribute into expoitation of Industrial ^{60}Co Facility installed (February 1999) at Center of Radiation Technology in HoChi Minh City.

Do Environmental Values and Customer Opinions Effect on Fuel Choices in Power Companies?

Ritva Toivonen, Liisa Tahvanainen
Pellervo Economic Research Institute (PTT), Eerikinkatu 28, FIN-00180 Helsinki, Finland
Tel: +358-(0)9-3488844, FAX: +358-(0)9-34888500, Email: ritva.toivonen@ptt.fi

About 10-15 millions cubic meters of biomass, i.e., logging residues and small sized wood is available in Finlandïs forests annually. This wood biomass is suitable for energy production purposes, and its energy use is aimed to be increased in Finland. The Kyoto agreement from 1997 requires that CO_2-emissions should be reduced, and replacing fossil fuels with wood would clearly help Finland to reach this target. Increasing production of wood energy requires that power companies, in particular small to medium sized (SMS) companies, invest in new combustion capacity.

The purpose of this study was to describe the present use of biomass and the fuel choice criteria in the SMS power companies in Finland. Second aim is to describe the bioenergy and in particular wood energy related beliefs and investment plans of the SMS power companies management. The population of this survey study comprises 363 heating power companies having the maximum capacity of 40 MW. The data was collected in 1996 through a mail survey using structured questionnaire. The response rate was 43% (157 companies).

The results show that 30 respondent companies already used wood as their main fuel. The management in most respondent companies believed that use of biofuels will increase in the future, but they also assumed that subsidies will remain necessary to make biofuels competitive. About 20% of the respondent companies planned to start or increase their usage of wood within the next few years.

Factor analysis showed that on the background of the bioenergy attitudes of company management, there exists two major dimensions: A belief that 1) there exists insecurity related with biofuels, mainly due to unstable availability and quality, but that 1) the use of biofuels is beneficial for the society. The respondent companies emphasised especially strongly the environmental impacts in their fuel choices, even more strongly than customer needs. Environment was emphasised most strongly by companies located in the most heavily populated region and least by companies located in the most rarely populated region. But when relating various fuel choice criteria with fuel price, the relationship between price and technical suitability and availability of fuels seemed to matter most. The most ecologically oriented companies, however, found environmental impacts as more important than fuel price. The most market oriented companies emphasised customer needs as more important than price, which was also logical. It was generally believed that consumers support bioenergy production due to environmental reasons, but are reluctant to pay a price premium. Companies using wood were most assured that their customers support bioenergy, but few of these companies used bioenergy as a marketing argument.

The results of this study imply that SMS heating companies in Finland are investing to increase their heating generation capacity based on wood fuels. But these investment plans are small compared to the large potential of wood fuel usage in Finland. Environmental values seem to be fairly strongly emphasised by the SMS heating companies, and customers are generally believed to favour biofuels. However, emphasis on environment does not seem to be clearly reflected in the SMS heating companies actual fuel choices nor in marketing communication. Since major insecurity related with biofuel supply was a general belief in power companies, special effort should be put in securing stable availability and quality of wood biofuel in order to reach the potentially much larger markets of wood fuels. In addition, the SMS heating companies should put more effort in marketing of bioenergy since the companies believe that customers favour bioenergy. These efforts would probably benefit immediately at least those companies which already use wood as their main fuel.

The Extraction of Essential Oil from Indonesian Keruing (*Dipterocarpus*) Species

Bambang Wiyono
Forest Product Research and Development Center, Jl. Gunung Batu P.O. Box 184 Bogor, Indonesia
Telephone: 62-0251-326378, Fax: 62-0251-313613, E-mail: Bambangw@usim.or.id

Key words: Keruing wood, oleoresin, physical-chemical properties, essential oil, wood wastes, distillation technique

Woodworking or plywood industries which use keruing wood as their raw materials produce oleoresin and wood wastes that are not as yet utilized as raw material resources to produce Indonesian keruing oil.

The present study was conducted to determine the proper organic solvent to separate essential oil from the oleoresin and the effect of distillation techniques on the physical-chemical properties of essential oil.

The oleoresin, in the wood working industry, was separated from sortiments by soaking in 2 % boiling salt solution. It was then diluted in organic solvent consisting of petroleum ether and hexane with the ratios of oleoresin and solvent comprising 1 : 2, 1 : 3 and 1 : 4, respectively. The solution was centrifuged for 30 minutes and the removed supernatant was then evaporated until it became concentrated. The concentrated solution was added with enough water and afterwards the hydro-distillation was performed on the solution to separate keruing oil. Further, wood wastes, after being milled into small particles of 80 mesh size, were distilled using two methods, namely water and steam distillation, and water distillation, for 18, 24 and 30 hours, respectively. The obtained essential oils from both raw materials were then analyzed for their physical-chemical properties.

Results showed that the keruing oil yield separated from oleoresin was around 17,95 % (w/w) which had a 0.9735 –0.9771 specific gravity, a 1.4952 – 1.4989 refractive index, a –13.04 - -12.17 optical rotation, a 0.394 – 0.879 acid number, a 3.482 – 5.240 saponification number, and a 2.752 – 4.955 ester number, and a 1.013 – 3.910 % solvent residue. Both petroleum ether and hexane did not give a significant difference on oil yield and the properties of the oils. However, the ratios of oleoresin and solvent gave a significant difference on the specific gravity, saponification number and an ester number of the oils. The higher the oleoresin and solvent ratio, the lower the specific gravity, saponification number and ester number. Furthermore, compared to the water and steam distillation technique, the water distillation produced higher oil yield. The product had a 0.9111 – 0.9761 specific gravity, a 1.5022 – 1.5075 refractive index, and a 5.74 – 8.37 acid number.

The best condition to extract the essential oil from oleoresin is to use petroleum ether or hexane with a 1 : 4 ratio of oleoresin and solvent by volume. In terms of oil yield and simplicity, the water distillation technique is the better technique to produce keruing oil from wood wastes. This technique is suitable for producing keruing oil on a cottage industrial scale.

5.07.01 Fundamentals of wood carbonization

New Activated Carbon Produced from Olive Cakes by Steam Pyrolysis

A. Bacaoui, A. Yaacoubi, A. Dahbi and C. Bennouna
University of Cadi Ayyad, Faculty of Science-Semlalia, Department of Chemistry, B.P. 2390, Marrakech, Morocco
FAX: 212 4 43 74 08, Email: fssm.chim@cybernet.net.ma

The increased exploitation of forest for energy needs is accompanied by problems of deforestation and ecological unbalance. In Morocco, experts estimate indeed that between 15.000 and 40.000 ha of forests disappear each year. For these reasons, we have opted for the valorization of olive cakes, which are a cheap product, abundant and under used in Morocco, in order to prepare a new activated carbon and their use for adsorption of pollutants from liquid phases in water treatment.

To achieve this study, an experimental design, using a Doehlert matrix, has been carried out to study the effect of temperature and activation time on the preparation of activated carbon. The choice of the Doehlert matrix is justified by a number of advantages such as:(i) the possibility of presenting a uniform distribution of experimental points in the space studied (ii) ability to explore the whole of the domain (extremes and internal field) (iii) usefulness of interpolating the response (iv) possibility of adding new factors without altering the quality of the matrix. The adsorption of iodine and methylene blue has been used as a primary indicator of the adsorption capacity of the activated carbons prepared. The choice of these molecules is justified by their properties. Thus, the mesopores of carbon are often studied by methylene blue adsorption and this also serves as a model compound for adsorption of organic contaminants from aqueous solution. The iodine molecule gives interesting information on the surface area contributed by pores larger than 1nm. All the pyrolysis reactions were performed in a thermolyne electric oven with a temperature control device linked to a thermocouple, a silice reactor and a water steam generator placed at the entrance of the reactor. At the end of the reaction, the oven was cooled to the ambient temperature. Activated carbon was recovered, boiled 30 min in distilled water, washed, ground and tested in water. The result obtained shows that:

- The experimental response studied varied between: 8.4-22.4% for the total yield, 131-396 mg/g for the adsorption of methylene blue and 778-1390 mg/g for the adsorption of iodine. In Morocco, the minimum required (for any activated carbon used in drinking water treatment) is 180 mg/g and 700 mg/g for methylene blue and iodine respectively.

- An increase in both temperature and activation time entails an opening and enlargement of pores, which enhances the adsorption of these molecules. The experimental conditions of preparation which permit a better adsorption of small molecules like iodine are those which also favor the adsorption of methylene blue.

- The interaction between activation time and activation temperature is important than the direct effect of each factor.

The response surface methodology using Doehlert's matrix is an appropriate tool to study optimization of the activation process to prepare activated carbons to be used in a given technological process.

The olive cakes are a good precursor for the production of activated carbons with interesting characteristics (great adsorption capacity.).

Keywords: activated carbon, olive cakes, pyrolysis, adsorption.

Comparison of Physico-chemical Properties of Charcoals Made from Australian Acacias with Charcoals Marketed Commercially in Abidjan

Brahima Coulibaly, Anna-Maria Mengolini
CIRAD, CNRA, Programme Bioénergie, 08 BP 33 Abidjan 08, Cote d'Ivoire
Tel: +225-44.28.58, FAX: +225-44.21.08, Email: dominique.louppe@cirad.fr

The city of Abidjan, to satisfy its household energy demand, will continue to need an assured supply of charcoal even though the government is trying to introduce a policy of substituting charcoal with gas, of which deposits exist in the country. The annual demand for charcoal is about 300.000 tonnes, produced from 5 million tonnes of wood. This demand is difficult to satisfy from remaining forest resources as the forests that in 1960 covered 15 million ha of the Ivory Coast had shrunk to only 2.5 million ha by 1998. In parallel with the introduction of policies favouring substitution of charcoal by gas it is essential, in the medium term, if not in the short term, also to develop a new biomass-energy resource. This resource could be developed quickly by using Australian Acacias, notably *Acacia mangium* and *Acacia auriculiformis* that are perfectly adapted to local conditions. These two leguminous species also contribute to the restoration of agricultural soils whose fertility has been exhausted.

The objectives of this study are, firstly, to determine if the age of a tree and/or its agro-ecological source has an influence on the characteristics of the charcoal produced from it and, secondly, to compare the quality of charcoal produced from the above two species with that of charcoal sold commercially in the city.

The first stage of the study concerned the carbonization under laboratory conditions of woods from trees of the two Acacia species aged 7 to 15 years old. Pyrolysis was carried out in a 100 litre retort oven, heated with gas. The charcoals produced were analysed to determine moisture content, specific gravity, calorific value, volatile matter, ash content and fixed carbon content.

In the second stage, we studied the quality of charcoals from these two species of Acacia, carbonised in metal ovens (of Magnien type) of 4 m^3 capacity. These were compared with charcoals sold commercially in the city of Abidjan. The samples of commercial charcoal were collected according to a predetermined sampling program.

Pyrolysis tests showed no effect of tree age on the quality of the resulting charcoal.

The specific gravity of the commercial charcoal ranged from 0.34 to 0.73. (Specific gravity affects the rate of charcoal combustion and is a useful predictor of charcoal quality.) Of the two Acacia species carbonised in the experimental kilns, *Acacia mangium* produced a charcoal of specific gravity 0.30, comparable to that of the poorest commercial charcoals. *Acacia auriculiformis* gave denser, better quality charcoals. With regard to ash contents, those of the experimentally obtained Acacia charcoals were less than 2%, while those for the commercial charcoals were 2 to 6%.

The charcoal products from the two Australian species studied are of a quality that, in theory, should be acceptable to consumers in the city of Abidjan. These Acacias, in addition, improve the quality of soils. Encouraging their introduction in the agricultural areas in the south of the Ivory Coast would help supply the energy demands of Abidjan's households while regenerating the exhausted soils and also creating additional income for farmers.

Keywords: *Acacia mangium*, *Acacia auriculiformis*, carbonization, charcoal, energy supply, Abidjan, Ivory Coast.

Potential Application of Light Briquette Manufacture Method for Charcoal Production

Gradimir Danon, Bujanovic Biljana and Matic Ljubica
University of Belgrade, Faculty of Forestry, Kneza Viseslava 1, YU11030 Belgrade, Yugoslavia
Email: danon@altavista.net

Recently we have developed new method of light briquette production from lignocellulosic waste materials of different origin, regardless of moisture content. Cohesiveness of the light briquette is achieved by the addition of recycled paper waste. Low-pressure application (3-5 bar) proved to be satisfactory for briquette formation. The light briquettes are characterized with high porosity and therefore low density. The light briquette structure does not decline upon moisture absorption or water suction, the problem commonly associated with the wood briquettes produced by conventional methods.

The two methods of enhancement of light briquettes heat characteristics are developed. The first series of enriched light briquettes are obtained by addition of pulp of recycled paper (as adhesive) in charcoal fines in course of the procedure of briquette formation. Our further investigations are directed to the carbonization of light briquettes, what is the second method suggested for heat characteristics enhancement. Preliminary experiments indicate that the briquettes maintain form and consistency upon carbonization, which could open new area of light briquette application.

Process of carbonization was carried on in the laboratory retort without air presence at 500 0C for three hours. Volatile content and charcoal were determined by JUS.B X8.317 method by annealing the briquette samples at the temperature of 900 C, during 7 minutes, without the presence of air. Ash content of investigated briquette samples was determined by the method TAPPI T 15 wd-80 by annealing the briquette samples at the temperature of 600-850°C during 1h. Higher heating values of investigated briquette samples were determined by standard method JUS.B X8.318 in the calorimetric bomb. Combustion characteristics of briquette samples were determined in the furnace of 3000W with maximum temperature up to 1000°C. The testing was carried out in the conditions of constant temperature in the furnace place repeated in the range between 425°C and 800°C, advancing at constant intervals.

The production of light briquettes characterized by different shapes and dimensions is provided during compression in mold. Charcoal produced from light briquettes and light briquettes produced from charcoal could be alternative to that produced by conventional method.

Briquettes made of charcoal fines and pulp could be used in households for cooking and for barbecues. This could be a way for better using of charcoal fines made during carbonization. Characteristics of briquette made from charcoal fines are presented in next table:

Density	Higher heating value	Volatiles	C-fix	Ash
kg/m^3	kJ/kg	%	%	%
450	28,000	21.4	62.8	5

Charcoal made by carbonizing of light-briquettes are made for production of activated charcoal and filters of all sizes and shapes. Characteristics of charcoal made from light briquettes are presented in next table:

Density	Yield	Volatiles	C-fix	Ash
kg/m3	%	%	%	%
104-143	28.2-37.8	17.8-18.0	72.38-74.78	7.25-9.78

C-fix content of charcoal produced by light briquette carbonization is lower than it is necessary for activation. By increasing temperature from 5000C to 6000C it is possible to increase C-fix content with simultaneous decrease of yield. Ash content is influenced by the way of waste gathering. The low density of charcoal is the consequences of high porosity of light briquettes. The dimensions of briquette samples were reduced significantly after carbonization (between 41 and 55%) but original shape was kept. The structure of carbonized light briquettes is gently and fragile what can be corrected by appropriate change of parameters of light briquette production process.

Novel Potentials of Chemical Activation and Carbonization of Biomass Components

G. Dobele, N. Bogdanovich, T. Dizhbite, G. Telysheva
Latvian State Institute of Wood Chemistry, 27, Dzerbenes St., LV-1006 Riga, Latvia
Tel: +371-7-545142, FAX: +371 7 310135, Email: ligno@edi.lv

Pyrolysis is a widely accepted method for utilization of wastes obtained after mechanical and chemical biomass conversion. It is known that inorganic substances as catalysts regulate the thermal transformation and permit the creation of solid products with desired properties. The present paper concerns the production of highly effective carbon and ferromagnetic carbon-mineral sorbents. These sorbents, which are able to preserve human environment, have been prepared by pyrolysis of biomass wastes using alkali metals and ferric salts as catalysts. A complex of investigations has been performed to try sodium compounds (NaOH, Na_2SO_4, Na_2CO_3) as chemical activators in the pyrolysis of various types of lignin-containing raw materials. The investigations are aimed at the production of effective carbon sorbents simultaneously with regeneration of inorganic substances. The use of standard energetic equipment in the sulfate pulp mills for the pyrolysis is proposed. It has been shown that in the presence of sodium hydroxide or sodium sulfate or sodium carbonate the formation of perfect microporous structure occurs regardless of the raw material (saw dust, bark, hydrolysis lignin, sulfite and sulfate liquors) without usage of gaseous activating agents. The volume of micro- and mesopores in the sorbents obtained exceeds 1.5 cm^3/g. The specific surface (determined by the BET method) is more than 2500 m^2/g. A mechanism for the catalytic action of sodium compounds has been found. It has been demonstrated that it is possible to obtain more than 20 types of active carbons by varying the parameters of prepyrolysis and thermochemical activation, and the amount of catalysts. The sorbents are different concerning the volume of micro- and mesopores and the physical properties (e.g., dispersity, density). By regulation of the process the application range of the sorbents are amplified. They can be used for purification and recuperation of gases, selective removing of admixtures from liquid media, etc. Ferric salts, which are used as catalysts in the processes of thermal gasification of organic raw materials, change the mechanism of redox reactions during the pyrolysis of biomass and the structure of the carbonized products. The conditions of a catalyst introduction (impregnation with the solutions of salts at various pH, removing of anions of ferric salts) and nature of the organic matrix (wood, cellulose, lignins, sewage sludge) are the main factors influencing the activity of the ferric ions during pyrolysis. The impregnation mode influences the redox properties of the catalysts system and the redistribution of paramagnetic centres, which determine the subsequent process of thermal destruction. Introduction of ferric salts into the organic matrix through ion exchange increases the reduction rate of iron, inhibits the formation of large pores and promotes the formation of microporous structure. A mechanism for heterogeneous interaction of the ferric ions with cellulose and lignins has been proposed. It has been demonstrated that there are differences in their reducing properties during the pyrolysis. Unlike the cubic form of iron resulted from carbonization of the cellulose systems, in the case of lignins the reduced iron is an oversaturated alpha-iron-carbon solid solution in the tetragonal form. Carbonized products obtained are highly ferromagnetic and have a well developed porous structure. The maximum magnetizability is 60 $A*m^2/kg$, the sorption activity by iodine equals 1200 mg/g, and the clarification capacity in terms of methylene blue is more than 400 mg/g. The possibility to remove the ferromagnetic sorbents from solid and liquid media in the magnetic field can be considered as an advantage over the other approaches.

Production and Testing of Charcoal Briquettes from *Pinus radiata* Wood Residues

Paul Fung, S. Ng, A. de Vos and V. Muruganathan
CSIRO Forestry and Forest Products, Private Bag 10, Clayton South MDC, 3169 Vic, Australia
Tel: +61-3-95452222, FAX: +613 9545 2448, Email: Paul.Fung@ffp.csiro.au

Production of sawn timber from *Pinus radiata* is an important sector in Australia. These sawmills are typically large with log throughputs of over 300,000 m^3/yr. Residues in the form of sawdust, bark and dockings are often used as fuel for timber drying but these are far in surplus to the mill's energy requirements. A project was undertaken to carbonise sawdust residues in a fluid bed carbonisation unit and to produce charcoal briquettes for cooking purposes. A test cell was designed and built to evaluate and monitor burning properties of briquettes, ignition tests, cooking temperatures and cooking times. Ignition tests showed that the test briquettes were easier to ignite than commercial briquettes using brown coal based charcoal with ignition 2.7 times faster. Combustion time and cooking temperatures was adequate for a normal cooking session. The pine char briquettes burnt for 2.3 hours, approximately half the time of the commercial briquettes measured at 4.1 hours. Maximum cooking temperature was 180°C measured 25mm above the briquette compared with 195°C for the commercial product. Drop tests and compressive strength tests on the briquettes were also conducted which showed that they could withstand the rugged treatment that normal handling and storage conditions generally require. Drop test onto a steel plate from a height of 1.8 m showed no breakage after 20 drops for all briquettes. Ultimate compressive strength measurements showed a value of 0.28 MPa for the pine briquettes compared with 0.21 MPa for the commercial briquettes.

Production of Activated Carbon from Palm Kernel Shells by Steam Activation

Hoi Why Kong
Forest Research Institute Malaysia, Kepong, 52109 Kuala Lumpur, Malaysia
Tel: +603-6342633, FAX: +603-6367753, Email: hoiwk@frim.gov.my

Palm kernel shells were carbonised in an indirect pyrolysis reactor to 750°C. The charcoal were then crushed, grind and sieved. Under intense heat and steam, the charcoal gradually turn into highly micro porous activated carbon. The granulated shell charcoal was then activated at 800°C in an atmosphere of superheated steam. It was found that good palm kernel shells activated carbon with an average CTC and 12 value of 50% and 900 were obtained respectively. The bulk density of the material was found to be 420-540 g/cc and its hardness index was found to be 95-98%.

A typical activated carbon plant will require a land space of not less than 0.6 ha with a built up area of the factory should be approximately 2050 m^3. Two reinforced concrete Rotary Kiln stand will have to be built with piling, to withstand 80 to 100 tonne weight each. The factory must have normal public water supply and electric supply requirement should be approximately 200A.

Based on a production capacity of 1250 tonne per annum and the current market price of raw material, direct labor cost, factory overhead, the net profit return of the plant was found to be 34.6%-

37.8%. The profitability of a typical company's operations can be summarised as follows.

	Year				
	1	2	3	4	5
Gross Profit Rate (%)	44.3	43.8	43.1	42.6	41.9
Net Profit Rate (%)	37.8	37.3	36.3	35.4	34.6
Return of Capital Employed (%)	34.8	35.7	34.7	33.9	33.1

Palm kernel shell activated carbon has been found to have very diverse usage, as it offers itself as a raw material that can be conditioned into myriad form of applications for purification of air, gas, liquids and in recovery of precious metals (i.e. gold) from ores. It has immense capacity for adsorption. The quality ranges from mainly iodine 900 to iodine 1300 with the price quoted as USD1000 to USD1500 per tonne respectively.

Keywords: activated carbon; charcoal; palm kernel shells; profitability; pyrolysis

Yield, Apparent Density, Volumetric Shrinkage and Quality of Charcoal as Affected by Raw Material and Charcoaling Properties

Mabrouk Megahed Megahed, M.L.M. El-Osta; Omran, T.A. and Hindi, S.S.Z.
Alexandria University, Tech. Department, Fac. of Agriculture, Tech. Department, Fac. of Agriculture, 21545, Alexandria, Egypt
FAX: +(203) 5971780, Email: Mmmegahed_a@yahoo.com

The consumption of charcoal in Egypt increased in the last two decades as a cooking fuel and in industry. All charcoal used in Egypt are produced by earth pit method. The quality of produced charcoal did not meet the need of different uses. It is essential to study the different quality parameters from different local grown wood species under different charcoaling parameters.

Accordingly, this study was designed to evaluate the quality properties of charcoal produced from some local grown species as affected by carbonization conditions i.e., maximum final temperature, heating rate and residence time. Wood specimens representing four hardwood species, namely eucalyptus (*Eucalyptus camaldulensis*), casuarina (*Casuarina glauca*), tamarisk (*Tamarix aphylla*), and acacia (*Acacia saligna*) were charred in a flowing nitrogen atmosphere using tube furnace at maximum temperature of 450°C and 600°C, heating rate of 10 and 25o C/min. and residence times of 90 and 120 min. Yield, apparent density, volumetric shrinkage, gross heat of combustion, volatile matter, ash and fixed carbon contents of charcoal made the four wood species were evaluated according to ASTM Standards (D 1762-1984 and D 2015-85).

The charcoal yield differed significantly according to species and carbonization conditions. The yield from tamarisk and eucalyptus (33.45% and 32.86%, respectively) was higher than that from casuarina and acacia (27.62% and 27.58%, respectively). Increasing the maximum final temperature and heating rate decreased the yield significantly. However, the residence time had no effect on the yield.

Apparent density (AD) of charcoal was affected only by heating rate. It decreased as heating rate increased. The maximum final temperature and residence time did not affect significantly the AD of charcoal. There was no direct relationship between the AD of charcoal and specific gravity of the parent wood.

The volumetric shrinkage (VS) of charcoal is dependent on species and carbonization conditions. It affected by maximum final temperature, whereby it increased by increasing maximum final temperature and no effects were evident due to heating rate and residence time.

Species and carbonization conditions affect significantly the quality properties of charcoal. At lower maximum temperature (450°), the gross heat of combustion (GHC) and fixed carbon content (FC) were lower, and volatile matter content (VMC) was higher than that at maximum temperature of 600°C. However, ash content only in tamarisk charcoal was increased with increasing final temperature for all species heating rate and residence time did not affect or have a minor effect on the charcoal properties.

Charcoal produced from tamarisk was generally lower in its quality than other species at the same carbonization conditions. This is due to its higher contents of ash, volatile matter and fixed carbon as well as its lower gross heat of combustion. Acacia charcoal is generally of better quality compared to that of tamarisk but is lower in its quality due to higher ash content than charcoal obtained from casuarina and eucalyptus.

Keywords: Carbonization, charcoal, charcoal yield, properties, charcoal quality, processes.

Productivity of Pine Gum Producing Tree (*Pinus merkussi*) due to Stimulant Degree and Covering the Tapping Holes

Suwardi Sumadiwangsa
Forest Products Research and Development Centre,
JI.Gunung Batu 5, PO Box 184, Bogor, Indonesia
Tel: 62 0251 326378, FAX: 62-0251-313-613

Pine resin obtained by tapping of living pine tree (*Pinus merkusii*). In Java there are three system of pine tapping, the leading one is by narrow face (U reverse side) system, the others in a limited area are "rill" (V) system and "drill" system. One another is with and without chemical stimulant.

The paper deals with pine gum productivity of narrow face tapping which was seriously affected by the stimulant degree as well as by covering the tapping holes. The stimulant degree, which is used as usual by the harvesters, is too high and have to be reduced. Covering on tapping holes increased either on the quantity or the quality of pine gum instead of the usual manner.

Manufacture of Active Carbons from Woody Waste Materials

Yoichi Tomimura
Forestry and Forest Products Research Institute,
P.O.Box 16, 305-8687 Tsukuba Norin Kenkyudanchi, Japan
FAX: +81-298-73-3797, Email: tomimu@ffpri.affrc.go.jp

Keywords: Active carbon, Woody waste material, Wastepaper, Adsorption test

A lot of active carbons will be required in the future to remove many kinds of pollutants and clarify water and air. In the process of manufacturing active carbons it is interesting, that we can utilize the heat from the incineration of woody waste materials in the carbonation step and even more we can use the resultant gasses in the activation process, because the most powerful green house gasses, water vapour and carbon dioxide are often use as activation gasses. Furthermore we can also use the reaction product gasses that forms during the activation. The use of carbon dioxide and water vapour in the activation process forms carbon monoxide and hydrogen gasses which can be used as fuels for carbonization. Thus combustion gas can be recycled.

The present study was conducted to manufacture active carbons from woody waste materials such as plywood, fiberboard, particleboard and wastepaper with activation gas mixed carbon dioxide and water vapour.

Waste panel products were cut into cubic pieces before carbonization and activation. Wastepapers were defibrated and converted into paper pellets. The carbonization and activation were carried out in one step in one reactor. Each sample (c.a. 20g) was set into a net cage and inserted to a reactor made of stainless tube. Then the tube was heated under the flow of mixed gas of carbon dioxide and water vapour. Mixed gas was obtained by bubbling carbon dioxide into hot water. Activation time was estimated when the temperature of reactor reached 900 degrees centigrade.

After 1 hour activation process, the yield of active carbons from panel products became about 10% based on starting materials. On the other hand, in the case of wastepaper made of mainly cellulose, after 20 minutes activation, active carbon yield was about 6%. In the results of adsorption test of iodine(c.a.800-1000mg/g) and decolorization test of methylene blue(c.a. 150-200ml/g) by Japanese industrial standard, active carbons from woody waste materials showed almost the same values as commercially available active carbons. Although starting materials such as plywood, fiberboard and particleboard contained urea resin, plywood charcoal had no nitrogen. But fiberboard and particleboard contained a few percent nitrogen after carbonization.

Active carbons can be manufactured from various kinds of woody waste materials by using mixed gas of carbon dioxide and water vapour.

Preparation and Micropore Structure of Activated Carbon Moldings

Yasumitsu Uraki, Satoshi Kubo and Yoshihiro San
Hokkaido University, Laboratory of Wood Chemistry,
N-9, W-9, Kita-ku, 060-8589 Sapporo, Japan
FAX: +81-11-716-0879, Email: uraki@for.agr.hokudai.ac.jp

Acetic acid lignin (AL) was obtained by atmospheric acetic acid pulping that was developed to separate the wood components efficiently. AL had a unique thermal property, fusion property in addition to glass transition property, although technical lignins, such as lignosulfonate and kraft lignin, had only a glass transition property. Thereupon, AL was readily transformed into fibers and sheet by fusion spinning and thermal compression method, respectively.

These thermal moldings were converted to activated carbon (AC) moldings by carbonization followed by activation to produce the agents for environmental clarification. In the case of the AL fibers, they were carbonized at 1,000°C after thermostabilization in air atmosphere, which was performed to preserve fibrous shape. The resulting fibers were converted to activated carbon fibers (ACF) by steam activation. The ACF activated for 40 min had similar adsorption properties, such as specific surface area and iodine adsorption capacity, to commercial AC powder. The ACF activated for 80 min had very large surface area (ca 2,000 m^2/g) comparable to the commercially highest grade of ACF. Furthermore, such ACF had rapid adsorption rate to methylene blue. Thus, AL based ACF fulfills a prerequisite of ACF.

The adsorption mechanism of AL based ACF was investigated by determining its pore distribution (obtained from the nitrogen isotherm). The ACF was found to have only meso-, micro- and ultramicro-pores; it had no macro-pores. The adsorption mechanism of AC powder is proposed generally as follows. Adsorbates diffuse through macropores to meso and micro-pores as adsorption sites. The transport process is the limiting step, and therefore the adsorption takes a long period to reach equilibrium. By contrast, the adsorption of adsorbates to ACF occurs at the surface of the fibers without transport though micro-pores. This mechanism brings about rapid adsorption.

To develop new type of AC moldings, AL was transformed into AC sheet by thermal compression method. When the sheet was carbonized without thermostabilization, the sheet was deformed markedly probably due to the ejection of volatile material and softening of lignin. Thermostable cellulosic material was added to the sheet before carbonization to restrain the deformation. In the case of the sheet in the diameter of 5 cm, the deformation was restrained by the addition of 10% pulp. For the sheet in the diameter of 10cm, the complete restraint was attained by 20% addition. The AC sheet activated for 2 h had similar iodine and methylene blue adsorption capacities to commercial AC powder and granules, although the specific surface area of AC sheet was smaller than commercial ones. This adsorption property was suggested to result from large internal surface area that involved the adsorption directly. The AC sheet had more rapid adsorption rate to p-chlorophenol in addition to methylene blue than the AC granule. Moreover, it also had methane adsorption capacity three times as large as the AC powder. Thus, AL based AC sheet could be utilized as an agent for environmental clarification in not only liquid phase but also gas phase.

In conclusion, thermoplastic AL was readily converted into AC moldings by thermal forming method followed by carbonization and activation. In particular, AL could be transformed into ACF because of fusible property. The resulting moldings had excellent adsorption property superior to and/or comparable to commercial AC powder and granules. Therefore, AL is a promising source for the production of AC moldings.

Wood Carbonization Products as Accumulators for Carbon and Energy

J. Zandersons, A.Zhurinsh, A.Tardenaka, B.Spince
Latvian State Institute of Wood Chemistry, 27 Dzerbenes St., LV-1006 Riga, Latvia
Tel: +371-7551552, FAX: +371-7310135, Email: tpd@edi.lv

The accumulation of greenhouse gases, forest devastation and environment-unfavourable backward technologies are the main problems being faced not only the forest industry but also the entire mankind. The use of energy dense fuels and carbonaceous materials produced from lignocellulosic biomass may improve the environment situation, will solve problems of transportation and favour a sustainable forestry.

Charcoal-making industry could be termed environmentally friendly if it would be energetically self-sufficient, ensure a low emission level, be neutral to the carbon cycle and cause no deforestation. The latter can be achieved by making use of dispersed wood residues and alternative raw materials of charcoal production. Partial combustion equipment of charcoal production is not environmentally friendly. Afterburners of charcoal kilns improve, to a certain extent, the situation of noxious emissions, but worsen the joint energy efficiency. We suppose that a technology employing 4-6 medium-size indirect heating retorts and a joint furnace, developed by the Latvian State Institute of Wood Chemistry, is an environmentally friendly solution for lump charcoal production from logging and saw milling wastes. The installation is an energetically self-sufficient one and uses piroligneous vapours as a fuel for production of heat carrier.

The same principle of energy self-sufficiency is employed in a two-stage pyrolysis system for pyrolysis of dispersed wood wastes (sawdust, crumbled wood, chips), developed by us. The two-stage pyrolysis reduces the overall construction costs, improves the charcoal quality and yield. Sawdust pyrolysis eliminates the problem of the leakage of contaminants from the wastes storage in landfills. The charcoal yield is up to 25-26% on the oven dry wood basis, and high-quality briquettes can be produced.

Carbonization of other types of dispersed lignocellulosic biomass (sugar-cane bagasse, straw) is more complicated due to a low bulk weight as well as high ash and moisture contents. Nevertheless, the use of the two-stage pyrolysis concept and the proposed methods of fine biomass charcoal processing enable to produce a high-energy density fuel (briquettes) and carbonaceous materials. The development of new carbon materials for industry and building materials for long-term application will give a possibility to stabilize or decrease the global warming because no real decrease in the use of fossil fuel is expected in the nearest future. More intensive research activities should be directed not only to increasing the efficiency with which energy from biomass can be obtained, but also to develop new materials for long-term use.

5.08.00 Production and utilization of bamboo and related species. Challenges for the new millenium

Effect of compound fertilizer and soil mounding on natural stand bamboos of *Gigantochloa scortechinii* in Peninsular Malaysia

Hj Mohamed Azmy, John B. Hall
Forest Research Institute Malaysia (FRIM), Kepong, 52109 Kuala Lumpur, Malaysia
FAX: +60-03-6367753, Email: azmy@frim.gov.my

Gigantochloa scortechinii is one of the most important commercial species available in Malaysia. It is found growing profusely in the forest immediately after logging has taken place. This species is widely distributed throughout Peninsular Malaysia and its culm is mostly used in producing such as chopsticks, skewers, joss-sticks, baskets, blinds and handicraft's item. The raw material has been extracted from the forest without prior systematic management by the locals and the resources tends to deplete. Due to this reason, it is timely to have e proper silvicultural management of the culms. In addition, future value-added products such as lamination panels tend to play an important role as a substitute for the local timber supply. Owing to its importance, a trial study has been dona by FRIM to see the effect of compound fertilizer and soil mounding experiment at Nami, Kedah in Peninsular Malaysia. The experiment involved 20 treatments and four-fold replications (four compact group of 20 clumps each as a replicate). Each one of the 20 clumps within the replicate received a different combination of mounding level and fertilizer application. Parameters of numbers of shoots, diameter- breast height (Dbh) and height were monitored twice in October 1991 and August 1992 and the observations took on year to complete. Treatments such as fertilizer with rates of 0, 2, 4, 6, 8 kg including soil mounding levels of 0, 10, 20, 30 and 40 cm above ground were done once a year. Significant effects only showed for the first 3 months period after the treatments in comparison for a duration of one year.

The Pandanus, Mengkuang and Ribu-Ribu Weaving Industries in Malaysia: The Role of the Malaysian Handicraft Development Corporation

Ibrahim Darus
Malaysia Handicraft Board, 1, Km 20, Jalan Ipoh-Rawang, Taman Rekreasi Templer, 48000 Rawang Selangor, Malaysia
Tel: 603-69125322, FAX: 603-6915322, Email: ibrahimdarus@kraftangan.gov.my

This paper aims to highlight the role of Malaysia Handicraft Development Corporation in the developmental works related to the vegetables fibres weaving especially those of the non-timber forest-based materials of Pandanus, Mengkuang and Ribu-ribu. This is important since the institute plays an important role in development of the industry with the emphasis on product development, skill training and marketing. Product development entails the product diversification, new designs, patterns and new functions. In order to ensure the survival of the industry and the use of proper production techniques, young apprentices are trained at Handicraft Training Centres as well as at their working places. The woven products need to be sold to ensure that the craftsmen can earn a living. Therefore efficient marketing agencies are needed to tailor this objective. The setting up of marketing companies and Craft Cultural Complexes under the auspices of Malaysia Handicraft Corporation is expected to relieve the craftspeople from the extra burden of marketing on their own.

Product Development From Laminated Bamboo (Lamboo)

Hamdan Husain, Zaihan Jalaludin and Abdul Hamid Salleh
FRIM, Kepong, 52109 Kuala Lumpur, Malaysia
Tel: +603-6342633, FAX: +603-6367753, Email: dann@frim.gov.my

Keywords: laminated bamboo - Lamboo, bamboo furniture, new product development

Bamboo utilization are gradually progressing from a traditional entities into a more machine intensive products. Its usage are however confined to inferior house hold items and other low recovery products that prevent it to mark its presence dominantly comparative to rattan. This inherent problem is not only associated to non-profitable ventures or labour intensive, but also due to in-competency in product management and quality control. Lack of in-depth R&D and product development partially contributed to this pathetic scenario while the abundant raw material are left idle and non productive.

Globally, the bamboo based industry is estimated to worth about RM 15 billion a year. While Taiwan's bamboo industry contributed about RM 650 million a year, Malaysia exports a meagre RM 1 million (US$265,000 at RM3.80 per US$1.00) in 1997. There are 287,000 ha of natural stand bamboo available in Peninsular Malaysia capable of supplying about 250,000 tonnes of raw material annually.

The federal and state government gives full support in promoting bamboo industry by allocating sufficient funds and land area for plantation. Of late, with mechanization and proper industrialization, bamboo usage are slowly experiencing changes transforming into more elaborate and appealing products. Development in bamboo products in the form of laminated bamboo (Lamboo) into flooring, building panels and other house hold items has long been exploited locally and overseas. This paper aims to address the upper market such as furniture which would enable to provide higher return. It will address superficially on the production of Lamboo, from raw material preparation until laminating by jigging into laminated bamboo blocks.

The manufacturing of furniture from Lamboo provided new dimensions in product diversity and market potential. The production methodology is continuously being improve to increase its capacity and ensure continuous product quality. Already it has created interest from both local and international participants at the 1999 Malaysia International Furniture Fair when some prototypes was exhibited. Description on the various stages involved in the production will be illustrated and discussed in this paper. The problems encountered, its machining and lath properties, jointing and the finishing qualities will also be discussed.

Study on Establishment and Management Technology for Sympodial Bamboo Sub-branch Cuttings-Garden

Fu Maoyi, Xie Jinzhong, Zhang Guangcu, Li Daiyi and Chen Xiumei
Research Institute of Subtropical Forestry, CAF, 73# Daqiao Road, 31400 Fuyang Zhejiang, China
Tel: 0086-571-3310001, FAX: 0086-571-3341304, Email: risf@fyptt.zjpta.net.cn

A trial has been laid out by using orthogonal design with 3 factors and 3 levels in three different locations in order to find out the proper establishment and management technologies in promoting sub-branches from adventitious buds and the best propagating materials in the field i.e. *Bambusa textilis* (Guangzhou city), *Dendrocalamopsis oldhami* (Nanping city) and (*B. multiplex*) in their cuttings-garden. The results indicated that the proper technology for establishing cuttings-garden could be achieved by 1). keeping the mother offset culm with 7 internodes, 2), damaging all buds on its culm base and, 3). applying MS nutrient solution with 6 BA+NAA of various concentrations for several times in accordance to the species, which can produce about 142500, 54000, 114000 sub-branches per ha each for *D. oldhami*, *B. textilis* and *B. multiplex* respectively. The sustainable management technology for *D. oldhami*, on the other hand could be done by 1). keeping 1 or 2 new culms during the latter-middle shooting stage, i.e. making the culm age structure of clump as 1-year old: 2-year old=2:1 or 1:1 and 2). chopping their top in next early spring and keeping the culms with 7-internodes height, which will give a sustainable amount of 120000 or 160500 sub-branches per ha in each year.

Processing and Utilization of Bamboo in Vietnam

Pham Min Thoa
Forest Science Institute of Vietnam, 108 B2 Thap The Dong Xa, Mai Dich, Cau Giay, Hanoi, Vietnam
FAX: +84-4-843-8814, Email: sfm-wwf@netnam.org.vn

This paper basically highlights the scenario of bamboo processing and utilization activities in Vietnam, where bamboo grows widely, both in natural as well as in plantation forests and becomes an important alternative forest resource to timber. The total area covered by bamboo is about 1.5 million ha and extending to all over the provinces of Vietnam. The plant is valued for its versatility usage for the making of various products either targetted for domestic or export market. The

processing and utilization of this giant grass have been analysed mainly through application and technological aspects. The advantages and disadvantages of each technology were also assessed in order to facilitate future development of the processing and utilization sectors. The problems and constraints were also discussed. General concensus indicates that there is a need for the right orientation and clear yet synchronous plan by the government to foster development of this bamboo-based industries as well as to obtain the highest social, environmental and economical advantages to the communities.

Bamboo Composites - Material of the Future

Arun K. Bansal, S.S. Zoolagud
IPIRTI, Bangalore, India

Bamboo is an important traditional resource on which around 2.5 billion people all over the world depend greatly for wide range of products and livelihood. Bamboos have more than 1000 documented uses. About one billion people live in bamboo houses. Bamboo, a tree like grass, represented by 1250 known species, is found in all regions of the world, tropical, sub-tropical and temperate except in Europe and West Africa. Bamboos account for approximately 25% and 20% of the total biomass respectively in the tropics and the sub-tropical areas. Bamboos have several unique advantages viz. (i) ability to rejuvenate degraded areas, (ii) grow well in plantation models in harmony with other species, and hence there is no need for monoculture, (iii) have short rotation cycle of 2-5 years, and (iv) as traditional resources bamboos are widely recognised by people and their products are easily and willingly accepted.

Panel composites made from bamboo have great potential as an alternate panel material with improved strength and other characteristics compared to other panel products made from some fast growing plantation timbers. Bamboo mat board (BMB) is important bamboo composite development at IPIRTI. Its use in place of plywood to the tune of about 25% in the country is expected to save about 8000 ha of natural forests while generating around 60 million workdays in mat making alone, in which economically weaker sections of the society are generally involved.

Additional positive aspects of bamboo based panel materials are: environmental friendly-reduction of pressure on forests through wood substitution; people friendly as uses traditional resources; enhances rural employment generation, participation of women and community development.

BMB technology development at IPIRTI has been found to be an exemplary demonstration of implementation of Agenda 21 by the International Selection Commission EXPO 2000 and has been recommended for registration at EXPO-2000 Hannover, Germany.

This paper discusses R&D work related to development of bamboo based composites being carried out at the Institute and its relevance for people oriented development programme.

Treatment of Round Bamboo

K. S. Gan, Choo, K.T.
Forest Research Institute Malaysia (FRIM), Kepong, 52109 Kuala Lumpur, Malaysia
Tel: 603-6342-633, FAX: 603-6367753, Email: ganks@nt1.frim.gov.my

In Malaysia, the use of round bamboo for high quality furniture production is increasing. The treatment of round bamboo using traditional techniques such as leaching in running water, smoking with fumes and dipping/soaking in chemical solution often do not offer the necessary long-term protection. This paper discusses the treatment of round bamboo using a specially designed machine based on the High Pressure Sap Displacement or "Boucherie" process. With the High Pressure Sap Displacement technique, preservative solution is forced under pressure through a "treatment cap" into one end of the freshly cut bamboo. The preservative solution displaces the sap from the bamboo and this is forced out from the open end at a rate dependent upon the applied pressure and length of bamboo. The treatment pressure can be set up to 4.2 kg cm^{-2} (60 psi). To ensure effective treatment of bamboo, it is important that the bamboo should be as fresh as possible. This is to minimize the blocking up of pit openings of the parenchyma cells as the sap being dried during the initial drying process and the possibility of air trapped in the vessels that inhibits the passage of the preservative solution during treatment. Results of CCA treatment on buluh minyak (*Bambusa vulgaris*) carried out using the machine indicated that a minimum penetration of 11.5 kg/m^3 could be achieved. This amount of preservative is sufficient to protect bamboo from either insect or fungal attacks, and provide an expected service life of more than 15 years.

Bamboo Industries in Malaysia: Challenges in The New Millenium

Abdul Latif Mohmod, Ashari Amin

Forest Research Institute Malaysia (FRIM), Kepong,
52109 Kuala Lumpur, Malaysia
Tel: 603-630-2393, FAX: 603-6367-753, 603-686-3082,
Email: drlatif@pc.jaring.my

The bamboo industry in Malaysia does not fall into the mainstream of prominent industries. However, its potential is tremendous. Worldwide, bamboo contributed USD 4 billion annually. The local market grossed a meager USD 3 -4 million per year and less than USD1 million is posted for export market. The bamboo in the wild survive without human management. The results are - dire shortage of supply of desired species, uneven aged material on harvest, all of which ultimately resulted in inferior use of materials and of final products quality. A managed bamboo plantation would spell a more systematic regimes for fertilization, thinning and harvesting. The bamboo industry models as a precursor to other innovations. As such, policy decisions should be taken to fulfill the required ends. The inventory work, growing efforts, and the industrial components - each has to be tackled with devote and vigor. The utilization of bamboo in various categories of uses are discussed. The categories include its use in construction, transport, medicine, arts and crafts, music and sports, tools and utensils, as decoration and for aid to fashion, protein and food resources, in religion and mystics. The challenges faced by the bamboo industries in Malaysia are also discussed. This paper also highlights some of the key strategies for future development of the said industries.

The Starch Content of two Malaysian Bamboos in Relation to Age, Culm Height, Site and Harvesting Month

Walter Liese, Abd. Latif Mohmod
Hamburg University, Leuschnerstr. 91, D 21031
Hamburg, Germany
FAX: 49-40-722-8991, Email: Wliese@aol.com

The variation in starch content of one-, two-, three- and four-year-old *Bambusa vulgaris* and Gigantochloa scortechinii collected from four experimental sites in Peninsular Malaysia at 12 consecutive harvesting months is reported. The starch content differs significantly with species, site, age, culm height and harvesting month. The starch content, regardless of site, harvesting month, age and height, varies from 2.9-7.4% and 0.35-10.1% in *G. scortechinii* and *B. vulgaris*, respectively. The highest and lowest starch content of the two bamboos occurred at the top than the basal portion, and in the older than the younger culm. With regards to seasonal changes, the starch content in each bamboo species tended to increase with decrease in monthly rainfall but increase with the increasing temperature at each site. The difference in starch content levels in both species between the driest and wettest month is relatively higher at the top than the basal portion, and in the older than the younger bamboo.

Soil Suitability for Bamboo Planting

Abd. Razak Othman
Forest Research Institute Malaysia (FRIM), Kepong,
52109 Kuala Lumpur, Malaysia
Tel: 603-6342-633, FAX: 603-6367753, Email:
abdrazak@frim.gov.my

The growth and productivity of shoot and culm production of selected Malaysian bamboos in various experimental sites were carried out. From the experiment sites, it shows that sandy clay loam areas (Renggam series) is the best and followed by shallow laterіteic soil mixed with fine sandy clay (Jitra series) than those of the lateriteic soil (Terap series), bris soil (Jambu series) and tin tailings areas.

Propagation Study by Branch Cuttings of *Gigantochloa levis*

Abd. Razak Othman
Forest Research Institute Malaysia (FRIM), Kepong,
52109 Kuala Lumpur, Malaysia
Tel: 603-6342-633, FAX: 603-6367753, Email:
abdrazak@frim.gov.my

Specific propagation study by branch cutting of *Gigantochloa levis* in the nursery showed that there is no different in percentage of survival either on nursery beds or polybags used. Cuttings prepared on nursery beds yielded better growth rate in term of root length, culm/shoot and rhizome production and leaves. The use of hormone IBA 2000 Powder was also observed to promote the growth of cuttings as compared to other IBA hormone treatments. The planting of *G. levis* in the field showed that the polybag branch cuttings gave the highest survival percentage (92.6%) than those of the bare root planting (50.9%) and the newly branch cutting planting (30.6%).

Comparative Efficacy of Bamboo Treated With Boron Compound By Dipping and High Pressure Sap-Displacement Processes

Mohd. Tamizi Mustafa, Razak Wahab
FRIM, Kepong, 52109 Kuala Lumpur, Malaysia
Tel: 603-6342633, FAX: 603-6367753, Email: tamimi@frim.gov.my

A lot has been said about the effectiveness of high pressure sap-displacement technique in treating round green bamboo. This paper evaluated the effectiveness of this technique by comparing it to that of the dipping process. Evaluation through accelerated 8 weeks laboratory fungal tests shows that the dipping process gives better protection to the treated bamboo. The percentage of fungal attacked on the treated bamboo samples through the dipping were found to be far less when compare to those treated by the high pressure sap-displacement process. This was further supported by the under shed insect exposure study.

Study on Associated Nitrogen-Fixation of Bamboo Plants Rhizosphere

Xiaoli Wu, Gu Xiaoping
The Research Institute of Subtropical Forestry CAF, 73# Daqiao Road, Zhejiang 311400 Fuyang, China
Tel: 0086-571-3310171, FAX: 0086-0571-331001, Email: guxp@fyptt.zjpta.net.cn

It was proved that the Gramineae plants have the character of associated nitrogen fixation with some azotobacter. Bamboo plants belong to the Gramineae, which is important forest resource with numerous species in China even in the world. Their associated nitrogen fixation characteristics or any resemblance with other Graminae crops, however, have not been well reported. Some studies have been conducted by us on this field since 1994.

In this paper five bamboo species [*Phyllostachy hetercycla var. pubescens* (Mazel) Ohwi, *Phyllostachy meyeri* McClure, *Dendrocalamopsis latiflorus* Munro, *Dendrocalamopsis beecheyana* (Munro) keng f, *Bambusa textilis* McClure] have been investigated and determined at many sites with a number of samples on nitrogen fixing activity of roots by acetylene reduction method. It was shown that the acetylene reduction activities of bamboo plants, in general, are higher than other Gramineae crops. Meanwhile the sympodial bamboos' are higher than the monopodial bamboos'. The maximum nitrogen fixing activity of sympodial bamboo root can reach to 921.5 nmolC_2H_4.$h^{-1}g^{-1}$ of fresh root determined by enrichment culture method; 24.5 nmolC_2H_4.$h^{-1}g^{-1}$ of dry root determined by direct determination technique. Counting (MPN method--most probable number) and isolating to azotobacter from bamboo plants rhizosphere, it was found that there were a lot of azotobacteria in bamboo rhizosphere. Generally, the numbers of azotobacteria for the sympodial bamboos could be more than 108 cells g-1 of dry roots in root surface, over 108 cells g-1 of dry roots in root inner, over 109 cells g-1 of dry soil in rhizosphere soil. So far, 11 and 17 azotobacter strains have been isolated from the sympodial and the monopodial bamboo rhizosphere respectively. Identification of azotobacteria isolated from *P. pubescens* and *P. meyeri rhizosphere* has also been conducted. The results revealed that there are a lot of *bacillus azotobacteria* in *P. pubescens* rhizosphere, which mainly belong to *Bacillus polymyxa* and *B. licheniformis*. In *P. meyeri's* rhizosphere, the azotobacter was identified as *Klebsiella pneumoniae* (Schroeter) Trevisan. So far, eight strains with quite high nitrogen fixing activity have been sifted. Using those strains to inoculate moso (*P. Pubescens*) bamboo seedlings, it is shown that the seedlings' growth can be promoted. The effect of inoculating four strains (GW-2, GW-12, GW-14, G-7) was observed to reach the significant or the remarkable significant levels in seedling height, plant bio-mass and plant total nitrogen content than that of CK. The roots growth, the fresh root bio-mass per plant was also found to increased from 44.1% to 76.9%, because the lateral roots are increased significantly and the roots look stronger than CK group. Through this research it is verified that bamboo plants, being a big member of Gramineae have the character of associated nitrogen fixation like other Gramineae crops. This research brings us a hope to resolve bamboo’s nitrogen supply finally by biological nitrogen fixing and lays a foundation for further studies.

Structure of Bamboo-Based Reconstituted Panel Composite in View of the Characteristics and Properties of Raw Bamboo

Hong-Jian Zhang
Southwest Forestry College, Wood Products Research Institute, Post Box # 126, 650224 Bai Long Si, Kunming, China
Tel: 86-871-3863014(O), FAX: 86-871-5637214, Email: hjzhang@public.km.yn.cn wpri@public.km.yn.cn

Based on the results from the studying of the biological characteristics and properties including the texture, main physical and mechanical properties and chemical composition of the four typical thick-growing woody bamboos (*Dendrocalamus giganteus*, *D. brandisii*, *D.*

membranaceus and *Bambusa lapidea*) in Yunnan of China, this paper suggested that both the proper structure and quality of the bamboo-based panel composites and the appropriate dimension, structure, and property of the unit to compose the panels, i.e. bamboo-based veneer, particle or fiber, should be designed and got, in view of the influence originating from the special characteristics and properties of the raw bamboo, such as the hollow structure of the culm with the knot, the green skin outside and the yellow covering inside but without any ray, the high content of extractives and the difference of the wall thickness, the texture and the physical and mechanical properties from the species and the position on the culm, to ensure the most reasonable cost and economic benefits for the industrial production of the panels. As structural panel materials for engineering, various bamboo-based laminated veneer plywoods possess the merits of very high strength and elasticity. However, the strict requiring of the wall thickness which limited from the species and the part of the bamboo culm, the low coverage of the raw bamboo and the uneven structure, surface and properties of the panels are their deficiencies. Compared with this, despite of lower strength and elasticity, bamboo-based particleboard and fiberboard own the advantages of accepting various species and almost all part of the culm, no matter how thin the wall is, the high coverage of the raw bamboo and the even structure, surface and properties of the panels. As compensation with each other, it is suggested that the best way to reduce the cost of raw bamboo to ensure the economic benefit is to combine the production of laminated veneer plywood with bamboo-based particleboard or fiberboard. Bamboo-based waferboard is an excellent reconstituted structural panel composite because of its reasonable structure, stable properties and low cost. It has got both high strength and elasticity like bamboo-based laminated veneer plywood and the wide acceptance of the species and the part of culm of bamboo as its raw material with a high coverage up to 92% like bamboo-based particleboard or fiberboard.

Keywords: bamboo, characteristics and properties, bamboo-based plywood, bamboo-based particleboard, bamboo-based fiberboard, bamboo-based waferboard

An investigation of the roles of household individuals on the furniture consumers behavior

Hasan Ayyildiz, Onder Barli, Salim Hiziroglu
Karadeniz Technical University, Department of Forest Products, Trabzon, Turkey
Tel: (405) 744-5445, FAX: (405) 744-9693, Email: hizirogl@okstate.edu

Keywords: furniture, consumer behavior, demographic group.

One of the most significant factors affecting the process of consumers' behavior for furniture purchasing is influence of the individuals of the household. The members of each household have important roles on the purchasing decision. In general furniture purchases can be termed as postponable compared to other higher priorities on expenditure for clothing, shelter and transportation. Therefore disposable personal income and, more importantly, discretionary purchasing power have a significant influence on the demand for furniture. The effect of family on the purchasing behavior can be analyzed based on several factors, namely the number of the family member, the level of income level, population characteristics, and living in a small town or metropolitan area.

In this study, furniture purchasing process from the producers and consumers viewpoint was analyzed within the scope of above factors. It was determined that producers that consider effect of members of household for the purchasing process were more successful and effective in their overall production management including advertising and budgeting. Study also evaluated various parameters including age and income level, related to consumers behavior which are responsible for furniture manufacture. A significant relationship was found between income level, demographic group and furniture purchasing decision based on the variance analysis at 95% confidence level. Consumers behavior as function of different age groups of household individuals were also analyzed and it was determined that persons in the 30-40 age group purchase more furniture than any other age category. However, the data showed that furniture demand is influenced as the age distribution changes over the time. Finally, suggestions related consumers behavior for the future market analysis and production management for the furniture industry.

A Marketing Approach Applied to the Wooded Sector of Rio Branco, State of Acre-Brazil, 1995

Zenobio A.G. P. da Gama e Silva, Joáo Carlos L.G. da Silva
Fundaçãode Tecnologia do Estado do Acre-FUNTAC, Av. das Acácias, Lote 1, Zona A, Distrito Industrial, CEP 69.917-100 Rio Branco, Acre, Brazil
Tel: (068) 229-1665, Email: zenobiosilva@hotmail.com

Although the State of Acre (located in western Amazon-Brazil) has 93% of its area covered by original forest, its forest sector has faced a stagnation of even reduction in timber operations. It is also important to note that the studies on Amazonian forest sector, some approached the economy in this region, but did not detail the State of Acre, other researches analyzed the Acrean forest sector, however did not focus commercialization points of wooden products from Rio Branco City (Capital of State of Acre) or even just studied technically the local wooden industrialization. Thus, marketing proceedings adopted by the local timber sector was not studied yet. Due to these facts, this study will be important in order to give support to marketing strategies for commercialization of wooden products coming from this region. The study was carried out in 1995 with the objective of analyze marketing procedures adopted by the timber sector in this region.

The study covered 39 sawmills, 43 furniture manufacturers and 16 retails lumber yards located in the Rio Branco. The main aspects considered in the analysis were: (1) pricing strategies; (2) promotional mix and (3) target markets.

The main results obtained from this studies were: (1) wooden sector of Rio Branco, during 1995, consumed 143,262 m^3 of wood in log and the total retail segment, in turn, sold 4,800 m^3 of timber; (2) in 1995, about 89% of sawmills consumed cumaru ferro species, 67% used cerejeira species and 58% processed cedar species while among furniture manufacturers, cedar and cerejeira species were used in 83.7% and 97.7% of these industries, respectively; (3) for 41% of sawmills and 31% of the local retails, the market price of timber was priced in function of a price-list set by Timber Enterprises Syndicate of Rio Branco enterprises, while 27% of furniture manufacturers fixed their prices considering its production costs; (4) the local, national and international markets consumed, respectively, 46%, 29% and 25% of production from Rio Branco's sawmills in 1995; (5) the most of furniture manufacturers sold to Rio Branco market and. the retail, in turn, sold to small consumers as well as to building enterprises, both located in this city (it was small the sale to external consumer in this segment); (6) 53% of sawmills sold with a cash descont, 65% supplied freight of the product and 18% considered that such actions could arise a negative profit; (7) 18% of sawmills, 27% of furniture manufacturers and 38% of retails divulged their products by radio and television (such procedures could increase the sale to 10%, as these sale is compared to sale without such strategies); (8) 77% of the furniture manufacturers supplied a home delivery (this procedure include an assembling process supplied by the furniture industry), while 68%, depend on the sale value, sold a cash discount and 18% warranted the quality of its product or substitute it in case of defects.

Miombo Woodland Utilisation by Small-scale Farmers in Handeni / Tanzania: Strategies for Income Generation as an Incentive for Woodland Preservation

Marion Karmann
Universität Freiburg, Institute für Forstbenutzung & Arbeitswissenschaft, Werderring 6, 79085 Freiburg, Germany
Tel: 0761-203 3767, FAX: 0761-203 3763, Email: karmann@pop3.uni-freiburg.de

(i) Problem addressed:
Within African dry lands the increasing displacement of Miombo woodlands is a special problem. The yield of traditional management of these ecosystems (frequent burning and shifting) is not longer sufficient to cover the needs for food supply and cash crop of the growing rural population.

(ii) Research question/hypothesis
The study is based on the controversial assumption that comprehensive woodland management with agroforestry systems, including timber as well as non timber products utilisation, will positively influence the economic and social situation of the population, and thereby contribute to a higher valuation of these resources by the inhabitants themselves. The know-how about the multiple use of Miombo woodlands is a basis for further development of properly resource utilisation systems. These systems should not only guarantee the capability of the woodlands to fulfil the subsistence needs of local household, but also an ability to generate income through marketing of products from the woodlands.

A consequently integrated management according to agroforestry systems while considering timber and non timber products of trees and shrubs should influence the economic and social situation of people in this area to more positive conditions. Non wood forest products (NWFP) which, on the one hand contribute to the subsistence of single families, on the other hand can be marketed and build up a source of income, should rise up the prestige of that forest type or at least for single tree species in the awareness of the users.

(iii) Objective of research
Based on these presumptions the main objective of a study in Handeni District, North Eastern Tanzania was to improve a better understanding about the situation of Miombo utilisation in the research area through descriptive analyses. Derived objective was to describe the potential development of the region in case of fulfilment the subsistence needs, income generating, and ergonomic aspects such as labour organisation and qualification.

The investigation was focused on the inhabitants of four villages from two different ecological zones of the Miombo woodlands. Information related to the utilisation of forest-resources, especially the potential use of NTFP, based on the knowledge and experiences of local people and the local experts, was collected through individual interviews and group discussions as well as field observations and key interviews within and outside the research area.

Most of the people in these villages belong to the Zigua- and Nguu-tribes. Both tribes basically depend on small scale agriculture. Moreover, Maasai – a semi-nomadic cattle rearing tribe -live in this area at times. They depend on milk and other cattle products. Because life style and diet of Zigua / Nguu are basically different from that of Maasai, different knowledge about useful NTFP on Miombo woodlands was to be expected.

(iv) Methodology and workplan
To get access to the traditional knowledge about woodland utilisation, tools of PRA were used to record the actually used NWFP and also the way of harvesting and use of these products, their contribution to subsistence and their economic means.

The following research steps lead to the main objective:
1. Assessment of the role of forest utilisation in general, and especially of the role of non wood products, for the predominantly agrarian subsistence livelihood.
2. Identification of the present role of selected non wood forest products (NTFP) of Miombo woodlands, taking into account ecological, economical and socio-cultural aspects of land use.
3. Description and evaluation of the possibilities and constraints of diversification of the product range, and an increase in the direct utilisation of trees and shrubs of Miombo woodlands for the people, based on the carrying capacity of the ecosystem.

(v) Results and conclusions and their relevance for development
All three tribes consider woodlands first of all as a resource for agriculture and cattle grazing. Honey, mushrooms, other wild foods and barks were identified as most promising NWFP in the region for subsistence households and income generation.

In the research area the marketing of woodland products, also of NWFP, fundamentally can be considered as an incentive for the conservation of the woodlands. But today the marketing of forest products is already problematic, expanding the markets would become even more risky because of uncertain conditions of delivery and purchasing.

The acceptance levels for accelerating propagation of utilisation and marketing of NWFP vary between and within communities. For subsistence economies a strengthened use of NWFP can be recommended in each case, except for bark splitting. On the contrary, strengthening commercialisation is only with caution recommended because of the high risks. An establishment of collaborative processing and marketing can favour the marketing possibilities of all product samples.

Key word: Miombo, NWFP/NTFP, Social Forestry; Zigua, Nguu, Maasai

Product Oriented Wood Research Improves Market Chances For Small Scots Pine Logs

Udo Hans Sauter
University Freiburg, Institute für Forstbenutzung und Forstliche Arbeitswissenschaft, Fischmatte 9, D-79244 Muenstertal, Germany

Keywords: western larch, *Larix occindentalis*, specific gravity, stand density, x-ray densitometry

Western larch (*Larix occindentalis* Nutt.) is one of three native Larix species in North America, besides subalpine larch (*Larix lyallii* Parl.) and tamarack (*Larix laricina*(Du Roi) K. Koch). Western Larch occurs mainly throughout the Upper Columbia River basin of southeastern British Columbia, northwestern Montana and northern Idaho. It easily reaches 50m in total height. High wood density and strength usually characterize its wood. Throughout most of western larch's natural range, existing stands originated from natural regeneration following wildfires, and are often overstocked. Therefore, early reductions of stand densities by precommercial thinning became an important management tool to establish stabilized stands and to concentrate stand growth potential on fewer vigorous, well-formed trees. This process of maximizing total stand value rather than maximizing yield can be completed by later commercial thinning and artificial pruning. The intent of this study, carried out by Forintek Canada Corp., was to provide basic information on the relationship between tree spacing and the two major wood quality parameters wood density and branch size to support stand management decisions. From young western larch experimental stands in northwest Montana, 618 sample trees were chosen representing different stocking levels ranging form 270 to 4300 trees/ha. From two pith-to-bark cores, taken at breast height for each tree, density profiles were obtained using Forintek's x-ray densitometer. We also measured the largest branch diameters below 4 m stem height. The sample trees showed a strong relationship between width of spacing and tree height and diameter breast height. As expected, trees in the widest spaced plots grew the fastest. Despite large differences in diameter growth, no significant differences in average wood density occurred between spacings. A second moderate thinning on the best sites clearly showed that enhancing the wood density of western larch is possible. For the most valuable part of the tree, the branch sizes do not exceed 20mm even when a wide spacing as 4.6 by 4.6 m is applied. High wood density levels and reasonable knot size confirm that western larch from sustained managed stands remains a valuable tree species in future markets.

5.11.00 Non- wood forest products

Germination Requirements of *Calamus subinermis*, an Important Rattan Species in Sabah, Malaysia

Mohamad Aminuddin
University Malaysia Sabah, School of International Tropical Forestry, Locked Bag 2073, 88999 Kota Kinabalu, Malaysia
Tel: 608-849-3411, FAX: 608-849-3909, Email: aminmohd@ums.edu.my

Calamus subinermis (rotan batu), a rattan endemic to Sabah, Malaysia, is commonly used in the furniture industry. The species are commonly found along the coast of Sabah from Labuan up to Tawau. Seeds are procured for the germination study from Ulu Sugud in Sandakan and Luasong in Tawau, Sabah. The seeds are placed under different light intensity and watering regimes to look into the possibility to enhance the germination of the species. The species is known to have staggered germination ranging from three weeks to about one and half years. This paper highlights and discusses the results.

Improving The Strength and Stiffness Of Joints In Rattan Furniture-An Overview

Wan Tarmeze Wan Ariffin
FRIM, Kepong, 52109 Kuala Lumpur, Malaysia
Tel: +603-6342633, FAX: +603-6367753, Email: tarmeze@frim.gov.my

This paper gives an overview on the research and development aspects of improving rattan furniture jointing system to enhance the in-service performance of the joints. It describes some faults found in the current practices of jointing rattan furniture components that weaken the joints based on the author's observation and previous research results supported by mathematical models on the strength and stiffness characteristics of the joints. Using the knowledge, methods for improving the jointing system are suggested and some relevant works by the author are disclosed.

Utilisation of Eucalypt Oils for Sustainable Weed Management

Daizy R. Batish, H. P. Singh and R. K. Kohli
Panjab University, Department of Botany, 160 014 Chandigarh, India
Tel: +91-172-546666, 547777, FAX: +91-172-541409, Email: kohli%botany@puniv.chd.nic.in

Trees - the dominant components of forest ecosystems are known for their longevity and can thus provide a number of goods and services to society. Rapid population growth coupled with the needs of changing society has further increased the dependence of man on non wood forest products like resins, cork, mushrooms, food and oils. The oils extracted from the forest trees like the *Eucalyptus* and *Pinus* species are mainly used in perfumery or medicinal purposes. However, in the present study, their exploitation for managing the noxious weeds was explored. Volatile oils comprising mainly of terpenes were extracted from leaves of eucalypt trees by steam distillation and purified. Of these, cineole and citronellol were used in the present study. The oils were demoistened before use. Under simulated conditions, different concentrations of these oil were vaporised in the environmental chambers. The seeds of noxious weeds like *Parthenium hysterophorus* and *Ageratum conyzoides* collected locally were subjected to germination in these chambers. A parallel control was also maintained in which the environmental chambers were without oil vapours. The study reveals that oils (both crude as well as purified forms) inhibited the germination, initial growth and subsequent development of the weeds. Further, in the fiels conditions, the effect of oils was also assessed on the growth of one month old plants of these weeds. The total chlorophyll content and cell survival values reflecting the respiratory metabolism were significantly less in treated plants compared to that of control. The treated plants also wilted after 20 days. However, the inhibitory effect was observed more on germination, which is a crucial factor in the proliferation of weeds and hence can be utilised to suppress the germination of weed seeds. Though in the present study the oils were used in vapour state but they can easily be mixed with water with the help of surfactants and can, thus, be applied in a simplified way. The present study is particularly important in the modern times when the efforts are being made world over to explore alternatives of synthetic herbicides which are posing a threat to mere existence of human beings by polluting the environment. The plant products on the other hand are not only bio-degradable but possess a number of other eco-friendly properties such as easy applicability, longer shelf life, cost effectiveness, easy storage methods etc. and can be safely used for the management of noxious weeds and pests.

A Method for Comparative Analysis of Non-Timber Forest Products Cases: A Test with Cases from Indonesia

Brian Belcher, Manuel Ruiz Perez; Dede Rohadi, Ramadhani Achdiawan
Centre for International Forestry Research (CIFOR), Post Box # 6596 JKPWB, 10065 Jakarta, Indonesia
FAX: +62 (251) 622 100, Email: b.belcher@cgiar.org

Non-timber forest products have been targeted as key entry points for both development and conservation initiatives. Significant investments have been made in a variety of project interventions, and new attention is being given to policy options to encourage NTFPs development. And yet, understanding of the true role and potential of NTFPs to contribute to development or conservation, based as it is on scattered and inconsistent case-based research, remains limited.

This work is part of an ongoing effort to develop and refine a methodology and to undertake comparative analyses of cases. The overall aim is to develop an analytical framework that will facilitate systematic NTFP policy and management decisions. This paper describes the rationale, the approach, and the results and conclusions of the first stages of the work.

The method was designed to help to find patterns among divergent cases, to develop classes of cases, to identify those variables that are most useful for classification, and to analyze the relationships between different classes of case and observed development outcomes. In this study a set of 12 studies of NTFP cases from Indonesia was organized, with each case described using a standard set of descriptors. The products included benzoin resin, gaharu (incense wood), damar (resin), bamboo, tengkawang (nuts), wild gathered and cultivated rattan, wild honey collecting, butterfly ranching and farming, palm sugar, and sandalwood (fragrant wood). The cases were selected to represent a range of kinds of products (animals, plants, plant products), of production systems (from pure extractive to cultivated) and market systems (from local markets to export markets). The variables were organized into several categories, describing different aspects of the production-to-consumption system, including:

- Geographic setting
- Production system and ecological implications
- Socio-economic characteristics
- Policy aspects
- Institutional aspects
- Characteristics of the processing industry
- Characteristics of the trade and marketing system
- Type and focus of external interventions

Expert judgement was used to assign ranks to each case, on a variable-by-variable basis. Cases were compared using these data in: 1) non-linear principal components analysis to identify key variables that account for dissimilarity between cases; and 2) cluster analysis, to classify and group similar cases.

Several interesting classes of case were identified, based on characteristics such as remoteness, management intensity, the role of the product in livelihood strategies, level and kind of state intervention, degree and kind of processing required, characteristics of trade and marketing, and degree of external intervention

This trial confirmed the feasibility and the utility of the method, and helped to identify areas for improvement. Some problems were encountered with the definition of variables. Important limitations were experienced due to use of mainly qualitative data and rank-ordering. Personal knowledge and expertise about the case by collaborators was found to be very important, at least during the methodology development phase. Work is still needed to facilitate linking development and conservation outcomes with case characteristics. These lessons have been taken into account in the design of a new international comparative analysis.

Growth, Money Flows and Income Distribution of the Brazil Nut Industry in the Bolivian Amazon

Alan Bojanic
Programa Manejo de Bosque de Bolivia (PROMAB), Bolivia
FAX: 62 251 622100, Email: w.de-jong@cgiar.org

This poster analysis the money circulation in the Brazil nut economy in northern Bolivia. It first analysis the functioning of the entire harvesting production selling cycle. Supply of raw material stems from concessions or barracas and from independent communities. Brazil nuts are processed in factories or beneficiadoras. Additionally these have their own commercialisation and marketing channels. In this entire industry there are a number of quite different actors, including collectors, intermediary contract holders, concession owners, independent communities, factory owners, Brazil nut crackers, deposit owners and transporting agents. Each has a different role, set of activities. In addition there are non-direct stakeholders like the suppliers of equipment and other input, the state, brokers and consumers.

This poster will indicate the detailed cash flow between stakeholders. How much money is transferred, and where does it go. What are the expenditures of the stakeholders. Importantly linkages will be established between several industry and non-industry agents like food stores, banks, money lenders, transportation agents, and inputs suppliers. This analysis allows to calculate the share that different actors capture, as well as to calculate the accumulation along the chain, capital formation, savings and reinvestments.

The Importance of Forest Product Commercialisation to Rural Households: The Case of Craft Markets in Chivi Communal Area, Zimbabwe

Oliver Braedt
Institute for World Forestry, Federal Research Centre for Forestry and Forest Products, Leuschnerstr. 91, 21027 Hamburg, Germany
Tel: +49-(0)40-73962-100, FAX: +49-(0)40-73962-480, Email: braedt@aixh0101.holz.uni-hamburg.de

Since Zimbabwe's independence in 1980 the tourism sector has evolved into one of the most important sectors of the national economy. Along with the rise of tourism, an increase of craft markets offering forest based products as curios was observed. At the end of the eighties not more than twenty craft markets existed along the major roads of the country, compared to over two hundred in 1998. The markets are mainly located in the communal lands. Decline in the productive capacity of agriculture, the rising number of unemployed people in communal areas and the expansion of the tourist industry, are factors likely to attract even more people into the craft industry. Previous studies on the craft industry revealed the dominance of wooden items. The rapid growth of the craft industry and the discriminate use of local trees has raised concern on environmental degradation from governmental institutions and environmental groups. At present the existing legislation regulating the use of natural resources in communal areas prohibits the harvesting of tree species used by the craft industry, but no serious action has been taken to either prohibit or promote the growing sector. A general hesitation whether to advance or hinder the craft industry is prevailing.

The uncontrolled growth of the craft industry in Zimbabwe and the discriminate use of natural resources for material supply needs organisation. Decisions on how to go about with growing social and environmental problems are necessary, if the craft industry in Zimbabwe is to grow sustainable. Government institutions, policy makers, craft traders, researchers and development workers are equally concerned about the future of the trade. However, significant data is missing for further elaboration of possible guidelines or recommendations. The number of people involved in the craft industry is unknown. There is no data on the economic importance of the craft trade at village and ward level and no information to what extent the craft industry contributes to household income. Whether the income is beneficial to the poor and thus could signify a potential sector where development efforts could assist in alleviating economic hardships, needs identification. Of primary importance is also the lack of information on environmental impacts.

Social and environmental impacts originating from an expanding craft industry has raised attention in many sectors of society in Zimbabwe. Though general concern has been expressed, significant data for further elaboration of possible guidelines or recommendations on the future of the craft industry is lacking. The data underlying this investigation were collected during 1997 and 1998. Participatory rural appraisal (PRA) tools were used in group meetings, formal household questionnaires were administered, and semi-structured and open-ended interviews took place with groups and individuals. Emphasis was laid on participatory and direct observation at craft markets and in households. This poster examines the value of the craft industry for rural livelihoods in southern Zimbabwe. Households involved in the production of craft items are compared with households that are not, and cash income earned from the sale of craft items is set into context with cash income earned from non-craft based activities (other forest based products, farm produce, labour and remittances). This, in order to identify socio-economic differences and the proportion the craft trade contributes to household income. The paper also establishes whether the distance from the craft market location and the actual homestead has influence on participants level of income and whether the number of households participating in the craft industry diminishes with distance away from the vending locations.

Identification of Morphological Parameters for Catechin Content in *Acacia Catechu* Willd

K. C. Chauhan, AK Praharaj
Dr. Y.S. Parmar University of Horticulture and Social Sciences, College of Forestry, 173 230 Solan (HP), India
FAX: 91-01792-52242, Email: asc@yspuhf.hp.nic.in

Key Words: *Acacia catechu*, Catechin, Morphical traits, Chi- square and Selection index

Acacia catechu is one of the commercial timber of India and Myanmar. It is mainly used for Katha (Catechin) and cutch extraction and is subsidiary source of income for rural poor, vital for quality of life. The economic importance of catechin is digestive, abortive, expectorant, aphrodiastic and cooling agent. It increases milk secretion in the cattle, useful in cough, diarrhoea dysentery, and sore throat and externally in the preparation of ointment for local application. There is great variation for catechin content among trees in the same stand and, therefore, needs some physical parameters for its identification.

The present study was conducted to determine correlation between morphological traits and catechin content and to develop a selection index to identify main traits responsible for higher catechin production, which may help in selecting the superior trees for raising improved plantations.

Three sites in two forest divisions in the state of HP were selected for the study and named as S1 (Jandhuta), S2(Subathu) andS3(Nauni). In each site four different plots of 30x30m were laid out and numbered as P1,P2, P3and P4.Within each plot 20% of the trees were randomly selected and marked asT1,T2, T3---Tn with yellow paint at dbh for identification and recording of data. Tree characters viz; tree height, dbh, crown width, no.of primary branches, stem pattern (straight, crooked, forked and lean), fruiting status (heavy, medium and poor) , leaf area, pod size, no. of seeds per pod, 100-seed weight and specific gravity were recorded and analysed. Soil chemical analysis was done for pH, EC, avalable N, P and K. Approximately 200-250 g of heart wood chips were collected from the standing trees at a height of 30 cm above ground level of the bole by making an opening of 5x5cm. Catechin was extracted from each sample as suggested by Rao and Mishra (1983). Carl Pearson's correlation and chi-square test were performed to find out the existence of association between morphological traits and catechin content, stem pattern (straight, crooked, forked and lean) and catechin content (high or low) and between fruiting status (poor, medium and heavy)and catechin content. Subsequently, selection index was developed based on Fisher (1936).

The study revealed that S2 (Subathu) possessed high catechin producing trees and S3 (Nauni) the lowest. Southern and western aspect yielded more catechin as compared to northern and eastern. Significant variation was observed for all morphological and reproductive traits at three sites. Height, dbh, crown width, pod width, leaf area and specific gravity gave positive and significant association with catechin content but non-significant association with distance from adjacent trees, no. of aborted seeds/pod and 100-seed weight. Catechin content revealed positive but non significant correlation with soil pH, EC, P and K; negative and non significant with N.

Chi- square analysis revealed that leaned and forked trees produced maximum catechin content.

In general, high catechin producing trees were found poor in fruiting quality. Height, dbh, crown width, leaf area, pod width and specific gravity of a tree showed positive and significant correlation with high catechin content. Selection index gave information on proportionate weightage of dbh, number of primary branches, pod width and specific gravity for high catechin content possessing *Acacia catechu* trees.

The Sustainable Utilization of Insect Resources

Xiaoming Chen
Chinese Academy of Forestry, The Research Institute of Insect Resources, Renmindonglou, Wangdaqiao, 650216 Kunming City, Yunnan, China
Tel: (087 1) 3854821, Email: xmchen@public.km.yn.cn

Insect is an important component in forest ecological system. In forest ecological system, many insects feed on plants and affect growth and development of plants. Meanwhile, insects can be used as edible insects, medical insects, natural enemy and pollination medium. So insect is a kind of valuable resources. Insect and insect products are very important resources for chemical and other industry materials, protein, natural medicine and others.

Insect usually is prevented and eliminated as pest. In fact, the resource value of many insects is much higher than the damage of insect. Some insects can be used as natural enemy and control other pest population. Some insects can be cultured and utilized, such as lac insect, white wax scale, kermes insect, Chinese gallnut insect, silkworm, bee and others. The utilization for these insects can develop to a new kind of industry. In utilization of forest resources, people mainly use wood and ignore other resources, especially insect resources.

The cultivation and utilization of insect resources have close relation with forestry. The core of insect industry is that insects grow and develop in coordination with host plants. In order to develop insect resources industry, the first thing to do is to culture host plant and afforest. Afforestation can promote to green barren hill and have good ecological benefit. Meanwhile, on the foundation of ensuring normal growth and development of host plants, the obtainment of insect products will produce economical benefit. In this paper, from point of insect resources development and utilization, it is discussed that relationship of insect industry and sustainable development of forestry, combining with forestry, agro-forestry, economic development of mountain areas and environment protection.

Keywords: utilization of insect resources, eco-forest construction, agro-forestry, sustainable development

Consumption and Marketing of Wild Vegetables

Hanne Christensen, Mertz, O.
University of Copenhagen, Institute of Geography, Oster Voldgade 10, 1350 Copenhagen, Denmark
Tel: +45 35 32 25 00, FAX: +45 35 32 25 01, Email: om@geogr.ku.dk

Wild vegetables and flavours from the forest are of major importance to local communities in Borneo as supplier of food and cash income. This study is based on 1) ethnobotanical collection and identification of wild vegetables in an Iban and a Kelabit community of Sarawak, Malaysia; 2) food diaries by eight households in the same communities keeping a daily record of all ingredients in their food during one year; and 3) weekly market surveys of vegetable prices and quantities during one year in five urban centres of Sarawak.

In both communities, a total of 218 wild vegetables are used compared to 87 cultivated species. Wild vegetables are as frequently consumed as cultivated species, notably various ferns and palm shoots which represent about 10% of all vegetable intake. The main reason for this given by the communities is the high labour requirements for vegetable cultivation. The frequently consumed wild vegetables are often common in secondary forest, but a number of minor species are only found in old secondary forest and climax forest. These are likely to disappear if their habitats are degraded, and domestication or habitat protection may therefore be necessary if consumption is to be maintained.

Wild vegetables are very popular in urban markets and prices are comparable to cultivated products. The interest is partly sparked by concern over high pesticide residues in cultivated vegetables, but taste, flavour and tradition also play a significant role. Some of the most popular products are fern fronds, palm shoots, various products of Zingiberaceaes, and leaves of Gnetum gnemon which all fetch good prices. A large number of vegetable species consumed in the villages are not marketed, but may potentially be valuable cash crops if introduced to urban populations. An overall seasonal variation in supply is not seen for most products but periods of heavy rain appear to reduce harvest intensity and marketing. Further research on nutritional composition and domestication of wild vegetables is strongly recommended, both regarding popular species that

are already consumed and marketed extensively and minor species that are likely to disappear.

Domestication and Improvement of Jujube tree *(Zizyphus mauritiana*) - State of Art in Senegal

Pascal Danthu, Amadou Bƒ, Ismaila Diallo, Gilles Delhove, Emile Victor Coly, Pape Sall
CIRAD-Forêt Programme Arbres et Plantations, B.P. 1716, Dakar, Senegal
Email: pascal.danthu@cirad.fr

Forests have always been instrumental in guaranteeing the dietary security of African populations. Exploitation of forest fruit-trees has traditionally been based on the gathering of wild fruit. In the long run, this has led to the erosion of genetic resources, worsened by the recurring periods of drought that affect the Sahelian zone, hence the need to protect, safeguard and increase the worth of these species. That is the reason why the CIRAD and the ISRA started a program of improvement and domestication of the most important species, with the threefold view of taking part in the dietary security of populations, increasing their yields and protecting the genetic resources that are sometimes endangered because of overexploitation. Research focused most particularly on *Zizyphus mauritania* Lam., the jujube tree, which is one of the most widespread forest fruit-trees in dry areas.

The general problematic that was developed in Senegal follows two complementary routes. The first one consists in setting up a program of selection and improvement of the local jujube based on fruit characteristics (fruit size, sugar content, taste, earliness). The second option aims at transferring and adapting the improved varieties that have been produced and spread in India. This paper reviews the work currently going on in Senegal. It describes the knowledge gained, the experiments under way and the perspectives of research and development constituting the items of a technological package that will, in fine, make it possible to turn the jujube from a wild tree into an orchard tree.

In order to reach this goal, several lines of research are at present developed in Senegal.

- The improvement of local jujube trees started with individual selections that were made in different natural or artificial plantings in Senegal between 1988 and 1997. Thirty progenies were singled out and submitted to comparative testing in the Bandia station in 1996. Most trees bore fruit right from the first year plantation. The assessment under way will lead to the selection of the best plants that will make up the basis of a new cycle of recurrent selection.

- Tests on the introduction of Asian jujube trees have been carried out over the last three years. These tests focus on the India-originating Gola variety whose fruit volume is multiplied more than 20 times in comparison with the local jujube. The plants that were introduced (grafted onto a rootstock belonging to an Indian species, *Z. rotundifolia*) appear to have adapted well to the edapho-climatic conditions of Senegal.

- -Studies of horticultural and *in vitro* vegetative multiplication methods have been made. The jujube can be propagated through grafting, but the Indian method is not readily usable in Senegal and adaptations are required (these are the object of current work). Research on the micrografting of *Z. mauritania* has enabled us to develop an original and efficient technique for the micropropagation of selected adult trees.

- Studies of floral biology have enabled us to define a methodology for the controlled cross-breeding of jujube trees, which is an important tool within the framework of the improvement programme.

- Individual management of trees, in particular the development of pruning systems (date, intensity) enabling better fruit yield, has been given full consideration. The first assessments of pruning tests based on the Indian model are currently being made. Manuring and irrigation tests are scheduled to take place in 1999.

- Inoculation of mycorhizal fungi (such as *Glomus aggregatum*) which allow natural phosphates to act more efficiently, has shown that mycorhized jujube trees make better use of the phosphorus lying in the ground than non-mycorhized jujube trees. The impact on fruit yield is being appraised.

Methods to fight pests, such as the setting of traps aimed at mature pests, the use of food lures or repellents made from the essential oils of plants will be developed in 1999. Special attention will be paid to fruit flies (the determination of these insects is under way) as these pests put a curb on the development of improved species because of the important damage they are responsible for.

Beyond technical and scientific aspects, however, the fundamental issue to be addressed is whether these new products are likely to be accepted by the population. Will local jujube trees, even after they have been selected and improved, be attractive enough for farmers to regard them as orchard trees? Will Indian jujubes meet the tastes of African populations? Although the initial response seems to be positive, many points will have to be ascertained before it is possible to consider the jujube as a domestic species in Africa.

Improvement in Tapping of Philippine Canarium Trees for *Manila Elemi*

Arsenio B. Ella
Laguna College, Forest Products Research and Development Institute (FPRDI), Department of Science and Technology, 4031 Manila, Philippines
FAX: (63-49) 536 3630, Email: e.ella@cgnet.com

Trees of the genus *Canarium* growing naturally in the Philippines were experimentally tapped for resin. Four tapping lengths (10, 15, 25 and 35 cm) and four levels of aqueous sulfuric acid treatment (0, 15, 30 and 45%) were teased of effects on resin yield of 32 trees. The influence of rainfall on resin yield was studied over a 12-month tapping period. Resin yields differed among the tapping length within six months, the 15-cm length gave the highest yield. No significant difference in resin yield was noted among the acid concentrations. The interaction between tapping length and acid concentration was not statistically trees. A workable method of tapping *Canarium* species was developed.

Plant Gums and Resins: An Alternative Potential Source of Income for the Pastoralist Communities of the Dryland Kenya

Francis Gachathi
Kenya Forest Research Institute, NWFP Research Programme, P.O. Box 20412, Nairobi, Kenya
Email: kefri@arcc.or.ke

Drylands account for about 80% of Kenya's land surface. The people living in the drylands are mainly nomadic pastoralists, deriving their livelihood from keeping livestock, and practicing a form of land use that involves seasonal movement of both people and animals in search of pasture and water.

Increasing human and livestock population coupled with annual fires and droughts has resulted in degradation of the vegetation in the drylands. This has greatly affected the pastoralist's socio-economy with serious loss of animals. With fewer or no other options of alternative resources for supporting livelihood of the local communities, drylands have become famine-prone and aid dependency zones.

However livestock production is only but one source of livelihood that drylands of Kenya can support. Most plants hold known or potential promise as resources of economically viable products whose possible wild exploitation could offer considerable benefits in improved rural livelihood by providing food security, gainful occupation, cash income and contribute to foreign exchange earnings.

Plant gums and resins are such products that could be sustainable exploited for profit and still conserve most of the biological diversity and ecosystem functions of the dryland forests. Gum Arabic from *Acacia Senegal*, frankincense from *Boswellia neglecta* and myrrh from *Commiphora* spp. are abundant in the drylands of Kenya. They represent a group of non-wood forest products with opportunities in income and employment generation thereby uplifting the socio-economic status for the local pastoralist communities.

The paper gives a general background on the potential of exploiting gums and resins and indigenous knowledge systems for the economic development of the pastoralist communities of the dryland Kenya.

Domestication of Indigenous Forest Products

Cory Ham, G van Wyk
University of Stellenbosch, Faculty of Forestry, Private Bag X1, Matieland, South Africa
FAX: +27 21 808 3603, Email: ch2@maties.sun.ac.za

The Faculty of Forestry of the University of Stellenbosch, South Africa, is currently conducting research into the sustainable utilisation of forest and woodland products, with special emphasis on the domestication of indigenous fruit trees. The long-term goal of this program is twofold: (i) to develop indigenous products that can be used on a sustainable basis for economic development in rural areas, where it is desperately needed, and (ii) the conservation of natural forest and woodland resources by maintaining the balance between biotic diversity and the utilisation of natural products.

For this program a four-phase model is used. The program has started with the identification of forest products on a regional level through community surveys. Products were rated according to popularity and level of utilisation amongst local inhabitants. To compliment this phase a national data base on available forest product information is being maintained.

The second phase of this program is the selection of popular and highly utilised indigenous products and the screening of suitable provenances within the distribution ranges for domestication studies. Different methods of testing for genetic variation, like electrophoresis, chromosome counts and electron microscope studies, are being used to study biotic diversity and to select provenances with the highest potential for domestication.

From the second phase study, provenances of the selected indigenous trees are selected for cultivation studies. Cultivation through seed and cuttings forms the cornerstone of this process. This can be a long process as a couple of growing seasons is required for the development for the best cultivation techniques and the raising of trees for orchard development. While the cultivation studies is in progress, the potential for sustainable utilisation of the in situ forest products is also investigated as well as the development of potential markets for the products. The sustainable utilisation of in situ forest products is an interim measure as the demand for forest products can reach a higher level than the sustainable supply level. The balance between supply and demand may then be maintained through supplemental cultivation of products. Ecological and biological studies is also incorporated in this phase to investigate the impact of utilisation on the forest and woodland ecosystems.

The fourth phase of this program is the development of enterprises based on the sustainable utilisation of forest products. The focus of this phase is on entrepreneurs in rural areas. The aim is to create employment and improve the quality of life in the areas of South Africa where it is needed most.

The four phases of this program are ongoing. Different products will be produced at different phases throughout the programme. The aim of this project is incremental economic empowerment in rural areas with minimisation of environmental impacts.

Molecular Biology of Natural Rubber Biosynthesis in *Hevea Brasiliensis*

Kyung-Hwan Han, Hunseung Kang, Soo Kyung Oh, Dong Ho Shin, Jaemo Yang, Keng-See Chow, Hoon Yeet Yeang
Michigan State University, Department of Forestry, 126 Natural Resources, MI 48824-1222 East Lansing, USA
Tel: (517) 353-4751 (Office), FAX: (517) 432-1143, Email: hanky@pilot.msu.edu

Rubber (cis-1,4-polyisoprene) is an important raw material for many industrial uses. The diminishing acreage of rubber plantation and life-threatening latex allergy to Hevea rubber, coupled with increasing demand, have prompted research interests in the study of rubber biosynthesis and development of an alternative rubber source.

Rubber biosynthesis takes place on the surface of rubber particles suspended in the latex. Rubber particle-associated proteins have been speculated to play an important role in rubber biosynthesis. We isolated and characterized a novel cDNA clone encoding the small rubber particle protein (SRPP). SRPP is one of the two major rubber particle-associated proteins, along with rubber elongation factor (REF). Sequence analysis revealed that this protein is highly homologous to the REF and the *Phaseolus vulgaris* stress-related protein. SRPP gene is expressed abundantly in latex and plays a positive role in *in vitro* rubber synthesis. We suggest that SRPP is a part of the rubber biosynthesis machinery, if not the rubber polymerase.

As rubber is synthesized in latex, the genes uniquely or preferentially expressed in the latex may be important for rubber biosynthesis. To study the gene expression profile in latex, we constructed and analyzed two cDNA libraries (complete and subtractive) from the latex of *H. brasiliensis*. Single-run partial sequencing of the cDNA clones identified a total of 245 expressed sequence tags.

As expected the most abundant transcripts were rubber biosynthesis-related genes. Detailed gene expression profile in the rubber-producing tissue will be presented.

Computation of Annual Forecasts of Non-wood Forest Products

Jaakko Heinonen, Salo, K.
The Finnish Forest Research Institute, Joensuu Research Station, Post Box # 68, FIN-80101 Joensuu, Finland
Tel: +358 13 2514000, FAX: +358 13 2514567, Email: jaakko.heinonen@metla.fi

Keywords: Forecast, theme map, kriging, permanent plot, wild berries, commercial mushrooms, non-wood products, Finland.

The Joensuu Research Station of the Finnish Forest Research Institute started a project in 1997 concerning with the yield of wild berries and edible mushrooms that are of considerable economic and commercial importance in Finland where 2.1 million people pick wild berries and edible mushrooms every year. One of the main purposes of the project is to inform Finns about the season and abundance of the wild berry and mushroom yields and on what kind of sites the main yield occur. The flowering season of berries, the harvesting seasons of berries and mushrooms, the abundance of the yield and the factors affecting the yield are forecast and reported on TV, on local radio stations and in newspapers during the growing season. Most of the information is delivered in the form of theme maps.

The forecasts are based on a national observation network, which consists of 440 forests and peatlands (2200 permanent experimental plots). The number of flowers, unripe berries and ripe berries of bilberry (*Vaccinium myrtillus*), cowberry (*Vaccinium vitis-idaea*) and cloudberry (*Rubus chamaemorus*) are counted three times during the growing season. Edible commercial mushrooms are identified and the number of fruit bodies are calculated at least three times during the mushroom season. The most common and the most popular edible mushrooms are ceps (*Boletus, Suillus* and *Leccinum* species), milk caps (edible *Lactarius* species), mild *Russula* species, and some other good mushrooms, e.g., *Cantharellus cibarius*, *Rozites caperatus*, and *Craterellus cornucopioides*.

A new, more precise method of computing the theme maps was developed in 1999. The method applies universal kriging predictors and takes advantage of the permanent sample plots of the national forest inventory (3009 plots). Variables assessed in the national forest inventory in 1985-1986 included the percentage coverage and the height of the swarf-shrub of cowberry and bilberry and the productivity class of each sample plot. Productivity was assessed on the basis of the number of flowers and unripe and ripe berries. The predictors use these variables together with the site index, temperature and rain fall variables, tree species composition, the basal area of the trees, the development class of the trees and the geographic location and altitude of the site.

Potency and Taxonomy of Endemic Rattan Species (*Calamus Occidentalis* J.R. Witono & J. Dransfield) in Ujung Kulon National Park, West Java

Titi Kalima, Marfu'ah Wardani
Forest and Nature Conversation Research and Development Centre, Jl.Gunung Batu 5, 16122 Bogor, Indonesia
Tel: 0251 325111, FAX: 62 0251 325111, Email: slitbang@indo.net.id

Among the 25 species of rattan in Java, about two are endemic. One of them is in West Java: *Calamus occidentalis*. Since research in a distinctive botanical region is natural the potential value in exploration should be the subject of inquiry. Studies concerning the potential and taxonomy of endemic rattan species has been carried out in Ujung Kulon National Park. The inventory rattan endemic in the south part of Ujong Kulon National Park is predicted has a potential source of good shape. Methods use in conducting the field research consisted of measuring the density and frequency of rattan endemic using formula developed by Cutis (in Muller and Dumbois and Ellenberg, 1974). Data were collected from July 1997. Illustrations of rattan endemic species found in the area were described and analyzed both in Forest Botany Herbarium in Forest and Nature Conservation Research and Development Center in Bogor and in Herbarium Bogorience, LIPI. It is expected that availability of these data could be given away in this conservation area and also other resources as well.

Non-Timber Forest Products Research: Challenges for the Future

Jelle B. Maas Bijker
The Tropenbos Foundation, Post Box # 232, 6700 AE Wageningen, Netherlands
Tel: +31-317-426262, FAX: +31-317-423024, Email: j.b.maas@iac.agro.nl

Keywords: non-timber forest product, certification, people, sustainable forest management

Mid 1980's optimistic views emerged about the potential of commercial extraction of NTFP to contribute to forest conservation as well as improved livelihoods. Research strategies aimed at identifying requirements for ecological sustainable, economic feasible and social acceptable commercial extraction were launched. The goal is that NTFP extraction is recognised as a potential land use option in natural resource management (Ros-Tonen et al, 1995). Three central issues can be distinguished in NTFP related research: product, source and people.

Product

A particular feature related to NTFP is their great number and versatility (Lintu, 1996). Within NTFP a floristic and faunal origin can be distinguished, but other classifications could be made just as easily (harvesting method, processing, end product, market, etc.). A well defined classification is the cornerstone for the efficient collection of data and information. A number of organisations, such as the International Organisation for Standardisation (ISO), have established specification and testing conditions for various NTFP at the national and international level, but a general agreed upon classification system of NTFP is lacking.

Source

In natural resource management it is important to distinct human altered systems from natural forests. Both systems are important sources of NTFP, but require different management strategies. For NTFP form natural forests the Forest Stewardship Council (FSC) (Pierce, 1998) Working Group and the Rainforest Alliance (1998) and Smartwood (Shanley, 1998) have prepared specific sets for management. However a sound scientific basis for many of the criteria is still lacking, such as allowable harvesting levels and other management practices.

People

A range of people, from gathers, through processor and trader, till customer, can be distinguished. A good interaction between the different actors in NTFP management is essential for effective management. The Fair Trade Labelling Organisation (FLO) coordinates 17 national fairtrade systems, focussed on socio-economic criteria and principles, such as an equitable sharing of the benefits. While FLO is mainly concentrated on international trade, NTFP markets tend to range from local subsistence to international commercial markets. Each market has its specific requirements (quantity, quality), and therefore different management implications, which need to be incorporated in a participatory manner. Research on all items mentioned above is essential to evolve into a natural resource management practice in which NTFP is seen as a viable and compatible land use option and practice. NTFP extraction is being applied on a daily basis by millions of people now, and research is essential to sustain it for the future.

The relevance of local controls for the management of woodland resources: the case of Zimbabwe

Alois Mandondo
Center for International Forestry Research, PO Box 6596 JKPWB, 10065 Jakarta, Indonesia

FAX: 62 251 622100, Email: w.de-jong@cgiar.org

There has been much interest in the last decade in local knowledge and its validity for the management of natural resources. This interest has fed into the debate on Common Property Management, where rules, rule adherence, rule enforcement and the recognition of resource boundaries are considered to utmost importance. A case study in Zimbabwe was conducted, using sociological and ecological methods, to investigate the impact of local controls on the ecological state of the woodlands.

The work shows the richness of the local controls (including codified rules, taboos, and regulatory norms and emotions) for the management of woodlands and trees. The domains of human habitation (home bases and home fields) were found to be the spaces where the greatest number of local controls applied; the least controls were evident for the woodland commons. However, work on rule adherence and rule enforcement showed that there was much contestation, negotiation and breaching of local controls, with very low levels of enforcement of the controls. Greater respect for local controls was evident in the areas of human habitation. The resource use boundaries differed for each of the resources collected from the commons, and showed no relationship to local traditional boundaries (where they existed) or to any of the local administrative boundaries. The traditional boundaries between villages can be regarded as soft boundaries, with reciprocity amongst villages widespread. Elites within the villages are able to manipulate situations and local controls to their benefit. Thus, for instance, `sacredness' can be re-negotiated, where necessary. The result of the `control framework' for areas around human habitation showed a consistent enrichment of the tree component, through conservation and planting. In the commons, the `control framework' made little impact, except that some sacred areas still were being strongly protected.

The possibilities for common property management based on local controls are regarded as being rather limited. The study concludes with an analysis of how systems of local control can, or cannot be, incorporated within the on-going exercise to devolve power to local authorities (Rural District Councils). National legislation needs to be reformed so as to provide a framework for Councils to have the tools to support local controls, in the form of, for example, by-laws and locally-relevant enforcement mechanisms.

NTFP Management and Participatory Process of Forest Conservation

Indu K. Murthy, Ravindranath N. H.
Indian Institute of Science, Centre for Ecological Sciences, 560 012 Bangalore, India
Tel: 91-80-331 5455 / 334 0985, FAX: 91-80-331 5428 / 334 1683, Email: indu@ces.iisc.ernet.in

Joint Forest Management (JFM) is considered as a watershed in the history of Forest Management in India as it seeks to develop partnerships between local institutions and Forest Departments for sustainable management of forest areas on the basis of trust and mutually defined rights and responsibilities of both parties. Managing forests for multiple products including NTFP at local level is a challenge facing India where JFM is being implemented widely. This paper attempts to discuss the existing hurdles to this shift and also highlight the importance of NTFP and the need to focus on its management for sustenance of the current management system. It also attempts to suggest ways and means of involving local communities in management of forests.

The current policy framework, lack of value addition methods, gender and equity imbalance and existing silvicultural practices are some of the hurdles to a shift from timber oriented system to an NTFP oriented system. It has been proved time and again by several studies that communities value more, regular flow of NTFPs and other benefits from the forests rather than a one-time share of the harvested timber. This is because the local communities are unable to wait for 8 to 10 years to get a share from the timber revenue as the opportunity cost borne by them becomes too high. This pressure on the locals could possibly lead to a collapse of the protection system itself. In order to avoid such a situation, it is very essential to make arrangements, for accrue of increased benefits to the communities. The fist step towards realization of this goal of real participation is "Informed Decision making".

Communities need to be involved in decision making apart from being involved in protection and management operations. Some work done in Africa has proved that local communities will manage a forest if they have:

- Adequate rights and access to resources
- A sense of belonging to the forest and
- Have the desire as well as incentives to manage it

This interest of communities in sustained yield of forest products will ensure that the process of forest conservation is successful and there will be hope for the future. This mode of forest protection and management will not only fulfil the needs and aspirations of forest dependent communities but will also aid in realizing the long-term goal of forest conservation for sustainable forest management.

Extractivism and Socio-Cultural Dynamics for the Development of Rattan and Almaciga Resin Resources: A Case Study in Palawan, the Philippines

Honorato G. Palis, Bernadette S. Alcantara, Jose Alan A. Castillo and Celia A. Lat
Ecosystems Research and Development Bureau, UP Los Banos Campus, College, 4031 Laguna, Philippines
FAX: 63-049-536-2850, Email: hgpalis@lgn.pworld.net.ph

The investigation was conducted in the island province of Palawan, home of the unique tribal communities, to assess, from multidisciplinary perspective, the conditions of existence, the potentials and limitations of extractivism as an alternative strategy for the development of rattan and almaciga resin in the context of sustainable development of forest land. It also aims to assess the indigenous knowledge and the influence of socio-cultural forces related to extraction. Data derived from vegetation survey and micro-climate measurements were analyzed using two complementary methods, namely: Two-Way Indicator Species Analysis (TWINSPAN) and Canonical Correspondence Analysis (CCA). On the other hand, socio-economic/cultural data were assessed and subjected to descriptive and non-parametric analyses.

Data gathered shows that rattan grows at a wide range of elevation though the concentration of the species, particularly the commercial ones, is at higher elevation and on less accessible areas interspersed in the natural dipterocarp forest. This is due to the fact that the species are gathered and used for livelihood by the tribal community and other individuals that frequently traverse the area for the same reason. Meantime, almaciga (*Agathis philippinensis*) trees are observed to thrive mostly along ridges and side slopes to the gullies from 340-740 meters above sea level (masl). The tapped trees are large but the incisions for the resin to exude out appear to be too many and oftentimes larger and deeper than the prescribed limits set by the Philippine government. In addition to the problem on unregulated tapping methods is the lack of reproductions and lower diameter almaciga trees that would ensure continued production of the resin.

Socio-cultural information revealed that extraction of rattan and almaciga resin is an ancient practice among Bataks. Nowadays, it has become the major source of income of these indigenous peoples (IPs) including other rural folks. Rattan is a raw materials used for manufacturing furnitures and handicrafts while almaciga resin is utilized for production of paints, varnish, adhesives, among others. Due to this, rattan and almaciga resin are highly in demand both in local and international market. The economic popularities of these non-timber forest products (NTFPs) eventuate to encroachment of outsiders in the gathering areas of the (IPs) bringing with them conflicts because of competitions and destructive extraction methods which later was learned and adopted also by the IPs. Likewise, their constant business transactions with traders influenced not only their lifestyles but also their cultural practices.

As the global economic crisis, particularly in regional level was being felt, the demands for these NTFPs began to decline which consequently affected the traders and gatherers. Much more for the case of IPs who are more vulnerable and prone to exploitation and have no livelihood alternatives. The limited livelihood opportunities for these upland gatherers make them heavily dependent on rattan and almaciga extraction. This is compounded by the local policy that prohibits kaingin (swidden agriculture) in the uplands. Without alternative sources of income, incessant extraction of materials proceeded throughout the year even under inclement weather conditions.

Usos económicos y etnobotánica de las cercas vivas en Cuba.

José Ramirez Molinet, Barbara Rodríguez Duran, Maritza Bagu, Pérez y Emigdio Rodríguez del Sol
Jardín Botánico Sancti Spiritus, Adolfo del Castillo 67 sur E/ Raimundo y Tello Sánchez, CP 60 100 Sancti Spiritus, Cuba
Email: fidict@yayabo.inf.cu

Se realizó una amplia revisión bibliográfica, consultas a especialistas y entrevistas a campesinos para conocer las especies utilizadas en Cuba como cercas vivas, así como sus usos. La información fue introducida en una base de datos automatizada, que incluye nombre científico, sinonimias, familia, nombres comunes en Cuba, hábito, forma preferente de reproducción, observaciones, entre otros aspectos. Se describen 88 especies pertenecientes a 55 géneros de 27 familias; las familias mejor representadas fueron *Cactaceae* (13 especies), *Agavaceae* (9), *Euphorbiaceae* (8), *Fabaceae* (8) y *Mimosaceae* (7). Se reportan 45 empleos posibles. Los usos más frecuentes fueron ornamental (53 especies), medicinal (43), melífera (35), comestible por el hombre (30), comestible por animales (15) y maderable (14). Se reportan además 4 especies endémicas y 14 tóxicas. Se destacan aspectos vinculados a la creencia de la población pero aún sin comprobar.

Palabras Claves: cercas vivas, usos, etnobotánica, Cuba.

Management System for Non-Timber Forest Products in Three Community-Based Forest Management Projects in Quezon Province, Philippines

Ambika P. Regmi, Teodoro R. Villanueva
University of the Philippines, Department of Forest, Los Baños, Laguna, Nepal
Email: Lucrecio L. Rebugio [llreb@laguna.net]

The study assessed the management practices adopted by the communities and the factors affecting the management system for non-timber forest products (NTFPs). The study described the problems and possibilities of developing a management system for NTFPs. Policy recommendations were made. Three community-based forest management projects were selected for this study in Quezon Province.

Data were gathered from 84 households in the project areas and from eight project technicians as key informants. Secondary data were collected from PENR Office and DENR Offices. Descriptive and simple statistical tools such as frequency counts, percentage, range, means were employed in data analysis.

The study showed that the biophysical environment, socio-economic and psychological characteristics of the people influence the management system for NTFPs. Most of the respondents engaged actively in forestry activities were middle aged. They all have obtained formal education. They practice agroforestry system for their livelihood. The respondents were highly aware of the utilization of non-timber forest products mostly for their subsistence use. They have skills and knowledge of management and utilization of NTFPs. They have positive attitude towards the management for NTFPs. There exists a good potential sustainable NTFPs in these project sites. However, these potentials are not fully tapped. High participation in management of NTFPs is not observed due to low market price, poor market access, lack of information on new technologies and low external support for NTFPs.

The results of this study showed that the practical and best way to manage and utilize NTFPs in the CBFM projects is to tap the knowledge of the local people. External support such as financial, technical and material subsidies are needed to

encourage and promote the existing knowledge and practice of the participants of the projects. Resource inventory, assessment of existing utilization system and technology, adoption of silvicultural practices, training, infrastructure development, market assessment, promotion of processing and small scale enterprises are important for the management of non-timber forest resources.

Based on the actual analysis of the gathered data and field observation, it was found that three basic inputs namely more financial, material and technical supports are needed for the sustainable management of NTFPs.

Usos no madereros de las especies forestales en Cuba

Barbara Rodriguez Durán, José Ramírez Molinet, Julio Martínez, Katia Manzanares, Orlidia Pérez, Emigdio Rodríguez del Sol
Jardín Botánico Sancti Spiritus, Adolfo del Castillo 67 sur E/ Raimundo y Tello Sánchez, CP 60 100 Sancti Spiritus, Cuba
Email: jbss@yayabo.inf.cu

Alternatives of use of wooden trees growing up in Cuba are described; reported by literature; experts (interviews), and specialist (consults); with the objective of promoting an organized profit of woods, contributing to a supportable manage of forest and a rational reforest. An automatized database was made, which contains scientific name, synonyms, common names, fitogeografical, and kind of vegetation where it is present, among other elements. 229 infragenus taxa of 157 genus and 55 families are described. It was tested that almost every Cuban wooden species has, at least, and alternative for being used, which could perfectly be used and taken advantage of, before or after being cut, getting sustentation in such way. The commonest usages were medical (150 species); useful for bees (145 species), ornamental (77 species) and eatable for men (53 species). 45 ways for being used are mentioned.

Cultivation of Two Medicinal Plants *Andrographis paniculata* and *Rauvolfia serpentina* in the Floor of *Acacia auriculiformis* Stands

Shyamal K. Roy
Jahangirnagar University, Department of Botany, Savar, Dhaka, Bangladesh
FAX: 880-2-833054, Email: shkroy@juniv.edu

Andrographis paniculata is a medicinal herb. Andrographolide is the main active bitter principle of *A. paniculata*. It is used as stomachic tonic and anthelmintic. It protects alcohol induced toxic effect on liver tissues and accelerates intestinal digestion and absorption of carbohydrate. In Bangladesh and India the plant is extensively used in traditional and Ayurvedic medicine. *Rauvolfia serpentina* is a perennial herb. Its roots are extensively used as medicament. The importance of the root drug and the alkaloids obtained from it has been recogniged in the allopathic system of treatment of hypertension. In the present investigation, seeds of Andrographis paniculata were sown by broadcasting method, in the floor of three plantation regions (plot-1, 2,3) of 5-year-old *Acacia auriculiformis* vegetation, for exploiting the intercropping method of cultivation of these two species under agroforestry system. Each plot consited of 400 sqm area of land and 100 plants of *A. auriculiformis*. One plot (plot 4) was prepared in the open field for direct sunlight. The whole aerial parts of the plants were harvested at the phase of appearing inflorescence branches. Plants (*A. paniculata*) were raised in two consecutive years. After harvesting they were dried in the sun and weight of the dried plants were taken.

In the present investigaion it was also undertaken to study the commercial feasibility of cultivation of Rauvolfia serpentina, in the floor of *Acacia auriculiformis* vegetation, for its undergraound biomass production. 10-15 cm long plantlets of *R. serpentina* were planted at the espacement of 50x50 cm in the floor of two different plots (plot-1 & 2) of 5-year-old established *A. auriculiformis* vegetation. The plantations of *A. auriculiformis* were at 2mx2m espacements and each plot consisted of 400 sqm of land and 100 trees. One plot (plot-3) was prepared in the open field, for direct sun light, in an area of 100 sqm. The number of *R. serpentina* plants in each plantation plot under *A. auriculiformis* were 1581 and in the open plot were 441. The roots were harvested and dried in the sun and whole weight of roots grown in a particular plot was weighted.

The results show that both the species of *A. paniculata* and *R. serpentina* could be cultivated in the forest floor as the total weight of the dry matters obtained from vegetation floor and open plots were significantly parallel. The study has amply shown that the intercropping of medicinal plants with nitrogen fixing *A. auriculiformis* is quite feasible. It is also revealed that through this system of cultivation, the endangered medicinal berbs or undershrubs could be saved from extincition and a yearly recurring income is possible for rural livelihood as well.

Diversity of medicinal plants in Bangladesh and their conservation needs

Shyamal K. Roy, Pinaki Sinha
Jahangirnagar University, Department of Botany, Savar, Dhaka, Bangladesh
FAX: 880-2-833054, Email: shkroy@juniv.edu

The medicinal plants played very important role from times immemmorial among the illiterates and the highly civilized persons in the folklores connecting with healing of diseases which are still practised by men and women of the east and the west, not to speak of tribals. In Egypt, India and China good informations of medicinal plants are available in the old literature, folklores, mythological stories etc. The Rig-veda, an old repository of human knowledge (4,500-1,600 B.C.) mentioned the medicinal uses of plants. The Ayurveda, evolved much later, compiled the properties of drugs and their uses.

Bangladesh has a rich heritage of medicinal plants. Geographically, the location of Bangladesh is very unique. It is a short stretch of land between the Himalayan mountains and the Bay of Bengal. It is a fertile deltaic region criss-crossed by the Ganges, the Brahmaputra, the Meghna and their network of tributaries. Naturally, Bangladesh has a rich forest resources having diversified ecosystems, such as in mangrove forest, hill forests, plainland forests, unclassed state forests, village groves etc.

There are no less than ten tribal races in Bangladesh and the country is rich in sources of ethnobotanical information. An ethnomedicinal survey was conducted in different forest regions of Bangladesh among the tribal people to record their knowledge about the use of plants for the cure of different diseases. More than 200 plants growing in the forests are found to have medicinal values. We also visitied different Ayurvedic and Unani manufacturing firms in Bangladesh and enlisted the names of plants being used as raw materials. 110 plants are extensively used by these manufacturing firms to produce crude drugs.

There is a growing interest in medicinal plants and traditional medicine within the last decade. With the increasing use of medicinal plants in many countries, and with the accelerating destruction of natural resources in the tropics, it has become clear that the exploitation of medicinal plants must be accompanied by conservation measures. Otherwise these plants become depleted as resources or may even face extinction.

At present, there are more than 300 Ayurvedic and Unani manufacturing firms in Bangladesh, of these, nine are quite big and supplying the major bulk of the traditional medicines in the market. These manufacturing firms exploit the nature by collecting the medicinal plants indiscriminately for their raw materials. So the conservation of these plants is needed for their sustainable use.

Influence of Silviculture Measures on Preservation and Productivity of Wild Berry Plantaions

V. G. Sergienko
Saint-Petersburg Forestry Research Institute, Institutsky pr., 21, 194021 Saint-Petersburg, Russia
FAX: 812 552 80 42, Email: spb330@spb.sitek.net

Keywords: non-wood forest resources, wild berry plants, productivity, sylviculture measures, cutting.

Wild berry plants are of great importance as kind of non-wood forest resources. Measures to assist the natural regeneration of wild berry plants after cutting are developed insufficiently now. At the same time they are needed on the areas with irregular distribution of berry plants and on cutovers.

The present studies were conducted to determine the influence of different types of cutting, sowing of seeds, planting and rejuvenation of wild berry plants on conservation, restoration and raising productivity of bilberry (*Vaccinium myrtillus*), bog whortleberry (*Vaccinium uliginosum*), cowberry (*Vaccinium vitis-idaea*) and cranberry (*Oxycoccus palustris*).

We studied the influence of cuts on preservation and restoration of wild berry plants. Thinning cuts were carried out in myrtillosum and vaccinosum forest types. They increased projective covering of berry plants in some times and subsequently increased productivity of latter. Non-clear cuts (sheltewood and selective) damaged berry plants much less, than clear-cuts do. Clear-cuts were carried out as a rule in areas where bilberry, cowberry and sometimes bog whortleberry grow.

Good fruiting and phytomass growth of cowberry are noted on clear-cut areas and in *Pinetum vaccinosum* types when canopy density is 0.5. Thinning of stand canopy on cranberry bog (sphagnosum type) from 0.4-0.6 up to 0,1 results in increase of a crop of berries as much as 25-50%.

By regulating of light availability and canopy density using different types of thinning high productivity of berry plants can be obtained. All types of cuts and thinning should be carried out in winter time when timber is transported using machines and in any time in case of hand transporting. The minimal damages of berry plantations are noted after selective thinning. For instance, the most productive cranberry plantations growth at canopy density of 0,1-0,4 when yield reaches 1000-1200 kg/ha. Cowberry prefers premature pine stands with canopy density about 0,4-0,5.

When projective cover of berry plants is about 35% (on clear-cut areas and in disturbed stands), the sowing and planting bilberry, cowberry and bog whortleberry are used. To increase density of cranberry and bog whortleberry plantations, an assistance to regeneration by seeds are recommended. To do that the seeds and berry wastes from processing are sowed in microraises of bogs.

Rejuvenation of bilberry, cowberry and bog whortleberry by removing old plants and cutting of sprouts are used for increasing their productivity. Mechanical method and using managed fire are developed for rejuvenation as well. Growth activity is increased at 5-10 times after this rejuvenation, which results in raising productivity.

Thus, in taiga zone of European Russia the complex of measures is used to restore and increase a productivity of wild plantations. This complex consist of following measures: thinning of forest canopy, assistance to a natural regeneration, cutting of berry plants, sowing the seeds, planting the perspective forms of berry plants.

Apical Role of NTFPs in Sustainable Forest Management & Research

Mahabir Prasad Shiva, Alka Shiva
Centre of Minor Forest Products (COMFORPTS), 8, Indirapuram, P.O. Majra, 248 171 Dehradun, India
Tel: +91-135-621302, FAX: +91-135-629936, Email: shivamfp@nde.vsnl.net.in

While defining Non Timber Forest Products (NTFP), Non Wood Forest Products (NWFP) or Minor Forest Products (MFP) and classifying NTFP in twenty six categories, pivotal role of NTFP species has been emphasised for various forestry programmes of Management and Research in the posters. Mechanism to overcome problems on the subject has also been conveyed. Future action plan required for conducting Research, Documentation of information in files and MFP Database and NTFP based enterprise development for community forest management have also been addressed in the posters.

Definition of NTFP:

Forest usufructs or utility products from forests except timber are termed as minor forest products (MFP) or non – wood forest products (NWFP) or non-timber forest products (NTFP). Viz. Edible plant products; spices and condiments; medicinal; aromatic; fatty oil; gum and resin; tans and dyes; fiber&flosses yielding plants; bamboo's; canes; fodder; leaves for bidis, platter, soapnuts etc., of plant origin. Honey, lac, silk etc., of animal origin.

FAO defines NWFP/NTFP/MFP as all goods for commercial/industrial or subsistence use derived from forests and their biomass, sustainably extracted from a forest eco-system in quantities and ways that do not downgrade the plant communities basic reproductive functions.

Suggested solution to problems on the subject

1. Pivotal role of NTFP species with Multi disciplinary integrated holistic approach needed to meet the challenge of Management and Research.
2. Strengthen IUFRO as a nodal agency for global guidance, through Centre of MFP, Dehra Dun (India).
3. Shift fom Timber - dominated to NTFP-oriented Need Based Sustainable Forest Management.
4. Understand the diversity of NTFPs (Not only restrict to Medicinal Plants).
5. Make choice of right species of the trees/ shrubs/herbs according to the edapho-climatic situation for raising plantations for replenishment of depleting stock and man made forests for NTFP-based enterprises (for sustainable forest management and biodiversity conservation).
6. Create awareness on NTFP and collect primary and secondary data in about 54 parameters on plant species, their distribution; their uses; climate; soil type; silvicultural requirements/characters; propagation; harvesting techniques; grading, processing and storage; value addition; production; marketing, trade and revenue earnings; employment generation; short and long terms gains; recommendations/future vision.
7. Document and strengthen information to create awareness and generate training material.
8. Extension of MFP/NTFP database of Centre of MFP, Indirapuram, Dehra Dun (programme on T.V. Van Darshan and other media).
9. Conduct NTFP- related enterprise development.
10. Create awareness through training programmes and revise school/college syllabi.
11. Re-orient working plans for choice of NTFP species for different forest programmes viz., JFM, JRD, Watershed Management, Global Warming, Biodiversity and Environmental Conservation.
12. Recast legal issues for people's participation and equitable distribution of profits.

FUTURE ACTION PLAN
Research
* To increase production of NTFP species for maintenance of biodiversity.
* Identify appropriate choice of species according to edapho-climatic factors.
* Ensure increased productivity:
- Standardize methods of propagation and models for raising mixed crops.
- Standardize harvesting techniques.
* Marketing research for:
- Equitable distribution of profits.
- Upliftment of disadvantaged groups of people.
- Study marketing channels and price regime.
- Assessment and regulation of demand and supply of NTFP enterprises and trends.
Documentation
* To upgrade documentation and MFP Database according to parameters for every species with primary and secondary data.
NTFP based enterprise development for community forest management
* Training programmes to all user groups through education programmes.
* Offering expertise to NTFP based enterprises.
* Augment plantations to ensure healthy and rich biodiversity/environment and socio-economic development.
ACTION TAKEN
By Team members of Centre of Minor Forest Products
HIG-2, No. 8, Indirapuram
Dehra Dun-248 171 (India)
(The only Centre in India and abroad specifcally and exclusively working on NTFPs)
under the team leader

Website (IUFRO): http://iufro.boku.ac.at
ACTION TAKEN AND CONTINUING BY COMFORPTS:
* COLLECTION OF PRIMARY AND SECONDARY DATA FROM INDIA'S MEGA DIVERSITY.
* DOCUMENTATION ACCORDING TO THE STANDARD NTFP CLASSIFICATION AND DOCUMENTATION MANUAL BY DR. SHIVA AND MATHUR.
* STORED 3000-4000 SPECIES IN MFP DATABASE COMPATIBLE WITH THE ABOVE MANUAL AND PUBLISHED A BOOK ON INVENTORY OF FOREST RESOURCES WITH 2204 SPECIES.
* DISSEMINATION OF NTFP RELATED INFORMATION.
* COMMUNITY DEVELOPMENT THROUGH NTFP SPECIES.
RESEARCH ON VARIOUS ASPECTS: RAISING MIXED CROPS OF MULTI-PURPOSE TREE SPECIES YIELDING BOTH WOOD & NTFPs & SHRUB & HERB SPECIES OF NTFP IMPORTANCE.

Sundarbans, Role of NWFPS in National Economy and Management Practices.

A. S. M. Helal Uddin Ahmmed Siddiqui
Bangladesh Forest Research Institute, Mangrove Silviculture Division, 9000 Muzgunni,Khulna, Bangladesh
FAX: 88-041-762927, Email: KhulnaNet Services [luxury@khulnanet.net]

The Sundarbans is the largest single tract mangrove forest in the world. It is famous for its Biodiversity and economic potentialities of Non Wood Forest Products. The Sundarbans mangrove forest is enriched with its natural regeneration of multipurpose species. The Non Wood Forest Products of the Sundarbans is traditionally used as food, firewood, tannin, medicine, thatching materials, housing, fencing post, roof trusses, woven utensils, cheap furniture, handicraft etc. The NWFPs also play a vital role to the environmental enrichment. The different component of the forest area and parts of plants and animals are used for different purposes in various ways by people. Especially medicinal plants may be used and popularized in commerce and trade by dint of scientists and naturalists for conservation of the forest and to use the resources properly, because medicinal plants are still unknown and not yet been popularized. The Sundarbans is a unique natural resources not only Bangladesh but also universal worth. Considering its economic importance UNESCO declared Sundarbans as "World Heritage" and the Honorable Prime Minister of Bangladesh inaugurated Sundarbans formally "World Heritage" last 4 February, 1999. In the Sundarbans Sundri (*Heritiera fomes*), Gewa (*Excoecaria agallocha*) is the predominant plant species and Royal Bengal Tiger (*Panthera tigris tigris*) and deer (*Axis axis*) is important and most common fauna. The NWFPs are goran (*Ceriops decandra*), golpata (*Nypa fruticans*), singra (*Cynometra ramiflora*), hogla (*Typha elephantina*), hantal (*Phoenix palludosa*), cane, grasses, shells and different types of fishes such as shrimps, king crab, dry fish etc. Honey and wax and all other NWFPs are extracted from the forest annually and managed by the Sundarbans Forest Division for sustainable development. From these resources the Government earns a lot of revenue, which influence our national economy and improve socio-economic development.

Ecological Effects Associated with Rattan (*Calamus zollingeri*) Harvesting in Sulawesi, Indonesia

Stephen F. Siebert
University of Montana, School of Forestry, MT 59802
Missoula, USA
FAX: 406-243-6656, Email: siebert@forestry.umt.edu

The sustainable harvest of non-timber forest products (NTFP) has been advocated as a means to simultaneously encourage economic development and the conservation of biological diversity, and now forms the basis of many tropical forest conservation efforts. Some ecologists argue that the sustainable harvesting of NTFP resources is flawed, that conservation and development are incompatible, and that there are few, if any, documented examples of sustainable extraction that consider ecosystem-wide effects over ecologically significant periods of time.

This study documents ecological impacts associated with the extraction of the most important NTFP from Southeast Asia, rattan, based on four years of field work (1995-99) in two village areas in Central Sulawesi, Indonesia. Specifically, I quantify and evaluate: 1) effects of cane harvesting on the abundance and growth of the premier commercial rattan, *Calamus zollingeri*, through monitoring of 175 randomly selected plants for three years; 2) nutrient losses associated with *C. zollingeri* extraction through leaf and cane tissue analysis; and 3) forest-related impacts associated with gathering and transporting cane by monitoring five permanent 10 x 1000 m transects for three years and the extent and volume of tree cutting to float cane to market.

Evidence of rattan harvesting is widespread in the study areas and marketable supplies of cane (i.e., > 10m in length) have become increasingly scarce. Permanently marked *C. zollingeri* plants experienced no direct mortality from cane harvesting despite repeated removal of mature canes. However, production of new ramets and ramet growth were lower where harvesting pressures were intense which suggests that vegetative reproduction and cane growth may be adversely affected by cane harvesting.

Significantly greater amounts of nutrients (i.e., total N, P, K, Ca and Mg) were found in the leaves than in the stems of *C. zollingeri*. Since all foliage is left on site when canes are harvested, only nutrients stored in canes are removed. On-going work will ascertain the dry weight equivalencies of these losses on a per ha basis, but nutrient removals appear to be less than natural inputs through weathering, atmospheric deposition, and N-fixation.

Rattan harvesting involves cutting canes at their base and pulling them down from supporting vegetation. Cane harvesting did not affect supporting trees or understory vegetation in this study (i.e., no damage was observed to other vegetation immediately after harvesting or one or two years later). However, in some cases trees may be cut if rattan cannot be pulled down. Natural tree fall gaps comprised 16% of the transect areas and their number and size were unaffected by pulling cane. In 1996, there was no evidence of tree felling to gather rattan, but in 1997 an average of 0.3-3.0 trees/ha had been to felled gather rattan. Tree felling is increasing due to the scarcity of easily extractable, large-diameter cane and now exceeds natural tree fall rates in intensively harvested areas.

Tree falls, both natural and to extract cane, can affect the growth and survival of rattan. Natural tree falls crushed 6.6% and killed 2.8% of marked rattans over a 20 month period where cane was not intensively harvested. Where cane extraction was intense, three times as many rattan were crushed by cut trees than natural tree falls and rattan mortality increased 2.5 fold.

The transport of rattan to market entails floating cane down river to road transport points and the use of floater logs to prevent cane sinkage. Eight tree species are regularly utilized as floater logs and all are light-weight, fast-growing, early-successional species. Floater trees are harvested primarily from fallowed shifting cultivation fields and regularly disturbed riparian zones.

Between October 1996 and September 1997, 135 and 100 tons of cane were extracted from the two study areas requiring 2350 and 1667 floater logs (averaging 25 cm diameter and 3 m length), respectively.

Harvesting floater logs appears to have little effect on biodiversity conservation. Floater trees are harvested in early successional, disturbance-associated forests and farms, thus their removal does not affect primary forests, some species coppice when cut, and the leaves, twigs, and bark are left on site so nutrient losses are not appreciable.

The collection of rattan cane is economically important at the household, village and provincial levels in Central Sulawesi. Fifteen years of *C. zollingeri* harvesting has reduced the supply of mature canes and, where intense, may have reduced ramet production and growth. There is no evidence that cane harvesting affects the survival of *C. zollingeri* plants or ecosystem nutrient stores, or that the cutting of small trees to float cane is a major environmental problem. On the other hand, tree felling to extract cane has significantly increased the number of canopy gaps, which may alter future forest species composition and successional patterns.

Margins Approach to the Performance of Non-Timber Forest Product Markets: A Study of the Woodcarving Markets in Southern Zimbabwe

W. Standa-Gunda
Center for International Forestry Research, PO Box 6596 JKPWB, 10065 Jakarta, Indonesia
FAX: 62 251 622100, Email: w.de-jong@cgiar.org

The commercial trading of wooden carvings is a recent phenomenon in Zimbabwe. Most markets have been sited along 'tourist routes' usually in areas designated for smallholder agriculture (it is in these communal areas where poor people are concentrated). The carvings are largely sold to foreign tourists and the carving industry probably plays an important role in sustaining the livelihood of poor people. The increase in the number of markets that trade in carvings has been attributed to macro-economic policies, recurrent droughts and the growth of the tourism industry.

The markets where wooden carvings are sold perform a number of essential functions that facilitate the trading of such artifacts, namely the exchange function (buying and selling), physical function (storage and processing) and facilitating function (risk bearing and market intelligence). For wooden carvings, a diverse number of market chains exist. Within these chains, distinct functional levels are evident. The first level is the acquisition of woodland-based raw materials and their transportation to the market, while the second level involves the carving of the product. The third level is the finishing (sand-papering and polishing) of the product. The final level is the trading of the product to consumers.

This poster presents data on the market performance of the wood carving industry in Zimbabwe. This assessment is done using data from three case study markets from Chivi district. From this data gross market margins and net market margins will be used to assess the returns to factors of production at various levels of the market chain including the cost of performing each function and the rules and regulations governing each level.

Using a gross margin approach to the analysis of woodcraft production and trade, the overall cost of processing and marketing of traded NTFPs was less than the selling price. Although some functions in the marketing chain were loss-making, most participants had countered this by integrated such functions with profit making ones. Carvers also trade to capture the high net margins associated with this function. The distribution of costs along the market chain are not uniform. As such, the paper acknowledges the disparities in incomes accruing to different functions in the market chain. These also vary with product type and the tree species.

The margins approach as applied to this paper depict the trading of woodcarvings in Chivi District as an economically profitable enterprise. Total net margins, are all positive, ranging from US$23 to US$565. A decontsruction of these total net margin shows that most of these accrue to the traders in the market chain. The widely accepted thesis has been that the woodcarving markets in Zimbabwe are inefficient. This poster demonstrates how this notion is a fallacy, exposing that participants in woodcarving markets are rationale given their socio-economic environment.

Extractivism, Peasantry and Wage Labour in an Amazonian Context: Shifts in Rural Livelihood Strategies of Northern Bolivia

Dietmar Stoian
University of Freiburg, Institute of Forest Policy, Markets and Marketing Section, Freiburg, Germany
Email: w.de-jong@cgiar.org

In the late 19th and early 20th century, rural livelihoods in the northern Bolivian Amazon were largely based on the commercial exploitation of rubber. Extraction was organised in a highly oppressive debt peonage system leaving most of the rubber tappers in permanent indebtedness to their patrons. But the slump in rubber prices following World War I called for adaptations of the organisational mode underlying forest product extraction. Rural livelihood systems changed accordingly, as rubber tapping became supplemented with subsistence agriculture and Brazil nut collection. This agro-extractive mode of making one's living was prevalent until the mid 1980s. In 1986, the withdrawal of Brazilian rubber subsidies, which had been granted to Bolivian rubber, too, brought about the collapse of rubber trade in Bolivia. The renewed rubber crisis was overcome through the expansion of the Brazil nut, palm heart and timber industries which nowadays provide employment to thousands of unskilled labourers in towns and income to the vast majority of about 7,000 rural households.

This poster presents results of the dynamics in rural livelihood strategies against the backdrop of the rubber demise. Household economies in northern Bolivia reveal various trade-offs between agriculture, extractivism and wage labour. Notwithstanding the loss of rubber-based incomes, virtually all rural households continue to depend on earnings derived from the sale of non-timber forest products. This is especially true for remote settlements where Brazil nuts and palm hearts combined provide up to 90 percent of a family's cash income. Even in settlements closer to one of the towns, where ease of access to agricultural markets provides further income opportunities, extraction-based incomes do play a significant role. Varying dependencies on NTFP-based income are analysed through a typology of rural households. Key factors for their distinction are access to land and markets, economic life histories, and labour division within a given settlement. Based on the typology conclusions are drawn for tailor-made extension programmes taking into account the individual history and present specialisation of rural households.

Some of the main conclusions of this study are that the commercialisation of forest products has long been part of rural livelihood strategies in which agriculture and extractive activities were embedded. Partly new is wage labour as additional source of income. The underlying reasons of the resulting intra-community differentiation are analysed to better predict future trends in off-farm income. There is high variation both within and across the communities as regards trade-offs between agriculture, extractivism and wage labour. As there is no such thing as a uniform rural household and, moreover, intra-community specialisation increases, extension programmes need to be adjusted to meet the demand of a fairly heterogeneous group of forest dwellers. The Brazil nut and palm heart industries are indispensable sources of cash income. But along with a slump in Brazil nut and palm heart prices, as well as the ongoing depletion of natural stands of *E. precatoria*, rural dwellers (will) face increasing difficulties to gain sufficient monetary income. In the light of lacking economic alternatives expansion of agriculture and increased rural-urban migration are likely to be adaptive responses

Impact of Logging on Species Diversity of Palms in the Lowland Forest of Pasoh

Nur Supardi, Dransfield, J. and Pickersgill, B.
Forest Research Institute Malaysia, Kepong, 52109 Kuala Lumpur, Malaysia
Tel: 603-6342-633, FAX: 603-6367-753, Email: supardi@frim.gov.my

We compared the species diversity of palm community, including rattans in the unlogged and logged forests of Pasoh in Negri Sembilan, Peninsular Malaysia. The latter was logged in 1955. Both forests are on soil developed on shale parent materials and characterized by the presence of band of laterites. Four 0.12 ha plots in the unlogged forest, and nine in the logged forest were established and assessed for all palm species at four growth stages: seedling, juvenile, intermediate and mature stage.

Logging reduces the species richness of palms. The number of palm species for the unlogged and logged forests were 27 species (6 genera) in 0.48 ha and 18 species (5 genera) in 1.08 ha, respectively. Eight out of eleven commercial rattan species recorded in Pasoh are found in the logged forest. Most species occurring in small numbers in the unlogged forest were absent in logged forest. Variation of species richness between plots exist but not crucial. The impact of logging increased the variability in the number of species per unit area across all growth stages. However, it appears that the element of chance plays a greater role in determining species richness as there is no clear indicator for lack of species in some plots. A larger sampling area for the logged forest is required for better and precise estimation of palm species richness.

The most prominent effect of logging, even after forty-two years is the low density of palms. There were only 1008 individuals per ha as opposed to 8691 individuals per ha in the unlogged forest. Most number of species and individuals are those in seedlings and juvenile growth stages. One of the main factor for low palm density is the damage caused along trails made by log-hauling tractors. Only a few palm seedlings were observed to be growing on old logging trails which soils are compacted and sparsely covered. No information on the logging intensity was available for comments. Other factors observed to contribute to the low density of palms are the past distribution of palm species present prior to logging, growth characteristics of the species and topography.

Palm densities were also observed to be influenced by light gaps, the damage to the undergrowth or forest floor, fruiting frequency and seed dispersal and recruitment of seedlings from outside the plots. These influencing factors were also observed in unlogged forest.

Ecological status of non-wood forest produce extraction in the tropical forests of W.Ghats of Tamil Nadu, South India

P.S. Swamy, SM. Sundarapandian and S.Chandrasekaran
Dept Plant Sciences, School of Biol Sciences, Madurai Kamaraj University, Madurai – 625021, INDIA
Tel: ++91-452-858928; Fax: ++91-452-859139

Non-wood forest product utilization in the tropical forests in Veerapuli and Kalamalai Reserve Forest in the Western Ghats of Tamil Nadu, South India. Kani's the local tribal people in this region largely depend up on the collection of non-wood forest produce for domestic and other uses. The non-wood produce of 12 plant species were extensively extracted and sold to local traders for commercial exploitation. Unwise and over exploitation of this produce might cause a potential threat to the survival of the plant species such as *Cinnamomum, Cycas, Canarium, Bambusa, Calamus* and *Emblica.* In addition to that the activity of non-wood products collection in these forest ecosystems has resulted in alteration of population dynamics of certain size classes of tree species such as *Cinnamomum malabathrum, Canarium strictum* and *Caryota urens*. The present study suggested that the unscientific exploitation of non-wood products and associated anthropogenic perturbation in tropical forests may result in the decline or may even gradual extinction of certain species. In addition to that this anthropogenic perturbation occasionally result in forest fragmentation, which in turn may lead to loss of local biodiversity.

Biodiversity of Rattan Species in Mount Halimun National Park District, West Java

Marfu'ah Wardani, Titi Kalima
Forest and Nature Conservation Research and Development Centre, Jl.Gunung Batu 5, 16122 Bogor, Indonesia
Tel: 0251 325111, FAX: 62 0251 325111, Email: slitbang@indo.net.id

For a management of a forest, it is believed that much basic knowledge about the nature of the forest is needed. One of them is to develop the forest a resource of cane industry in sustainable way. For these purpose the composition, distribution and density of rattan species in Gunung Halimun National Park (TNGH) were studied as a model. Data were collected from December 1994 until May 1995. For species composition on rattan in TNGH, three areas were observed namely in Gunung Kencana, *G. Pameugpeuk*, and *G. Pangkulahan* using a continues square transact method, from elevation 800-1,400 m asl. From three areas in TNGH, it was found that three are 13 species of rattan in the region. In terms of species richness and densities, *G. Pameunpeuk* comes first, follows by *G. Pangkulahan* and *G. kencana*. *Calamus heteroideus*, *C. javenals*, *Daemonorops melanochaetes*, and *Plectocomla elongata* are dominant both in seedling and nature forms, The rattans are relatively abundant in areas less than 1000 m asl. and decrease in number of species as well as the minimal population in the higher altitude.

Production and Research of Gum Oleoresin in China

Song Zhanqian
Chinese Academy of Forestry, 210042 Nanjing, China
FAX: 86-25-5413445, Email: zqsong@public1.ptt.js.cn

Keywords: gum oleoresin, chemical utilization, *Pinus*

The pine species, about 22 species and 10 varieties, is widely distributes in China, amounts to 16 million ha. Main pine species valuable for oleoresin production include *P.massoniana, P.yunnanensis, P.langbianensis* and *P.latteri*. Rosin and turpentine can be produced from oleoresin.

For more than 1700 years ago, pine oleoresin had been used as medicine described in a Chinese ancient medical book "Shen Nong Code of Medical Herbs". In mountainous area oleoresin as a byproduct provides considerable benefit to the local people. Approximately 200,000-250,000 farmers are engaged for part time in gum oleoresin tapping in China per year. The total income of tapping workers amounts to nearly 100 million U.S. Dollars. Now oleoresin output in China is around 500,000 tons yearly, increasing 20 times in the recent 50 years. It takes the first place in the world. The quality of gum rosin has been upgrade. The export quantity of rosin is about 200,000 T/Y, occupying 40-50% of the world trade exported to more than 50 countries and districts al over the world.

Since 1966, many chemical modified products of rosin can be already researched and produced in China such as polymerized rosin, disproportionated rosin, hydrogenated rosin, maleated rosin, rosin amine and serial esters of these modified rosins and so on. Now the total producing capability of these modified products is more than 60,000 T/Y. Pine oil, terpineol, synthetic camphor, borneol and polyterpene resins are main modified products of turpentine in China. The perfumes from turpentine have been developing rapidly. Now China can produce all main modified products of rosin and turpentine abroad. Their qualities can be satisfied with that of the same products in abroad basically. Some modified products have been exported.

At present, developing fine chemicals from renew resource, instead of less and less petroleum resource has been paid more and more attention in world. Since 1990, we begin to prepare many new fine chemicals products, which have not been mentioned in literature and patents at home and abroad. New plasticizer for PVC, high electric insulating rosin, rosin type heat resistant polyamideimide, modified rosins used in soldering flux, rosin type of surfactants, synergist for insecticides and so on can be produced. We have prepared colorless rosin used in electronic and adhesive industry instead of colorless hydropetroleum resin. These above fine chemicals will compete with some petro-chemical products and extend the uses of oleoresin products, thus bring more and more economical benefits to China.

5.11.02 Medicinal and aromatic plants

Anti-inflammatory Activities of *Tabebuia chrysantha* (Jacq). Nichols

Rasadah Mat Ali, Nik Musa'adah Mustapha
Forest Research Insitute Malaysia, Medicinal Plants Division, Kepong, 52109 Kuala Lumpur, Malaysia
Tel: 603-6302290, FAX: 603-6365793, Email: rasadah@frim.gov.my

Anti-inflammatory activities of *Tabebuia chrysantha* were evaluated using the *in vitro* (soya 5-lipoxygenase) and *in vivo*) 12-0-tetradecanoylphorbol- 13-acetate (TPA)-induced mouse ear oedema and carrageenan-induced rat paw oedema) methods. Lipoxygenase activity is associated with the antiiinflammatory response and thus inhibitors of this series of enzymes may provide compounds of interest. It was found that the dichloromethane extract of *T. chrysantha* (stem) showed strong inhibitory activity on soya 5-lipoxygenase. Bioassay- guided chromatographic fractionation led to the isolation of a naphthoquinone, lapachol. The inhibitory activity of lapachol from *T. chrysantha* against soya 5-lipoxygenase (IC500.76 µg/ml) was equivalent to that of the positive control fisetin (IC500.97µg/ml). TPA-induced ear oedema in mice and carrageenan-induced paw oedema in rat are the model for detecting the topical and oral antiinflammatory agents respectively. A dichloromethane extract of *T. chrysantha* (stem) was found to inhibit oedema in both tests. Topical application of *T. chrysantha* inhibit the oedema by 77% at a dose of 0.5 mg/ear in the TPA-induced mouse oedema. The dose-response relationship of the extract showed that the maximum effect (100%) was given at a dose 1 mg/ear. The extract administered orally (1g/kg) significantly reduced the oedema by 33% and 28%, 2 and 3 hr respectively after carrageenan injection. These results may imply that *T. chrysantha* is topically and orally effective and have the potential to be used as an anti-inflammatory agent.

Investigation into the Induction of Gaharu in Standing Karas (*Aquilaria malaccensis*) Trees

Yu Shyun Chang, Reader, Sarah, A. Spiers, M.A.Nor Azah, A. Abu Said, Lok, Eng Hai
Forest Research Insitute Malaysia (FRIM), Kepong, 52109 Kuala Lumpur, Malaysia
Tel: 603-6342633, FAX: 603-6365793, Email: changys@frim.gov.my

Gaharu or agar wood is a resin-infused wood produced under certain conditions in the karas (*Aquilaria malaccensis*) trees. The fragrance produced on burning the wood is greatly valued. Gaharu is collected from the forests and despite the wide distribution of karas in Malaysia, the supply is diminishing. Gaharu is a valuable NTFP (Non-Timber Forest Product) and contributes towards the national income revenue as a minor export. By identifying the inducer(s) for gaharu formation, a more sustainable or plantation type approach to manage this resource should be possible.

Previous research had shown that wounding and microbial infection could stimulate gaharu formation. In this study we investigated the combined effect of wounding and microbial infection in gaharu formation in standing karas trees.

Bacteria and fungi were isolated from fresh samples of naturally formed gaharu. Seven isolates were selected based on their ability to infect willow wood under laboratory conditions. Fungal isolates were grown on MEA (Malt Extract Agar) and bacterial isolates on NA (Nutrient Agar). The inocula were prepared by macerating ten stock plates each of the selected isolates in a Waring blender and made up to 500 ml with sterile water. A volume of 40 ml of each inoculum was pumped into the drilled hole under pressure (200 psi) using a patented Hort+Research pressure injector.

Treatments were placed 10 cm apart in a spiral with 30 cm between spirals to minimise the influence of one treatment upon another. A total of eight treatments were set up on three mature karas trees in two localities. The treated trees were left for 10 months. Samples from the treated areas were collected for examination of the extent of infection, presence of gaharu and chemical analysis by GC and GC/MS. In view of the commercial potential, karas wildings were planted to observe their growth performance under plantation conditions.

Our preliminary results were encouraging. By burning the wood samples collected from the treated regions, majority gave off the gaharu scent. Transmission and scanning electron micrographs clearly showed the deposition of resin in channels in the intercellular spaces. Profiles of oils obtained by hydro-distillation of the treated wood samples when compared with oils from natural gaharu indicated similar major constituents but in different proportions. The major constituents were basically sesquiterpenes and oxygenated sesquiterpenes. The presence of two major compounds, jinkohol and jinkohol II, was observed in some of the treated samples as well as a commercial gaharu oil. These results strongly indicated the presence of gaharu after treatment. Continued monitoring of the planted wildings showed that this species could tolerate shade and relatively high acidity in the soil. They grew well under established trees and also did not suffer under exposed conditions.

We conclude that gaharu can be induced successfully by artificial means. However, more research is needed to focus on the selection of treatments for effective induction on a large scale, and more trees are needed for further induction trials. After selection and verification of selected treatments, the quality of gaharu produced will need to be determined.

The Utilization of *Eurycoma longifolia* Jack (Tongkat Ali) in Peninsular Malaysia

Mahd Azmi Muhammad Idris, Norini Haron
Forest Research Insitute Malaysia (FRIM), Techno-Economics Division, Kepong, 52109 Kuala Lumpur, Malaysia

Medicinal plants are known to be used by various ethnic population around the world since early time. As important ingredients, the practice and knowledge of the traditional medicine are still persisted passed on though many generations. Malaysia is richly endowed with a diverse flora with e great potential to develop into various useful natural products. Ethnobotanical/ethnomedical study suggests that at least about 20% of the estimated total of higher plant flora of 15,000 species comprise plants, which have been reported to possess medicinal and other therapeutic properties. One of the famous medicinal plants being utilized in Malaysia *is Eurycoma longifolia* Jack (Tongkat Ali). This plant has been widely used in the Malay traditional medicine for many years. With its special aphrodisiac properties, which are much touted about, *E.longifolia* had stimulated public awareness on its use. Its parts (roots and stems) have been a primary source of traditional medicine products for the pharmaceutical industry, especially the Malay traditional medicine manufactures. This paper discusses the utilization of *E. longifolia* Jack by Malay practitioners, which focussed on the process of harvesting by collectors as well as the production process of *E. longifolia* Jack roots and stems by industries including *E. longifolia* Jack are also being highlighted.

Soil Fertility Improvement Following Application of Mulch Mat from Oil Palm Empty Fruit Bunches

Wan Rasidah Kadir
Forest Research Institute Malaysia, Kepong, 52109 Kuala Lumpur, Malaysia

Through a collaborative research with a private company, FRIM scientists have successfully development a product called "mulch mat". This product is made from the palm oil mill residue that is rich in plant nutrients particularly potassium. Technically, the process of making mulch mat is simple The oil palm residue, in this case empty fruit bunches (EFB) are shredded, mixed with biodegradable binder and pressed to form a mat. With this simple technique, however, problems associated with handling of EFB are minimised. For example, unlike EFB which contains high moisture, these mulch mats are dry and light thus allow for storage and cheaper transportation cost. Mulch mats are flat of standard with size, no spikes and minimal oil content thus handling in the field is easier.

Field trials carried out at two different locations showed that the many mats is capable of soaking rainwater and remained moist underneath even though the surface layer was very dry. The studies also revealed important increase in soil pH of acid soil and improvement in soil nutrient content particularly potassium. Conspicuous changes were observed in the first 15-cm soil layers where the feeder roots are most concentrated. For example, exchangeable K increased from 0.6 $cmol_c$ kg^{-1} to 3.8 $cmol_c$ kg^{-1} in a trial in Perak and from 0.08 $cmol_c$ kg^{-1} in a trial in Kedah in the first 5 cm soil layer after one month of mat application. Similar trends were also observed for other soil parameters such as pH, available phosphorus and organic carbon. The only parameter analysed that did not exhibit any important increase was total nitrogen. This is due to the initially low nitrogen content of oil palm empty fruit bunches.

Utilization and Cultivation on Selected Medicinal Plants in Malaysia

Azizol Abdul Kadir, Mohd Ilham Adenenan, Lean Teik Ng
FRIM, Kepong, 52109 Kuala Lumpur, Malaysia
Tel: 603-6302352, FAX: 603-63657753, Email: nglt@frim.gov.my

Many of the Malaysian medicinal plants have long been used as medicines, health foods, flavours or fragrances and cosmetics. They are either used directly for preparation of dishes or as aqueous or oil extracts prepared in a crude traditional manner. Medicinal plants, which are commonly used by the locals for preparation of traditional medicines, are *Centella asiatica* (pegaga), *Cinnamomum zeylanicum* (kayu manis), *Curcuma domestice* (kunyit), *Eurycoma longfolia* (tongkat ali), *Kaempferia galanga* (cekur), *Languas galanga* (lengkuas) and *Zingiber officinale* (halia). These plant materials are mainly imported from abroad or collected from the wild, with some of them being grown by households in small garden plots to flavour dishes, or grown by vegetable farmers as minor cash crops. Although the Malaysian environmental conditions are suitable for large-scale cultivation of medicinal plants, the commercial potential of these plants has yet to be explored. With the view of developing a Malaysian medical plant industry, the Forest Research Institute Malaysia (FRIM) has initiated several programs to document, domesticate and commercially cultivate selected economic medical pants in the country.

Prospecting For Anti-Methicillin Resistant *Staphylococcus Aureus* (Mrsa) Plants At Pos Lanai

Khozirah Shaari, Mastura Mohtar,
Zainon Abu Samah
Medicinal Plants Division, Forest Research Institute Malaysia (FRIM), Kepong, 52109 Selangor
Tel: 603-6302292, Fax: 603-6367753, E-mail: khozirah@frim.gov.my

Methicillin Resistant *Staphylococcus aureus* or MRSA, first detected in the UK in the early 1960's, has recently hit the headlines as the 'hospital superbug'. It has become endemic in many countries and is a significant cause of nosocomial infections in large hospitals worldwide. Approximately 100 patients a year die from infection with MRSA, and the bacterium is acquiring greater resistance to antibiotics almost by the day. Treatment of MRSA infections often require multiple drug therapy using available antibiotics. However, scientists are now concerned that MRSA may even become resistant to the last known conventional treatment, as some strains are now resistant to all antibiotics except vancomycin, a powerful drug with toxic side effects. Hence the threat to patient care posed by such organisms has stimulated continuing efforts to search for potent anti-MRSA agents and one such source of alternatives are phytochemicals.

Phytochemicals form the basis of many drugs currently in use and is forseen to continue to be so in the future. Accounting for about half of the world's flowering plant species, the megadiversity of the tropical rainforest represents a natural target for the discovery of phytochemicals as potential therapeutic agents. Although a large number of new phytochemicals are being discovered, as reported in many natural products publications, not many of these discoveries come from the Malaysian rainforest which houses about 12,000 species. This indicates that there would be many more potential drug candidates yet to be discovered from our diverse flora, including new antibacterials to combat MRSA.

Based on this scenario, during an ethnobotanical survey carried out on medicinal plants of two Orang Asli villages *viz*. Perkampungan Orang Asli Pantos and Perkampungan Orang Asli Suar, at Pos Lanai, Lipis in the state of Pahang, the opportunity was also taken for a short survey on anti-MRSA plants. A total of 20 medicinal plants from 14 genera were analysed for anti-MRSA activities towards a panel of 15 clinical isolates of MRSA. The MRSA isolates were taken from blood, throat, puss and the environment. Assaying method employed was the paper disc diffusion technique, the strength of activity denoted by size of inhibition zones around each plant extract impregnated discs. Out of the total number of plants tested, nine were found to inhibit the growth of ≥10 of the MRSA isolates. The active plants included species from the plant families Opiliacea, Moraceae, Sapindaceae, Piperaceae, Gesneriaceae, Lauraceae and Myrsinaceae.

Evaluation of Medicinal Flora in Western Ghat Forests of Karnatka State: Plants Used in Dental Care

R. Shubharani, V. Sivaram
Century Foundation, # 3391, 13th Main, H.A.L. 2nd stage, 560008 Bangalore, India
FAX: 91-80-3348346, Email: cenfound@sparrl.com

The studies on the medicinal flora with particular reference to the plants used in dental care of Western Ghat forests of Karnataka state, India, was undertaken during 1996-1998. The tropical forests of Western Ghats of Karnataka widely acknoledged as one of the most species rich terrestrial ecosystems in the world. The Phytogeographical zone of Western Ghat forests stretching from Belgaum to Mysore in Karnataka with total area of 6191187 ha. The medicinal plants are very important components of tropical forests. Traditional medicine has been used since the existance of homosepians, and its importance is still in practice even today. During the present investigation, the comprehensive data on the plants used by the indigenous people and local health practitioners for various dental problems were recorded. The study revealed that 75 species of 43 plant families are most important and widely used for curing dental disorders. Some of the plant species used in dental care are: *Azadirchta indica*, *Acacia sp.*, *Artocarpus heterophyllus*, *Syzygium aromaticum*, *Emblica officinalis*, *Glycyrrihiza glabra*, *Pongamia pinnata*, *Pterocarpus marsuopium*, *Datura metel*, *Barleria prionitis*, *Mangifera indica*, *Semecarpus anacardium*, *Elephantopus scaber*, *Terminalia arjuna* etc.

The present study highlights the conservation status of the plants used in dental care and draws attention to more intensive and integrated efforts to protect, conserve, investigate and utilize the valuable natural plant resources for human needs.

5.11.03 Edible products from the forest

Tree Borne Oil Seeds as a Source for Subsistence to the People and Raw Materials for Industries

Ashok K Pandey
Indian Council of Forestry Research & Education, Centre for Forestry Research & Human Resource Development, Nagpur Road, 480 001 (M.P.) Chhindwara, India
Email: mpchwra!nicnet@mp.nic.in

Oil and fats are not only an essential part of human and animal diets but are also an indispensable ingredient in numerous industries such as, Paints and varnishes, soaps, cosmetics, hardened fats, textiles, leather. pharmaceuticals, lubricants etc. Satpura Plateau of Madhya Pradesh (India) has been bestowed with vast forest areas which contain a very rich flora, tree borne oil seeds being a part of it. Tree borne oil seeds have tremendous potential and if it is harnessed in full it will lead to the productivity of forests. This will help to improve hte socio-economic conditions of the tribals and rural folks. It will also generate huge employment opportunities to the rural poors. The demand of fatty oils are also increasing world wide and this is likely to increase with the rapidaly increasing population. Hence there is need to identify more and improved sources of the fatty oils and to prescribe scientific methods of collection, preservation, processing and extraction practices for maximization of economic production/growth.

5.12.00 Sustainable wood industry

Procedure for Evaluating and Monitoring the Sustainability of a Lumber Production Forest

José Nivaldo Garcia, Israel Luiz de Lima
University of Sao Paulo, ESALQ/LCF, PO Box 9, 13418-900 Piracicaba, Brazil
Tel: 55 19 430 8638, FAX: 55 19 430 8666, Email: jngarcia@carpa.ciagri.usp.br

Keywords: sustainable forestry, *Eucalyptus grandis*, plantation, wood products

A reliable estimate of the standing volume of sawn wood enables a strategy to be formulated for the sustainable management of production forests. This study proposes a method for estimating the sawn-wood volume stocked in any standing plantations. Only a few variables are required to make such prediction and each of them is very easy to be obtained for a particular forest, either planted or natural one. The accuracy of that proposed theory was verified in an *Eucalyptus grandis* experimental plantation which was being grown and managed according to the Correlated Curve Trend (CCT) method. The paper shows that stem shape and round wood volume can be predicted very well by a studied function, which is based on the DBH and the height of the tree only. This function permits to obtain the diameters of all logs that are intended to be obtained from that stem. Another function was obtained from logs processing in an industrial sawmill for predicting the recovery rate, which is expressed by the relationship between sawn wood volume and its early round wood volume. This function is based on the smaller diameter of the log only. The combination of those functions permits to obtain the sawn wood volume stocked in each DBH class of a standing population. Also provides a good estimate of the total round wood volume and sawn wood volume available in the entire forest. It was important to note that round and sawn wood prediction curves get closer each other as DBH becomes larger. This means that at some extent smaller trees do not contribute effectively with an optimized lumber production. In the case of natural forest, smaller trees can be saved for contributing with the regeneration process, without introducing great impact on lumber productivity of the whole forest. It is important for the sustainable management of forests that companies obtain an accurate assessment of end-product volume. They must know how large their forests have to be in order not to have either problems concerning to raw material supply or to explore above of the forest capacity. It is possible from this study to calculate either the exact area needed to supply a specific sawmill or the exact size of a sawmill that will operate, at optimum, based on a specific forest area. The proposed methodology estimates the potential of a forest lumber production and arrives to an indicator that brings together all people who work consciously exploring and protecting the environment. It may be considered as an interesting tool, which increases the capability for monitoring the maintenance of the lumber productivity.

Made to Compete: A Hybrid Product for Forest Products Industry

David N.-S. Hon
Clemson University, School of Natural Resources, 29634-1004 Clemson, USA
Tel: (864) 656-4834, FAX: (864) 656-3304, Email: dhon@clemson.edu

Keywords: engineered wood products, composite products

Wood has long been considered as an engineering material. Recent survey showed that many builders do not consider wood as a suitable material for construction use. They see wood as the least durable material. In order to improve wood's competitive position, forest products industry is facing many challenges. One of the attractive and practical approaches is to produce a hybrid product from wood and plastic materials. The potential of producing a high wood fiber, low plastic characteristic wood fiber-thermoplastic composite is discussed. Current upward trend in cooperation between the forest products and plastics industries is exhilarating.

Implementation of Sustainable Forest Management: Application of Criteria and Indicators in Korea

Joong Myung Kim
Forestry Research Institute, 207 Chongnyangni, Seoul, Korea R.
Tel: 961-2532, FAX: 961-2530, Email: johnjmkim@hotmail.com

Since the UNCED in 1992, sustainable forest management has been the major theme of conservation, management, and development of forest resources around the world. While addressing the promotion of efficient utilization and assessment to recover the full valuation of the goods and services provided by forests, forest lands and woodlands at UNCED, governments agreed to pursue, in cooperation with special interest groups and international organizations, the formulation of scientifically sound criteria and guidelines for the management, conservation and sustainable development of all types of forests (Chapter 11 of Agenda 21, Programme Area C, Section 11.23[b]). Also governments recognized that sustainable management and use should be carried out in accordance with national development policies and priorities and on the basis of environmentally sound management guidelines; and that, in the formulation of such guidelines, account should be taken, as appropriate and if applicable, of relevant internationally agreed methodologies and criteria(paragraph 8(d) of the Forest Principles). To promote sustainable forest management in Korea, many actions have been taken in close cooperation with international and regional initiatives about forest resources. In particular, Korea has actively participated in the Montreal Process and others including Intergovernmental Panel on Forests under the UNCSD. Based on the major criteria and indicators for sustainable forest management, the current forest management conditions were evaluated in Korea. The average applicability of criteria and indicators for sustainable forest management in Korea was estimated at about 70% among major criteria, except for legal, economic, and institutional framework. In each criterion, the current status were discussed and future activities were suggested to achieve the sustainable forest management in Korea. In particular, the general conditions of forest management based on criteria in Korea was briefly described and major programmes towards sustainable forest management were explained in context with the long-term Forest Plan, started in 1998.

Sustainable Development of Rubberwood in China

Yu Dong Li
Chinese Academy of Forestry, Research Institue for Wood Industry (CRIWI), 100091 Beijing, China
Tel: +86-10-6288.8324, FAX: +86-10-6287.4623,
Email: yudongli@public.bta.net.cn

Keywords: sustainable forestry, plantation, China, preservative treatment, marketing, value-added products

As the 4th largest rubberwood resource in the world, Chinese rubberwood plantations occupy 618,500 ha of which 374,000 ha are on Hainan Island, 156,500 ha are in Yannan Province and 88,000 ha are in Guangdong Province. The rubberwood industry on Hainan Island is more developed than in other areas of of China. Between 1988 and 1997 the production from the General Bureau of Hainan State Farms (GBHSF), which owns 66.5% of rubberwood plantations on Hainan Island was approximately 350,000 m^3 annually from a growing stock of 13.5 million m^3. The demand for rubberwood is expected to increase in the near future because at the end of 1998 China adopted a policy to protect natural forests that will reduce wood supply for quite long time. An annual harvesting of 3% of the standing volume of rubber trees is planned in Hainan State Farms sector. This will yield an annual supply of rubberwood of 418,000 m^3 of logs and 188,000 m^3 of branches. The industrial use of rubberwood began at 1985-1987. The annual production capacity was 400,000 m^3 of sawn timber, 20,000 m^3 of plywood, and 39,000 m^3 of MDF at 1998. The average annual output of rubberwood products from 1991 to 1996 was 60,000 m^3 of sawn timber, 15,000 m^3 of plywood, 25,000 m^3 of particleboard and 779,000 sets/pieces of furniture. Other rubberwood products were flooring, blockboard, moulding board, laminate, and handicrafts.

China has had an active rubberwood research program since the 1980s when the rubberwood industry was established. Research has included sawing, prevention of attack by mold and blue stain fungi or insects, preservative treatment, drying etc., but the main focus is on primary processing. This research provided the basic technical information needed by the rubberwood industry at that time. With the emergence of environmental protection as a critical issue in industrial development, and the consideration of sustainable management of forests in national development, many new problems have arisen in the rubberwood industry. Sodium pentachlorophenol, which is highly toxic to both humans and the environment, is still used as preservative. There are no clear specifications for processing control. And the conversion efficiency during manufacture of rubberwood products is relatively low, which results in waste of drying energy and preservative chemicals.

In order for the conservation of natural forest and the sustainable management of plantation forest, appropriate fast growing tree species should be selected that thrive under the climatic and growing conditions in China while still producing timber with satisfactory characteristics. Rubberwood is such a species. It fits the sub-tropical climate region of China and has acceptable wood properties. Research and development work on rubberwood products, should emphasize improvements in efficiency and competitiveness of the Chinese rubberwood industry. Some important topics to address in this R & D effort include:
1. Identification of clones that can provide high wood volume with good quality;
2. Replacement of sodium pentachlorophenol (NaPCP) with environmental friendly alternatives;
3. Formulation of specifications for raw materials, each stage of production, end-products, and end-uses;
4. Assessment of the end-use performance of manufactured rubberwood items;
5. Manufacture of value added products;
6. Market study and marketing of rubberwood products.

Pelleted Municipal Sludge - A Key Element in Future Resource Cycling and Sustainable Forest Management?

Tord Magnusson, Björn Hanell
Swedish University of Agricultural Sciences, Dept of Silviculture, 901 83 Umea, Sweden
Tel: +46 (0)90 786 58 88, FAX: +46 (0)90 786 77 50,
Email: Bjorn.Hanell@sek.slu.se

Keywords: municipal sludge, fertilization, shrubs

Field experiments have been established in northern and southern Sweden on the basis of the vision that forests may become important links in the cycling of waste by-products, such as e.g. municipal sludge and wood ash, and that cycling of environmentally safe sludge pellets could be an important element in sustainable forest management.

New technology, including spraying of newly formed sludge pellets with lime or wood ash, which prevents pellets from sticking together, allows for producing dry and hygienic (non-infectious) pellets that are easily stored and transported. This method eliminates severe problems that are associated with the handling of wet or moist sludge, i.e. high water content, pathogenic bacteria and bad smell. Partly due to these problems and credibility gaps between the general public and public agencies regarding the fate of waste water products, amendments of municipal sludge to agricultural or forest soils have not been generally accepted and become common practise - in spite of the fact that the quality of sludge has constantly improved with respect to e.g. the content of toxic trace metals. Our study was restricted to:

- testing a method of spreading sludge pellets in forest stands
- the pellet fertilization effects on the rate of nitrification and nitrogen turnover
- the heavy metal content in berries, mushrooms and field vegetation in fertilized and unfertilized plots, and
- number of mushroom species and changes in their relative abundance following various amounts of pellet amendments.

In order to test the value of a forest application program with respect to environmental and ecological effects, including single tree and stand growth, dried and hygienic sludge pellets were amended in doses of 0, 4, 8, and 16 tonnes ha^{-1} in Scots pine and Norway spruce dominated forest stands. The pellets contained approximately 32% C, 2.9% N, 1.8% P, 0.2% K, 0.3% Mg, 7.2% Ca and 0.4% S. Each treatment was replicated three times. Nitrate reductase activity (NRA) in vegetation was measured according to Högberg et al. (1986).

The results show that:

(i) an ordinary farm tractor equipped with the most common type of centrifugal spreader designed for commercial fertilizers, can be used for spreading sludge pellets as well. These were evenly distributed after spreading in perpendicular direction from strip roads 10-12 m apart.

(ii) the nitrate reductase (NR) activity in leaves of *Deschampsia flexuosa* (L.) Trin. was moderately (but statistically significant) increased 6-8 weeks after pellet amendments of 4-16 tonnes ha^{-1} (fig. 1). In another set of experimental plots NR activity was still somewhat raised two years after application of 4 tonnes ha-1.

(iii) two years after treatment, the heavy metal concentrations in edible lingonberries (*Vaccinium vitis idaea* L.), blueberries (*Vaccinium myrtillus* L.) and fruitbodies of mycorrhizal fungi, did not differ between untreated control plots and plots recieving 4 tonnes ha^{-1} (Table 1). (iv) inventories of fungal fruitbodies 6-8 weeks after pellet amendments of 4-16 tonnes ha^{-1}, showed that the number of species remained unchanged, while species composition changed significantly. The very large and important genus of Cortinarius decreased in relation to other groups.

Despite constantly improved quality of municipal sludge in Sweden since the 1970´s, pellet concentrations of most heavy metals are higher than in the organic matter of surface soils in the Swedish forests. Possible biological enrichment in microbes, plants and further up in food chains have to be checked. In this investigation no such enrichments were indicated. The results encourage further efforts to find out whether or not cycling of pellets from municipal sludge into silvicultural systems for intensive and extensive production rates can be justified. Provided environmentally sound, relatively large amendments of pellets could be made in areas selected for intensive forest production (pulpwood, fuel) whereas smaller pellet doses could favour timber assortments in forest stands which are reaching the end of the rotation period.

Alternatives to Clearcutting in the Old-growth Forests of Southeast Alaska

Michael H McClelland, Robert L. Deal
USDA Forest Service, PNW Research Station, 2770 Sherwood Lane, 99801 Juneau, AK, USA

Keywords: sustainable forestry, clearcut, landscape ecology

Clearcut logging of old-growth temperate rain forests is one of the most visible and contentious forest management issues in southeast Alaska. This issue touches the cornerstones of southeast Alaska's economic and social well being: the timber industry, fisheries, tourism, and subsistence. Broader concerns for biological diversity, threatened or endangered species, and the value of wild and remote places have focused national attention on this issue. Observations suggest that southeast Alaskan forests and the associated animal taxa are well adapted to the widespread small-to-medium-sized disturbances caused by wind, disease, and landslides. The use of silvicultural systems other than even-aged management with clearcutting could take advantage of this adaptation to provide a sustainable supply of timber-along with a host of other important values.

The alternatives to clearcutting (ATC) study uses experimental and retrospective approaches to evaluate several silvicultural systems for managing old-growth western hemlock-Sitka spruce (*Tsuga heterophylla-Picea sitchensis*) forests-including even and uneven-aged management-and their biological, physical, and socioeconomic effects. The ATC study integrates research on stand dynamics, forest health, understory plant communities, wildlife habitat, stream ecology, slope stability, hydrology, economics, visual quality, and social acceptability.

Three factors and their interactions are tested in the experimental study: the stand density retained after timber harvest, the spatial pattern of the retained trees (uniform vs. patchy), and the size of patches (gaps or uncut reserve areas). The matrix-patch design includes both 'hard' and 'soft' edges. Post-treatment stand densities range from 0 to 100% of the initial stand basal area (clearcut and uncut control, respectively), with three intermediate densities. Nine treatments are replicated in three blocks located across the Tongass National Forest, and each experimental unit is 18 ha, on average.

The purchase of two major ATC timber sales and the successful harvest of one demonstrated that ATC systems are viable in the current timber marketplace and that the treatments are feasible from technical and safety points of view. In general, residual trees at the first harvested block showed higher levels of harvest related damage in 25% retention prescriptions (top breakage in 5.2-10.2%, bole wounds in 4.0-26.8%) than in 75% retention prescriptions (top breakage in 3.4-4.5%, bole wounds in 3.4-6.4%). Group selection employing gaps with diameters of 200-300 feet was operationally efficient, but 100-foot gaps created severe difficulties during falling and yarding operations.

Second-Growth Western Hemlock Product Yields and Attributes Related to Stand Density

Gerald Middleton, David Munro, Chunping Dai, Paul Morris, Conroy Lum, Derek Williams
Forintek Canada Corp, Western Laboratory, 2665 East Mall, V6T 1W5 Vancouver, B.C., Canada
FAX: (604) 222-5690, Email: Gerry@van.forintek.ca

Keywords: western hemlock, *Tsuga heterphyla*, young-stand management, mechanical properties, pulp

The effect of stand density on 90-year old western hemlock tree and wood characteristics was determined to assist foresters with stand density management. Trees were selected from three Vancouver Island stands. Stand densities were 580 and 930 stems/ha (sph) at two northern locations, and 930 sph at a stand 500 km south. Mean breast-height wood densities were .42, .45 and .47 respectively. The 580 sph stand trees had fastest early growth rate, were taller, larger in diameter, had largest branches, and highest taper. The southern 930 sph stand had the slowest early rate-of growth. Tested in bending, lumber mean modulus-of-elasticity (MOE) and mean modulus-of-rupture (MOR) differed significantly by stand density, and average early growth rate. The 580 sph stand had the lowest proportions of high grade structural lumber and the lowest MOE and MOR values. Structural properties of veneer, LVL, and small clears were consistent by stand with those of lumber. Lumber machined as well, and treated more easily than old growth hemlock. Kraft and TMP pulp properties did not differ significantly by stand. Kraft pulp yields were 1 to 3 percent higher than those published for western hemlock.

Saving the Wooden Rhino in Kenya through Responsible Sourcing and Sustainable Use

Meshack O. Muga, J.K. Githiomi and B.N. Chikamai
Kenya Forestry Research Institute (KEFRI), Box 30241, Nairobi, Australia
Tel: 254-2-761063/761246, FAX: 254-2-767944 254-154-32844, Email: meshackmuga@hotmail.com

Keywords: Kenya, Wood Carving, 'Responsible sourcing', Sustainable use, *Azadirachta indica*

Wood carving industry in Kenya is a significant source of income for more than 50,000 families and generates about US$ 20 million annually. Like any other wood based industry in Kenya, it relies on raw materials from fast diminishing forests and woodlands. Currently there is widespread awareness and concern amongst wood carvers, conservation organisations and some wood carving exporters that the two major sources of wood, *Dalbergia melanoxylon* (Mpingo) and *Brachylaena huillensis* (Muhugu), have been overexploited. Large trees of the other two popular species, *Olea europaea* subspecies *africana* (Mutamaiyu) and *Combretum schumannii* (Mugurure), are also increasingly difficult to obtain. The preferential demand for these few popular species, a high rate of expansion in wood carving industry, declining forestland, low regeneration capacities and slow growth rates of these species has resulted in acute scarcity of wood carving materials. The carvers have resorted to immature wood from these species or substitutes. Among the alternative species *Azadirachta indica* (Neem) is the most viable substitute.

This paper compares *Azadirachta indica* with the four popular wood carving species in terms of wood properties, quality and cost of products and recommends strategies for substituting these species with it.

The four species have very high density ranging from 0.93 g/cm^3 to 1.23 g/cm^3, very high Janka hardness from 10 KN to 19.7 KN and are very durable. *Azadirachta indica* has a moderately high density of 0.70 g/cm^3, moderate Janka hardness (6.2 KN) and is moderately durable. Its macroscopic and microscopic features are similar to those of the four species except for the interlocked grains, coarser (medium) wood texture, predominantly heterogeneous and multiseriate rays and thinner fibre walls. In terms of costs, wood carvers are currently paying as much (and sometimes a higher price) for Neem (3800-5800 Ksh./m^3) as compared to Muhugu (4600-7700 Ksh./m^3), producing carvings indistinguishable to tourists.

It is concluded that, *Azadirachta indica* has properties that can make it a good substitute for the traditionally used wood carving species. Its use will enable the recovery of wild stocks of the overexploited indigenous species, leading to environmental conservation. To ensure a sustainable supply of wood, it is recommended that wood carvers and farmers plant *Azadirachta indica* as an investment to diversify farm incomes using seeds, wildlings and cuttings. Resource assessment surveys to determine the current stock levels, natural regeneration potential and growth dynamics of Neem have been proposed. Product labelling and certification are recommended.

Jacaratia spinosa: An alternative in the Multiple Use of the Forest

Roberto F. Pascutti
Universidad Nacional De Misiones, Facultad de Ciencias Forestales, Calle Bertoni 124, 3382 Eldorado-Misiones, Argentina
Tel: (0054) 751 -31526 / 31780, FAX: (0054) 751 -31766, Email: Pascutti@correo.facfor.unam.edu.ar

Keywords: food, chemical modification of wood, *Jacarati spinosa*, plantations

The objectives of this technology development project were: a) to evaluate the possibilities of converting the wood of the tree *Jacarati spinosa*, into a raw material for the production of foods for human consumption, b) to study the conditions necessary for the reproduction, cultivation and growth of this species. After evaluating the chemical components of the wood and its extractives a process was developed to alter their characteristics. This method consisted of hot water extraction to remove compounds that impart an unpleasant flavor followed by hydrolysis with weak acids of natural origin, to modify the wood structure. The second step softens the wood to allow it to be chewed and swallowed. Adding color, flavoring, sweeteners, and perfume then gelling the resulting material completes the process. The final product maintains the aesthetic characteristics of the wood and has an excellent taste. This is not conventional food but the result is an original and novel product that can command a premium price, which in turn leads to acceptable profitability of the process. Information was also gained on the cultivation and tending of this species.

Jacarati spinosa can reproduce without difficulty if it is protected from extreme high and low temperatures are during first years of its development. The best method is to grow young trees under cover. Development of this unique product and evaluation of cultivation techniques has allowed us to improve the value to a species that until now was not commercially important. Commercial recognition promotes its cultivation and provides a non-traditional forest product.

Biodiversity Conservation, Non-Timber Forest Products Management, Rural Livelihoods and Sustainable Forest Management Linkages - Insights from Western Ghats, India

D. S. Ravindran, Dr.M.H.Swaminath

With the shrinkage of forest resources, the issues of sustainable management of forests (SFM) and conservation of bio-diversity are gaining importance. The likely positive impact of managing the forests for non-timber benefits on sustainable management of forests, is receiving increasing attention. However there is need for greater clarity on the linkages between bio-diversity conservation, NTFP management and rural livelihoods with the sustainable forest management, to develop appropriate policy initiatives for better management of forests. The western Ghats forestry project has attempted to address the issue of SFM of the mega-bio-diversity area of Western ghats through approaches combining conservation and collaborative forest management. The present study specifically explores the linkages between the forest management, use and the livelihoods in western ghats. Through a survey of the forest use by the communities in the Western Ghats the study maps the dependencies of communities on NTFPs for their livelihoods. These studies are inter linked with the studies on the bio-diversity status of the forests to provide insights into bio-diversity conservation, livelihoods and SFM linkages.

Keywords: Biodiversity, Western Ghats, Livelihoods, Sustainable Forest Management, India.

Thinning Western Larch Stands Improves Sustainability of a Valuable Resource

Udo Hans Sauter, J.S. Gonzales, J.R. Gordon, W. Schmidt, B.C. Jaquish

Tel: +49 7636 1016, FAX: +49 761 203 3763, Email: sauter@ruf.uni-freiburg.de

Keywords: western larch, *Larix occindentalis*, specific gravity, stand density, x-ray densitometry

Western larch (*Larix occindentalis* Nutt.) is one of three native Larix species in North America, besides subalpine larch (*Larix lyallii* Parl.) and tamarack (*Larix laricina*(Du Roi) K. Koch). Western Larch occurs mainly throughout the Upper Columbia River basin of southeastern British Columbia, northwestern Montana and northern Idaho. It easily reaches 50 m in total height. High wood density and strength usually characterize its wood. Throughout most of western larch's natural range, existing stands originated from natural regeneration following wildfires, and are often overstocked. Therefore, early reductions of stand densities by precommercial thinning became an important management tool to establish stabilized stands and to concentrate stand growth potential on fewer vigorous, well-formed trees. This process of maximizing total stand value rather than maximizing yield can be completed by later commercial thinning and artificial pruning. The intent of this study, carried out by Forintek Canada Corp., was to provide basic information on the relationship between tree spacing and the two major wood quality parameters wood density and branch size to support stand management decisions. From young western larch experimental stands in northwest Montana, 618 sample trees were chosen representing different stocking levels ranging form 270 to 4300/ha. From two pith-to-bark cores, taken at breast height for each tree, density profiles were obtained using Forintek's x-ray densitometer. We also measured the largest branch diameters below 4 m stem height. The sample trees showed a strong relationship between width of spacing and tree height and diameter breast height. As expected, trees in the widest spaced plots grew the fastest. Despite large differences in diameter growth, no significant differences in average wood density occurred between spacings. A second moderate thinning on the best sites clearly showed that enhancing the wood density of western larch is possible. For the most valuable part of the tree, the branch sizes do not exceed 20mm even when a wide spacing as 4.6 by 4.6 m is applied. High wood density levels and reasonable knot size confirm that western larch from sustained managed stands remains a valuable tree species in future markets.

Ecosystem Management of Forests In Russia: Place of The Forest Certification

Valentin V. Strakhov
All- Russian Research and Information Centre for Forest Resources, Novocheremushkinskaya STr. 117418, Moscow 69 Moscow, Russia
Tel: 7-095-332-5338, FAX: 7-095-331-0533, Email: aricfr@aha.ru

Forest certification in Russia developed as an obligatory system according to the Article 71 of the Forest Code of the Russian Federation (1997) and the Ordinance of the Government of the Russian Federation from February 2, 1998, 1131 "On obligatory certification of wood stumpage sale and of secondary forest resources" (further referred as FC). Promotion of this system is assigned to the Federal Forest Service of Russia, which will carry out necessary organisational measures according to norms of the Russian Federation Law "On the certification of products, goods and services".

The FC system was developed by a team of specialists, the core of which was the staff of the All-Russian Research and Information Centre for Forest Resources (ARICFR) and Federal Forest Service of Russia, with participation of the experts from many scientific institutions of different Russian ministries and agencies, ecological NGOs (WWF, IUCN, Greenpeace) and other interested federal executive authorities. The team, guided by rules and procedures issued in 1994, with the subsequent agenda and corrigenda, has worked out "Rules of obligatory certification of wood stumpage sale and of secondary forest resources in the forests of the Russian Federation". The FC system is entered into action since July 1, 1999 in several members of the Federation for approbation.

When working out the FC system, the available international experience was taken into account, in particular, principles of the sustainable forest management agreed by the FSC (Forest Stewardship Council) and ISO Standard 14001 "System of environment management. General requirements and management guidelines establishing requirements to the system of environmental management" In the mentioned international systems of certification the assessment of activities on conformity to the normative documents is not stipulated, and instead of the standards of running forest management and use, only requirements of submitting applications are prescribed. The procedure of FC developed in Russia, as well as the systems of voluntary FC working at the moment, are based on assessments of provenance of wood and secondary forest resources, i.e. assessments of forest sites. But in contradistinction to international systems, the Russian FC system provides for an obligatory certification of wood stumpage sale and of secondary forest resources on conformity to the existing Forest legislation, the executive acts of which, with their ecological requirements, have been widely discussed and are agreed with the Russian Ministry of natural resources and the State Committee on environmental protection.

The FC system includes a Central board of forest certification (CBFC) and accredited FC centres. A Council of the System and a Committee of Appeal are being created as bodies of the CBFC. The Council of the System will draw experts of forest management timber industry, representatives of scientific centres dealing with problems of environmental protection and representatives of ecological NGOs. Such centres would organisations independent from forest management units, forest users and consumers and possessing experience in the running of forest management and use (scientific and inventory and planning establishments). Thus, the created FC system allows of the legal acts, and thus to provide the local level of forest management with an effective tool of ecosystem-minded forest management.

Developing Criteria and Indicators for Sustainable Forest Management at the Forest Management Unit Level in China

Chunquan Zhu, Lei Jingpin, Zang Rungou, Zhang Shougong,
Zhang Chenglin, Wang Weiying
Chinese Academy of Forestry, Sustainable Forestry Research Centre, Wan Shou Shan, 100091 Beijing, China
FAX: 86-10b872015, Email: Zhucq@rif.forestry.ac.cn

Keywords: criteria and indicators, sustainable forestry, wood

Criteria and indicators (C&I) for sustainable forest management have emerged as a central element of international and domestic forest policy discussion. They also have been described by some as the most important innovation of the decade in the field of forestry. To implement C&I requires the collective commitment of stakeholders, including forest managers and the scientific community, which is particularly true for the development from national-level down to the forest management unit (FMU) level. Based on the framework of C&I for sustainable forest management at the national level, a case study for the further development of the C&I at the FMU level is introduced. The requirements for forest products and services are different at the national, provincial, and FMU levels because the natural, social and economic conditions, and the forests status should be considered during the development of C&I. The forest managers, technicians, research scientists, and national and international consultants jointly identified the appropriate indicators and this process is described. The methodologies and procedures for testing and reporting the identified indicators are also described in this paper.

Forest-Socioeconomic Framework for Time Series Analysis of Global, Regional and Country-wise Forest Resources and their Utilization

Emmanuel R.G. Abraham, Tatsuo Sweda
Ehime University, United Graduate School of Agricultural Sciences, 3-5-7 Tarumi, 790 Matsuyama, Japan
Tel: +81-89-946-4876, Email: erga@agr.ehime-u.ac.jp

Forests have always played important roles for human welfare by providing material and economic benefits to the society in terms of forest products and amenities. The magnitude and sustainability of these contributions through time are linked to the manner in which these forests are utilized and exploited by those countries under whose stewardship these resources fall, often as influenced by global forest resource interdependence. In this work, an analytical framework was developed for studying global, regional and country-wise patterns of forest resource changes vis-…-vis temporal patterns in some socioeconomic indicators such as GNP/capita within the three decades from 1960 to 1980. Using this framework, time series statistics on population, land-use, forest products and trade of FAO from 1961-1991 as well as annual data on GNP from 1970-1989 were analyzed. The work progressed from a macro global view to micro country-wise case studies. As a baseline, countries of the world were first classified into six groups differing in economic status and forest resource basis. In general terms, the classification allowed a broader perspective of the present global status in forest endowment and income levels, which in some ways are indicative of economic development or industrialization. Further analysis identified countries with significant changes in forest resources basis within the last three decades. Almost 60% of those were industrializing countries in South America and Southeast Asia. On a phase plane of income versus forest resource basis, the global trend showed decreasing forest resources vis-…-vis increasing income. However, country-wise patterns included periods of decreasing forest resources along with declining income or slowed economic growth. Countries of Southeast Asia, whose economies greatly benefited and is still benefiting from forest resources, particularly exhibited this pattern. Forest products production and trade patterns in Indonesia, Malaysia, the Philippines and Thailand, who altogether accounted for 13% of the 380 M ha global decrease in forest and woodland cover from 1961-1991, were analyzed as case studies. This was to further understand how these countries used their forest resources for material gains and the sustainability of these benefits. For these countries, primary forest products significantly contributed to their economies but this contribution was either not sustained with the forest resources being depleted, as illustrated by the Philippine case, or remained significant, as in the case of Indonesia. The patterns of utilization shown by these countries revealed that the rate, timing, and scale of transition of forest product production and export from raw to processed forms relative to changes in forest resource basis, could be a major contributor to the success or the decline of forest-based industrialization and the resultant state of forest resources. Indonesia who phased out the export of industrial roundwood within a short period in the 1980s while at the same time expanded their wood-based panel industry exemplified this pattern. The transition was drastic and large-scale and occurred when the forest resource base was still high. Despite temporary reduction in the early 1980s, processed forest product exports steadily rose to account for more than 10% of the country's total merchandize exports in 1991. For the Philippine case, forest products exports (mostly in raw form), which accounted for 22% of total merchandize exports in 1961, peaked in the late 1960s and dropped to only 0.96% in 1992. The forest resource base was already on the decline when exports of processed products were increased. With much reduced domestic raw material sources and undeveloped industry, such expansion was not sustained and the Philippines became a net importer of forest products by 1990 with forest per capita at 0.15 ha.

Total Valuation of Environmental Services of the Tropical Rain Forest: Policy Implications

Juan Antonio Aguirre
CATIE, Apartado 52-7170, Turrialba, Costa Rica
Tel: 00506-5568514, FAX: 00506-5568514, Email: jaguirre@catie.ac.cr

One major limitation to integrated the forest and society needs has been the fact that when in the past we have look at the forest we think only of one product timber resulting such a consideration in one major shortcoming that when policies to deal with the forest and its problems are design what the thinking is only in terms of the consideration related to timber production.

The paper will report the individual of the past 4 years at the Tropical Agriculture Research and higher Education Center (CATIE) were we have conducted a series of research studies on the valuation of Environmental Services in order to attempt to do two things a) test some possible methods and b) tog et a feel for the possible values of the different environmental services other than timber. The goods and services that we have developed preliminary values are: carbon sequestration for, water production under different uses, ecotourism, biodiversity for pharmaceutical purposes and non-timber forest products.

The major problem that we have observed when dealing with environmental services is that fact that the money that can be estimated to be attributed to such services are imputed social values and it has been very difficult to developed mechanism for collection and allocation of a part of such values to the owners of the forest which the persons in the final analysis responsible for the safe keeping of the forest this problem does not happen with timber that can be appropriated and sold by individuals with the logical benefits deriving from such actions it is felt that unless such mechanism are developed to make the transfer payments environmental services will only be of academic interest.

Other problems that have been identify for such environmental services have been: lack of credit mechanism to promote them, markets, adequate balance between production and conservation practices and reliable technical and inventory data to permit relevant physical quantification elements that united to the transfer payment problems cited above make policy recommendations and decisions associated with them very complex.

Social and Economic Problems of Society and their Influence on Mountainous Forests of Tajikistan

Hukmatullo M. Ahmadov, Kokul H. Kasirov.
Tajik Forest Institute, 724055 Dushanbe, Tadjikistan
FAX: (3772) 213332, Email: farhod@kokul.td.silk.org

Tajikistan is the mountainous country, which situated in the Central Asia. After destruction of the USSR, acquirement of independence and the civil war this republic collided with many social and economic problems which hadn't be seen at the past. These were the such problems like lack of the fuel and food which directly influenced on mountainous forests. The total area of forests in Tajikistan is the 3% from whole country's area. Most of them are situated in mountain region of republic. In the valley zone there is some areas of jungle which situated by small fields in the hood-lands of big rivers. But in the last time the areas of tugai forests are abrupt decreased. In the Soviet Union period the biggest part of tugai forests was cut and made for the cotton. At the moment the only in "Tigrovaya balka" preservation there is strong tugai forests grow. But now there also started to cut them down.

Pistachio, hawthorn and another small leaved forests are situated in the front and low mountain zones. Small leaved, wide leaved and juniper forests are grow in the middle mountain zone of republic. Juniper forests are situated in the high mountain zone. All forests of Tajikistan have nature protective and soil protection meaning for country.

Forests play the huge role in the mountainous landscape's preservation and restoration. The inconsiderable violation of mountainous ecosystem by society may lead to destruction of whole mountainous landscape. The influence of society on landscape happens by the scheme of social and economical problems. At the beginning of this scheme the cutting of forests takes place and then destroying of vegetation and developing of the steep slopes. In the center of this scheme the society with its problems takes place. This society can render the double influence on forest formation. They are negative and positive influences.

The negative influence can lead to decreasing of natural forest's areas. It may intensify the erosion processes. Degradation or desertification are strongly influence on social and economical problems of society. The soiling of the water, the decreasing of agricultural productivity, the destroying of productive soils etc. are negatively influence on society's life.

The various strata of society in the upper watershed zone of the mountainous rivers are destroying walnut, juniper etc. forests and shrubbery which grew several centuries. That is the reason of the floods formation in the cold period. They flood and destroy the populated territories, irrigated lands and economic objects.

The main aim of the society at the moment is the providing people by the products of nourishment and widening of the cotton fields. So at the south of republic the several thousands ha of forests was cut down. These forests reliably fixed the soil from wind erosion. Now these erosion become strength and many barkhans which slowly move to the populated points and destroy the agricultural areas. It is known that the cutting of tugai forests in the long period is increased the area of desertification in the south side of republic and it is became the reason of population migration. These forests protected this territory of Tajikistan from the strong afghan winds in the past. In north of Tajikistan the tugai forests also was destroyed. The goal of this destroying was the increasing areas of cotton fields but it leaded to intensify of desertification.

Now in all high geomorphologic zones of the Pamirs-Alai mountain system the biggest negative load of society on forest territory can be observed. It is the using the forests as fuel, the extension of slope developed lands at the expense of pasture's and forest's lands which used for cereal cultivation and biggest load on the pasture forest lands. These and many another anthropological factors often lead to formation of soil degradation, landslides and sliding of upper layer of productive land.

The integration of Urban Forestry and Soft Landscape Plantings: The Case Study of the City of Kuala Lumpur

Nik Ismail Azlan
MARA Institute of Technology, Department of Landscape Architecture, Malaysia
Email: niara@tm.net.my

This paper presents the history and the development of trees and shrubs planting in the city of Kuala Lumpur, Malaysia. Beginning with its founding at the confluence of two rivers, Kuala Lumpur during the colonial era has seen the introduction of a combination of exotic and local tree species by the British that were based on the needs for shade and beauty amidst the humidity of the tropical climate. The lack of seasonality in this city of humid tropic affects the vegetation profoundly. Since growth takes place throughout the year the vegetation has somewhat come in conflict with the pace of the development of the city. Some of the trees have been downsized, pruned or even cut down to make way for urbanisation. This is more apparent after Kuala Lumpur was declared a territory of the federal government in 1974.

The administration of the city was under the jurisdiction of the Kuala Lumpur City Hall (Dewan Bandaraya Kuala Lumpur or affectionately known by its acronym as DBKL) which undertook a majestic task of transforming it into a tropical garden city. Rows and rows of trees were planted along the streets, housing areas, office buildings and commercial centres. Millions of dollars were allocated yearly for the purpose of urban plantings, maintenance, and tree preservations. Many new species of trees were introduced and planted alongside low and medium sized shrubs for functional and aesthetic purposes. The lists of some of these species most used in urban plantings, their families and botanical names are mentioned in this paper. Such an immense effort by DBKL has produced result that transformed Kuala Lumpur into a garden city where people can live and work in a balanced and healthy environment. However, such transformation is not without problems but nevertheless DBKL has managed to solve them with high imagination and perseverance. These challenges are in many ways similar to other cities throughout the world, so the lessons learnt in Kuala Lumpur may be applicable to others.

Insertion Potentialities of the Uruguayan Forest Research in the South Cone Region (Cono Sur)

Zohra Bennadji
Instituto Nacional de Investigación Agropecuaria, Estación Experimental del Norte, Ruta 5-Km.386, C.C.78086-C.P.45000 Tacuarembo, Uruguay
Tel: (063)22407, FAX: (063) 23969, Email: Zobenn@tb.inia.org.uy

Keywords: Forest research; policy; Latin America; South Cone Region; Uruguay.

The objective of this poster is to present a synthesis of the current state of the Uruguayan forest research and a study of his insertion potentialities in the South Cone Region (Cono Sur) of Latin America.

Uruguay has traditionally been a livestock producing country and, comparatively, forestry may be assimilated to a new alternative economic activity. In the eighties and nineties decades, a highly structured forestry policy with an exceptional package of incentives, was developed by the government, bringing on sound changes at institutional levels. In this context, the state of the forest research will be presented through a description and an analysis of the institutional policies as applied nowadays in the country, as well as the trends and scopes of the prospection and generation of technology. The role of the private sector will be also assessed and networking and international co-operation highlighted, taking into account the present and potential actions of international organizations such as FAO (Food an Agriculture Organization of the United Nations), IBD (Inter-American Bank of Development), IIAC (Inter-American Institute of Agricultural Co-operation), IUFRO (International Union of Forestry Research Organizations) etc. The role of the National Agriculture Research Institute (INIA) and his National Forestry Program will be specially emphasized.

The insertion potentialities of the Uruguayan forest research in the South Cone Region (Cono Sur) will be evaluated by the mean of a comparative study of the research systems of the main neighbouring countries (Brazil, Argentina, Chile essentially) and the weighing of the strengths and debilities of the Uruguayan system. The short and long terms goals to be reached for the concretion of this potential regional insertion and the actions for achieving it will be exposed.

A multiple-objective Forest Estate Planning Model Based on the Montreal Process Criteria: A Case Study for a Beech Forest in Chile

Horacio Bown, Eduardo Arellano
Universidad de Chile 1, Facultad de Ciencias Forestales
Departamento de Ciencias Forestales, Pontificia Universidad Católica de Chile 2, Casilla 9206 Santiago, Chile
Email: hbown@abello.dic.uchile.cl

A multiple-objective planning model for the management of forest estates based on the Montreal Process criteria is proposed. Economic, social and environmental objectives were clearly identified as well as restrictions on non-decreasing yield for economic, social and environmental value (our "weak" attempt to achieve the condition of sustainability). We explored the influence of the profile of distinct decisions makers over the policy of management of a forest estate.

A case study was developed regarding a forest estate (15.000 ha) made up by three croptypes of three native beech species located in the Comuna of Panguipulli, Province of Valdivia in Chile. The management regimes were a combination of silvicultural methods (clearfelling or shelterwood system) and size of the maximum area harvested (<25ha, 25-50 ha, >50ha). The model was run for a planning horizon of hundred years, and time was aggregated in periods of ten years. Seven scenarios were analysed considering the profile of different decisions makers. The profile was defined by the relative weight each decisions maker assigned to the economic, social and environmental objective. These objectives were set up as a combination of different indicators of the first six criteria of the Montreal Process. Preliminary results, showed that for those decision makers that weight the economic objective ten times over the social and environmental ones (achievement of 87%, 38% and 46% respectively), the decision of harvesting was mainly on clearfelling in large areas (>50 ha), replacing gradually by the end of the planning horizon for the shelterwood system in small areas (<25 ha).

Prediction of bioprospecting policy implementation in the Philippines

Manuel V. A. Bravo
Ecosystems Research and Development Bureau, Laguna, Philippines
FAX: 049-536-2850, Email: erdb@laguna.net

In response to the Convention on Biodiversity, the Philippine government promulgated the Executive Order 247 together with the Department Administrative Order 96-20 (DAO 96-20) in 1995-1996 to regulate access to biological and genetic resources in the country. Prospecting of flora and faunal resources, including microorganisms for commercial, industrial and agricultural applications is covered by academic and commercial research agreements (ARA, CRA) with concerned departments such as Department of Agriculture (DA), Department of Environment and Natural Resources (DENR), Department of Science and Technology (DOST) and Department of Health (DOH). Applications for bioprospecting agreements are processed through the Technical Secretariat at the DENR and at the Interagency Committee on Biological and Genetic Resource (IACBGR). The latter recommends specific actions to the concerned Department, depending on the kind and species of materials to be collected and researched on.

One salient requirement for the research agreement is the prior informed consent (PIC) obtained from stakeholders where the resources are located such Protected Area Management Board (PAMB) for national parks, reserves and refuges, Local Government Unit (LGU) for those in public domains and private land owners in titled lands. The PIC process which involves public notification and hearings, sectoral consultations, community assemblies, posters and billboards whereby the research undertaking are presented in a language/dialect understood by the concerned stakeholders and local people. It should include purpose/s, methodologies, species/ specimen and quantity to be collected and equitable sharing of benefits.

With the executive order being in effect for two (2) years now and in the light of the provisions involving civil society, local government units and indigenous people, the paper will present the status of implementation with the use of the Situation-Structure-Performance (S-S-P) paradigm of Schimdt (1981) in the analysis. Prediction of whether the policy process is effective or efficient and compared with the realities encountered in the implementation will be made. Reasons behind the scenario and recommendations will be discussed for possible amendments or revision of the policy statutes. In the S-S-P paradigm, situation refers to the attributes of the resources covered by the policy, structure refers to the institutions and mechanisms operating in the process of implementation while performance results from the interaction of S-S to determine result of implementation.

Land Use Management For Sloppy Areas Using Four Appropriate Schemes in the Philippines

Ernesto C. Bumatay
Visyas State College Of Agriculture, Department of Forestry, 6521-A Baybay, Leyte, Philippines
Tel: 521-2027, 588-692, FAX: (632) 525-6849, Email: vicarp@mozcom.com

In the Philippines, interest on agroforestry as a land-use management particularly in sloppy areas was intensified over the last decade because of some factors: there is tremendous migration of population in sloppy areas and the increased cultivation activities in sloppy areas resulted in tremendous soil erosion which consequently adversely affected agricultural and marine production. The objective of the study were to design and test various appropriate land.use management schemes in the Philippines; and to evaluate each scheme according to the following: soil erosion control, soil fertility changes, crop production, farmers acceptability and financial costbenefit analysis.

Result indicated that, multi-storey Cropping Scheme had the least soil erosion. The average soil erosion was 2.88 cm during the two years of observation. Alley Cropping Scheme had the highest soil erosion of 3.91 cm during the two years of obversation. Soil fertility changes differed variably with each soil parameters measured in four appropriate land-use management schemes. Yield of annual and horticultural crops grown in Sloping Agricultural Land Technology (SALT) Scheme was highest. The lowest was observed in multi-storey Cropping Scheme. Farmers preference to the appropriate land-use management schemes introduced were SALT Scheme and Alley Cropping Scheme as first choice. In terms of financial analysis using net present value and benefitcost ratio, SALT Scheme ranked first.

Employment and the Social Sustainability of Forest Sector

Pertti Elovirta
The Finnish Forest Research Institute, Unioninkatu 40 A, 00170 Helsinki, Finland
Tel: +358 9 85705735, FAX: +358 9 5705717, Email: pertti.elovirta@metla.fi

Wood resourses are considered to be the most important of the economic resources supplied by the forest, and roundwood is considered to be the main product of the forestry. Especially in Finland, wood is the only domestic and renewable natural resource which can be sustainably utilised. The exploitation of wood recources also creates the main source of forest-based employment. Consequenly, the employment effect of the wood consumption is specifically emphasised in the discussion concerning the socio-economic effects of forest protection. The employment level achieved by utilising wood resources is one of the criteria of the social sustainability framework of the forestry sector. The aim of this paper is to discuss how employment can be measured and in which way it should be considered in order to achieve a functioning indicator of social sustainability in the forest sector. When using absolute values of the employment, persons or man-years, it is not possible to compare areas or countries of different sizes. If forestry employment is compared to the total employment, the relative significance of the forestry sector as employer is achieved. The social sustainability embodied in this figure is not necessarily indicated, because the employment shares ashieved do not contain the information as to how the renewable natural resource is utilised. If the frame of the sustainable utilisation of the renawable natural resource is to be included in the employment indicator, then the employment achieved must be compared to the quantity of roundwood used. This is defined as the labour input intensity coefficient, LIIC=1 man year/1000 m^3 roundwood. The LIIC is defined as the labour input, which is contained in the unit volume of roundwood leaving forest and its manufacture into forest industry products in a given country or region. Labour input is contained in wood raw material in three stages, in the forestry stage, in the primary manufacturing stage and in the secondary manufacturing stage. The end product of forestry is roundwood, to which end all extension-, improvement-, silvicultural-, harvesting- and transporting work is aimed. Primary wood manufacturing includes sawmilling and the plywood-, board-, pulp- and paper and peperboard industries. Secondary wood manufacturing includes carpentry, furniture, paper- and peperboard products, as well as the printing industry. The LIIC depends on the value-added- and on the productivity of the forest sector-production. In the empirical part of this paper is comparisons made by regions, by country and by industry. For example, the employment of forest sector in Finland in year 1997 was 140 000 man years and the consumption of roundwood in the same year was 70 million cubic meters solid volume. Thus the labour input intensity coefficient for the Finnish forest sector in the whole in year 1997 was 140000/70000=2. LIIC= 2 man years/1000 cubic meters round wood.

Bamboo as a Source of Livelihood in Philippine Rural Areas

Zenita B. Espiloy
Forest Products Research & Development Institute, Department of Science and Technology, 4031 Laguna, Philippines
Tel: 63 94 536 2377, FAX: 0063 94 536 3066

Bamboos, the tallest grass, have a long history as an exceptionally versatile and widely-used resource that provide sustenance, shelter and income especially to the rural poor. The uses of bamboo vary from place to place depending upon the choice of the local people as well as on the priority export products identified by the Department of Trade and Industry and the Department of Science and Technology. The industry receives full assistance and support under the Medium Term Research and Development Plan.

One strategy by which to increase productivity among makers of bamboo products, provide equitable benefits and assure quality of life to the farmers and weavers, is to form/organize a cooperative among themselves to minimize layers of middlemen and maximize the profit. The cooperative would supervise a trading center that will showcase the finished bamboo products as well as the marketing of the goods for local and foreign markets, with support and proper linkages with government an non-government organizations, other agencies and private companies.

Traditional systems as models for agroforestry development in Europe

Felix Herzog, GJ Lawson & R Elena Rosello
Centre for Environmental Research Ltd, Post Box # 2, D-04301 Leipzig, Germany
Tel: +49 341 234 20 41, FAX: +49 341 235 25 11, Email: herzog@alok.ufz.de

Agroforestry was a common practice all over Europe until about two centuries ago, when industrialisation made labour more expensive, and agronomic progress allowed the maintenance of soil fertility without recourse to reforestation. Nevertheless, a wide range of land-uses remain which integrate trees with animals and crops. Two of the most successful traditional systems are 'streuobst' in temperate Europe (namely Germany and neighbouring countries), where fruit trees are grown on agricultural land undersown with crops or grassland, and the Iberian Peninsula 'dehesa/montado' system, where wide-spaced evergreen oaks are grown in pastures grazed by pigs, sheep and cattle.

Recent decades in temperate Europe have brought an intensification and specialisation of land use, leading to overproduction of agricultural commodities and environmental damage in many regions. Intensification has also occurred in Mediterranean Europe, but it has been accompanied by extensification and abandonment of marginal agricultural areas. Traditional forms of agroforestry such streuobst and dehesa/montado systems have been diminished by both processes of intensification and extensification. However, streuobst still has a considerable im-pact on the European fruit market, and covers 1 Mha in temperate Europe. The evergreen oak dehesa/montado system covers more than 4 Mha in southern and southwest Spain and 0.6 Mha in Portugal. Total silvopastoral land-cover in the Iberian Peninsula, including more general forest grazing, extends to over 9 Mha. Some of these systems are now protected by law, and grants are becoming available for their re-establishment. This trend has been triggered by a combination of pressure from farmers and environmental NGOs, and has apparently stopped and reversed the loss of agroforestry in Europe.

The history and present status of traditional agroforestry systems in Europe holds lessons for the policy makers which will be examined in the particular context of streuobst and dehesa/montado systems:

1. Agroforestry provides environmental and socio-cultural services like biodiver-sity enhancement,

water quality protection, erosion control, fire limitation, landscape aesthetics, recreation and cultural functions;

2. The economics of agroforestry needs to be compared with forestry and farming on a 'level playing field', without considering distortions caused by competing grants, in order for traditional systems to be preserved, and for the advantages of novel systems to be recognised;

3. Farmers' attitudes to agroforestry depend on its place in local tradition, and, in those areas where it is no longer a traditional practice, whether it can be re-introduced using modern and cost-effective techniques;

4. Public support, based on the recognition of environmental and socio-cultural benefits, is a key to the preservation of existing agroforestry as well as to the spread of modern systems. Agroforestry needs both marketing opportunities and a favourable legal framework.

Policy-makers attitudes towards agroforestry (e.g. in the interpretation of EU Regulation 2080/92) varies considerably between countries and regions, and is given particular consideration in this paper. The reform guidelines for the Common Agricultural Policy ('Agenda 2000'), which aim to change the emphasis from agricultural price guarantees to farmer income support, will be examined with respect to the scope for traditional agroforestry systems to contribute to a 'European Model of Sustainable Agriculture and Forestry'.

Identification of technological demands: a methodological proposal

Vitor Afonso Hoeflich, Arnaldo Jose de Conto, Erich Gomes Schaitza
Universidade Federal do Paraná, Embrapa Florestas, Brazil
Tel: 041-3425332, FAX: 041-244-1545, Email: hoeflich@cnpf.embrapa.br

The characterization of any agricultural or forestry business requires a knowlege which is not only technical

The characterization of the agribusiness demands knowledge that transcends the tchnical disciplinary area and is based in three theoretical vertices: 1) systemic approach 2) marketing studies and segmentation and 3) prospective vision.

A thorough market analysis is fundamental to the definition of a technology generation strategy and latter transference. It is widely known that technologies that do not meet society requirements tend to fail.

The main problem of research and development institutes is finding the answer to the following questions: 1) what should be researched? and 2) how human and financial resourses should be distributed among different proposed projects.

This paper aims at describing a methodology which leds to the identification of factors affecting sustainability and competitivity of agroforestry businesses, potencial markets fror their products and propose actions to local forest development and to the definition of research opportunities and requirements.

The methodology proposed includes the identification of agroforestry business elements based on the concept of demand prospection, systemic approach and market segmentation.

Forest Certification - Some Principle Issues Related to Economics and Policy

Hans Fredrik Hoen, Solberg, B. &Tromborg, E.
Agricultural university of Norway, Department of forest sciences, P.O.Box 5044, As, Norway
FAX: +47 6494 8890, Email: hans.hoen@isf.nlf.no

Certification and labelling of forest products are being proposed by several interest groups to promote sustainable forestry. This paper aims at analysing more principally various economic and policy aspects related to forest certification often overlooked in the general debate. The following questions are emphasised in the paper:

- Do various certification systems create particular problems in the forest sector?
- What are the actual costs of certification - for the various stakeholders and society at large?
- What are the benefits? Under which conditions is certification a good investment for the forest owners?
- What are the likely distributional impacts between stakeholders and regions of various certification schemes?

Can we get differentiated markets-one market for certified forest products and another for non-certified ones - and what are the consequences?

The Globalisation and Europeanisation of Forest Politics: Impacts on National Actor Constellations

Karl Hogl
University of Agricultural Sciences, Institute of Forest Sector Policy and Economics, Gregor Mendel-Strasse 33, A-1180 Vienna, Austria
Tel: +43 1 47654 4402, FAX: +43-1-47654-4407,
Email: hogl@mail.boku.ac.at

Keywords: forest policy, multi-level governance, EU forest politics, Austria

The interest intermediation system has always attracted the attention of forest policy scientists. However, research on this subject has focused on the national level, despite the fact that forest issues are increasingly prominent on international and European agendas. Accordingly, the peculiarities of multi-level policy processes have not been sufficiently taken into account. The poster aims at representing how interna-tional forest politics and the integration of na-tional actors in the EU system of joint decision-making affect national actor constellations. To this end, it primarily draws on hypotheses of multi-level governance scholars as well as on my own empirical results regarding the mechanisms inherent to multi-level policy-making that affect the na-tional ac-tors' perspectives and influence.

In some European countries (Austria, e.g.) rather closed forest policy networks have emerged in the past. This actor networks are firmly rooted in legal and adminis-trative in-stitutions and characterised by a limited number of participants, a high degree of consis-tency in membership and out-comes on the long term, and a rather broad consen-sus on policy core beliefs and preferences. However, the secto-ral networks have come increasingly under pressure in recent years. On the one hand, pressure stems from in-creasing public awareness about forests and the subsequent develop-ment of in-terna-tional re-gimes. On the other hand, domestic ac-tors from EU-countries are increasingly in-volved in intergovernmental as well as supranational forest policy-making.

The European states and the EU itself were strongly involved in interna-tional initiatives on forestry in the wake of increasing public awareness of forest issues in the 1980s. The definite break-through of the 'forest issue' onto the international agenda came through the 1992 Rio Earth Summit (UNCED) and the commitments that were made there. Since then, the interna-tional dialogue on forests has continued at the UN and the pan-European levels. Furthermore, one has to take into account the ini-tiatives on forest certification that took place in recent years on international, regional as well as national levels.

Besides intergovernmental dialogues on forests EU policy-making is also quite significant with regard to national forest policy networks: The EU level provides a political arena for co-ordinating national policies and positions in the context of international processes; there is a large body of EU policies that affects the national forest sector either directly or indirectly; and - last but not least - the evolution of a multi-level system of joint decision-making has brought about sub-stantial changes in the logic of influence for domestic actors. It com-prises new actors and institutionalised arenas, and provides additional points of access. Since there is an additional supranational dimension, the EU typifies a political system quite dif-ferent from the inter-govern-mental arenas men-tioned above. One of the main aims of the poster is provide a comprehensive explanatory framework for analysing different mechanisms of the "Europeanisation" of forest policy-making and their domestic impacts.

Summarising, I offer some hy-potheses and indications suggesting that national forest policy net-works are subject to significant change. For the time be-ing, the external demands for policy change have manifested primarily in institu-tional changes at all levels. From an actor-centred perspective it is shown that forestry interest groups still tend to favour national strategies, as well as national channels of interest interme-diation, whereas other groups that do not en-joy privileged access at the national level are more likely to attempt to shift forest issues to the EU/international agenda. Perhaps most interestingly, I argue that the Globalisation and Europeanisation of for-est policy entail some mechanisms that provide public actors with additional opportunities to mitigate the influence of private in-terest groups. Public actors may gain additional lee-way to pur-sue their own strategies; the loss of autonomy that they have to suffer because of EU inte-gra-tion can be compensated by gains in autonomy vis-…-vis other national actors. Political scientists call this phenomenon the 'paradox of weakness'.

A Rural Promotion Plan in Sub-Mountainous Area

Masaru Ken Iwamoto
Nishi-nippon Institute of Technology, Dep. of Civil Engineering, 800-0394 Fukuoka, Japan

Agriculture had no competitive productivity compared to another industry in Japan. However, they still have more efficiency on environmental conservation. When developing a rural area, the most important matter is to harmony development with nature and human life. Especially in agricultural region, the total assessment method for ecosystem and nature should be done to evaluate the watershed conditions before and after development. In these, ecosystem map was evaluated by the natural condition scores of Vegetation and animals. Landslide risk map was calculated by the Quantification analysis method I. Flood risk map and water resource map were simulated by the synthetic unit-graph method respectively. Successively, the agricultural promotion plans were suggested by considering the charaeteristics of rural site conditions. These plans are summarized as follows:

1. Promotion of a side business farmer is the actual sustainable agriculture because of the economical condition in a small field.

2. Modernized house construction is useful for the young generation because of the difference of life styles between new and old generations.

3. New producing system with the co-operative working groups is necessary for them efficiently to maintain a small and separate fields.

4. New crops with a high additional value are the most suitable ones in a submountainous field.

5. Synthetic use of rural resources, hot-spring and landscape etc., is the foundation of a new industry (welfare facilities) for the coming of aged society in Japan.

6. To support these plans, the transportation net work system should be constructed to link the rural to a large city at first.

The Coordination between Government and Non-government Organisation (NGOs) for Agroforestry Systems Implementation in Nepal

Murari Raj Joshi
Lincoln University, Post Box # Box: 84, Canterbury, New Zealand
Email: joshi@whio.lincoln.ac.nz

Agroforestry in the hills of Nepal is an indigenous system where agricultural crops and trees are grown together for the sustenance of farming systems. Currently, the government and Non-government Organisations (NGOs) are involved in the promotion of agroforestry activities on private land, community land, degraded forest and community forest in order to increase the forest products needed for the protection and management of national forests, community forests and fragile mountain environments. The process of agroforestry systems implementation and the role of the Department of Forest (DOF) and the NGOs differ according to the area in which agroforestry systems are practiced. DOF has a significant role in the implementation of agroforestry activities in community forest and degraded forest land, whereas NGOs are playing vital role in private land and community land. However, NGOs are also encouraged for the support of community forest user group for agroforestry systems extension in some hill districts. The process which they have used for the implementation of agroforestry activities by involving local community in coordination with the government staff in various areas is supportive to the government and people for forestry development in Nepal.

Forest in Discussion in Austrian Printmedia with Special Consideration on Forest Restoration

Daniela Krumland
University of Göttingen, Institut für Forstpolitik, Forstgeschichte und Naturschutz,
Büsgenweg 5, D-37077 Göttingen, Germany
Tel: +49/0551/393418, FAX: 0049+551+393415,
Email: dkrumla@gwdg.de

Due to the continuous successful research of the scientists the knowledge about the forest restoration increases. However this knowlegde may have an impact on the forest state of health if it is furthermore part of the political discussion. Regard to this subject the media is of essential importance to enter the scientific knowledge in the political process. Communication through the mass media is a central part of political life. In the role of the mass media as a multiplicator they make contributions to determine the agenda setting and to inspire confidence and acceptance in the population. Therefore communicators of different groups compete for their position in the media, forestry as well, both from the scientific and practical side.

The interaction of the media with the respective participants leads to some sort of topic-career, passing certain phases of media reporting (RUSS-MOHL 1981). Many themes, however, particulary of the forestry sector, do not exceed the preliminary phase as they cannot pass the threshold of attention.

One of only a few themes that captures great public attention is the phenomenon forest die-back. In the initial phase some "damage to forest" became the topic "Waldsterben" in the media. A report in the magazin SPIEGEL in the year 1981 can be considered the effecting event. During the following upswing-phase this topic was quite often used in the media and was reflected in a spectacular way.

It pushes other forest topics absolutely away from the media. The reversal phase is characterized by objective description which overweighs the spectacular reporting. According to RUSS-MOHL the regressive and the termination phases constitute the final of the topic-career.

Following these phases of media reporting, the topic forest die-back which has passed the upswing-phases already long ago (1984/85 and 1987) must have already disappeared from the media's visual angle. Publications of GLÜCK 1986, KRÄMER/SUDA 1987 and KROTT 1987 already presumed the approaching end of the career of the dying of the forests. Recent publications regarding the topic dying of the forest in the media clearly show that the dying of the forest only - at least only - has the status of an average daily incident and it can be rewrite stereotyply and it can be conjure up everytime (ZIERHOFER 1998 and HOLZBERGER 1995).

The analysis of 564 articles of Austrian newspapers (Der Standard, Die Presse, Die Neue Kronen Zeitung, Der Kurier) from 1994 to 1998 support this hypothesis. The main topic forest has a large variety of subtopics such as timber production, spare time, finances, restoration of barrier woodland etc. Yet, in 20% of the articles places special emphasis on the topic dying of the forests and the moderate form of damage the forests. Half of all articles on the dying of the forest also contain the topic forest restoration. The description of these restoration measures varies a lot.

The result in front underlines that the forest die-back and the connected forest restoration measures are still published as problems in the media. It follows from this the second main hypothesis of this paper. The policy analysis says that problems can never be objective. According to WINDHOFF-HERETIER (1987) are the definition of problems the result of political demands of different social groups. Different groups, like environmental groups, foresters, scientists and politicians, compete for the definition of the problem of forest die-back and forest restoration measures. This leads to the following hypothesis: The scientific description and knowledge and the powerful interest reporting of forest die-back and forest restoration of the media are far apart from each other.

The content analysis of the articles of the four Austrian newspapers shows that scientists - in spite of their knowledge - don't dominate the discussion about forest die-back and forest restoration measures. Of those who thanks to the dying of the forest gained a place in the media, it is above all the political actors who are in the best position. Especially the Austrian minister of forestry Molterer is repeatedly mentioned. By way of comparison the scientists and the foresters are fare less mentioned in the newspapers. A second important result of this analysis is that in the discussion about dying of the forest in the media environmental groups are of no importance.

It follows from that the question why the politicians and not the scientists dominate the definition of the problem of forest die-back and forest restoration measures in the media. A possible answer on this question could be the analysis of KEPPLINGER (1998). According to the most recent research report of KEPPLINGER the events with regard to their causes can divide into the following three classes: Genuine events are independent from the reporting of the media. An example for this are the forest cut, forest restoration measures like seed collection or debates about the state of the forest report. Media events are occurences which would happen presumable without the expected reporting of the media but which get with regard to them a specific media character. Example is the tree of the year. Produced events are only arranged for the reporting and therefore not happen without the expected publicity. Examples are most demonstrations, press conferences and meetings at special, spectacular locations (Dead spruce in the Harz). KEPPLINGER supposes that the politicians adapt to the media and produce more and more events for the media. Following this analysis results the third hypothesis of this paper: The reasons of the published events with the topic forest die-back and forest restoration measures are most of all produced for the media. This means that not scientific results enter the media but produced events. This will be checked by an empirical analysis. If this become true the scientific state of art of forest restoration is not reported to the stakeholders but a very different picture drawn by the media.

Keywords: policy science, forest restoration, media, Austria

Active perception of forestry in the media

Daniela Krumland
University of Göttingen, Institut für Forstpolitik, Forstgeschichte und Naturschutz,
Büsgenweg 5, D-37077 Göttingen, Germany
Tel: +49/0551/393418, FAX: 0049+551+393415,
Email: dkrumla@gwdg.de

Similar to the discourse in specific literature, the way in which the subject of "forest restoration" is presented and framed in the media differs considerably from the scientific way to describe the problem. Communication theory indicates that the picture of forests in the media is created by single messages which are often repeated in articles (such as dying forests, forests as an important economic factor, forests as symbols for unspoiled nature). In the (over)simplifying logic of the media, forest-related messages are often attributable to either of two (apparently) conflicting sectors: forestry or nature conservation. In addition, there are messages in newspapers which cannot be assigned to any of the two sectors (as for example forests as a symbol for crime). Political analysis relies on the fact that news messages reveal the different values of the sectors and report about their central functions.

Worldwide Urban Forestry Trends for the New Millenium

Guido Kuchelmeister
Graf-Kirchberg-Strasse 25, 89257 Illertissen, Germany
Tel: +49-7303-43776, FAX: +49-7303-42114, Email: 100441.3577@Compuserve.com

The future of mankind is urban. In the next decade, most of the developing countries, which are not yet urban societies, will become predominantly urbanized. Urbanization of poverty is the greatest challenge. However, still most efforts to carry out forestry, recreation, and poverty alleviation have focused on rural areas, while urban people tend to live in degraded natural environments. Trees and related vegetation in urban areas have been considered less important than the built structures, roads, and utilities. However increasingly municipalities around the world have launched urban forestry programs. Only in development cooperation the forestry profession is conspicuously absent in urban initiatives. This paper examines the present status and the outlook of urban forestry around the world. The focus is on poverty alleviation, innovative approaches of public-private partnerships and multi-resource management. Major conclusions of the review are: (1) The need and influence of urban societies will dramatically change the priorities in forestry research and development, in favor of urban areas. (2) Urban forestry is a modern approach to urban tree management, encompassing long-term planning, professional coordination and local participation. (3) Urban forests are economic assets. The overall values of urban forests are such, that they are increasingly regarded as a vital component of the urban infrastructure essential in maintaining a livable and sustainable environment. (4) To develop and sustain urban forests in poor neighborhoods the initial focus must be on meeting immediate needs for basic necessities. This can be best achieved by multiple resource use. Most successful urban forestry initiatives in developing countries are those that achieve generating and sharing of short term profits with the need of long term urban forest conservation among different stakeholders. (5) Urban forestry is no longer an exclusive domain of the public sector. Diverse innovative public-private partnerships, as evolving around the world demonstrate this new urban forestry concepts in action. (6) Financing of urban forestry programs must come from a creative mix of public and private sources. Debt-for-nature swaps, trust funds with the private sector, International Conventions (e.g. UN Framework Convention on Climate Change, Convention to Combat Desertification) need to be further explored as new mechanisms to fund urban forestry research and development projects.

The Cognition of Forester and its Implication to the Establishment of Forestry Fund in Taiwan

Shaw-Lin Lo, Chiou-Shya Torng, Chien-Shiun Tzeng
National Chung Hsing University, Forestry Economics LAB. Department of Forestry, 402 Taichung, China-Taipeh
Tel: 886-4-2850300, FAX: 886-4-2850300, Email: wlb@mail.intellect.com.tw

This study tries to draw up a forestry fund institution that is suitable for nowadays social economical situations in Taiwan. It explores on the basis of some principles in establishing fund and carried out by questionnaires, collecting data and events as well as in comparison with other countries' experiences. The results show that most respondents think the government should set up forestry fund ,and factor analysis shows that both the purpose and source of that have a concentrated trend. The purpose of that focuses on the reforestation and the source of that is looking into cost of water utilization and feedback charges of slopeland developing. This study also emphasizes the meanings of water use right cost and feedback charges in laws, as well as the practice rule. Furthermore , it is calculated the unit cost of water use for setting up a reasonable rate for different departments in the future.

People’s Dependence on Forest and the Changing Legal Profile

Neil B. Majumdar
Indian Institute of Forest Management, Post Box # 357, 462 003 Bhopal, India
Tel: 91-0755- 775716, FAX: 91 0755 772878, Email: neil@iifm.org

People in India are dependent on forests for the goods and services produced since time immemorial. Apart from timber poles, and fueldwood, which were classically categorised as "major forest produce", the dependence is also and even to a larger extent,on several other produce which were referred as "minor forest produce". Though the nomenclature for the later has been changed in the recent years, as "non timber forest produce" (NTFP), dimension and magnitude of the problems remain unchanged. Present paper opts for two such produce viz., Bamboo and Tendu leaves (*Diospyros melanoxylon*) to elaborate people's dependence and the changing legal profile in the country.

As per the Indian Forest Act, the prime act regarding forest, bamboos are classified as timber. Poor forest dwellers use bamboo in the construction of their huts though the other modes of use vary from eating young bamboo rhizome, fencing their field to making mats, baskets and various other artifacts and selling them in the market to earn livelihood. "Nistar rules" (rules for concessional supply of forest produce to the villagers) at many places have provisions for supplying bamboo to the villagers though due to shrinkage of forest resources provisions can hardly be followed.

Tendu leaves on the other hand, are used in the large scale "Bidi" manufacturing process (Bidi is country cigarette prepare by rolling tobacco within the dried tendu leaves) and forest dwellers / villagers come in the picture in this regard, as labourers to collect the leaves from the forests and to sell it to the contractors. As per the Minor Forest Produce (Regulation) Act in most of the cases, trade in tendu leaves is a state monopoly. An amendment to the Wildlife (Protection) Act, in the early nineties has created distinct hardship in the life of the people collecting tendu leaves from the wildlife sanctuary areas.

Though National Forest Policy and various Acts did not provide an important status to the NTFPs, various management systems partially recognised its value. In "coppice with reserve (CWR)" system of management, which is an Indian modification of "coppice with standards (CWS)", the need of the local people particularly for NTFPs has been given due weightage.

In the present philosophy of forest management, in the participatory line, people's dependence on NTFPs is being considered as a crucial determinant for the success. Forest Protection Committees (FPCs) constituted by the villagers for protecting and regenerating the forests, as per the standing order of the government, have been given the 'usufructary rights' on the NTFPs. However, "Panchayat Extension to the Scheduled Area Act (PESA, 96) empowered 'Gram Sabha' (i.e. village committee) members with the ownership right on the NTFPs. This underlines the conflict between the usufructory rights and the ownership rights being enjoyed respectively by the Forest Protection Committee and the village committee members, in case they are not exactly the same. Forest play an immensely important role in the ecological security of the country. However its contribution as a natural resource being used by the people, most of whom stand below the poverty line, cannot also be undermined. An apt forest policy therefore should maintain a balance.

Shaping Public Attitudes: the Case of Forestry Professionals in Slovenia

Brina Malnar
University of Ljubljana, Biotechnical Faculty - Department of Forestry, Vecna pot 83, Ljubljana, Slovenia
FAX: +386 61 271 169, Email: milan.sinko@uni-lj.si

Research aim

The paper will analyze public discourse of forestry professionals and forest-conservation activists, acting as opinion leaders with respect to forest-related issues in Slovenia. In the second step, the paper will examine the influence of opinion leaders' discourse on attitudes of Slovenian general public toward forests.

Our explanatory model is based on a hypothesis, that public attitudes are not primarily shaped on the basis of personal contact and experience with forest, but rather through the mass media, which operate as transmitters of opinion leaders' discourse. The leading role of forestry professionals in shaping public attitudes is secured by their professional authority and privileged access to forest-related knowledge. Accordingly, they are very much an exclusive source for providing information and especially interpretation of forest-related data, facts, statistics, and knowledge in general. We will examine how successfully forestry professionals exploit the mass media (and political channels) to promote their views in public and pursue interests of their specific interest group. We do not expect a direct, 'manipulative' influence in the mass media, but rather an influence in the sense of the agenda setting theory: raising relevant issues, offering interpretations, providing accents. In this way media indirectly limit the audience's ability to see issues in alternative ways.

Methods

To asses the functioning of opinion leaders -> public attitudes model, a two step empirical analysis will be performed. Two potentially most productive methods were selected for each step. The analysis of opinion leaders' discourse will be accomplished by means of computer assisted content analysis. Key-word-in-context and frequency count procedures will be performed on a selected sample of written materials (i.e. publications and public speeches) of forestry professionals and activists. The result are expected to indicate key issues and key aspects which appear in opinion leaders' public discourse. The analysis of public attitudes will, however, be based on survey data. Various forest-related concepts were recently included as part of an annual Slovenian Public Opinion Survey, such as the evaluation of the economic, recreational and aesthetic value of forests, perceptions of forest-related threats, attitudes toward private owners, attitudes toward private vs. public forest management etc. The survey employs a national representative sample of adult population and constitutes the most relevant basis for comparing public attitudes with opinion leaders' discourse and assess the influence of the latter. We shall examine at which points and to what extent public attitudes converge with the views of opinion leaders and at which points they deviate from them.

Mediterranean Forests: Societal Changes and New Institutional Forms for Forest Management

Américo M. S. Carvalho Mendes
Universidade Católica Portuguesa, Rua Diogo Botelho, 1327- 4150 Porto, Portugal
Tel: +351-2-6196294, FAX: +351-2-6196291, Email: americo@porto.ucp.pt

The 60 millions ha of forests existing in the twenty five countries of the Mediterranean Rim feature only marginally in the major international debates and research efforts about forest issues, compared to tropical and temperate forests. Probably this is due, in part, to the fact that they are not major wood producers, non wood forests products being often more important. Many times these products are positive externalities or common goods not priced by the market, but essential for other economic activities (agriculture, tourism, etc.) and for the cultural identity on which are based the life and well being of the Mediterranean societies. This non existence of the right price signals is a threat to Mediterranean forest resources, together with other threats typical of the Mediterranean ecology such as the high risks of wildfires, erosion and desertification. Because forests in the Mediterranean Rim have strong complementarities with other human activities (domestic production, agro-forestry, tourism, recreation, etc.), societal changes are transforming the uses and management of forest resources in the region, with forms which differ from country to country. In the existing research efforts focusing on the Mediterranean forests, namely the networking promoted by FAO through Silva Mediterranea, all the attention so far has been oriented towards sylvicultural topics, leaving aside the socio-economic and institutional issues. Or without a better understanding of the relationships between societal changes and uses of forest resources it will be difficult to manage and anticipate the dynamics of Mediterranean forests so heavily shaped by human activities. After surveying some of the socio-economic research that has been done on the interactions between societal changes and forest management in the Mediterranean Rim, this paper looks more closely at institutional issues. More precisely, we examine forest policy debates and initiatives, as well as the diversity of institutional forms which are emerging to deal with the changing roles of forests in the different types of Mediterranean societies. Some examples of institutional topics covered are the following: - the new forest policy laws and the development of private forest owners' organisations in countries where private forestry is important, but was not collectively organised before, like Portugal and Spain; - the different paths of institutional change to deal with forests in the public domain, like the debate and the resistance to privatisation of forests in Turkey, the creation of Collective Interest Forest Associations in Tunisia, or the shift of responsibility to the regional level in Italy since the 70s.

Monitoring the Socio-economic Situation of European Farm Forestry

Anssi Niskanen, Pentti Hyttinen
European Forest Institute (EFI), Torikatu 34, FIN-80100 Joensuu, Finland
Tel: +358-13-252020, FAX: +358-13-124393, Email: anssi.niskanen@efi.fi

Keywords: Socio-economic, Farm-forestry, Sustainability, Forest policy, Rural development

Policy issues, such as sustainable development, forest certification and rural development, to mention but a few, imply a rising demand for information on the socio-economic situation of forestry. Socio-economic aspects have been well recognised in the recent international conferences and processes aimed at promoting sustainable development. These processes include the Agenda 21 of the United Nations Conference on Environment and Development (UNCED) in Rio de Janeiro (1992), resolutions adopted by countries of Europe and the European Union at the ministerial conferences held in Strasbourg (1990), Helsinki (1993) and Lisbon (1998), as well as the recent Forestry Strategy for the European Union (1999). However, proper tools to measure and monitor socio-economic sustainability especially at the farm level are still missing.

In the European Union, privately owned forests account for more than half of the total forest area. There are approximately 12 million private forest owners in the 15 member countries of the Union. A large part of the private forest holdings are owned by small-scale family enterprises where farming and forestry activities are combined. These management units or 'farm forestry enterprises', are often in a key role in the implementation of various policies aimed at addressing the above mentioned policy issues.

Several European countries, such as Austria, Germany, the Netherlands and Finland have established monitoring systems for farm forestry enterprises. Common to these monitoring systems is the idea to systematically collect data on socio-economic variables to help in analysing and adjusting the policies related to farm forestry enterprises.

The aim of the paper is to present the state-of-the art of the possibilities for monitoring the socio-economic performance of farm forestry enterprises, and the approaches on how the heterogeneous methods of country-level monitoring systems could be harmonised. The paper also presents generally applicable guidelines for collecting and analysing socio-economic data on farm forestry enterprises, adaptable to different purposes and various socio-economic environments.

The paper (i) outlines the major problems and importance of farm forest enterprises in Europe, (ii) introduces means and principles of how to develop a farm forestry accountancy monitoring system applicable to different purposes and various conditions, and (iii) draws special attention to the problems in including the heterogeneous characteristics of farm forestry enterprises into these monitoring systems. The ultimate goal of the paper is to get more consistent and comparable information on European farm forestry, and more specifically, on the socio-economic variables of interest.

Monitoring the socio-economic situation of farm forestry comprises three main types of problem areas, to which the paper proposes solutions: (i) selection of the accounting methods to be able to produce the desired parameters; (ii) selection of the sampling method to be able to produce statistically representative information; and (iii) practical implementation, including the organisational arrangements to run the accounting network system. These problems also interact with each other.

By adopting the principles and procedures presented in the paper, the body in charge of a new or an existing accounting network can produce information that can be better compared to the information produced by other monitoring networks, especially in the case that the other is also using the same principles as a basis for their system. The guidelines of the paper can therefore be considered as a first revisable working step in the evolution before more detailed studies on the approaches and principles adopted are further developed.

Regional Employment in Forest Sector in Europe

Anssi Niskanen, Mr. Chijien Lin
European Forest Institute (EFI), Torikatu 34, FIN-80100 Joensuu, Finland
Tel: +358-13-252020, FAX: +358-13-124393, Email: anssi.niskanen@efi.fi

The question of maintaining and increasing employment, regional income and value-added production in the remote and rural regions is reality throughout Europe. Even the role of the forest sector could often be substantial in regional development, it varies in actual circumstances a lot between different regions. Each region has its own traditions and ways to utilise their forest resources, and their capacities in utilisation of forest resources vary also. Consequently, it is difficult to find common denominators for the success of the forest sector in terms of employment and income.

This difficult task was challenged, and the opportunities of the forest sector in contributing to the vitality of rural areas in Europe were examined in a cross-national study called "Forest Resources for Work Opportunities and Regional Development" between 1995-99. The projects aim was to identify and analyse the factors of the forest sector contribution for regional level employment and income in different socio-economic environments in Europe. This paper presents the major findings of the quantitative part of the research project, including the assessment of variables characteristic to those regions where employment and regional income have been high.

The paper discusses the analyses and data of employment and income, on the one hand, and natural resource base, population characteristics, industrial structure, recreation and policy oriented variables, on the other.

The paper concludes and presents the potentials and practices in utilising local forest resources for high value added production, and discusses how forest-based income and employment could be increased. Among the conclusions of the paper are:

- in the remote regions of Europe, land use, the role of forests and the prospects for the forestry sector development differ along with the traditions and history of the region;
- regions with abundant timber resources are generally focusing on raw material production and semi-final products, whereas regions with scarce wood resources produce more high value-added products and even import wood for the processing industries;
- education and research, especially in conventional forest based activities like wood production, have largely been focused on timber production in large private or public estates. Obviously, not enough emphasis has been given to small-scale ownership structures, which are usually dominant in Europe.

Forestry Research in the National Park Bohemian Forest - Meet the Social Needs

Vilem Podrazsky
Czech University of Agriculture, Faculty of Forestry, Kamìck 129, 165 21 Praha 6- Suchdol, Czech Republic
Tel: 042 02 2438 3403, FAX: 042 02 2092 3132, Email: podrazsky@lf.czu.cz

National Park Bohemian Forest was declared in 1991 on the border between Czech Republic and Bavaria (Germany). The total park area is 69.030 ha, mostly covered by forests. These forests are in general in unfavourable conditions. There are relatively small territories of land of natural type (swamps, peat bogs, block fields, rocks, rarely forests on extreme sites). Most of forest stands were commercial forests until 80ies of this century. They were on large areas replanted after great wind storms in 70ies of the last century. They represent nowadays even-aged spruce monocultures, sometimes of allochthonous origin.

Big storms resulting in large forest damages have repeated since 80ies of this century. The military zone presence on the Czech side caused large prolongation of the consecutive bark beetle calamity processing - no measures were taken in the Bavarian Forest National Park (Germany) at all. After National Park declaration, probably 15.000 ha were declared as I. zones, without any silvicultural treatments (natural processes only). This favoured bark beetle expansion and forest decline on large areas.

Increasing portion of the dead forest and the danger of ecosystem changes on the regional scale initialised great interest of the Czech Ministry of Environment and the National Park Administration. There is a big amount of research done in this region, but its use for forest ecosystem management is considerably limited. Despite of large amount of analytical material, there is a lack of synthesis. A new research project was initialised on ecosystem dynamics research and management concepts formulation. It is oriented especially on zones II, with silvicultural aim to establish close-to-nature forests. Its title is Restoration of biodiversity and stability of forest ecosystems in the zone of natural growth of Norway spruce on the Sumava Mts. National Park territory and will be a synthesis of 4 sub-projects.

First sub-project is oriented on Changes in forest ecosystems. Its objects are stand structure and its development, natural regeneration, anthropogenic changes in forests, dynamics of plant as well as animal communities, dynamics of introskeletal erosion. Second part deals with Dynamics of damages by abiotic as well as biotic factors, extraordinal attention is paid to the bark beetle expansion and static stability. Technologic and economic parameters of forest ecosystems restoration is a technically oriented part of the project. It aims directly the decision strategy formulation of the forest practice. Finally, Silvicultural treatments part seeks for the synthesis of all outputs for practical management of forest stands. Faculty of Forestry of the Czech Agricultural University in Prague and Research Station in Opocno of the Forestry and Game Management Research Institute are institutions responsible for this project.

Women's Role in Forest-based Systems - A Case Study from Himachal Himalayas of India

Punam, Atul
COA, Himachal Pradesh Agricultural University, Department of Agroforestry and Environment, COA, Himachal Pradesh Agricultural University, 176 062 Palampur, Himachal Pradesh, India
Tel: 91-1894-33961, FAX: 91-1894-30511, Email: atul@hpkv.hp.nic.in; atul1028@email.com

Keywords: Women, Participation, Forests, and Himachal Himalayas

Forest resources in the Himalayas have been depleting at an alarming rate, during the last few decades and with this pace we are not only miles away from the sustainable forest management but heading for a biological erosion. Though forestry has grown from the concept of production forestry to conservation forestry yet it lacked the active involvement of local people.

Present study was carried out to understand the role of women in the forest-based systems of the Kangra valley of Himachal Himalayas. PRA exercise with some modifications was conducted in the villages and the local women were motivated to express their views fearlessly. The information gathered was recorded and analyzed critically. It was found that keeping in view the shuttling men population between cities and villages, the axe to undertake the field work - fodder and fuelwood collection, forest produce, collecting grasses from grass lands, fetching water for household use and sharing larger agricultural operations etc., falls on the rural women only. But this participation by women is treated as invisible. This is not only the case of Kangra valley alone but is also the true picture of the entire Himalayas. Depletion of forests has increased her working hours for meeting these necessities. In addition to this, the technologies generated by the scientific world, many a times do not match the rural client i.e., woman. Besides, in many cultures and castes, women are discouraged from participating in the meetings and training programs along with men and hence their participation in resource development and conservation programs is negligible. However, our experiences show that when given opportunities, rural women do participate actively in the meetings and training camps and are able to identify their problems and suggest solutions.

This study also helped in the planning of the motivation strategy on one hand and in identification of the key units on the other. It was found that with the use of the appropriate tools of motivation, the local rural women groups, which were earlier inactive, could be gradually involved. The strategy of " If you educate a woman, you educate a family" and "If you educate a girl, you educate two families" was given a live form and implemented in totality. Approximately 25 ha of land was developed under different agroforestry systems. Her preferences for the species were based on multiple utility within the household, including food, fodder, fuel, medicine and income needs. The major lesson learnt through this study was that if we want to plan effectively for any natural resource management program, input should be from the stake holders who use and depend on the natural resources and these are often women. Secondly, involvement and participation of the people is possible provided there is a committed and sincere leadership to educate, organize and motivate the people for the attainment of a common goal. This study also highlights the role of the women extension worker in developing a package of the successful women participation in forestry based systems.

Need of the hour is to change our mindset at all levels. The forest laws, norms, regulations and procedures need a radical change if this prime but silent force "women" is to be given their long due place in the forestry sector development. If we look forward to succeed in reducing rural and natural resource poverty, the balance between women and their forestry resource must be restored. The lessons learnt during this study can act as a useful tool for replicating the forest ecosystem conservation program by the society for the society in the other mountain areas of the world.

Community Participation in Sustainable Forest Resources Management in the Philippines: A Policy Review

Lucrecio L. Rebugio
UPLB College of Forestry and Natural Resources
College, P.O. Box # 132, Laguna, Philippines
Tel: 63-49-536-3996, FAX: 63-49-536-3206, Email: llreb@laguna.net

The participation of communities in sustainable forest management and development has been an expressed government policy in the Philippines for over two decades now. This policy is justified by the recognition that government alone cannot adequately cope with the task of sustainable development of the countries forest resources. Thus since 1971, more than ten programs and projects with participatory component have been designed and implemented; they have come to be collectively known as community-based forest management programs and projects. Given the number of existing participatory forestry programs as of date, a policy review was conducted to determine the constraints to the effective implementation of community-based forest management programs, and to recommend measures to enhance more effective community participation in sustainable forest management. The review employed variety of methods including survey of relevant data and documents and field observation and interview with community forestry program personnel and other key informants. To provide depth, the review involved case studies of six major programs. Review results indicated that the activities designed to achieve the development goals of community-based forestry have been in place, but the full realization of these goals is impeded by many constraints, the more salient of which are:

1. Community participation is high for only a small sector of the community that is better off educationally and economically. Conversely, the poorer majority who need to benefit more from the program appear inhibited, less motivated and incapable of active participation.

2. Community organizations in most community-based forestry project areas are still in their nascent stages of development.

3. The variety of tenurial instruments serves to create confusion and present difficulties in administration.

4. Restrictive policies on the harvesting and utilization of forest products discourage forest communities from actively participating in the program.

5. Access to capital is limited and the institutional mechanisms to facilitate this are weak.

6. Imbalanced education and training and support programs that emphasize technical forestry skills over management and enterprise development skills.

7. A weak extension system that hampered the diffusion to and utilization of relevant technologies by the participating communities.

8. Physical infrastructure to facilitate access to product market is poor or non-existent and market mechanisms for market mediation are underdeveloped.

9. Central and field coordination of programs are diffused thus resulting to disjointed operations.

To address these constraints, the following measures are recommended:

1. Strengthening the management effectiveness and efficiency of the executing agency (DENR) and support organizations (local government units and non-governmental organizations).

2. Strengthening community organizing to ensure the sustainability of community-based forestry programs through such ways as utilizing production incentives as entry points to the community organizing process, or integrating income generating forestry development or livelihood activities in this process.

3. Ensuring access to production incentives by speeding up the processing and awarding of appropriate tenurial instruments to community participants, devising a more liberal policy on forest harvesting and utilization, enhancing institutional capability for capital intermediation, improving market access by building more farm to market roads, and improving community access to relevant technologies by strenthening research and extension systems.

4. Reaching out to the more disadvantaged sector of the community for membership by strictly implementing, for example, the recruitment guidelines and conducting recruitment in a more participatroy and transparent manner.

Monitoring System for Non-industrial Private Forestry in Finland

Pekka Ripatti, Hänninen, H. & Karppinen, H
Helsinki Research Centre, Finnish Forest Research Institute, Unioninkatu 40 A, FIN-00170 Helsinki, Finland
Email: pekka.ripatti@metla.fi

In the countries dominated by nonindustrial private forest ownership one of the prerequisites for a successful forest policy is the up-to-date information on the structure of private forest ownership and the behaviour of forest owners, as well as the knowledge of their objectives of forest ownership. The number of forest owners is usually large and the structure of forest ownership is continuously changing. Therefore the most feasible procedure to collect information on private forestry is to conduct separate survey studies based on representative samples of nonindustrial private forest holdings. As the same type of information is collected periodically, the various data can be combined into a database providing a monitoring system for private forestry. This kind of monitoring system can produce information concerning holding and ownership characteristics, forest owners' timber sales and silvicultural practices. Furthermore, the knowledge of owners' participation in forestry extension as well as understanding of their objectives of forest ownership are of crucial importance. In addition, the monitoring system can produce data for separate studies on up-to-date topics. In Finland, nonindustrial private forests are divided into 300 000 forest holdings with at least 5 ha of forest land. Private forests have an important role in Finnish forestry, supplying 70-80% of the domestic roundwood purchased by the forest industries. Until the 1960s, holdings were typically owned by farmers and they were mostly permanently resided. During the last thirty years, a rapid pace of change has taken place in the Finnish society. The main changes have been occupational differentiation and migration of the population. These changes have had a powerful impact on nonindustrial private forest ownership and on the objectives of forest owners emphasising the need to monitor the development. The Finnish monitoring system for private forestry consists of three country-wide cross-sectional data collected in 1975, 1990 and 1999. Based on this monitoring system data, the development of non-farmer and absentee ownership, and owners' objectives will be presented by graphs. In addition, the development of age structure of forest owners as well as a three stage age-cohort table on timber sales will be shown in order to enlighten the life-cycle and generational effects on cutting behaviour.

Law Enforcement In The Forests: How It Can Be Made more Effective

Mohd Rusli bin
Universiti Putra Malaysia, Department of Forest Management, Faculty of Forestry, 43400 Serdang Selangor, Malaysia

Forest authorities in many countries enforce forest laws as an instrument to regulate the conduct of individuals, loggers, and timber companies in dealing with the forests in line with the forest policy of the government. Generally, the law either promotes the conduct of certain activities through the giving of incentives (carrot approach) or prohibits the conduct of certain other activities by imposing various kinds of punishment including fines and imprisonment (stick approach). In the stick approach, it is believed that imposing stringent punishment would have a deterrent effect on the occurrence of forest offences. It is always the case that the maximum punishment for forest offences are increased whenever necessary in order to deter likely offenders from committing forest offences. This paper stresses the fact that there are many factors which influence the occurrence of forest offences of which the maximum prescribed punishment is one of them. It is rather the expected punishment, and not the prescribed maximum punishment that greatly influence the occurrence of forest offences. Even though the maximum punishment is very high, due to low probability of arrest and conviction, the expected punishment can still be low. As such, the deterrent effect of high prescribed maximum punishment is now always felt by likely offenders. Preliminary results are given in this paper which show that the expected punishments for forest offenders are quite low. Forest offenders can internalise these punishments as part of their operating costs. Some suggestions will be put forward to increase the effectiveness of law enforcement in the forests.

Assigning Monetary Value to Plant Diversity on Forest Floors

Kamaljit K. Sangha, R.K. Jalota and R.K. Kohli
Panjab University, Dept. of Botany, 160014 Chandigarh, India
Email: sangha_7@yahoo.com

The distribution of plant species on forest floors represents an important ecological service for the sustainability of ecosystem. However, this service has usually been ignored due to its non-marketable value. The failure of market systems to capture the value of the ground floor vegetation of forest floors sends the wrong notions for value judgments. The absence of any other appropriate methods to count the monetary equivalence lead to exclude this

component in the accounting of total economic value of forests. Though, recently a few standard methods like Contingent Valuation Method, Hedonic Price Method or Travel Cost Method have been practiced to estimate the monetary value of biodiversity preservation or some other such particular uses. But the application of such methods varies with the socio-economic structure of the society. Moreover, these methods provide the economic value for particular usage of a plant species while a single plant provides a number of ecological services. Keeping this mind, the various phytodiversity components of forest floors are evaluated in terms of scores following Ordinal Analysis. The scoring is done based on the criteria of longevity and biomass productivity of a plant species for five major uses i.e. food, fuel, fodder, medicine and soil stabilization. The scores of each plant species are further converted into monetary equivalence to estimate the monetary value of all the plant species growing on the forest floors. The data generated from the floors of monoculture forest plantations of *Eucalyptus tereticornis* (an exotic species in India) and indigenous Dalbergia sissoo in the same edapho -climatic zones, has been taken as a sample study with interesting results. The floor of *D. sissoo* yields almost double monetary value than that of *E. tereticornis* on account of its plant diversity.

Role of Non Governmental Organisation (NGO's) in Forest and Mountain Development

Om. Prakas Sharma, D. D. Sharma
Dr. Y.S. Parmar University of Horticulture and Social Sciences, 173 230 (HP) Nauni (Solan), India
Tel: +91-1792-52288, FAX: +91-1792-52242, Email: dext@yspuhf.hp.nic.in

Forests are one of the most important natural and renewable resources, which play a significant role in the development of any country. The quality of environment depends to a great extend on the entire forest ecosystem. According to the latest official estimates on land use statistics, the forest cover at present in India is 19.52% compared to 22% at the time of Independence. In view of the growing depletion of forest wealth, there is an urgent need to launch massive programmes for meeting the basic amenities of life with the help of central and state governments, voluntary agencies, non governmental organisation and the involvement of local people to solve the problems of soil erosion, reclamation of marginal lands, shortage of fuel wood, fodder, timber an other forest products.

Transfer of technology for forest and mountain development is not a function of one individual or one single system but it is a multi dimensional conception which all the development organisation are directly or indirectly involved. non governmental organisation (NGO's) in India are found in almost all areas of human activities, such as, environment protection, human rights protection, technology transfer and the like. Being small and autonomous in nature, voluntary organisation have flexible approach in ensuing the needs of rural populance. They develop n and adopt a work culture well understood by the villagers, believe more in institutional rather than individual approach and ensure better co-ordination and team work. Since NGO s have dedicated an committed field workers with high degree of closeness to the climent group, innovativeness and ability to stimulate interest in the community as well as skill to involve the people right from planning to implementation starge, therefore, they should be treated as an important part of any development programme. The rapprot credibility and decision making ability of NGOs should be fully exploited for strenghtening the weak links in the transfer of technology programmes for forest and mountain development. The essence and objective of the government and NGO being the same, the interdependence between the two must be recognised and the efforts should be made to seek the latter's c cooperation in enhacing the peope's participation in sustainable forest and mountain development programme.

Co-management Approach in Afforestation Programmes: A Case Study

P. R. Siyag
Forestry Training Institute, Jawahar Lal Nehru Marg, 302 015 JAIPUR, India
Tel: +91 141 510 034, FAX: +91 141 380 496, Email: siyag@jp1.dot.net.in

This paper relates field experience in NW Indian district of Bundi of working with local communities under the framework of co-management in execution of afforestation works. The basic philosophy was to ensure greater involvement of the grassroots institutions and the people in general in planning and execution of forestry works so that the assets created could be sustainable in the long run. Past experience over the years suggested that forestry plantations once created were forgotten for lack of aftercare and protection. The communities for whose benefit these assets were created were often blissfully unaware of the works and the philosophy behind these. They were not consulted for site selection, nor was the need for such works expressed by them in the first place. They probably thought it was some governmental necessity having nothing much to do with them. As a result, when the department withdrew with ceasing of flow of funds the villagers started grazing in the areas and the plantations were soon destroyed.

In light of this experience it was decided that heretofore all plantation works in the district should be executed through the agency of the Village Forest Protection & Management Committees (VFPMCs). In any case, a large number of VFPMCs in the district were clamouring for allocation of funds for developmental works in their areas, and on being asked whether they were willing to take on the responsibility of executing the works themselves, their response was positive.

The institutional arrangements made were such that while formulation of the project, and technical supervision would be the responsibility of the departmental personnel, the VFPMC would primarily handle planning and decision making tasks such as site selection and choice of species, and also the nitty-gritty of actual execution of the works such as requisitioning of workers, recording their attendance and disbursing their wages.

The issues that had to be addressed under the new framework of co-management were: promoting community-based institutions/organisations, management of change in its various aspects such as attitudinal change of the forest department's employees, power-sharing, joint work ethos, and technology transfer and capacity building.

The experience gained has proved that co-management is a superior approach in respect of both the sustainability and the quality of works carried out. The villagers have been greatly enthused over the new method of working. They feel they didn't know earlier that all this was their right to know what is going on in their village where workers were engaged by the department for raising plantations, and to be consulted while deciding a work program in their own village. They have time and again expressed a sense of gratitude and discovery of their rights. They feel what should have happened decades ago has happened now after all. The phenomenon of VFPMCs has caught on like a contagion. More and more villagers are forming VFPMCs. There s a flood of proposals for new plantations to be raised. Involvement of people has triggered greater interest among communities for protection and management of their forests. This has improved the prospects of sustainability of developmental programmes and assets created thereunder. It has improved knowledge and capability of communities in self-organising and self-help. The government need not recruit an army of bureaucrats or karmcharis for launching new and larger programmes of development if the people's capacity for self-action is built up. The departmental personnel have been rid of the petty chores of marking attendance and disbursing payments. Their role has now been elevated to that of facilitators, guides and supervisors. The capacity of a forester to execute works, for example, has increased manifold.

The experience also seems to prove some of the theoretical findings of game theory and sociological research in respect of group size, homogeneity, and other such factors affecting success of community level collective action.

Research Patterns During Four and One-Half Decades of Forest Science

Jeffrey C. Stier, Andrew Orlemann, Thomas W. Steele
University of Wisconsin-Madison, Department of Forest Ecology & Management, 1630 Linden Drive, 53706 Madison, USA
Tel: 608-262-3976, FAX: 608-262-9922, Email: jcstier@facstaff.wisc.edu

In 1995 Forest Science was launched on what was expected to be "... the beginning of a long and distinguished career in the field of technical forestry publications (Demmon 1955, p. 4)." Since then it has become one of the world's leading outlets for forest science research. We examined the publication patterns during the first 44 years of the journal, looking for information on which scientists publish in the journal, what subject areas in forest science receive the most research attention, whether there was evidence of concentration on particular regions or species, and how patterns tended to shift over time.

A total of 3,231 individuals published 3,065 articles in Forest Science during its first four decades. U.S. scientists have been the most frequent contributors (86% of articles), with the remainder split equally between Canada and all other counties. Initially, scientists from other countries contributed only sporadically. Since 1992, however, foreign authorship has increased dramatically.

Three countries-Australia, Finland and Sweden-accounted for 42% of all foreign contributors and supplied more than twice as many authors as any other country. Forest Science publishes papers on a wide range of subjects but not all subject areas have been equally represented. Ecology, forest biology, forest health, mensuration, and silviculture have been the dominant areas in terms of number of articles, number of authors, and number of published pages. From 1975-1994, average article length almost tripled. Since 1994 article length has declined dramatically, falling to about what it was in the 1980's.

The average number of authors associated with an article is one measure of the degree of collaboration among scientists (Harsanyi 1993) and generally this statistic has been increasing for most science journals. Broad (1981) reported that the average number of authors among 2,800 journals indexed by the Institute for Scientific Information rose from 1.67 to 2.58 between 1960 and 1980, but that there had been considerable variation across fields. The averages for Forest Science were very similar-1.52 in 1960 and 2.19 in 1980.

For the Congress, we proposed to add to the results reported above by addressing several questions relating to the emergence of modern scientific themes in forestry research published in Forest Science. Examples include: When did concepts like sustainability, biodiversity and ecosystem management begin to appear in the journal? What was the subject matter context within which they appeared? Are they equally represented in U.S. and foreign papers? Do the citations and authorship patterns reveal international connections among ideas and scientists?

Ecological Factors Affecting Labour Supply for Taungya teak Plantations in Myanmar

Yukako Tani
University of Tsukuba, Institute of Agriculture and Forestry, 1-1-1 Tennodai, 305-8572. Tsukuba, Ibaraki, Japan
Tel: +81-298-53-4610, FAX: +81-298-53-4761, Email: ytani@bres.tsukuba.ac.jp

Keywords: Teak plantation, Taungya, Myanmar, reserved forests, productivity, participation.

In spite of the various efforts, degradation and deforestation of forests in tropical countries are still continuing. Agroforestry has been expected to be one of the solution to rehabilitate degraded lands. Among the various types of agroforestry systems, Taungya which originated in Myanmar, has been applied by many governmental agents as a low cost plantation system. Taungya literary means 'hill-field' and is generally used for 'shifting cultivation' in Myanmar, and is acknowledged as an agroforestry system in which agricultural crops are interplanted between tree crops. Most of the research on Taungya till the 1980's had been focused on technical aspects. More attention has been paid to socio-economic factors after the 1990's, since these aspects were admitted to be important to realize sustainable management of man-made forests as well as natural forests. For example, the demand of people participating in the plantation effects labour supply for the programme.

This paper examines some ecological factors which effect the taungya farmers attitude towards participation in the plantation. Interviews to household heads of taungya farmers, using a uniform questionnaire, was carried out in 1995 in three plantation sites at Bago range which is one of the centre for teak. Bago Range is located between Yangon and Mandalay, the two largest cities of Myanmar, and is comparatively easy to access. The range is relatively low and covered by undulated hill which forms numerous lowlands of various sizes. These lowlands are suitable for paddy cultivation but not for teak. Bago range was declared as a reserved forest by the Colonial government in the late 19th century and then was nationalized after independence. Taungya teak plantation has been organized by the Forest Department since 1856. Data showed that the Taungya farmers changed their attitude according to the productivity of land in and around the plantation site. Taungya farmers apt to quit participating in the program and settle in the reserved forests if they could utilize lowlands outside the project site, which had a higher productivity than the land allocated for taungya On the other hand the Taungya farmers tended to continue participating in the program if the land for taungya were more productive. The difference in productivity was mainly due to the type of crops which they grew. Though, the land available is limited under the present situation, so that the taungya farmers showed a high reliance to the plantation in which 2nd generation could be observed. Thus, ecological factors was one of the important conditions to supply labour for Taungya teak plantation. However, it is assumed that the control of cultivation outside the taungya programme, and the social services to be provided to the taungya farmers who have to move every year following the project, would be crucial to secure the stability of future forest management. These elements may rise the cost for the Forest Department.

An Objective and Transparent Approach to Set Forest Research Priorities: An Imporant Policy Issue

Anjali Verma
Wayne State University, 5200 Anthony Wayne Dr. #803, Michigan-48202 Detroit, USA
Tel: 001-313-832-5113, Email: vermaanjali@hotmail.com

Institutional and scientific contexts interact with government policy to define the environment for forestry research. This environment determines the economic impact of research and development and has implications for research evaluation, priority setting and resource allocation. in any research institution budget represents the sum of all resources available and is always scarce. Because resources are scarce and can always find alternative use, it becomes necessary to be selective in choosing the nature and focus of research one supports. Proper chanellization of the allocated budget is, therefore, a must for successful research administration. For such allocation a comprehensive and analytical approach that is reasonably transparent is therefore essential. The priority setting exercise simply gives an order or ranking to the various research projects and enables the researchers and professionals to interact more effectively with policy makers, funding agencies and client groups. The five formal methods of research priority setting are: Scoring (Delphi), Economic Surplus, Mathematical Programming, Econometrics and Simulation Models. The first two methods were basically used to set priorities for the forest research projects being undertaken by the Indian Council of Forestry Research and Education, India. Scoring, a more subjective method was used to set priorities at national and institutional levels and Economic Surplus, a more objective method was used to set priorities at the project level. Under the Economic Surplus method, individual research projects were evaluated under the three criterias of Economic Efficiency (that is to what extent the project can increase the contribution of forestry sector to the economy), Income Distribution (that is whether the project can reduce the disparity in income of rural and urban people in general and forest dwellers in particular) and Environmental Security (whether research project can provide some environmental security by conserving the forests). This analytical, transparent, objective, participatory and systematic approach of using economic tools for setting forest research priorities may bring the researchers and the administrators come closer. However, formal evaluation and priority setting procedures should not be used as a basis for replacing ingenuity, serendipity and scientific entrepreneurship with bureaucratic procedures.

Sustained Yield Forestry - The Implementation of an Idea

Gerhard Weiss
University of Agricultural Sciences, Institute of Forest Sector Policy and Economics, Gregor Mendel-Strasse 33, A-1180 Vienna, Austria
Tel: +43-1-47654-4405, FAX: +43-1-47654-4407, Email: weiss@edv1.boku.ac.at

European forestry is known for its concept of sustained yield. Foresters are proud of this management system as a moral concept. However, from a political science perspective it has to be asked how the development and implementation of "sustained yield forestry" was possible. Is it true that a "wise" government set the standard of sustained yield forestry in the interest of the people? For answering this question this paper undertakes a re-analysis of forest historical literature applying political theories to the material. This paper employs an analysis framework containing the elements: institutions, interests, and values. The first step in clearing up the politics of forest management is to identify the relevant actors in the policy field. For all of these actors their behaviour is described. This behaviour can then be explained by their interests, their values and their power resources. It is important that there is not a uniform "State": the abstract idea of the State consists of different actors: governments, interest groups and the forest administration itself have all different interests and are acting relatively autonomous. The paper looks at different historical stages of forest management regulation. Three main historical eras can be distinguished, in which different governing systems constituted different institutional settings for forest management regulation: the era of the commons, the era of the sovereignties, and the era of the constitutional state. The behaviour of the political actors, their interests and values are discussed by using different examples from forest history of Austria. Important such examples are areas with salt and ore mines, which can be found in different provinces of Austria. The broadly accepted view that the implementation of sustained yield forestry was possible because mineral coal relieved the forests from use pressure is questioned: If no interest in the forests existed any more - why would there still be efforts in implementing strong forest laws? This question is discussed by considering different hypotheses derived from political science and suggested in different studies on environmental history in central Europe. The paper presents differentiated explanations for the development and implementation of sustained yield forestry. On the contrary of the above cited popular view it holds that sustained yield forestry was not implemented against but with strong group interests. Another example of particular interest is the mountainous province of the Tyrol. Here, since the absolutist regime of the sovereign always a well-staffed forest administration existed. This usually is argumented as being necessary for securing sustainable forest management because of the specific conditions in this province: First, the protective functions of the forest are said to be of extraordinary importance for the land. Second, it is claimed that the community forests – a typical type of forest ownership in the Tyrol – need especially strong supervision. A critical review of the historical accounts question the cited arguments. A strong forest supervision lies in the interest of the forest administration itself. In contrary to other provinces with large private forest properties in the Tyrol the communities were not strong enough to defend implementation.

6.01.00 Tools to integrate nature conservation and recreation for landscape management

Evaluation of Recreational Potential of the Research Forest of Faculty of Forestry, University of Istanbul

Tülay Ayasligil
University of Istanbul, Faculty of Forestry, Bahçeköy, 80895 Istanbul, Turkey
FAX: +90.212. 226 11 13, Email: yahya@istanbul.edu.tr

Peri-urban woodlands as natural landscapes must be protected, and open space systeme must be created by including these the town development master plan together with other urban open spaces. The protection, care and restoration of landscape with woodlands depend on the planning of recreation centres. In this study the Research Forest of the Facutly of Forestry, University of Istanbul has evaluated as a recreation area within the urban open space systeme. Based on the investigations aim at the determination of recreation potential of the area a frame plan has been worked out. The planning principles can be given in five headings; such as land use, use of natural resoures, transportation and settlement, recreation and conservation.

Natural and semi-natural open spaces outside of the urban areas, from a which we moved far away, as a result of the technological progress and our modern life style, should be preserved, and opened to recreation, as far as possible. In order to put forward guidelines for the general planning, it is necessary to find out the recreational potential of those areas. Due to the needs mentioned above the study presented here is carried out. It deals with the recreational potential of the Bilezikçi Çiftligi Forest, an extension of Belgrad Forest. These are the most important forests of the Istanbul Metropolitan Area.

The study consist of two stages. The first stage covers the activities to obtain the basic data needed for determination of recreational uses. Second stage consist of a general evaluation of the existing data, and of the planning principles, as well as the desicions on the site program and site plan resulting from the general evaluation of land use, natural resource use, circulation, and structuring.

Finaly the areas suitable for development for land use, natural resource use, circulation, structuring and recreational intensive use are determined and conservation principles established. These principles are summarized as follows:

- In the planning for multiple use the primary consideration should be recreation. It should be followed by hydrology, research, wildlife, and agriculture. The harvest of timber for construction and for space heating must be terminated.
- Water, which is one of the natural resources of the forest must be utilized for recreation.
- The natural plant cover of the forest and its very rich floristic composition should be conserved carefully.
- With an eye to not disturb the natural balance of the forest the wildlife should be controlled.
- In the reforesrations deciduous tree species should be preferred to conform with the plant cover of the forest.
- The existing buildings in the Çiftlik area could be opened for recreational use after restoration. A small area should be specified for game. Additions to the existing structures must be avodied as far as possible. Each new building must match the existing ones.
- To provide control at the intensive use areas a control system should be established at the gates.

Bioclimatological Parameters and Forest Management for Recreational Purposes under Mediterranean Climatic Conditions

Gabriel Schiller
The Volcani Center, Department of Agronomy and Natural Resources, Post Box # 6, 50250 Bet-Dagan, Israel
Tel: +972-3-9683678, FAX: +972-3-9669642, Email: vcgabi@agri.gov.il

As the result of increasing living standards and leisure time, much attention is being devoted to problems of landscape assessment and management to enhance their recreational functions. There is need for an objective approach to problems of out-door recreation. Such a criterion is provided by the prediction of the heat stress, i.e., the sweat rate and the thermal comfort sensation of an average, recreation-seeking human being under given microclimatic conditions as influenced by the tree canopy closure which in turn is the result of management practices.

The objectives of the studies reviewed were: (a) to estimate the influence of different canopy closure resulting from silvicultural treatments used in ever-green, low-elevation Mediterranean forest ecosystems on the microclimate and the resulting sensation of thermal comfort of humans; and (b) to examine the implications of the findings for management of forests for recreational use.

Microclimatic measurements were conducted in natural and man-made landscape formations regularly used by the population in Israel for recreation. Human response to thermal environment and the mechanism of heat exchange between the body and the environment have been expressed by the Index of Thermal Stress. Thermal sensation, i.e., thermal comfort votes at given Thermal Stress was calculated.

The results presented show that the heat stress, i.e., sweat rate needed to keep homeothermy and the thermal comfort sensation are closely related to canopy closure. Specifically, gaps in the tall tree forest and oak scrub formations on S-facing slopes will provide the most comfortable sites in winter and early spring, while in the summer thermal comfort is directly related to tall tree forest canopy closure, preferably on N-facing slopes.

National Outdoor Recreation Demand and Supply Assessment Study in Finland

Tuija Sievanen, Eija Pouta, Leena Kopperoinen
Finnish Forest Research Institute, Unioninkatu 40 A, FIN-00170 Helsinki, Finland
Tel: +358 9 85705769, FAX: +358 9 85705717, Email: tuija.sievanen@metla.fi

A need to produce nationwide information concerning nature-based recreation and tourism has become actual in many countries. The use of forest and other natural resources has intensified. There are international and national level discussions about policy programs of sustainable forestry, and international and national programs for nature conservation (Nature 2000 in EU-countries. In Finland, many institutional changes have occurred as well. Forest and Park Service provides recreation services now partly on commercial basis, and partly as free of charge welfare services financed by government. Those are reasons why recreational use needs a strong information basis to be considered an important part of forest resource use. Also, the societal expenditure on recreation services needs to be grounded on well-documented and reliable basis.

This paper introduces the National Outdoor Recreation Demand and Supply Assessment Study (LVVI) in Finland. The project collects statistics and databases on a continuous basis in order to monitor changes in participation in outdoor activities and behavior patterns, as well as changes in the supply of recreation opportunities and the quality of services. A pilot study was made in 1997. The main study is carried out in 1998-2000.

The main issues in outdoor recreation demand study are participation rates in outdoor activities, last trip information (for both close to home trips and tourism), and distribution of visits in different types of areas (state, municipal and private lands). The study also includes special themes concerning recreation valuation, welfare and health impacts, state land use and nature-based tourism. A large population survey is the principal method of the data collection. Preliminary results presented cover participation rates, a typical visit to a close-to-home recreation area, a typical nature oriented tourist trip, and some other results of the large study. Some preliminary demand projection models are also presented.

Information concerning recreation areas, trails and other recreational services will be collected from municipalities and state agencies (Forest and Park Service, Forest Research Institute). The data includes quality descriptions of services, information about natural features of the areas, and use information. The information will be stored in GIS (geographical information system) and in the sports sites database, which is expanded to include recreation areas, trails and other recreational services than sports sites, as well. The preliminary results deal with the location of outdoor recreation supply in relation to e.g. distribution of population, classification of recreation areas according to their quality and characteristics, and the relationship between conservation areas used for recreation and specific recreation areas in different parts of Finland.

This poster will present the framework of organizing a national recreation assessment study in Finland, and some preliminary results of the demand and supply surveys. The need for the monitoring of outdoor recreation on national basis is also discussed. The nationwide databases of recreation are an important information basis for recreation policy in the context of general forest and natural resource policy. The discussion deals with the expected uses of the processed information and the possible impacts of the new information in terms of use of natural resources, institutional changes and the benefits gained by society.

The Evaluation Results of the Benefits of Tourism and Recreational Forestry Functions

Dijana Vuletic, Tomislav Dubravac, Miroslav Benko
Forest Research Institute, Jastrebarsko; Streljacka 1, Trnjanska 35, HR-10 000 Zagreb, Croatia
Tel: +385-1-484-7750, FAX: +385-1-611-3372, Email: dijana.vuletic@public.srce.hr

Tourism and recreational forestry functions are analysed from the standpoint of the total economic value (TEV, Pearce & Turner, 1990) as one of its component. The system of evaluating the TEV is comprised of: economic, social-ecological (Krznar et al, 1995) and social-environmental forestry functions (Krznar & Lindic, 1999; Krznar et al, 1999), where social-environmental factors are divided into tourism-recreation and health-landscape.

Analysis and evaluation were undertaken in the framework of the subproject "Evaluating the Capital Goods of Forests and Loss Caused by the Influence of Harmful Factors", which was financed by the public enterprise, Croatian Forests. The researched area was public forest on the island of Korcula, (Southern Adriatic near Dubrovnik). Korcula is the sixth largest island in Croatia, long in shape with total area of 276 km^2 and coast 182 km long, which is well separated by numerous bays (56), capes, gulfs and groups of smaller islands. It is a well-known tourist destination, which has up to 1,000,000 overnights per year. The forests cover 60% of the island area, and are composed of Aleppo pine (*Pinus halepensis* Mill.) and, in various stages of degradation, Holm oak (*Quercus ilex* L.) forests.

In this methodology a classification scale with related points evaluated the tourism and recreational forestry functions. The span of the point value is determined on the basis of estimated internal and external quality factors of these functions. The external factors are the level of tourism development, accommodation available in the region of evaluated forest, the number of inhabitants, tourists and their recreational habits and their tendency to visit the forest. The internal factors are evaluated according to the structural and aesthetic forest characteristic that are necessary for particular tourism and recreational activities, frequency of visiting and the developmental level of infrastructure.

The obtained results indicate a high potential of the forest area for tourism and recreational activities. Index values are from 0.8-1.0 in the very good (8) to excellent (9) quality categories. Contrary to this, visit frequency index was from 0.34-0.65 in the very bad (3) to satisfactory (6) quality categories. The function with the least amount of points was the level of infrastructure development, which fit the unsatisfactory (1) to critical (2) quality categories that reflect its real state, since there is a lack of sport and recreation activities in forest. The Aleppo pine associations have higher values of tourist and recreational functions than the Holm oak forests.

The evaluation of the forest tourism and recreational use and the probable number of visitors led to a conclusion that despite their exceptional tourism, sport and recreation potential. The results point towards a possible increase of the value of tourist and recreational forest functions by including these forests in to the tourism services, ensuring they are used in a planned and ecologically acceptable way.

6.03.02 Forest Terminology: How to get society understand forest terminology

How to Do Terminology Work in Forestry. Services Offered by IUFRO

Renate Prüller, Michèle Kaennel Dobbertin
IUFRO, Secretariat, Seckendorff-Gudent-Weg 8, 1131 Vienna, Austria
Tel: +43-1-877 0151 ext. 21, FAX: -43-1-877 9355, Email: prueller@forvie.ac.at

Keywords: Forest terminology, co-operation, terminology services

Efficient communication among scientists and with decision makers needs a precise and clear technical language. The network of IUFRO experts in forest science is an immense pool of living expert knowledge. Experts create the terms we use to communicate and thus constitute an ideal partner for IUFRO's services in their attempt to define and make accessible the forest technical language to a wider public.

At a time when English has become the *lingua franca* of science, it is crucial that other languages - and IUFRO has four official languages - keep playing an active role. This broadens the horizon of scientific thinking and knowledge, but also makes unequivocal communication more difficult to achieve.

Vocabularies, glossaries and terminological databases present the technical vocabularies and, if relevant, interpret them for the interested public. The role of forestry experts is to help and assist in this process of explication and definition of their own specialised language, in order to guarantee the high quality and liability of these communication tools.

IUFRO offers services with regard to terminological problems through its Working Party 6.03.02 "Trends in Forest Terminology" and its terminology project SilvaVoc based in the IUFRO Secretariat, which are interrelated and pro-active. Additionally we will show how 6.03.02 and SilvaVoc incorporate IUFRO officeholders in terminology work and illustrate the most important services that are provided by 6.03.02:
- electronic discussion groups
- terminological hotline for telematic-based terminological assistance;
and by SilvaVoc:
- on-line Bibliography of terminological publications in forestry
- terminological database SilvaTerm.

Traditionally IUFRO's role in terminology has been to make people aware of terminological differences. Our approach is therefore based more on descriptive than prescriptive principles, e.g. instead of aiming primarily at recommending definitions, it is our concern to point out differences in the use of the terms. Guidelines for quality forestry terminology projects will be distributed at the IUFRO World Congress.

As globally co-ordinated forest research becomes a priority in the context of sustainable management and global change, the need for concerted action in terminology will increase. Partners from various geographical and institutional backgrounds will have to base their collaboration on common definitions. They will also need to avoid duplicating terminological efforts. Together, WP 6.03.02 and SilvaVoc can significantly contribute to this collective effort by consolidating the network, resources and expertise they have built since 1995.

6.06.02 How are innovations applied in sustainable forestry

The Doon Valley Integrated Watershed Management Project: Marching Towards Sustainable Management of Natural Resources & Optimum Utilization of the Human Resources to Achieve Sustainability and Socio-economic Development

Diwakar Sinha
Watershed Management Directorate, Indranagar Forest Colony, 248006 Dehradun, Uttar Pradesh, India
Tel: +91-135-724229, FAX: +91-135-620334(attn: Diwakar Sinha), Email: diwakar42@hotmail.com

The Doon Valley Integrated Watershed Management Project is one of the leading Watershed Management Projects of North India. It is a nine-year project (1993-2001). The European Union grants (95%) and Government of UP (5%) is funding it. The lead agency is the Ministry of Agriculture, Government of India. Presently the project is being implemented in 255 villages covering an area of about 1854 sq.km. Its major components are Agriculture, Horticulture, Animal Husbandry, Minor Irrigation, Soil Conservation, Energy Conservation and Forestry. It is fundamentally an environment project.

The objectives of this project can be classified into two broad categories namely: Long term and Immediate objectives. The long term objectives are: a) Arrest, and as far as possible, reverse the on-going degradation of the Doon Valley Ecosystem b) Improve the living conditions of the rural people c) Ensure positive involvement of rural people in managing their environment. The immediate objectives are: a) Management of the natural resources in a sustainable manner b) Increase productivity from land and water c) Strengthening community participation d) Improvement in the socio-economic conditions of disadvantaged groups, especially women.

The project has identified pressure for fuel wood & fodder, mining of minerals, overgrazing, faulty land use and depletion of forest cover as the major causes of degradation in the area.

The strategy for project implementation revolves around participatory approach. The villages are treated as basic units in which the resources are developed through community participation. Villagers plan their work on the basis of village plans that evolve from participatory rural appraisal (PRA). Under this, the outsider is transformed into a facilitator, who encourages the villagers to identify their resources, capabilities and priorities.

With the project entering its seventh year of operation, marked changes are visible. Income-generating activities have started. Users groups are being formed and assistance provided in establishing savings/credit groups, with revolving funds, supported by contributions from the villagers and the project. This has helped to establish the credibility of the project staff and instill confidence amongst the villagers. Though the project has land related bias, the land less poor and marginal farmers have not been forgotten. Opportunity to achieve economic stability is being provided to them through income generating activities, skill formation and cultivation of high-income cash crops.

All possible efforts are made to point out the interrelationship between the environmental and economic sustainability to the rural mass. The project has a holistic vision in which concern for environment and community are integral components of an all encompassing Eco-system.

The posters would depict precisely and concisely the project issues, problems, tried-solutions, their impact, and success stories which are definitely of great significance to other such developing countries having the similar problems and geographical conditions.

6.06.03 Targeting the real forest managers

Analysis and impediments of Extension Issues for Forest Manager

N. R. Gangadharappa, P. Prakash
University of Agricultural Sciences, Department of Agricultural Extension, 560 065 Bangalore, India
FAX: 91-080-333 0277, Email: nrg@uas.blr.kar.nic.in

Forest Manager is a key person who is suppose to manage the forest resources in order to maintain ecology in equilibium and sustainability, by manning the human resources working in different organizations and in and around the forest. Forest Manager may be a person working in public, private and other informal organizations. The goals, objectives and strategies used by them, therefore, would vary in content and philosophy. The management of a forest by these managers must address the vital needs of people and make available to them, especially, livelihood support system, forest produce, fuel wood, minor forest produce and timber. The experience where forest land is under control of the Government revealed that, the area under the forest is decreasing considerably causing a threat to humanity. Therefore, different agencies including Governments have come out with different forest extension strategies to maintain and increase the area under forest. The successfulness of these strategies mostly depend upon the managers who are manning and managing the forest. To make the forestry programmes as household rituals, the following extension issues may be considered.

1. Forestry extension should use education as a tool for bringing conscious learning about the importance of the forest. 2. Techniques like PRA/PLA must be used to ensure participation and to assess the inhabitant's needs. 3. The manager along with inhabitants must carry out Metric Indices Analysis, Trend Analysis, Transect Walk, Seasonability Analysis, etc., to identify the combination of tree species required by the inhabitants. 4. Manager must develop strategic alliances to link the various groups such as NGO's, community based organizations and religious groups to ensure both conservation and development. 5. Carry out campaigns in order to create as awareness about the environmental degradation and bio diversity. 6. Manger must create a base for inhabitants in order to meet their basic needs like food and shelter. 7. Tribal development should be an important goal of forest manager emphasizing on empowerment through education and development of viable enterprises. 8.

Forest Manager must initiate Self Help Groups for planning and initiating forestry programmes. 9. Manager, wherever possible should also emphasize on tree growers cooperative societies at the village level. 10. The role of men and women in maintaining the forest must be duly recognized and their roles should be made complimentary specially in traditional societies. 11. Identification and promotion of indigenous tree species must be given importance along with the promotion of commercial tree species in order to maintain the biodiversity. 12. There should be information corners attached to manager to provide the information to motivate the inhabitants. 13. Marketing news with respect to forest produce including minor forest produce should be made regularly to the inhabitants. Effective marketing channels should also be ensured. 14. Promotion and research on tribal medicine and effective use of minor forest produces by way of good marketing and value addition. 15. The upgradation of the technical know-how of the grass root level workers working under the manager and also the training programmes may be extended to the farmers. Thus it is essential that we shift from a policy of protecting forest from the inhabitants, to a participative management using suitable extension strategies.

Preliminary Study on Modern Administrative Model of Forest Science and Technology Research Result Extension in World Bank Loan Project

Chen Jinghua
World Bank Loan Projects Management Center, National Forestry Administrative, NO. 18 East Street, 100714 Hepingli Beijing, China
FAX: 010-64217796, Email: junwang@263.net

Since the 1980s, approximately five World Bank loan projects in the forest sector were performed in China. The first one to implement forest science and technology research results was the National Afforestation Project (NAP). Vast experience was accumulated from this project. It is significant, from an administrative view, to sum up the experience of the NAP extension work, and to put forward modern administrative models of forest science and technology research results through extension, in order to guide future work. Through analysis and evaluation of forest extension in NAP, experience in forestry extension has been developed, and on this basis, modern administration models have been created. These models increase science and technology, possess the characteristics of market mechanisms, use the scientific administrative system, integrate management patterns, and apply high tech facilities.

Forest Wealth and Development Strategies for Indian Himalayan Region

B. R. Kanbid
Dr. Y.S. Parmar University of Horticulture and Social Sciences, Dept. Social Sciences, 173230 Nauni, India
FAX: +91 52242 522 79, Email: ss@yspuhf.hp.nic.in

The Indian Himalayan region constitutes 21% of total area embracing 9% of the country's population. This region is characterized by inaccessibility, fragility, marginality, diversity, niche and human adaptation mechanism. The cattle population is nearly half of the human population. Indian Himalayan regions supports a variety of forest ecosystems which are very vital for regulating the water discharge during rainy season and in maintaining perennial flow throughout the long dry period of the year. But overuse and misuse of this forest cover by the ever increasing human and animal population has endangered the Himalayan ecosystem. The problem of deforestation in the Himalayas is a serious one and leads to landslides, declining soil fertility, soil erosion, flooding, firewood and fodder shortage and birds and other wild life disappearance.

Therefore, the development of Indian Himalayan region is possible if all the inputs are channeled towards the right direction, keeping environment as a focal point and sustainability as a primary objective. It is desirable to understand the mountain perspectives and underlying interrelationships between different mountain specificity's by the hilly people. Only those developmental approaches or models which have been designed for hills, are to be implemented. There has to be a spearate planing cell for hills. A strong extension mechanism is required for transfer of forestry and agricultural technology to rural people. For women in hills there should be female extension workers who can infuse enthusiasm and confidence in them. The youth for a like Forestry Vikas Yuvak Mandals as a rural voluntary force to monitor developmental activities, should be established. The non-governmental organizations will have to be engaged for developing effective production and marketing plan of agriculture and forestry. There is a strong need to motivate and mobilize people in hills for family planning. The domestication of only highly productive animals should be encouraged. Commercial exploitation of medical plants and herbs should be properly regulated. Vanmahotsava, World Forestry Day and World Environment Day should be preserved and practiced sincerely and honestly. Local germplasm resources of wild and domesticated animals, avian birds, crop plants, forest trees, herbs etc., should be conserved systematically for future generations. There is an urgent need to observe and study the traditional wisdom of hilly people about forestry, horticulture, animal husbandry and agriculture.

An Effective Extension Tool in Targeting Real Forest Managers and General Public

K. Narayanagowda, D.V. Ramesh and B. N. Ramalingegowda
University of Agricultural Sciences, Department of Agricultural Extension, 560 065 Bangalore, India
FAX: 91-80-3330277, Email: kngowda@uasblr.kar.nic.in

The state of Karnataka has only 20 percent of geographical area under forest cover. With an objective of increasing forest area to 33 percent, the state forest department has fixed a target of planting 100 million saplings in the state during 1998. However, to attain the stipulated target the government has formulated virtually no extension strategies to create awareness among the landowners and general public about afforestation and eco-conservation. In this direction, the most significant extension tool employed by the department was displaying the posters. In the year 1998 Six different designs of posters, four on afforestation and two on wildlife conservation were brought out. Altogether 115 thousand posters were displayed. In the present study an attempt was made to analyze the posters developed by the State Forest Department during the year 1998, in attaining the desired effect. About 150 viewers, representing 50 each from the landowners, students and general public categories were asked to rate the effectiveness of these posters in creating awareness. For this experimental study six posters were numbered 1 to 6, each number representing a different design. Majority (86 percent) of the viewers, irrespective of their category, expressed that poster 3 was most effective in terms of message content, design, attractiveness and overall impact in creating awareness and triggering the desire for further action. 73 percent of student respondents preferred poster 5, they appreciated its colour, bold design and content. This particular poster was on wildlife conservation and blown up photographs of different animals in the poster were an added attraction for the students. While landowners preferred poster 1, general public liked poster 3. Further, 69 percent of the viewers, irrespective of their category said, poster is an important extension tool in creating awareness among the general public on afforestation, eco-conservation and wildlife preservation.

A Comparative Analysis of Impacts and Extension Approaches Adopted by a State Government, Non-Governmental Organizations, and the Corporate Sector in Forestry Expansion Programs

K. Narayanagowda, M.R. Suresh
University of Agricultural Sciences, Department of Agricultural Extension, 560 065 Bangalore, India
FAX: 91-80-3330277, Email: kngowda@uasblr.kar.nic.in

This case study was conducted involving the following organizations: the Forest Department, Taralabalu Rural Development Foundation, and Golden Forest (India) Limited, representing the state government, a non-governmental organization (NGO), and the corporate sector, respectively. These three organizations serve to motivate people to become involved in afforestation and eco-conversion programs. The Forest Department has given the least attention to involving and educating the people in planning, protection, regenerating, developing, and managing the forests. Occasionally mass media, such as radio, television, newspapers, posters, and leaflets, were used to create awareness among the public. No government forest official has adopted individual contact extension methods to educate the farmers. However, wherever the joint Forest Planning and Management Project is in operation, almost all extension approaches are implemented.

The Taralabalu Rural Development, a spiritual NGO, has given utmost attention to participatory approaches in afforestation programs, with the aim of producing upward development towards a more abundant life spiritually, mentally, physically, socially, and economically for rural people. The results are highly encouraging.

On the other hand, the Golden Forest (India) Limited, has a unique approach of producing attractive advertisements in leading newspapers, magazines, and television that motivate people to invest in tree growing projects, and to collect the dividends either in cash or in the form of timber after a specified number of years. In India, involvement of the corporate sector in forestry is of recent origin. Nearly forty private companies are functioning all over the country, planting thousands of acres of land in tree plantations. Additionally, the catchy advertisements, emphasizing economic returns, have motivated individual farmers to grow trees, particularly teak, eucalyptus, and mangium, on their farmland.

Successful Communication of Research Findings Requires a Systematic Use of Different Channels

Ingemar Nordansjo
The Swedish Forestry Research Institute 'SkogForsk', Uppsala Science Park, SE-751 83 Uppsala, Sweden
FAX: +46 18 18 86 00, Email: ingemar.nordansjo@skogforsk.se

If new research results shall be applied in practice they have to reach, be understood and accepted by those who can influence decisions, take decisions and/or implement the relevant changes. The greater part of the research findings that are implemented and the sooner this is achieved, the greater will be the return on the money invested in research. Thus the communication of research results are of strategic importance to all research institutions. The communication should be based on the answers of the following questions:

- What effects or changes do we want this research to bring about?
- Which target groups need to share the findings so that the desired changes can be implemented?
- What knowledge will these people need to be given?
- How shall we pass on this knowledge?

There are mostly a number of different channels for communication available such as publications of different kinds, courses and excursions, videos, radio, and TV. In addition to these traditional channels, modern IT offers new possibilities. In the paper different channels and their pros and cons are discussed.

If the new knowledge shall be applied in practice we normally have to use a combination of relevant channels. The choice has to be based on the subject and the target groups. Further, a successful communication system must cover all the steps that lead to a successful implementation: Knowledge, Interest, Assessment, Decision, and Implementation.

The vision for the communication of research findings can be formulated as follows: Everybody involved in forestry shall be able to access needed data and knowledge at any decision situation. Modern IT offers enormous scope for packaging knowledge in such a way that this vision can be realised.

SILVO Forestry Administration and Management System

Rafael Ortiz, Luciano Sanchez
Corporacion Nacional de Investigacion y Fomento Forestal-CONIF, Avda. Circunvalar Nro. 16-20 (detras del Inst. Roosevelt), A.A. 091676 Santafe de Bogota, Colombia
Tel: (57) 1 3417000, FAX: (57) 1 3376970, Email: conif1@colomsat.net.co

SILVO is a software system developed to automate the process of applying and controlling the Forestry Incentive Certificate-CIF ("Certificado de Incentivo Forestal"). The CIF is a grant given by the government to help foresters cover a portion of the expenses for the establishment and management of new commercial forestry plantations. The CIF is administered by the Autonomous Regional Corporations - CARs ("Corporaciones Autónomas Regionales") and the Agricultural Financial Fund-FINAGRO ("Fondo Financiero Agropecuario").

SILVO, version 1.0, was developed by CONIF (National Forest Research and Development Corporation) as a product of the project "Institutional Strengthening for the Sustainable Management of Planted Forests in Colombia," under an agreement prepared by ITTO (International Tropical Timber Organization), MINAMBIENTE (Environmental Affairs Ministry of Colombia), and CONIF.

The CIF includes five phases: ELEGIBILITY ("Elegibilidad"), GRANTING ("Otorgamiento"), EXECUTION ("Ejecución"), PAYMENT ("Pago"), and MONITORING ("Seguimiento").

The ELIGIBILITY phase has the objective of determining whether or not a forestry project and the person or institution are suitable candidates for a CIF grant. In this phase, the corporation should study and analyze all documents and make field visits to ensure the viability of the project.

The GRANTING phase corresponds to the formalization of the CIF through a contract between the regional corporation and the forester.

The EXECUTION phase is the development of the plan of establisment and management of the plantation proposed by the forester and accepted by the corporation.

The PAYMENT phase corresponds to the payments that FINAGRO makes to the forester. There are five payments during the first five years of the plantation. During these years, the corporation should verify the tasks planned and executed by the forester and then authorize the payment.

The MONITORING phase corresponds to the corporation's activities to verify that the forester is performing all planned activities based on the plan accepted by the corporation.

Once a CIF forestry project accomplishes all requirements, the CAR analyzes the information, visits the area, and then asks FINAGRO for the availability of the budget. The administration and management of a CIF project involves human and instituional resources that can be optimized through the automation of tasks that involve great amounts of information.

The immediate beneficiaries of this system are the CARs. Silvo helps, in an efficient way, in the administration of forest patrimony of CIF users and regions. The foresters and institutions also benefit from this resource because this is a modern tool to improve the administration and control of CIF resources and plans for establishment and management. This first version of the system was distributed to the 11 corporations that were included in the project. However, in the near future, version 1.0 will be extended to the remainder of the corporations in the country.

The SILVO system was developed to store, validate, process, and retrieve CIF project information presented to the CARs. SILVO takes into account the phases of CIF projects and their subphases or stages in such a way that the activities made by the forester, the corporation, and FINAGRO are reflected and stored by the system. SILVO is designed to record and process CIF project information, from its registration in the corporation until the last payment in the fifth year of the plantation.

In addition to the adminstration of CIF projects, the system will allow regional and national analyses about CIF plantations, planted areas, species, establishment, and management of forestry plantations plans, etc. The system also has an on-line help menu to facilitate its operation and administration.

Reforestation Behavior of Nonindustrial Private Forest Owners: Evidence from Finland

Ripatti, P., Hänninen, H., Karppinen, H.,
Finnish Forest Research Institute, Unioninkatu 40 A, FIN-00170 Helsinki, Finland
Tel: +358 9 857 051, FAX: +358 9 8570 5717, Email: ville.ovaskainen@metla.fi

In several countries nonindustrial private forests provide a substantial share of the timber required by the forest industries. Consequently, understanding nonindustrial private forest (NIPF) owners' reforestation behavior is essential for projections of long-run timber supply and planning of appropriate policy means to support sustainable timber production. This paper therefore seeks to increase the understanding of factors affecting NIPF owners' reforestation behavior based on theoretical considerations and empirical evidence from Finland. Unlike earlier studies, our analysis incorporates the role of ownership objectives.

In Finland, reforestation after final felling has traditionally been a legal obligation claimed by Forest Law, with private forest owners obliged to deposit a given amount of timber sales income on a special account to secure reforestation. While the basic obligation continues to hold today, major changes have taken place in the1990s. A special reforestation deposit is no longer required; the supervision of forest law has been relaxed; more space is allowed for individual decision-making in forest management; and the resources for forestry extension have been cut substantially. Although detailed monitoring results are not available, recent statistics suggest that forest owners' motivation to complete reforestation has been reduced. Thus, it would be most useful to uncover the potential reasons for the lack or delay of reforestation measures.

Our approach is as follows. Theoretically, the NIPF owner's reforestation decision is considered in a unified framework with his/her consumption and harvesting decisions under alternative assumptions on his/her objectives. The forest owner is either assumed to derive utility from consumption alone or to take into account the in situ value of the standing forest and/or the disutility from intensive reforestation measures as well. In the empirical study, the forest owners are first grouped on the basis of their ownership objectives (multiobjective owners, recreationists, self-employed owners, and investors). Using dummy variables indicating cluster membership, the owner's objectives are then included into the empirical model of reforestation success along with factors such as the owner's long-term stumpage price expectations, knowledge on forestry subsidies, and forest and owner specific characteristics.

The study is based on the monitoring data on NIPF holdings collected in 1990, 1991 and 1996 using the same sample of holdings. The 1991 data includes information on the required amounts of reforestation measures based on inventory data, stumpage price expectations for the next 10-year period, and the use of forest subsidies in the preceding 5 years. The 1996 data comprises the amounts of reforestation activities executed in 1991-1996, as well as forest and owner characteristics. The information on ownership objectives is available in the 1990 data.

Approaches to Evaluate Public Subsidies for Forestry in Finland

Heikki Pajuoja
Finnish Forest Research Institute, Helsinki Research Centre, Unioninkatu 40 A, FIN-00170 Helsinki, Finland
FAX: +358 9 8570 5717, Email: heikki.pajuoja@metla.fi

Many countries are reforming their forest policies in order to respond to economical, ecological, and social sustainability requirements. Policy targets are consequently becoming more complex. At the same time, the attitudes toward public subsidies in general have become more critical. In many countries there are very few proper ex post evaluations of the forest policy instruments in economic terms. In Finland there are two major types of investment subsidies: a) annual financing through the state budget, and b) national forestry programs to expand investments. This investigation examines public support for forestry assistance and extension programs. As a case example, an analysis is presented as to how public subsidies have been used to intensify private timber production in Finland, and the major impacts and results of these subsidies. The first attempts to evaluate the results of public expenditure are discussed in more detail. The evaluation of public intervention includes two parts: 1) the evaluation of the intervention costs to government, and 2) the evaluation of the intervention effects to society. Public ownership is characteristically a forest policy instrument, which may be financed from the state budget. In private forestry, instruments may be financial and technical assistance. Estimation of the effects of forestry assistance and extension programs is complicated. One reason is that forest improvement work, or any subsidized activity, has both short- and long-term effects on timber production and supply. The reasoning behind the evaluation of the intervention effects is to address the extent to which given policy tools are sufficient to achieve long-term policy goals, without any unwelcome effects on timber markets. Benefit cost methodology is a conventional way to analyze and evaluate the intervention effects to society, but it does not normally include any kind of timber market analysis. In this paper we are testing, using an econometric model for roundwood markets, whether financial support to forest improvement activities has had any market effects in Finland. The other aim of the study is to investigate and evaluate public sector support to forestry assistance and extension programs. Results of two different approaches, benefit cost and input-output methods, are discussed and recent results for Finland are presented.

6.06.03 Targeting the real forest managers

Indigenous Farm Technologies and Extension Strategies for Sustainable Development of Dry Temperate Cold Region of Indian Western Himalaya

Om. Prakas Sharma, KK Raina
Dr. Y.S. Parmar University of Horticulture and Social Sciences, 173 230 (HP) Nauni (Solan), India
Tel: +91-1792-52288, FAX: +91-1792-52242, Email: dext@yspuhf.hp.nic.in

Cold Deserts constitute the most fragile, isolated and marginalized uplands of the Hindukush Himalaya. Its inhospitable and harsh climate has been borne over the ages by the inhabitants by their ingenuity for their socio-economic sustenance. In the process, people have developed indigenous technologies which are not prevalent elsewhere and, for many of these scientific explanations, are not available as of this day. Cold Deserts pose great challenges and their development warrants strategic blending of acquired edaphic, abiotic, biotic and the socio-economic environment. Over the years its inhabitants have developed rich, traditional knowledge concerning crops, livestock and the environment for adapting to the inhospitable climate. The traditional cropping pattern is specified and adapted to the agroclimatic and socio-cultural needs. The sustainability of village ecosystems is ensured through indigenous resource management. The indigenous knowledge of farming, acquired through generational experiences, continues to evolve toward a better and sustainable livelihood. Now there is divergence from the traditional systems resulting in environmental degradation and decline in socio-cultural values. Hence, the documentation of indigenous technologies, with regard to land and soil management, water management, productivity (crop and animal) and natural biomass utilization, have provided an insight for complementing the old and new technologies. The mountain specific technology transfer approaches for the 21st century will involve special capsules on different crops and farming systems. The technology transfer mechanism will be more challenging and complex for the mountain areas. Specific strategies like plant clinics, vocational training, on spot guidance, distant education and video films and the internet will form an integral component. A computerized data base system with internet capabilities will be quite useful for marginalized mountain areas. A due respect has also to be paid to traditional ethos and wisdom. Participatory approaches and the farmer-scientist interactions will form the basis for incorporating the rich traditional knowledge possessed by the rural masses, and to blend the same for sustainable socio-economic development and ecological sustenance of the Cold Deserts of India.

Social Forestry Research Activities through NGO Network

E. S. Thangam, Sanjay Shukla
Society for Social Forestry Research and Development, Tamil Nadu, 1 C Adwave Towers 9 South Boag Road, Chennai 600017 Thiyagaraya Nagar, India
Tel: 91-44-4343092, Email: ssfrdt@md2.vsnl.net.in

In Tamil Nadu State, India, the forest occupy 17% of the geographical area, as against the 33% fixed in the National Forest Policy, 1988. The has more than 0.3 million ha of wastelands and afforestation of these wastelands was taken up in 1984 under the Tamil Nadu Social Forestry Project (TNSFP) aided by Swedish International Development Agency (SIDA) to increase the forest areas. The Society for Social Forestry Research and Development Tamil Nadu (SSFRDT) was established in 1989 under this project to provide the necessary technical support to the Forest Department by taking up research programmes in social forestry. SSFRDT organised research activities in five sections viz. Studies for Policy and planning, Tree improvement, Agroforestry models, Growth promoters and Fodder research by establishing a network of NGOs in the State. During the last ten years, SSFRDT has helped the local people, the elected village adminstative units and the Forest, Agriculture and Rural Development Departments in their tree planting activities through establishment of Provenance Conservation Stands (PCS) for Neem, Kapok, Kodukkapuli, Nelli, Iluppai, identification of biofertilizers for Babul, Neem, formulation of nutritive feed for cattle, conducting workships and training programmes under extension activities, publication of reports on its research activities. Local people participation was established through NGO network for field trials. The SSFRDT has come to occupy a niche in the research activities relating to tree species used by the people in the villages and has helped the farmers to plant high yielding varities trees in their lands to earn an increased income, bringing about a better economic change in the society.

Need for Establishing Demonstration Plots to Translate Research Results in Forestry

R. V. Varma, V.V.Sudheendrakumar; T.V.Sajeev
Kerala Forest Research Institute, Division of Entomology, Peechi-680 653 Trichur Dist, Kerala, India
FAX: +487-782249, Email: rvvarma@kfri.org

There exists a wide gap between the forest researcher and the forest manager and thus many of the research results are not put to practice. As such there is no mechanism to evaluate the reliability of some of the proven methods under large-scale field trials. In general, forest mangers stick to established management procedures and are reluctant to try out newer techniques. Thus the Forestry Scientists have the added responsibility to demonstrate the research results in order to convince the forest mangers about the efficacy of their findings.

The need for managing the teak defoliator, *Hyblaea puera*, a serious pest of *Tectona grandis*, has been presented here as an example. Studies carried out in the Entomology Division of Kerala Forest Research Institute over the last two decades have generated valuable information on various aspects of the teak defoliator problem. The most important of the research results being the elucidation of growth increment, if control measures are adopted against the teak defoliator (Nair et al., 1996). Though the forest mangers are aware of this pest problem, its impact on growth is not well appreciated. However, in recent times teak plantations have been established under the private sector in India and they have adopted intensive management practices which include control against the teak defoliator.

In the above context, we the Scientists of KFRI decided to demonstrate the impact of defoliation on growth of teak by preserving two plots in a young plantation in 1993. One left to natural defoliation and the other protected against the teak defoliator attack as and when it occurred. At the end of the 5th year, the visnal difference in growth was observable. This was further substantiated by the growth data gathered on height and GBH of the trees in the two plots. The plots are still being maintained and it is hoped that this demonstration plot will impress upon the forest managers on the need for adopting control measures against the teak defoliator.

Introduction of Group Structures in Motorized-manual Forest Work

Michael Weber
Forstliches Bildungszentrum, Rheinland-Pfalz, In der Burgbitz 3, D-57627 Hachenburg, Germany
Tel: 02662-9547-12, FAX: 02662/9547-60, Email: fbz.hachenburg@wald-rlp.de

In the Bundesland Rheinland-Pfalz of Germany, a group work project was started in February of 1999. In more than 70% of the Forest Divisions in Rheinland-Pfalz, there is a shortage of forest workers, particularly for dangerous jobs like motorized-manual harvesting with chain-saws. This labor shortage is partially overcome by using contract workers or transferring workers between Forest Divisions. Absenteeism and accident rates are considered unacceptably high. The group work project was established to create working teams to better use the talents of the workers and allow them to share in decision-making. The intent is to reduce absenteeism and accidents, and produce more contented and productive workers. In addition to forming and training worker groups, higher level managers need to be trained as well. Implementing the project required a series of training modules involving personnel management and cooperation, team building, group teamwork, and evaluation. All training is being conducted by outside consultants, and additionally, simultaneous monitoring of success indicators, such as accident rate, is occurring. In 1999, a total of 8 Forest Districts were involved in a pilot project, which will be expanded if it proves successful.

Sticks, Carrots, and Sustainable Silvicultural Investment

Daowei Zhang
Auburn University, School of Forestry, Alabama 36849-5418 Auburn, USA
Tel: 334-844-1067, FAX: 334-844-1084, Email: zhang@forestry.auburn.edu

Environmental regulations and public financial assistance programs are the typical "sticks" and "carrots" facing nonindustrial private forest (NIPF) landowners in the US. This paper presents a theoretical framework and empirical evidence on the impacts of possible enforcement of the federal Endangered Species Act, and cost-share and tax incentive programs, on their reforestation investments. The results indicate that NIPF landowners' reforestation investment is influenced negatively by environmental regulations and positively by public financial assistance programs. The results imply that both sticks and carrots can be used simultaneously to influence nonindustrial private forest landowners' reforestation behavior and thus promote forest health, productivity, and sustainability.

6.07.00 Tropical Forest History

Balancing Society and Environment: A Historical Approach to Forest Management Problems in Italy in the Last Fifty Years

Mauro Agnoletti
University of Florence, Institute of Forest Management and Technology, Via San Bonaventura 13, I-50145 Florence, Italy
Tel: +55+30231276, FAX: 319179, Email: mauro.agnoletti@unifi.it

The rapid development of Italian economy after the Second World War led to dramatic changes in the utilisation of forest resources, but also in the people's perception of the role of forests. In the fifties heavy utilisation were still carried out in the Alps and in the Apennine mountains. Concerning timber, the shortage of high stands and the increasing cost of their utilisation forced Italy to import more and more timber from abroad. However, most of Italian forest, placed in the central and southern part of the country, were coppice woods used to produce fuel wood and charcoal. In the fifties the introduction of new energy sources determined the end of charcoal burning and a strong reduction of fuel wood production. This caused the abandon of large extensions of woodlands and important changes in the economy of many regions. From the sixties the rapid economic growth of Italy slowly changed the social climate, especially for what concern the public perception of environmental values and damages due to common management practices. People began to perceive heavy harvesting operation to be environmentally unacceptable, but the responses of forest managers to the change in the public opinion, and the changing role of forests was quite slow, and so the political reactions. It took sometime to management theories and policies to adjust to these changes; the first attempt to change the management practice at large scale took place in the Northeast of Italy in the sixties, but the action was mostly concentrated in reducing timber harvesting. Today the problems of management are much more complex than before, as forest must accomplish a variety of purposes and their management must be integrated with the fast changes in society and adapt to case by case situations. From this point of view history is now not only a tool to understand the evolution of forest ecosystem, but a method to support the analysis necessary to plan conservation policies and the economic development of forest territories. Today the lack of knowledge about the factors, which affected the evolution of forest, is a limit to the development of effective forest policies.

History is not offering solutions but is giving the chance to analyse the processes, which affected forest dynamics during long period of time, a rare opportunity in forest research. The understanding of factors, relationships and time scale involved in the evolution of forests, allow a better evaluation of the level of risk of any decision, reducing the uncertainties and defining the limits of the action of foresters. This is especially important in Italy were economic and social development is rarely accompanied by a careful planning of environmental impact and historical analyses is rarely used to develop forest policies and management plans.

History of Forestry in the German Colonies

Egon Gundermann, R. Rösler
Lehrstuhl für Forstpolitik und Forstgeschichte, Chair of Forest Policy and Forest History, Am Hochanger 13, D-85354 Freising, Germany
Tel: +49-8161-71-4625, FAX: +49-8161-71-4623,
Email: beck@forst.uni-muenchen.de

Keywords: forest history, German colonies, forest activities

Nine European states (Portugal, Spain, The Netherlands, England, France, Belgium, Germany, Italy, Russia) and the USA have shaped the colonial history of the world during the last 500 years. At its height, in the late 19th century, these powers showed increasing colonial activity and initiated through the era of imperialism the 'scramble for Africa'. It was then that the newcomers Belgium, Germany and Italy gained their colonies. Germany alone acquired colonial territory of about 3 m. km^2 - mainly in the tropics. These colonies under German rule- Togo, Cameroon, German Southwest Africa, German East Africa, German New Guinea, German Samoa and the leasehold of Kiaochow in China - were 5.5 times as big as the German mother country. The German colonial era itself only lasted about 30 years, from 1884-1914.

Three stages can be distinguished in the development of the colonies:

- an experimental development phase, being characterized by the investment of German capital and the uncontrolled takeover of the colonies
- a conquering phase, establishing the balance of power according to plan, suppressing revolts of the native people, developing an administration system and evaluating the local resources
- a reform phase, in which development programs for the colonies and protection laws for the native people were launched

Forest activities were delayed by at least 20 years from the beginning of German colonialism in 1884.

During the second, developmental stage a State Forest Service identical to the German one was established. At the same time many expeditions were conducted into the heart of the colonies, aiming to collect and classify tree and shrub species, and determine their stocking volume by sample plots and their potential for commercial exploitation. The main emphasis was put on the tropical African colonies.

The major forestry problem in Togo was the low percentage of forest land (1,5% = 13 500 km^3). Hence, strict legislation was initiated in order to prevent the clearing of forest land and to declare protection forests. In the Savannah Region, cultivation trials with indigenous and exotic tree species were conducted, systematic afforestation took place, and plans were made to build a sawmill at the coast.

Forestry in German East Africa, which also had scarce forest resources (4% = 39 800 km3), included the following tasks:

- The reservation and safeguarding of abandoned forest land as crown land
- Commercial utilization of this land and its by-products (tanbark, liana rubber) on a concession basis
- Reforestation and systematic afforestation of waste land
- The setting aside of watershed protection forests
- Research on the technical wood properties of the indigenous tree species and their susceptibility to pests
- The enacting of laws on forestry and hunting

Cameroon, on the other hand, had a much higher percentage of forest land (16% = 127 200 km^2) and was the most important colony from a forestry point of view. Consequently the activities were primarily directed at making a profit by exploiting the timber, by managing the wild oil palm stands and by using the forest by-products (rubber, tanbark, kopal etc.). As a result, the export of precious timber like ebony and African mahogany showed a rapid increase by the end of the colonial era. However, it only made up about 3% of the total exports of the colony. The main export goods were rubber and cash crops like cocoa beans, palm oil and palm seeds.

In general, it can be stated that forestry in the German African colonies showed a promising development, especially in connection with the systematic opening-up of the colonies by railroads. This development, however, could not become effective till the end of the colonial era in 1914.

The Rise of Wasteland and its Recultivation in the History of the Alpine Region of Austria

Elisabeth Johann
International Union of Forestry Research Organizations, Wlassakstrassee 56, A-1130 Vienna, Austria
Tel: 0043 42 26 216; +43-1-8765885, FAX: 0043 42 26 216; +43-1-8796101, Email: elis.johann@carinthia.com

Keywords: Deforestation, landscape changes, public welfare, recultivation

In the past as well as today the way how men dealt with the forest cover has always been a controversy about exploiting, destructing and sustainable utilizing the natural resources. The comparison of forest history with the present problems of forests and forestry give evidence of similar characteristics. In case of emergency knowledge and experience as well various techniques have been developed which enabled people to handle the forest ecosystem in a sustainable way. In spite of the various research experience and scientific findings in history, today's forest ecosystem is still endangered by global overexploitation. This shows after all that the practical application of the gained proficiencies and perceptions has always been dependent on the existing political, legal, social and economic conditions. As long as the existence of a forest cover has been perceived as a matter of fact, forest legislation was restricted to a defensive attitude only and forests were protected in its hitherto existence at the best. The increasing demand of general public on the forest area led to a more and more offensive forest policy in the course of time. With regard to that as an indispensable precondition people have to be thoroughly convinced of the idealistic and financial values of forests.

The global discussion of the causes of deforestation in the tropics has led to renewed interest in the history of forests in countries which are now considered developed. What are the factors the process of deforestation and the subsequent expansion of forest area were based on? Can lessons be learned from this experience? The reason and insight of the time structure of environmental changes gained by the viewpoint of history has the effect to increase mankind's sensitivity in dealing with vital resources. Thereby recent changes of landscape, their causes, extent and dynamics are of particular interest.

At the turn of the century large unproductive areas of wasteland were noticeable on former forested areas in almost every European country and that in the plains as well as in the mountainous regions. On the territory of the Austrian-Hungarian Monarchy the extent of these waste areas came up to 430000 ha, to which the overgrazed forest pasture had to be added, covering an area of more than 950000 ha.

The submitted paper deals with the decrease of forests carried out over centuries also in the alpine region of Austria. In certain areas the overutilization for different purposes caused the destruction of forest stands possibly followed by the rise of wasteland when additional factors were contributing. The chain of causation will be discussed taking into account geological conditions, climatic influence, increase of population and anthropogenic influence on landscape changes by cultivation in context with the former political, legal, social and economic conditions. The damages caused by overutilization will be illustrated in detail on three examples: the origin of mattock, the cleared areas of the alpine region and the wind-borne sand areas of the plain. Subsequently the correctional actions and programmes having been taken in the particular regions for the recultivation and preventive measures against the further extension of wasteland are pointed out. The necessary requirements were met by the publication of various laws relating to the afforestation of the impacted regions. By that means the beneficial functions of the forests serving public welfare were improved. Furthermore the changes relating to landscape utilization are discussed causing also an improvement in rural income by the creation of additional jobs. The efforts relating to the reafforestation of the former wasteland have generally been successful looking at today’s forest cover of 46% of the whole Austrian landscape and a forest share of 0.5 ha per head.

Historical Reports on Wildlife Management and Hunting in Africa

Sigrid Schwenk
Universität Bamberg, Forschungsstelle fuer Jagdkultur, Gruener Markt 31, D 96047 Bamberg, Germany
Tel: 0049-171-7419092, FAX: 0049-911-512307,
Email: Elisabeth Johann [elis.johann@carinthia.com]

Keywords: Africa, hunting, conservation, literature

In the last decades of the 19th century and in the beginning of the 20th century hunting and conservation of game in tropical countries, especially in Africa, was of increasing interest in Germany.

First of all, in the 50ies, 60ies, 70ies and 80ies of the last century researchers have made long and difficult expeditions to the unknown parts of Africa, have given scientific reports on landscape, wildlife and the original life of the natives including their hunting methods. Secondly they reported how the participants of the expedition hunted to get meat for the expedition.

After 1882 (foundation of the "Deutsche Kolonialverein"; 1887 transformed into "Deutsche Kolonialgesellschaft") and the establishment of German colonies (so-called "Schutzgebiete") - Deutsch-Südwestafrika (1884-1915), nowadays Namibia; Togo (1884-1914), nowadays Togo and Ghana; Kamerun (1884-1914), nowadays Kamerun; Deutsch-Ostafrika (1885-1918), nowadays Tanzania, Ruanda and Burundi - the interest and influence on wildlife management and hunting increased enormously. Together with German soldiers and German farmers came German traditions; remainders of these traditions - especially on the field of wildlife management and hunting - can be discovered even nowadays. Experiments and plans of wildlife conservation and of game use as well as hunting experiences were subject of research work and publications.

Until now it is generally not known how many books have been written and published in German language (some of them translations of English originals) on the theme of wildlife, conservation and hunting in Africa. A recently published study on German hunting literature - Sigrid Schwenk: "Bibliographie der deutschsprachigen Jagdliteratur von 1851 bis 1945, Band 1, A -K" - has shown how many authors were involved in this subject.

The planned poster will give an overview on this new field of research, will analyse the different reasons why authors have taken this subject and show the goals of their literary works.

First the explorers, for instance Charles John Andersson (1857, 1858, 1863), Carl Graf Krockow von Wickerode (1867), Sir Samuel White Baker (1867, 1868, 1876), Gustav Fritsch (1868), Martin Theodor von Heuglin (1877), Emil Holub (1881, 1890), G.A Farini (1886), Wilhelm Junkers (1889), Adolf Friedrich Herzog zu Mecklenburg (1909, 1924). Then authors who are involved in the colonial development: Ernst Graf Hoyos (1895), Wildschutz-Kommission der Deutschen Kolonial-Gesellschaft (1912), Fritz Bronsart von Schellendorff (1898, 1900, 1912, 1915), Heinrich Fonck (1910), Wilhelm von Kleydorff (1910), Georg Escherich (1921, 1923, 1927), Hans Anton Aschenborn (1925, 1926), Herbert Kund (1931). Lastly authors of safaris: Berthold Körting (1914), Gustav von Hochwächter (1931).

6.11.01 Poverty and management of forest resources

Brazilian Mahogany in the International Market

Humberto Angelo, Camila Neves Soares
Universidade de Brasília, Departamento de Engenharia Florestal, Caixa Postal 04357, 70910-900 Brasília, Brazil
Email: humb@bsb.zaz..com.br

Keywords: mahogany, international market, sawn wood, Brazil

This paper estimated an export supply function for Brazilian mahogany sawn wood - *Swietenia macrophylla*, King. The variables applied to explain the mahogany export supply performance were the export remuneration related to domestic sales, domestic activity cycles, the extension of the road network in the Amazons region and the export restriction on tropical wood log, enacted by Resolution no 128 of the Foreign Commerce Council (CONCEX). The estimates with annual data for the period 1972-93 showed that all explaining variables affected mahogany export significantly and that there were no time lags in export adjustment. The price elasticity found for export supply was around 1.19, indicating a slight elastic supply.

Expectations of the Companies of Pulp and Paper in Relation to Future Barriers in the International Market - the Brazilian Case

João Carlos Garzel Leodoro da Silva, Nabor da Silveira Pio, Julio Eduardo Arce
Estratégico del Curso de Ingeniería Forestal UFPR, Rua dos Funcionarios 1540-Juveve, 80.035-050 Curitiba, Brazil
Tel: +55-41-252-3677, FAX: +55-41-30-5604, Email: garzel@agrarias.ufpr.br

Keywords: Pulp; Paper; Cellulose; Strategic Planning; Strategic Marketing

The last years were of great expansion in the international market; commercial barriers have fallen mainly in regional blocks. The marketing strategies accompanied this evolution. To formulate these strategies it is important the environmental analysis. Why the pulp and paper sector? This sector has presented in the last years an extremely significant evolution, having responded on one hand expressive of the Brazilian exports. This way, the present work has as main objective to analyze the future expectations of the high administrations in relation to the barriers in the international markets of pulp and paper.

They were defined 22 variables for the characterization from the barriers to international level. Variable multi-items were used with the objective of increasing the validation of these mensurations. For definition of the work universe, it was used the database of the National Association of the Makers of Pulp and Paper (ANFPC). The data were collected to the beginning of the year 1996. It was requested to the high administrations of the paper companies and cellulose that responds which the future importance is (its expectation) of the barriers at international level.

It was observed that all the variables analyzed by the test presented coefficients of Cronbach alpha superiors at 0,5, considered as satisfactory minimum approach to establish a reliable level of mensuration for variables multi-item. The future expectation of the high administrations in relation to the barriers at international level was from a smaller importance to the one imagined, visualized by the value of the variable denominated "macrobarrier". Such a fact was not only owed to the smallest importance presented by "internal barriers", because even same the prospective expectation for external barriers is only indicated as of moderate importance. Although the opposing results presented a smaller degree of importance that the prospective one, the high administrations trust in that the competitiveness that can exist for the Brazilian exports of pulp and paper will be mainly responsibility of the Brazilian public sector, indicated by the biggest importance in the barrier "Brazil cost" This result reflects the expectation that the state assumes the responsibility of orchestrating structural and economic improvements increasing the competitive capacity of the companies in the international markets. The concern with the "competition of exporters of other countries", perceived as the main prospective barrier, it is significant, indicating what type of strategies they will be carried out to make in front of this threat. When we analyze the group of "internal barriers", the high administrations mention that its expectation for the recent future will be of a smaller growth of the exports mainly to the lack of capacity to increase the offer in the external market.

Economic Comparative Analysis Among Different Sizes of MDF Plants to the Brazilian Reality

João Carlos Garzel Leodoro da Silva, Lourival Marin Mendes
Estratégico del Curso de Ingeniería Forestal UFPR, Rua dos Funcionarios 1540-Juveve, 80.035-050 Curitiba, Brazil
Tel: +55-41-252-3677, FAX: +55-41-30-5604, Email: garzel@agrarias.ufpr.br

Keywords: MDF; Production cost

This paper intends to compare the economic efficiency of four MDF (Medium Density Fiberboard) industry plants: 15,000m^3/y; 30,000m^3/y; 50,000m^3/y and 105,000m^3/y, respectively. The initial presupposition is that small and medium size plants have, at least, the same efficiency than the bigger plants, because the technology costs of the small plant are lower than for the big one (105,000m^3/y). The concept of economy of scale is usually concluding that the bigger plants are more efficient and have smaller costs than the smaller plants, because the technology is the main factor of the productivity definition and unit cost. Although, it is important to analyze the relationship between the technology costs and the production of the plant, and to optimize this relationship. This paper analyses the proposal of INDI – Instituto de Desenvolvimento Industrial de Minas Gerais (Industrial Development Institute of Minas Gerais State – Brazil) and the proposal of three sizes of plants from China and Brazil. The methodology included the identification of the technical coefficients of each plant and the factor prices (glue; labor; energy; raw material; equipment price etc.) in Brazil in order to homogenize the variables and to compare the plants. The comparison of the plants included analysis of the Return of Investment; Payback and Present Liquid Value. A sensibility analysis was performed to verify the change in the results when the MDF product price or the factor prices change. The preliminary results showed that, to the Brazilian reality, the plant that produces 30,000m^3/y is the most efficient among the four. A further advantage of the small plant is the greater agility to market changes, enabling this plant size to maintain greater proximity with the clients, and consequently, a greater fidelity. In Brazil there are a lot of micro size furniture and small size enterprises (74.74% and 22.22% of the Brazilian furniture enterprises, respectively). Strategically, the small plants can reduce the raw material costs in two important ways. Firstly, by using a smaller volume of wood, the range of transportation is reduced and consequently the cost is reduced. Secondly, the use of residues in the raw material composition is important to the small plants. This also reduces the raw material cost.

Survey of Path Forest-Wood of Paraná - Brazil

João Carlos Garzel Leodoro da Silva, Anadalvo Juazeiro dos Santos, Alex Carneiro Leal, Romano Timofeiczyk Júnior
Estratégico del Curso de Ingeniería Forestal UFPR, Rua dos Funcionarios 1540-Juveve, 80.035-050 Curitiba, Brazil
Tel: +55-41-252-3677, FAX: +55-41-30-5604, Email: garzel@agrarias.ufpr.br

Keywords: Filière; wood sector; Brazil; Paraná; Pulp; Paper; Venner; Saw wood

The Brazilian path wood is one of most dynamic of the Brazilian economy and sudden various structural changes. For this sector, the Paraná contributed of decisive manner to the production of both pulp; paper, saw wood and plywood. Of this fact, the government of Paraná solicited a specific analysis of this path wood in the Paraná State aiming to the realization of a development politics.

It has been analyzed the physical fluxes of path wood initially, since the forest until the final consumer. Then two separating path: path of pulp and paper; the path of mechanical transformation of wood, including sawed wood and plywood. This different fluxes are under detailed analysis in order to foresee the politics of development announced.

The forest activity of Paraná State consume approximately 21 millions of m3 of timber by year, to industrial transformation. The consumption of pine (exotic specie) is approximately 17 millions of m3, 82% of the total, in second place of the consumption, it is used *Eucaliptus* (exotic specie), 1,5 millions of m3, 7% of the total, in third place; native timbers in general, except Araucária, 6% ot the total and in short *Araucaria angustifolia*, specific South Brazilian conifer with 5% of the total.

The path of pulp and paper of Paraná Sate occupies the leader position at the national. It is the first producer of mechanical pulp of the country, the second producer of cellulose and paper of all types and the unique manufacturer of newsprint of Brazil. This path consumes the major part of timber of the State, 68%, and exclusively of reforestation.

With regard to the path of the mechanical transformation, the consumption of timber is approximately 6,4 millions of m3, at the rate of 77,7% intended to the production of saw wood and 28,3% of veneer.

Of the whole of the production of region-plated, principals markets are: the furnishings with 3,25%, the packing for 2,35%, the civil construction for 16,48%, the naval construction for 1,35%, the export for 35,3% and in short the resale for 41%. It has been determined that the major part of the market of this resale destines itself to the industry of the furnishings, but at present it was not possible to quantify this transaction.

EMU and Forest Products Pricing in Europe

Riitta Hänninen, Susanna Laaksonen-Craig and Anne Toppinen
Finnish Forest Research Institute, Unioninkatu 40 A, FIN 00170 Helsinki, Finland
Tel: +358 9 857051, FAX: +358 9 8570 5717, Email: Riitta.Hanninen@metla.fi

Keywords: Exchange rate pass-through; newsprint; pulp; Johansen's cointegration method

The purpose of this paper is to examine the effect of a pricing currency, national currency vs. US dollar, on pulp and newsprint export pricing in the UK and German markets. Earlier studies have shown that exchange rates have an important effect on forest products trade and export pricing. The US dollar has been, and despite the introduction of Euro in January 1999, still will be, an important invoicing and pricing currency in pulp and paper trade, both in the EMU countries and in the world market. Therefore, comparing US dollar and importer currency pricing in European markets is an interesting empirical case involving both the effects of an introduction of a currency area on export industry's pricing and the effects of third currency invoicing on competition. Thus, in the present study, exchange rate effects are studied also with respect to the US dollar, contrary to earlier studies that analyzed the effects only with respect to importer countries' currencies. The exchange rate effects are examined using the concept of pass-through and a markup-model for exporting countries' export pricing. The model is estimated for Finnish exports using Johansen's cointegration method for monthly FIM/USD, FIM/GBP, FIM/DEM exchange rates, as well as pulp and newsprint export unit value time series 1986-1997.

The Finnish, Swedish and Canadian export prices, measured in importer's currency, developed fairly uniformly in 1980' and 1990's. The results indicated low pass-through elasticities for Finnish exports, which is consistant with the competitive European pulp and newsprint markets. For the hypothesized effect of US dollar nominated pricing, prevailing especially softwood market pulp, practically no evidence was found. This would imply that the use of US dollars in price nomination in the UK and German markets has not affected the market pricing. As the coefficients for the importer currencies were also very small, in the light of these results, the introduction of Euro will probably not cause significant changes in forest products pricing or competition in Europe.

Potentials of Agroforestry for Conservation of Natural Forests and Sustainable Livelihood in India

Narayan G. Hedge
BAIF Development Research Foundation, 411 029 Pune, India
FAX: 00-91-20-366788, Email: mdmtc@pn2.vsnl.net.in / baif@vsnl.com

Rural people in most of the developing countries in Asia have been depending heavily on forests for meeting their basic needs. However, with the steep rise in the population, the pressure on the natural forests during the last five decades has increased beyond the level of tolerance. In the absence of suitable conservation measures and necessary investments, the forest cover has been fast depleting throughout Asia.

In India over 45% of the forest lands are devoid of vegetal cover, depriving 20 million rural families, particularly those belonging to backward tribal communities of their means of means of sustainable livelihood. Such severe deforestation is posing a threat to the eco-system and environment, while suppressing the water supply, agricultural production and employment. Therefore, conservation of natural forests, through promotion of alternative sources of woodfuel, fodder, timber and non-wood forest produce (NWFP) will be an important component of community forestry program during the next decade. Among many options, agroforestry has great promise because of the scope for ensuring food security and cash income, while expanding the green cover on non-forest lands through active participation of the stakeholders.

Various tree based farming systems launched in different agro-climatic conditions in India have confirmed that fruit tree species such as mango (*Mangifera indica*), cashew (*Anacardium occidentale*), custard apple (*Annona squamosa*), ber (*Zizyphus mauritiana*), tamarind (*Tamarindus indica*) and Indian gooseberry (*Emblica officinalis*) establish well in semi-arid zones and generate substantial income. This system which included fruit tree species as main crop, cereals, pulses and vegetables as intercrops, fuel and fodder tree species as windbreaks, established on contour bounds could enhance the crop yield. Introduction of watershed development, empowerment of women and recycling of biodegradable waste for soil enrichment as an integral part of this program had added advantages. A family maintaining aha of land under this system could easily earn a net annual income of US$ 400/year from the fifth year as compared to a US$ 100–120/ha from traditional farming. Wastelands which are not suitable for agri-horti forestry could be utilised for cultivation of NWFP such as Neem (*Azadirachta indica*), Pongamia (*Derris indica*) and Mahua (*Madhuca indica*) and other species, which are adopted to drought conditions and produce fruits and nuts useful for oil extraction and Ayurvedic medicines.

Such tree species were well accepted by local communities for establishing on common properties for joint management, as the income from such plantations were substantially higher than the fuel and roundwood timber plantations. There is good scope to introduce fuelwood species in the interspace in NWFP plantations. With such tree based farming systems it was observed that the farmers could produce adequate quantities of biomass for fuel and reduce their dependence on the natural forests.

Sociological Research for Forest and Society: The Integration of Sociological Research with Forest Management for Fuelwood-dependent Villagers in India

Rajeev Mishra, Margaret Terry
Indian Council of Forestry Research and Education, 248 006 Dehradun, India
Email: mishra@cfr.cfr.ncsu.edu

Villagers in northern India who live near the forest are dependent on the forest for most of their daily needs. It works as a lifeline for them, as they extract fuel, fodder, and other non-wood forest products from the forest for their livelihood. The main dependence is on fuelwood. Fuelwood collected from the forest is used in households as well as sold on the market for cash.

The analysis and conclusions drawn from this study highlight the importance of integrating sociological research with forest management. Consideration of these sources of information can be of substantial utility to the decision-making process for those charged with the management of forests, and for the quality of life of people whose livelihood has depended on forests.

This study demonstrates the utility and relevance of collecting three sources of information to facilitate decision-making about forest management: (1) information about how the forest is used, (2) sociological information on socio-economic conditions and quality of life for the people who use the forest, and (3) opinions and ideas of the people who use the forest concerning what they need, what they feel needs to change, and how they could contribute to beneficial changes.

The focus of the paper is on extracting information, which is simultaneously useful for forest management questions and for quality of life questions. Sociological research is used to examine such questions as the role of forest management for fuelwood use, interactions between fuelwood use and daily life, socio-economic conditions of fuelwood-dependent villagers, and policy questions regarding fuelwood use and fuelwood alternatives.

Specifically, the independent variables of the study are socio-economic information regarding caste, education, family composition, land tenure, and income. Two sets of dependent variables are examined. The first set of dependent variables gathers information about the fuelwood and the collection process: for example, type, quantity, frequency and daily time-involvement, self-provisioning and stocking, cash transactions, distance traveled from the dwelling, distance traveled into the forest due to depletion of fuelwood near the forest's edge. The second set of dependent variables solicits the views of villagers on questions that address their quality of life in relation to fuelwood-dependence: for example changes in forest management that would facilitate fuelwood availability, alternatives to fuelwood cutting, and changes in government policies that would facilitate fuelwood collection and/or alternatives. The solicitation of the views of villagers is based on principles of development practice which incorporate these views as an important part of fact-finding and potential problem-solving. Both forest management outcomes and social well-being outcomes can benefit from gathering this type of information from the people who use the forest.

Social Impact of Transmigration in Sumatra, Indonesia

Motoe Miyamoto, Thomas Tomich
CIFOR, Situ Gede, Sindang Barang, P.O.Box 161, 16001 Bogor, Indonesia
FAX: (62) 251 625416, Email: M.Miyamoto@cgnet.com

Transmigration interferes with the socio-economic conditions of local people in Indonesia. In Sumatra, where most of the transmigrants have settled, local people used to derive their main source of income from jungle rubber. They implemented a type of agroforestry by planting jungle rubber through selective and partial clearing of forestland combined with the cultivation of upland rice for a period of one to two years. Now the use of the forest by local people around areas of Transmigration projects has become limited. Therefore, in the local villages, buying and selling of rubber land have increased and the socio-economic differentiation of rubber smallholders has progressed.

Optimum Use of Agricultural and Forest Land Fund in Selected European Countries in Transition

Karel Pulkrab, Josef Gross
Czech University of Agriculture Prague, Faculty of Forestry, Kamìck 129, 165 21 Praha 6-Suchdol, Czech Republic
Tel: +420-2-24383703, FAX: +420-2-2092-3132, Email: pulkrab@lf.czu.cz

Keywords: Agricultural and forest land allocation, Optimum use, Countries in transition

The issue of optimum land fund use and namely of optimum land fund division between forestry and agriculture has been topical for the whole history of man's use of nature. There has prevailed univocal trend to increase the area of forests in developed European countries recently, i.e. to afforest non-forest and namely agricultural land. Extensive afforestations have been carried out for example in Spain, France and other countries, too. Up to 17 millions ha of agricultural land are estimated to be afforested within the EU. This process has been legally supported by the Directives 1609/89 and 2080/92. A significant benefit consists in the possibility to get a financial subsidy in performing the soil succession. The above mentioned trend has also started to come into effect in some European countries in transition (after changes of socio-economic conditions of these countries). There are actually two cardinal reasons for performed or proposed changes in land use:

- Environmental one, consisting in improvement of the landscape and the environment, in increase in forest cover and consequently in overall ecological stability of a territory.
- Economic one, consisting in decrease in agricultural produce surplus or in increase in forest production output.

The complex solution to the issue is considerably difficult as it involves inter-disciplinary and inter-sectorial aspects. A relevant restructuralisation of land fund impacts upon spheres of production, economy, society, environment, legislation, and institutions. Neither the harmonisation of owner's (or lessee's) intents with those of the society can be neglected. On the current experience and knowledge, the following process (concept) of agricultural land restructuralisation can be suggested in regions setting aside agricultural production:

a) Basically, the regions and localities expected to undergo the set-aside program will be presumably identified by a competent body.
b) Nature landscape potential will be assessed by relevant indicators in the region where agricultural production is expected to be set aside.
c) A system of criteria will be designed for taking a decision on proposed forms of forest stands being established depending on the original and anthropogenically affected natural conditions.
d) The expected environmental effect of established forests (or the ones being established) will be assessed in the relationship to the real natural landscape potential.
e) Procedural principles of establishment, improvement, and protection of forest stands will be set with the view to soil quality, climate, and potential adverse impacts considered in the region.
f) In cases of a more extensive afforestation, steps of forest planting, protection, and cultivation will be proposed.
g) Expected costs of forest establishment, improvement, protection and cultivation will be assessed considering the natural conditions.
h) A set of administrative measures to ensure afforestation projects and management of established stands will be performed.

The demanding character of vast agricultural land afforestation requires all steps to be carried out purposefully and organised under the principles and set procedures adopted in advance.

Economic Analysis of Forest Degradation Processes in Sub-Saharan Africa: A Bio-economic Modeling Approach

Prem Lall Sankhayan, Ole Hofstad
Agricultural University of Norway, Department of Forest Sciences, Post Box # 5044, N-1432 As, Norway
FAX: +4764948890, Email: prem.sankhayan@isf.nlh.no

Africa lost 24% of its forest/woodlands between 1958 and 1968 and the annual loss has been approximately 0.8% between 1981 and 1990. These losses occur both due to deforestation and degradation processes, of which the former appears to be relatively better analysed and understood than the latter. Even if these estimates of the rate of loss of forest wealth are doubtful and somewhat exaggerated, the need to understand the dynamic complex processes, particularly those of forest degradation, remain crucial for checking the negative externalities through sustainable forest management. Because of the complex and dynamic nature of these processes involving ecological, technological and socio-economic factors, the phenomena can be better understood through modeling the systems behaviour. Achievement of such a goal requires the use of theoretically sound and empirically testable biological and socio-economic models at a reasonably disaggregated level. This study seeks to use such an approach to analyse the economic causes of forest degradation in Sub-Saharan Africa by using bio-economic dynamic linear programming models at the village level. The emphasis is mainly on analysing the forest degradation processes arising out of clearing of open forest land for cultivation, cutting of wood for fuel and charcoal and use of vegetative bio-mass through grazing of livestock in three countries, namely, Senegal, Tanzania and Uganda.

A number of hypotheses explaining the role of economic factors are developed and tested by running alternate scenarios of the model for a few villages in each country. The aim is to present a theoretical basis for identifying the relative importance of different economic factors that can be used by policy makers for checking or at least slowing down the process of forest degradation and thus achieving sustainable management of forest wealth in this region of the world.

The model is specified with aggregate welfare of the village community (measured as the present day value of net income within the planning horizon from all crops, livestock, forest and miscellaneous activities as well as the imputed value of leisure time of human labour) as the final objective function in a hierarchy of objectives. Hierarchical attainment of objectives is sought subject to a number of constraints on the level, quality and distribution of key production factors, e.g., human labour, land, livestock, etc., and on market demand for crops, animal and forest products (e.g., wood fuel and charcoal), miscellaneous products (e.g., beer and bricks), etc. Incorporation of non-linear biological functions for the regeneration of stock of vegetation, i.e., bushes and trees, in miombo woodland, grazing functions for the livestock, growth functions for human and livestock population, technological improvements in crop yields, changing prices of inputs and outputs, demand functions for fertilisers, coal, wood fuel, recursive nature of cultivated land and woodland area constraints, increasing time required to collect a unit of fuel wood as one moves away from the village centre over the years, etc., are some of the highlights of the model. Besides, classification of village households into croppers, grazers and fuel wood cutters, division of the village into cropping, mixed and grazing zones, and land into upland and lowland classes, use of satisfying approach, accounting for uncertainty, etc., help the model to approximate reality better in describing the forest degradation processes. It would represent an improvement over the past efforts involving multi-country and aggregated form of analysis to understand the complexities of the involved phenomena. Funded by the European Union, socio-economic surveys and remote sensing of vegetative cover and degradation are being undertaken in each of the three countries to collect the necessary data for the proposed study.

Combining Slash-Burning Agriculture and Plantation Forest

Apul Sianturi, Budi Leksono, Udi Tyastoto
Departemen Kehutanan dan Perkebunan, Post Box # 179, Palembang Sum-Sel, Indonesia
Tel: +62-711-414864, Email: forti@palembang.wasantara.net.id

Slash-burning agriculture, a simple traditional plantation system is still carried out in Indonesia. This plantation system is one of the problems that causes degraded land on the forest area. This system is still used because could be operated by traditional poor farmers with a simple knowledge and low investment. Usually on the preparation land for plantation they use, slash and burning system that causes forest fire. Uncontrolled the degraded land increasingly as they le it after used and move to the new land and so on. This problem increase rapidly as the population increases. To solve the problem, it is needed to develop the system so that the farmer could settle on an area relative permanently. Industrial Forest Plantation (HTI) system that recently operates in large scale with large investment in Indonesia could be combined to the sifting cultivation as one alternative to solve the problem. The farmer who traditionally used the slash-burning agriculture system if the new system in applicable and give opportunity to increase their income. This paper explains about financial analyses of agroforestry system on the *Acacia mangium* plantation that was implemented in the trial forest Balai Teknologi Reboisasi Palembang, South Sumatera.

Problems of Non-Market Forest Services Monetary Valuation in Some Countries in Transition - Case of the Czech Republic

Ludek Sisak
Czech University of Agriculture Prague, Faculty of Forestry, Kamìck 129, 165 21 Prague, Czech Republic
Tel: +420-2-24383704, FAX: +420-2-20923132, Email: sisak@lf.czu.cz

Keywords: Non-market forest services, Forest externalities, Monetary valuation, Countries in transition, Czech Republic

Forests provide society with wide range of very important non-market functions - services and goods - connected with water, soil and air protection, with health, recreation and scientific cultural impacts on the society. Importance of non-market forest functions can be valued with great difficulties, from both theoretic and practical points of view.

When speaking about great problems with valuation of non-market forest benefits, questions on real aims and reasons of such problematic valuation are raised very often (both by the theoreticians and practitioners). Monetary valuation of non-market forest benefits can be used for different purposes, especially for:

- identification of share of forests' importance in natural and social welfare of the country;
- analyses of the state and development of social demands for forest externalities;
- expression of socio-economic effectiveness of multiple and sustainable forest management;
- decision making about land allocation between forestry and other kinds of land use;
- assessment of value of social losses caused by damaging of forests;
- stimulation of effective and wise use of forests, of all their goods and services;
- improving in forest planning and of forest running processes in the frame of multifunctional forestry.

In the case of the Czech Republic, the one of European countries in transition to market economy, two main methods for non-market forest services' monetary valuation are discussed and investigated. One procedure is based on a consumer surplus approach, on willingness-to-pay method, especially on the Contingent Valuation Method. The other procedure results from an expert approach, based on expert comparison of importance of non-market and market forest goods and services.

Results from the investigation, both theoretical and practical, including monetary values of individual non-market forest services and their comparison with value of market services are presented. Advantages and disadvantages of two basic approaches in conditions of most European countries in transition are discussed. The expert approach seems to be much more promising method for non-market forest benefits valuation under present conditions in some European countries in transition (the case of the Czech Republic) than the willingness-to-pay method.

The expert approach has been used in forestry and legislative practice in the Czech Republic since 1995 as a part of the Forest Act (No. 289/1995) in paragraphs dealing with the so-called "Withdrawal Fee". Withdrawal of plots of land designated for the fulfillment of forest functions (the "withdrawal") means the release of such land for other use. The fee, paid for the withdrawal of plots of land designated for the fulfillment of forest functions (categorized zones of protective forests and forests of special purpose), can be considered as the official administrative value of non-market forest services (positive forest externalities). The fee (price) is used as an economic instrument protecting forest lands and forests against deforestation, against using forest areas for other purposes.

Monetary values of individual non-market forest services are shown and discussed. Value of forests categorized (zoned) as "recreational forests", forests in suburban areas with increased health and recreational function, amounts to 791 thousand Czech Crowns (CZK) per 1 ha in 1998 but the value does not express only pure recreation importance of forests in the "recreational zone". Value of non-market forest functions in other zones, categorized by the main forest function in a respective zone, varied from 369.1 thousand CZK/ha to 1,318.3 thousand CZK/ha (for example core zone of national parks, national preserves-especially protected areas, etc.) in 1998.

The average non-market value of commercial forest as a source of non-market forest services reached 803.8 thousand CZK/ha in the CZR. For comparison, the administrative, official, value of forest, based on timber production function, amounts on average 310,2 thousand CZK/ha, which is relatively high figure criticized by many specialists. On the contrary, the non-market value of forest amounted to 3,142 thousand CZK/ha in the National Park Sumava in 1998.

6.11.04 Bridging the gap between monetary and non-monetary valuation of environmental amenities

The Different Concepts of Value and the Contingent Valuation Method.

Keywords: contingent valuation, values, lexicographic preferences, forest regeneration

This paper provides a framework to analyze how economic values are related to some other value concepts. Thus, it also clarifies the role of economic values in forest policy. The paper provides tools to analyze different value categories in the contingent valuation (CV) method. Contingent valuation has traditionally measured only the preference structures assumed in economics.

It is not surprising that the word value has many meanings. Philosophers have mentioned ethical values since Aristotle's time. The disciplines of social sciences, e.g., sociology, social-psychology, economics, all have their own meanings for value. There are, however, some structures of values that most social scientists probably can accept. In particular, the two following classifications of values are useful.

First, we can make a distinction between end values, instrumental values, and functional values. The difference between end values and instrumental values is important. End values are typically basic things human beings desire, like wisdom, happiness, freedom, equality, beauty, pleasure, and friendship. Instrumental values are the means to achieve a purpose related to some end value.

Functional values concern the purely non-human technical contributions an object has to another object. Second, we can separate held values and assigned values. Human values, i.e., end and instrumental ones, are held values. Held values refer to internal beliefs and attitudes held by individual humans. They are the ideals or models of the world that are desired.

Assigned or attached values are connected to some objects. Valuation takes place in the interaction between a human and an object, for example between a recreationist and a forest. The assigned value is the relative importance or worth an individual expresses in this interaction. Actions and words are two modes that can be used to express the assigned value. Further, a discussion, market transaction, voting, or survey is a possible interaction where assigned values can be realized. Assigned value expressions are influenced by the perceptions of end, instrumental, and functional values. It is thus worth noting that value expressions do not only reflect person's held values, but many contextual factors can also affect them.

The structural characteristics of value expressions, later called preferences, can be categorized with four types: non-rational, weakly comparable, non-compensatory, and exchange. The non-rational expressions deny any possibility to value a good. An individual with weakly comparable preferences may choose between alternatives but is unable to make a general value ranking. Non-compensatory preferences can produce a value ranking between alternatives, but is unwilling to make trade-offs between them. Moral issues and essential goods and services are, for example, ranked as non-compensatory characteristics. In economics, lexicographic preferences are an example of this preference structure. Exchange preferences use a common measure against which all alternatives can be valued.

In economics this kind of commensurable preferences is normally assumed. The contingent valuation literature has theoretically and empirically recognized different preference structures. For example, the lexicographic preferences have been measured in several studies with attitude-like statements and in a few studies with paired comparisons. Two methods have seemed to produce different estimates for the number of respondents having lexicographic preferences. In this study, we report a CV experiment where two methods are compared. The topic of the survey is the nation-wide forest regeneration policy concerning private forests in Finland.

6.11.07 Social science contribution to wildlife protection

The Myth and Realities of Forest Resource Conservation in a Tribal Village: An Ethnographic Inquiry into the Khasis in Bangladesh

M. A. Tarafder, Niaz A. Khan
University of Chittagong, 4331 Chittagong, Bangladesh
Tel: (88 031) 726311-14/4282, FAX: (88 031) 682030,
Email: nakhan@spnetctg.com

A number of popular environment-related myths have been observed in the course of the fieldwork. The content and implication of these myths have been evaluated in light of the `modern' knowledge as depicted in academic texts and `scientific' quarters. For example, there is a long myth, which in essence connotes that betel leaf including its farming techniques was an exclusive divine gift by the `hill gods' to the khasis in order for them to entertain and treat guests. The information on various aspects of the agro-farming technology, as collected from the `divine inspiration' - such as minimum tillage, use of trees as living support for betel plants, use of living fence around the plantation etc. - are in remarkable conformity with modern knowledge.

6.14.00 Urban forestry

People's Participation and Community Organization in Forest Management: Issues in Joint Forest Management in Madhya Pradesh in India

Debashis Debnath
Indian Institute of Forest Management, Nehru Nagar, Post Box 357, -462 003 Bhopal, India
FAX: 91-755-772878, Email: ddebnath@iifm.org

Forest plays an important role in the life of Indian rural residents from social, economic and institutional point of view, The National forest policy of 1988 significantly emphasized the involvement of the people, specially the tribal and women, in the protection, development and management of forest. In consequence after various experiments by the progressive foresters, Joint Forest management (JFM) has been a resolution passed by the Ministry of Forest and Environment on 1st June, 1990 for introducing collaborative forest management involving the local people in the forest protection and management and the voluntary agencies. So far 21,000 forest committees in the 19 states of India have been formed. It envisaged an institutional arrangement for the local people to jointly with the government to protect and manage the forest resources in return for a share in the yields from it. The state of Madhya Pradesh, the largest state in the central part, has an area of about 44.3 million ha. of geographical area. Of this about 19.6 million ha. area of the state is classed as agricultural land, of which 4.3 million ha. are irrigated. The live- stock population has been estimated as 45 million heads and migratory herds are through to number about 2 million during the year. The total human population of the state was estimated as 55.18 million in the 1991 census, giving at a rate of 2.6 percent per annum between 1981 and 1991. Of the total 15.3 million are tribal peoples and 9.6 million scheduled castes. Poverty in the rural areas is estimated to be 41 percent of the total area.

Under this socio-economic condition and the burden of the rural poor on the natural resources, in compliance of Govt. of India order, the Forest Department of Madhya Pradesh, has passed the JFM Resolution of the state on 1991 giving importance of people's involvement in forest protection and management. The amended resolution 1995 was passed to give more opportunity to the woman and weaker sections along with NGO's involvement. The Forest Deptt. has taken serious attempt under World Bank forestry project since September 29, 1995. Two types of people's institution - the Forest Protection Committee (FPC) and Village Forest Committee (VFC) - formed on the basis of crown density, set up various social norms rules and operational system to protect and manage the forest resources and to avail the usufructuary benefits and others net profits. As the sate is well known for the concentration of the indigenous peoples (23.22%) who mainly belong to the small farmers, marginal farmers and landless labors in the land-holding capacity, after inception of the JFM progamme the income generating activities for the sustained livelihood got the first priority either by providing employment or skill development in small-scale enterprises. The village resource development fund for community banking formed of the transfer of money from the various heads of government fund has provided support in income generation activities. In this care and share philosophy some good outcomes have been developed through collaborative and co-management system of protection and management for encouragement of natural regeneration and bio-diversity conservation. The promotion of indigenous knowledge system, redress of local problems, participatory and decision-making process, equitable benefits sharing are the key features in this forest management system.

On the various case the following issues have been identified: Awareness level has been raised but the institution building does not occur to that extent due to negligence in confidence building, unequal participation in the functioning of the forest protection, bureaucratic control by forest department, question of the equitability in the sharing of the benefits, social conflicts, less women's participation, lack of co-ordination between state govt. departments, conflicts related to the distribution of loan, no commitment of the sustainable income generation etc. Still many conflicts exist between villager's expectations and needs, and state guidelines for forest management and product sharing. Motivation in the development activities, more devolution of management responsibilities to forest committees and commitment for the equity sharing is the major issues to address for the sustainability in this management regime.

Community Involvement in Forest Management - A New Chance for Forest-related Rural Development in Tanzania?

Marion Karmann
Universität Freiburg, Institute fuer Forstbenutzung & Arbeitswissenschaft,
Werderring 6, 79085 Freiburg, Germany
Tel: 0761-203 3767, FAX: 0761-203 3763, Email: karmann@pop3.uni-freiburg.de

The increasing displacement of Miombo woodlands is a special problem in African dry lands. The yield of traditional management of these ecosystems is not longer sufficient to cover the needs for food supply and cash crop of the growing rural population.

The current situation in Tanzania offers an excellent opportunity to influence natural resource management in the region. Forest Faculties, Colleges and NGO have embraced community forestry and have made it part of their curricula.

The know-how about the multiple use of Miombo woodlands is a basis for further develop-ment of properly resource utilisation systems. These systems should not only guarantee the capability of the woodlands to fulfil the subsistence needs of local household, but also generate income through marketing of products from the woodlands. Basic for the willingness of people for a good resource management is their commitment mainly influenced by there stakeholder status and their legal access to resources and profit from resources.

Based on this presumptions a study in North Eastern Tanzania about actual woodland utilisation and chances for further development of resource utilisation was compared with success stories concerning Social & Community Forestry Projects in Northern Tanzania to find out, how sustainable land use systems can be implemented with chances for success. In the research area the marketing of woodland products, also of Non Wood Forest Products (NWFP), fundamentally can be considered as an incentive for the conservation of the woodlands. The acceptance levels for accelerating propagation of utilisation and marketing of NWFP vary between and within communities. Social & Community Forestry can give incentives for conflict management, and for the dissemination of information for production and marketing.

Community Resiliency and Change: a Socio-Economic Assessment of Resource Dependent Communities in the Upper Columbia River Basin

William McLaughlin, Harris, Charles; Becker, Dennis; Hollenhorst, Steve
University of Idaho, Department of Resource Recreation and Tourism, College of Forestry, Wildlife and Range Sciences, 82844-1139 Moscow, Idaho, USA
Tel: 208-885-6659, FAX: (208)885-6226, Email: billm@uidaho.edu

In 1995, the U.S. Forest Service and Bureau of Land Management were charged with doing a biophysical and socio-economic assessment of the Upper Combia River Basin (Columbia River Basin Ecosystem Management Science Assessment). As part of the assessment, empirical data from the U.S. Census Bureau were gathered in 1995 on all 387 small rural communities in the Inland Northwest and Northern Rockies to assess the characteristics of those communities. In addition, a random sample of 198 communities was selected and 1,350 representatives of the communities completed a ‘Community Self-Assessment Workbook’; they then participated in community self-assessment workshops that provided data on their community’s current characteristics and conditions (i.e., community character and attractiveness, social cohesion, civic leadership, quality of life, business attractiveness, economic diversity and resource dependence, and the community’s preparedness for the future). Resource dependence included measures agriculture, travel and tourism, timber and mining. Community officials were also contacted to provide other documentable or recorded details about each community’s character and conditions, (e.g., rate of population growth, economic changes, school and utility capacities, distance from major transportation routes or nodes, etc.). Results of this assessment and surveying project will be presented, as well as their implications for future management of the region’s natural resources.

Forest and Landuse Structure in Urban Landscape in Tokorozawa, Japan

Masayoshi Takahashi
Forestry and Forest Products, Research Institute, Forest Management Division, Post Box # 16, Tsukuba Norin Kenkyu Danchi-nai, 305-8687 Ibaraki, Japan
Tel: +81-298-73-3211 ext.635, FAX: +81-298-73-3799, Email: martaka@ffpri.affrc.go.jp

This study aims to show the historical change of Forest and land structure in Urban Landscape in

Tokorozawa, Japan. I digitized the vegetation map in 1956 and 1985 and analyzed 29 years of forest and landscape change using Geographic Information System. Tokorozawa is the city about 30 km north from Tokyo metropolitan area and its area is about 7,200 ha. In 1956, it had 1,940 ha (26.7%) of forest and 4,038 ha (55.7%) of agricultural field. But in 1985, there were rapidly decreased to 1,150 ha (15.9%) of forest and 2,343 ha (32.3%) of agricultural field. In contrast, urban area was growing up from 367 ha (5.1%) to 2,046 ha (28.2%). So the landuse change showed that Tokorozawa was dramatically grown up form forest and agricultural town to Satellite City of Tokyo. In the same time, forest use was changed. In 1956, forest was an important role to supply timber fuel charcoal and fertilizer for agriculture. So it was easy to find out the effect of forest use in the vegetation in 1956. Sympathizing with the rapid economic growth, a lot of substitute ware developed and imported, so the importance of traditional forest use was rapidly reduced. In 1985 in some area, we could find out that panted conifer forests ware naturally regenerated to deciduous substitutional community.

***Prosopis juliflora*- A Metallophyte for the Biorecovery of Aluminium from Urban Industrial Enclaves**

Palaniswamy Thangavel, V. Subburam, P. Shanmughavel and T. Muthukumar
Bharathiar University, Department of Environmental Sciences, 641 046 Coimbatore, India
FAX: 091-422-422 387, Email: thanvel@yahoo.com

Keywords: *Prosopis juliflora*; biorecovery; aluminum

Human, industrial and agricultural activities result in increased release of heavy metals in to the environment. Since, heavy metals readily accumulate in soils, their concentrations are likely to increase continuously. Severe pollution of urban soils can originate from heavy emitters of air borne particles. Major fall out problems result from mines, old smelters and foundries.

Coimbatore District (Tamil Nadu) harbours around 620 metal based industries. Of which, 32% are die-casting industries, which are potential source of aluminum pollution. Several plant species are indicators of soil heavy metal pollution. Rhizosphere soil and root samples of *Prosopis juliflora* were collected from 8 different sampling areas (S1-S8) around non-ferrous aluminum based industries with soil aluminum concentration ranging between 3-36 $\mu g\ g^{-1}$ of soil. The aim of this study was to assess the potential of *P.juliflora* in decontaminating heavy metal pollutants in soils. The results indicated higher aluminum accumulation of 25-79 folds in roots compared to their availability in the soil. Aluminum accumulation in *P. juliflora* roots were maximum in S3 (896 $\mu g\ g^{-1}$) and minimum at S4 (211$\mu g\ g^{-1}$). *P. juliflora* accumulated other metals (Cu, Cd, Hg and Ni) also indicating its capacity to accumulate several heavy metals. Therefore, the results clearly shows *that P. juliflora* could be used in decontamination programmes in metal polluted soils and also the suitability of using *P. juliflora* roots as an indicator of heavy metal pollution.

Urban Forestry Constraints

Enrique Oswaldo Videla Pilasi
Botanic Garden Santisima Trinidad, Asunción City, Paraguay

Continuing with that previously exhibited and published by the IUFRO Int. Congress held in Montreal, Canada during the year 1990, I have prepared a new contribution.

URBAN FORESTRY CONSTRAINTS is a pertinent title leading with an scientific understanding of the spatial dimensional dynamic declining our living spaces. We will be able to enhance this content by laying out an analysis coupled with a more complete meaning shown by the author's paper named: NEW SCIENTIFIC ANALYSIS ON MICROMETEOROLOGY WITHIN BIOMETEOROLOGY SOURCING DATA APPLIED TO URBAN FORESTRY" (Outlooks for our wellbeing at Indoor and Outdoor sites) which becomes printed in this Congress too. Settings of long-term scientific purposes are here clarified: Spectrality; Profile Principal and Secondary Components into Urban Forestry Biometeorology Simulation; Insights of the Subject Contexts made out into a Modeled "MOTIB" Project (Modules of Transfrontier Investigations on Biometeorology) which gives structural concepts and scientistKeywords. From these arises an upgrade meaning for one named: "totalities" in Forest Sciences, applied now to Urbanism Life Amelioration with a minded mitigation of diverty Urbanism Constraints.

So, Forest Coverture, as a biological and physical Entity, plays a new role in successes Entropy and Entalpy sourrounding our daily life. The neighbouring behaviour of these processes towerds our daily sensed thinking and keeneye strives underline the format of this scientific contribution without ignoring the nature of both "NATURE" and "HUMANS". Forest Biogeocenology and Forest Biometeorology could be judged as a

"United Disciplinary Forum" for any scientist dedication abroad.

6.15.00 Reconsidering study objectives and teaching methods

Identifying & Evaluating the Educational and TrainingNeeds in the Disciplines of Forest Products and Wood Science

Robert L. Smith, Eric Hansen, Robert Bush
Virginia Tech, 1650 Ramble Road , Blacksburg, VA 24061
Tel: 540-231-9759, Fax: 540-231-8868, Email: rsmith4@vt.edu

Key Words: Education; Needs Assessment: Wood Products: Technology Transfer; and Marketing

As scientists and practitioners in the fields of Wood Science and Technology, we often teach what we have been taught. This practice is in direct contradiction to current management and marketing philosophies that require us to understand the needs of the customer (students and adult learners). Through the years, the needs of this clientele may have changed as the forest resource and its products have changed. This paper presents the results of three independent studies that assessed the educational and training needs of individuals from the forest products industry. Two of the studies were conducted in Oregon and Virginia (United States) to evaluate adult educational needs for the development of continuing educational classes for adult learners. A mail survey to over 2000 forest products companies in the two states was conducted to collect primary data. The results indicate strengthening in areas of management and marketing, as well as communication. Personal contact was the highest method of teaching effectiveness. At the time of the research (1994-1996) electronic technologies rated the lowest form of a teaching medium.

The third study evaluated the current educational practices and needs from one of the leading Wood Science and Forest Products Programs in North America (Virginia Tech) by undergraduate, graduate, and employers of students. Mail surveys and personal interviews were used to collect primary data.

Participants rated training in traditional wood science areas high, while improvement was needed in communication and personnel management areas. This research has lead to adjusting the methods of teaching at Virginia Tech. Courses were redesigned to increase writing and speaking assignments, as well as team building skills.

The results from these studies may provide a foundation for strengthening Wood Science and Technology programs around the world and assist those programs that are struggling with student enrollments. These results indicate that Wood Science and Forest Products programs need to increase emphasis in the management and marketing aspects of their programs. This study also indicated that education in traditional wood science areas (such as drying, production and chemistry) were meeting students needs.

Environmental Education of Forests Using a Mobile PC

Tetsuhiko Yoshimura, Michiyuki Takeuchi and Tetsuro Sakai
Kyoto University, Graduate School of Informatics, Yoshida-Honmachi, Sakyo-ku, 606-8501 Kyoto, Japan
Tel: +81-75-753-3131, FAX: +81-75-753-3133, Email: yoshimu@kais.kyoto-u.ac.jp

Keywords: Environmental education; Mobile PC; Tree identification; GPS

The objective of this study is to educate students as well as citizens in a better use of an up-to-date information system so that they are able to learn better about nature and ecosystems in forests and to make informed decisions that will protect or conserve them. Not a few visitors often spoil or damage forests and their environment, for example, by littering or picking up rare plants. We believe that they do not understand enough why the forest and environment are important and that they need to be educated effectively and enjoyably on why forests should not be damaged. In this context, environmental education of forests has become more important for all people.

We developed a new information system for environmental education of forests. In this system, users can learn more and better about nature and ecosystem in forests with a mobile PC. It has a user-friendly interface, which is easy to use for those who are not accustomed to using computers. It has three main programs of navigation, tree identification and an eco-museum. We would like to give brief explanation of them.

Navigation: the system has a Global Positioning System (GPS) so that users are able to know their positions in forests. We know it is difficult to catch signals coming from GPS satellites in mountains because slopes or tree canopies block them. We conducted some basic researches on the utilization of GPS in mountains. It is also known that point positioning causes positional errors of max. 100m. The way to obtain more accurate positions is to use Differential GPS (DGPS), in which we use two GPS receivers as a rover and base station. We employed real-time DGPS, in which real-time corrections are transmitted by radio or by mobile phones. As a result, we found that positional errors were reduced to max. 10m in forests. In this system, users can input information or data of nature observation into a mobile PC as a text or picture. The data are accompanied by date, time and accurate position automatically when it is recorded in a mobile PC. The users can make a map of nature such as trees, plants, insects and animals with this system. In addition, this system has functions to navigate users and to provide them with useful information on nature according to their positions.

Tree identification: we know it is not easy to identify trees because there are so many species and they are sometimes very similar to each other. We developed an expert system to identify tree species in order to make it easier to identify trees. This system deals with only broad-leaved trees at present, however, it enables you to learn such tree species without a professional teacher or a guide. When you meet unknown tree species, you can identify the tree just by answering some questions. They are, for example, whether the tree is liana or not, whether it is alternate, opposite or whorled and whether it is simple, palmately compound, odd-pinnately compound, even-pinnately compound or bipinnately compound.

Eco-museum: it introduces you to trees as well as plants, animals, birds, fish and insects living in forests. It also shows you historical and cultural aspects of forests. In addition, eco-museum gives visitors the information on forestry because forest production is one of the most important aspects of the forest. Furthermore, we can walk in forests virtually using amazing 360-degree photos of forests even when we are in our rooms. This system can be used in classrooms as well as in forests.

Forest Liming and Root System of Beech (*Fagus sylvatica*): A Study Case in the Sauerland region

Norbert Asche
LÖBF, Leibnizstr. 19, 45659 Recklingshausen, Germany
Tel: 02361-305-1, FAX: 02361-305-370, Email: asche@mail.loebf.nrw.de

High acid loads led to acidification of forest soils. To compensate soil acidification, forests in North-Rhine-Westphalia are limed since the early eighties. As a consequence of forest liming, it is feared, that the root system of trees could degenerate into a shallow rooting. This would effect stability negatively. Up to now studies on the development of shallow root systems as a result of forest liming do not exist. To improve the knowledge on this topic, root ditches were excavated in a beech stand (age 130 to 150 years) on a limed (1983 and 1990 each 6t/ha) and an unlimed control plot. Root distribution, soil morphology and pH of the soil suspension were recorded. On the limed plot the pH of the soil suspension was significant differences between the two plots. Only a slight increase of finest roots (diameter 0-1mm) in the depth of 70 to 90cm was recorded on the limed plot. A correlation between soil-pH and beech root distribution could not be found. The study shows, that old beech trees did not develop a shallow root system on the limed plot compared to the control trees 15 years after liming.

The Effect of *Sphenoptera chalcichroa arenosa* (Col., *Buprestidae*) on Sustainable Management of *Acacia nilotica* (L. Willd. Ex Del) in the Sudan

Hashim Ali El Atta
University of Khartoum, Faculty of Forestry, Shambat, Sudan
FAX: 249 11 780295, Email: hashim41@hotmail.com

Acacia nilotica is the most valuable timber producing species in the Sudan. It is well adapted and regenerates successfully on the flooded sites along the River Nile and its tributaries. The area planted with *A. nilotica* has been progressively increasing and has now become established at 840-1260 ha per annum. The total plantation area in the Blue Nile State alone comprises 6000 ha. The contribution of *A. nilotica* to the total sawn timber production in Northern Sudan was estimated in the range of 40-50%. It contributes to fuel wood production by 10-15% and more than 80% of the total energy needs in the Sudan comes from wood. *A. nilotica* plantations started to suffer a die-back since late 1950th. Investigation of this problem was carried out in selected forests in the Blue Nile State where the plantations are even-aged and approaching maturity. The objectives of the study were to survey the infested forests to determine the cause and the magnitude of losses and factors affecting the spread of die-back. In all infested trees, larvae of *S. chalcichroa arenosa* were consistently found tunneling beneath the bark of the branches of all dead and dying trees. These tunnels disturb water passage in the vascular system which results in loss of vigour and die-back. This has resulted in considerably greater losses in all growth parameters especially tree D.B.H., height, volume and mean annual increment (M.A.I). The reductions as a result of infestation recorded were: 30%, 21%, 54% and 60% per year in D.B.H., height, volume and M.A.I, respectively. Since these forests were managed on a 10-year working plan to provide sustainable volumes of wood each year, the losses caused by the larvae of *S. chalcichroa arenosa* resulted in wood production that is extremely less than the forecasted volumes prescribed in the working plans due to the high losses as a result of the die-back. Considerable efforts were needed to create correction factors to the yield regulation and/or to efficiently control the beetle. Water stress (positive or negative) and siltation were the major factors affecting the incidence of the die-back. In good flood years the Nile deposits huge amounts of silt which may hide more than one meter of the basal part of the stem which weakens the tree and made more susceptible to beetle attack. Also, in poor flood years the plantations were severely stressed as well due to water shortage for irrigation. Thus, these fluctuations in Nile flooding play an important role in the incidence of die-back.

Impact of Forest Pests on Forest Sustainablility in Least Polluted Areas of Lithuania

Algirdas Augustaitis
Lithuanian University of Agriculture, Forest Monitoring Laboratory, 4324 Kaunas, Lithuania
Tel: 370 7 296067, FAX: 370 7 296531 (296832), Email: august@nora.lzua.lt

The main aim of forest monitoring in protected areas is to determine and predict the condition of forest ecosystems and their changes with respect to the regional variation and impact of air pollutants. Scots pine (*Pinus sylvestris* L.) is one of the most sensitive species for pollution in Lithuania and therefore it was chosen to be the main research object. In Dz–kija National park the investigations of forest condition have been carried out since 1992. Since 1993 pine stands have experienced intensive damage by insects *Lymantria monacha* and *Dendrolimus pini*. Only after application of biologic insecticide FORAY - 48B against Nun Month and Pine Caterpillar. In 1995 and 1996 the defoliation of Pine trees started to decrease and regeneration process has been registered. Data on long-term changes in defoliation and tree increment as well as estimated regularities and peculiarities of pest impact on tree condition and increment are presented in the article in question. Impact of biotic and abiotic factors on tree condition regeneration process are investigated. It is estimated that dominant trees in the stand are most sensitive for unfavourable biotic (impact of forest pests) and abiotic (climatic) factors. Their losses in foliage as well as increment if to compare with the trees from the other tree status groups are biggest. But the potential possibilities of these trees are very high because they do not experience energetic losses due to concurrent fight with other neighbouring trees. Therefore the condition regeneration process of these trees as well as annual tree increment occurs most intensive. Suppressed tree foliage losses due to pests were least, but their energetic losses due to concurrent fight were big and therefore the regeneration potential was very low. The main factors which affected tree defoliation and productivity in Dzûkija National Park were unfavourable climatic factors - droughts in 1992 and 1994. As a result of such a situation outbreaks of forest pests were registered. Therefore today it is quite difficult to estimate the anthropogenic impact and first of all the impact of long-range transboundary air pollution, which could have had an essential affect on Scots Pine stand dynamics.

CO2 Profiles in Coastal Mangroves Forest and Pasoh Forest Reserve

Muhamad Awang, Ahmad Makmom Abdullah and Shamsuddin Johan
Universiti Putra Malaysia, Department of Environmental Sciences, 43400 UPM Serdang, Malaysia
Email: johan shamsuddin [sudin2411@hotmail.com]

Two ecotypes of tropical rain forests namely primary and coastal mangrove forests were selected for measurement of CO_2 profile at different height during a dry period between September and October 1998. The aim of the study was to determine the spatial and temporal concentrations of CO_2 in these two ecotypes in order to establish a baseline data on the CO_2 emission from various type of forest ecosystems. Results of the study showed that a similar diurnal change of CO_2 concentrations were observed at different height levels in both ecotypes. High CO_2 concentrations were recorded in the nighttime while in the daytime, the CO_2 concentrations were fluctuated between 335-390 ppm. The profiles of CO_2 concentration show that at ground level of coastal mangrove forests CO_2 concentration were ranged between 335 ppm and 440 ppm, while the primary forest of Kenyir were between 330-370 ppm. On the other hand, the concentrations of CO_2 at Pasoh forest were ranged between 340-530 ppm. Results of the study also suggest that seedlings at the forest floor were continuously exposed to higher concentration of CO_2 (335-530 ppm). Consequently, study on the effect of elevated CO_2 on tropical rain forest seedlings need further elucidation.

Effects of CO_2 Enrichment on Gas-Exchange of Tropical Hardwood and Pioneer Species Seedlings Grown Under Low and High Light Intensities

Muhamad Awang, A.M. Abdullah and S. Johan
Universiti Putra Malaysia, Department of Environmental Sciences, 43400 UPM Serdang, Malaysia
Email: johan shamsuddin [sudin2411@hotmail.com]

The terrestrial biotic response to increased CO_2 concentration is important to understand in recognising the natural sinks for industrially produced CO_2, in predicting the effect of CO_2 elevated on crop and forest production, and in quantifying possible impacts of increased CO_2 on growth and carbon storage in natural ecosystem (Commins and McMurtrie, 1993). In achieving a deeper understanding, a study has been carried out on the effects of CO_2 enrichment on four selected tropical hardwood and three pioneer species seedlings at Department of Environmeantal Science, Universiti Putra Malaysia. The main objective of the study was to determine the effects of CO_2 enrichment on the gas exchange of the species subjected to different light growth environments. Seedlings were exposed to two level of CO_2 concentrations mainly at 350 and 700 ppm. Growth and physiological responses were measured. There were significant increased in relative growth rate (RGR) of seedlings established under low light conditions (50%) as compared to full sunlight exposure. Maximum photosynthesis (Pmax) was found in species grown under full sunlight, consequently had smaller leaf area and leaf number. The result also indicated that pioneer species (*Macaranga triloba*) had the better performance of the studied species in response to changes in irradiance.

Teak defoliator, *Hyblaea puera* Cram. in Bangladesh and Its Management Options Based on Some Research

M. W. Baksha
Bangladesh forest Research Institute, Post Box # 273, 4000 Chittagong, Bangladesh
FAX: 880-31-681566/681584/681584, Email: bfri@spnetctg.com

Keywords: Teak defoliator; *Hyblaea puera*; Bangladesh; Pest management

Teak (*Tectona grandis* L.f.) has been a major plantation species in the hill forests of Bangladesh, comprising about 70-80% of the total plantations established. Teak defoliator, *Hyblaea puera* Cram. (*Hyblaeidae*: *Lepidoptera*), is a major pest causing varying intensities of defoliation every year. The population of *H. puera* could complete their life cycle within about 22 to 39 days, depending primarily on temperature. A succession of about 13 generations was possible in a year. Defoliation started at the onset of the monsoon. Generally one to two population peaks occurred during April-July, followed in some years by a third peak during August-September. The infestations were distributed in discontinuous patches well separated in space and time, and within each patch the population was even-aged suggesting the possibility of a short-range migration probably linked with the pre-monsoon wind movement. Seven host plants including a mangrove were recorded of which teak was the most preferred food. Fourteen species of birds, four species each of insect predators and parasites and one species of fungus were identified. The maximum mortality attributed to all the parasites ranged between 19.2 to 41.7%.

An epidemic outbreak occurred in about 10 years cycle. General flushing of teak occurred during March-April. During initial build up phase trees with comparatively tender foliage were most heavily attacked with larval population distributed on tender terminal leaves of the canopy as tender foliage is essential for the initial establishment and survival of the young larvae. However, mature larvae could later attack older leaves. The commonly observed escape of some teak trees from the defoliator was due to asynchrony between their flushing time and the pest's population cycle. Thus raising plantation of early flushing varieties of teak seems promising as early flushers had a greater chance of escape from the attack. The invading pest population in small patch of initial build up sites could probably be eliminated by spraying with a microbial insecticide. High temperature and relative humidity prevailing during this season in Bangladesh further widens its prospect of use. Removal of alternative host plants particularly *Callicarpa arborea* in or near teak plantation during the deciduous period of teak would reduce the probability of population build up. Inundative release of selected parasite in early population build up phase and silvicultural measures conducive for shelter and breeding of resident natural enemies are expected to have a significant role in reducing the pest population. As *Tectona hamiltoniana* and teli variety of *T. grandis* were found to be resistant to teak defoliator, the possibility of inter-specific hybridization to transfer the resistant gene to *T. grandis* without sacrificing the wood quality and productivity seems promising.

Detection of Phytoplasma in Spike Disease Affected Sandal Using Serological and Molecular Biological Techniques

M. Balasundaran, Sunil Thomas
Kerala Forest Research Institute Peechi, Division of Pathology, Thrissur-680653 Kerala, India
FAX: 91 487 782249, Email: libkfri@md2.vsnl.net.in

Sandal (*Santalum album* L.), a semi-root parasitic tree is famous for its highly valuable scented heartwood and oil. The species is distributed in South East Asia, Australia and the Pacific Islands. Spike disease caused by phytoplasma, a non-culturable mycoplasma, confined to phloem tissues is the major disease of sandal. Spike disease affected trees die within two to three years after the appearance of visible symptoms of the disease. Early detection of the disease is hampered due to lack of suitable immunological and molecular biological techniques.

Initially the diseased plants and its hosts like *Lantana* and *Zizyphus* were screened for the presence phytoplasma using a DNA binding fluorochrome, 4,6,diamidino-2-phenyl indole (DAPI). The concentration of phytoplasma was found to be more in the phloem and inner bark of stem of diseased sandal rather than the leaf, petiole and root. No phytoplasma could be located in phloem of healthy sandal and hosts of diseased sandal.

Phytoplasma was purified from the inner bark and stem tissues using a differential filtration technique. The technique takes advantage of the property of phytoplasma to pass through 0.45 μm membranes. The purity of phytoplasma was assessed using electron microscopy. The purified phytoplasma was injected in rabbits to raise polyclonal antibodies. Ouchterlony double diffusion test confirmed the specificity of antibodies against phytoplasma, indicated by the formation of percipitin bands against the extract of diseased sandal only.

Direct and indirect ELISA techniques were used to detect the presence of phytoplasma in diseased sandal and its host. Phytoplasma was found to be confined to diseased sandal and not in hosts of diseased sandal.

Dot immunobinding assay (DIBA), a technique utilising the same principles of ELISA but employing a nitrocellulose membrane as the adsorbent rather than polystyrene plate in ELISA was used to detect the presence of the pathogen. This technique was found to be cheaper and very efficient. The test could confirm the presence of phytoplasma within three hours compared to ELISA which requires >6 hours.

The pathogen was also detected in situ using immuno fluorescent techniques wherein FITC conjugated-goat anti rabbit antibody was used as the probe to detect phytoplasma. This method is highly sensitive since minimum quantity of phytoplasma can be detected in the tissues.

Oligonucleotide primer derived from the highly conserved region of 16 S ribosomal RNA gene(rRNA) was used in the detection of phytoplasma. The primer pair could amplify the gene (558 bp) after 24 cycles of polymerase chain reaction (PCR) amplification. Restriction fragment length polymorphism (RFLP) analysis of the PCR products using Alu I restriction enzyme indicated that sandal spike phytoplasma belongs to the I group of phytoplasmas. Absence of phytoplasma in hosts of diseased sandal utilising these techniques confirms that sandal spike phytoplasma is specific to sandal.

Ecofriendly Method to Control the Bark Feeder/system Borer, *Indarbela Quadrinotata* (*Lepidoptera*: *Indarbelidae*)

A. Balu
Inst Forest Genetics and Tree Breeding, Indian Council of Forestry Research and Education, PB # 1061, 641 002 Coimbatore, India
Email: ifgtb.mis@x400.nicgw.in

Casuarina and Teak are two of the important commercial tree species grown largely in many parts of the country. *Casuarina* is a multipurpose tree, which is used as fuel, fodder, poles and in pulp and rayon Industries. It also serves as shelter belts in areas of high wind velocity and arresting sand dunes in the coastal areas. Teak is the most valuable indigenous timber trees of India which was mainly cultivated by the Forest departments till 1990. Since 1990 many private entrepreneurs have started cultivating teak through intensive management aiming high yields in a short rotation. Higher returns promised from these species have prompted the farmers and Non Government Organizations (NGO-s) also to grow them in agricultural field as agroforestry models, in the recent times. Though a number of insect species are known to cause damage and effect the growth of these plants, borer are the most serious ones which directly attack the timber at different ages and seriously affect the timber quality, of which *Indarbela quadrinatata* is one among them. It is a polyphagous lepidopteran pest commonly known as bark feeder. It is one of the key pest of *Casuarina* attacks the stem and branches of the plants, particularly in younger plantations at the age group of 2-8 years. Heavy mortality of *Casuarina* trees due to this pest attack in certain plantations and trials raised in dry land has been recorded. Feeding injury made on the plant by the pest may also facilitate the infection by pathogenic microorganisms, especially the dreaded Blister bark disease of *Casuarina* caused by *Trichosporium vesiculosum*. It is thus evident as the incidence and spread of the disease is observed to be more in the plantations subjected to the attack of the pest. Of late, the pest is also found to attack young teak saplings. The intensity of attack is more in irrigated plantations. The attack of the pest on the stem affect the quality of the timber and also sometimes leads to canker formation on the main bole.

Efforts on development of ecofriendly management strategy of the pest resulted in detection of an affective entomopathogenic fungus, *Beauvereia bassiana*. Record of this fungus on the pest is the first report. More detailed studies on its pathogenicity, efficacy and efficiency in terms of larval mortality in the laboratory as well in the field in a given time were undertaken and effective doses for field application were worked out. The result of the same is presented and discussed in the paper.

Soil Characteristics and Vegetation Development in an Age Series of Limestone Mine Overburden of Dry Deciduous Zone

S. Banerjee
Tropical Forest Research Institute, Ecology and Rehabilitation Division, Post Box # RFRC, Mandla Road, 482 021 Jabalpur, India
Email: tfri-mis@x400.nicgw.nic.in

Spoil characteristics and vegetation development in an age series (2, 5, 8, 15 and 25 years) of lime stone mine overburden of different microsites (flat, slope and lime patch margin) at Katni, District Jabalpur, Madhya Pradesh, India were studied. Analysis of variance indicated significant differences in almost all the physicochemical characteristics and nutrient status of the mine spoils due to age and microsites. All the spoils irrespective of age and microsites were alkaline in reaction (pH varying from 7.9 to 8.7) whereas the adjacent forest soil was acidic (pH 5.7). Organic carbon increased more than 5 times after 25 years of succession. Total and available nitrogen also increased significantly whereas $CaCO_3$ decreased significantly with age of spoils. Plant community composition changed with age as also with microsites. Species diversity increased and concentration of dominance decreased with age. There was an increasing trend of species richness with age. Impact of microsites on soil and vegetation development was prominent. With the modification of the spoil characteristics, there was a gradual development of ecosystem leading to succession of plants. Process of succession can be enhanced by broadcasting the seeds and propagules of the pioneering species invaded in 2-yr and 5-yr old sites so that quick ecological restoration can be achieved. To revegetate the mine spoils of such type emphasis should be given to those species which can aid in sustainable development of mined-ecosystem.

Keywords: Limestone mine, spoil characteristics, microsites, community characteristics, species composition, ecorestoration

Bioindication of Different Stresses in High Altitude Forests and Subalpine Belt (Julian Alps) in Slovenia

Franc Batic, Kotar, M., Mavsar, R., A. Rozman, Sircelj, H., Simoncic, P. & B. Turk
University of Ljubljana, Slovenia
Email: franc.batic@bf.uni-lj.si

Determination of the stresses operating on a forest ecosystem demands the use of several bioindication methods. Air quality indicators were assessed from an inventory of forest decline based on the assessment of tree crowns and lichens. Photosynthetic pigments, ascorbic acid and major macronutrients were studied in Norway spruce (*Picea abies* (L.) Karst.) and mountain pine (*Pinus mugo* Turra) needles as indicators of physiological and biochemical stress. Analyses were carried out on selected forest plots and transects in predominantly unpolluted areas within Triglav National Park, Julian Alps, Slovenia. It was assumed that air pollutant input in forest ecosystems is of two kind, e.g. local from the air pollution sources in the valleys on the Nord-West part of the national park and transboundary source at high altitudes, in the subalpine mounatain pine ("Krumholz") belt. For some bioindication methods, there was good agreement with measured air quality and climatological parameters. The best agreement was found between total foliar sulphur in needles and epiphytic lichens, especially in more polluted areas. Agreement with forest decline inventories and analyses of some needle stress physiological/biochemical parameters was less convincing. Soil characteristics and climatic parameters, influenced also by biotic parameters and forest stand history and management further decreased the strength of agreement. It was concluded that chosen indicator species allow differentiating among several stresses which occur in these very specific ecosystems.

Keywords: high mountain stress, air pollution, bioindication, Norway spruce, mountain pine, photosynthetic pigments, ascorbic acid, macro nutrients, epiphytic lichens, Slovenia

The Factors Effecting Infestation of *Picea obovata* Cones by *Adelges* (*Adelgidae, Homoptera*)

Nina V. Belova
Institute of Forest Siberian Branch Russian, Academy of Sciences, Krasnoyarsk, Russia
Email: dndr@ifor.krasnoyarsk.su

The study of ecology of insect larva, developing in unusual condition, is interesting for estimation of host-plant vulnerability and its response to unusual consuming. The investigations allow us to reveal the possible pest insects. Infestation of conifer generative buds by chermes (*Homoptera, Adelgidae*) is not characteristic of these insects. Usually *Adelgidae* larva of different generations feed on needles or under bark of coniferous trees, or develops in vegetative bud of spruce and transforms the latter into gall. The purpose of this work was to determine the factors effecting

infestation of *Picea obovata* Ledeb. generative organs by adelges and study their influence on development of spruce cones and seeds. The study was carried out in the Krasnoyarsk region in 1992-1998.

It was determined that among six species of adelges found in this region only *Pineus cembrae* (Chol.) infested female generative organs of spruce. In particular years up to 34,1% of cones is inhabited by this chermes. The development and behaviour of adelges larva in spruce macrostrobiles and scale modification resulting from larval feeding were studied. Cover scales degrade fast in not infested cones. On the contrary, in infected cones under effect of larva the hypertely of cover scales happens, Basic seed scales thicken, but in general growth of seed and seed scale are inhibited. Apparently, it is connected with that adelges usually form galls. Alata-migrans of the *P. cembrae* emerged from cones in June, 5 days earlier than from galls. It was revealed that infestation of spruce female generative organs took place when chermes population density in the stand is high and generative buds prevail over vegetative ones in the shoot. Phenology of *P. cembrae* allows them to assimilate successfully unspecific food object. However the number of survived larva was dependent upon density of colonists in the cone. The higher density of chermes larva in a cone, the lower their mortality is. Peculiarities of biotope and individual trees making possible infestation of spruce cones by adelges were revealed.

Predicting Risk of Leaf Blight Infections on Eucalypts

Trevor Booth, Tom Jovanovic, Ken Old and Mark J. Dudzinski
CSIRO Forestry and Forest Products, Post Box # E4008, ACT 2604 Kingston, Australia
FAX: +61 2 6281 8312, Email: Trevor.Booth@ffp.csiro.au

Eucalypts and other Australian tree species are of major economic, social and environmental importance to many countries. The most commonly grown eucalypt species in South East Asia is river red gum (*E. camaldulensis*). The future of eucalypts in Vietnam has been threatened by the appearance in the late 1980s of severe leaf blight epidemics in southeast and central Vietnam. Badly affected trees suffer reductions in growth rate and crowns. Even main stems may become deformed, with losses in merchantable volume. Several pathogens are involved, with *Cylindrocladium quinqueseptatum* leaf blight (CqLB) being an important causal agent.

With the support of the Australian Centre for International Agricultural Research (ACIAR) a major project is being undertaken to minimise disease impacts on eucalypts in South East Asia. One sub-project, which is briefly described here, is developing methods to identify areas of high disease risk at sites in mainland South East Asia and around the world.

Climatic interpolation and the use of simple simulation models have greatly improved techniques for matching tree species to site. Recent advances in mathematical interpolation allow climatic conditions to be estimated reliably for most locations in the world, whilst computer models allow complex growth-environment interactions to be simulated in more realistic ways. This disease hazard sub-project is applying these methods to identify areas of high risk for CqLB disease in plantations.

A literature review was carried out to determine which environmental factors are associated with C. quinqueseptatum infections. Very simple rules related to temperature and rainfall were developed to identify high risk areas. They were input to several climatic mapping programs previously developed to identify areas suitable for planting particular tree species. Each of these PC-based climatic mapping programs includes interpolated data estimated for tens of thousands of locations.

The simple model of CqLB risk proved to be useful for carrying out preliminary assessments of vulnerable areas in Vietnam, India, Africa, Australia and Latin America. In addition to identifying areas from which CqLB has already been reported (e.g. southern Vietnam, southern India, eastern Madagascar and northern Australia) the model suggested other potentially vulnerable areas (e.g. parts of Central and Western Africa and Central America).

Trophic Inter-Relationships Among *Milicia Excelsa*, *Phytolyma Lata* (*Homoptera: Psyllidae*) And Hymenopteran Parasitoids.

Paul P. Bosu, Joseph R. Cobbinah and Michael R. Wagner
Forestry Research Institute of Ghana, University PO Box 63, Kumasi, Ghana
FAX: 233-51-60121, Email: forig@africaonline.com.gh

Phytolyma lata is a galling-forming psyllid which seriously hamper the sustainable production of *Milicia excelsa* in Africa. As part of an integrated approach to manage this pest the influence of host plant genotype on parasitism of gall-inhabiting nymphs by Hymenopteran parasitoids was studied.

Seventy *M. excelsa* seedlings belonging to one of three genetic groups - Resistant Genotype (RG), Moderately Resistant Genotype (MRG) and Susceptible Genotype (SG) - were established in the field in a Randomised Complete Block Design.

Parasitism rates were determined respectively in the dry and wet seasons. Significant differences in percent parasitism were found among the three genotypes during the dry season but not the wet season. Percentage parasitism in the wet increased as SG < MRG < RG. This trend was attributed to the predominantly small galls that developed on resistant genotypes. It had already been established through a related study that the size of gall formed on *M. excelsa* by *P. lata* is inversely related to percent parasitism. We conclude from the study that integrating biological control and host plant resistance will be a very feasible management strategy against *P. lata*.

Monitoring of Phtophthora-decline of alder (*Alnus* sp) in Eurpoe with Special References to Austria

Thomas L. Cech
Federal Forest Research Center, Seckendorff Gudent-Weg 8, A- 1131 Vienna, Austria
FAX: +43 1 87838 1250, Email: thomas.cech@fbva.bmlf.gv.at

Decline of Alder (*Alnus glutinosa, Alnus incana*) caused by a species of *Phytophthora* resembling *P. cambivora*. has been a problem in several European countries since 1993. Epidemic occurrence is limited so far to the southern parts of the U.K., where numerous stands of Alders lining waterways are affected. In other countries, such as Austria, Denmark, France, Germany, the Netherlands, Norway and Sweden the distribution has been more a local one up to 1998. Nevertheless the disease intensity can reach values over 50%. Investigations in *Phytophthora* strains of numerous provenances conducted in the U.K. showed a high similarity in pathogenicity, but there are considerable differences in disease intensity and progress. Research is currently done in several European countries to elucidate the biology of this *Phytophthora* and its role among the complex of other factors. Within the scope of a Concerted Action a monitoring system was established following a standardised scheme. Plots comprise 50 trees each and are investigated once a year, in addition to isolation trials of *Phytophthora* from stem lesions. The main criteria of assessment are the condition of the tree, the distribution of symptoms in the crown and on the stem, the occurrence of insects mining the stem or attacking the branches and of dieback fungi in the crown. In Austria 9 monitoring plots have been established between 1997 and 1999, five of them with *Phytophthora* confirmed as the main cause. Intensity of diseased trees varied from 20 to 50%. Within the complex of other factors contributing to the decline root rot fungi, especially *Armillaria* sp., dieback and bark attacking species (*Ophiovalsa suffusa, Valsa oxystoma*) as well as insects mining the stem, mainly *Cossus cossus* (goat moth) are the most important. The role of climatic extremes (drought and frost) as predisposing factors is discussed.

Seed Pests and Their Impact on Quercus Regeneration in Western Himalayan Region of India

Rajeswar S. Chandel, C.V. Sarswat and K. S. Verma
Dr. Y.S. Parmar University of Horticulture and Social Sciences, Seed Technology & Production Centre, Post Box # Nauni, 173230 Solan HP, India
Tel: 1792 52323 (O), FAX: +91-1792 52242, Email: sps@yspuhf.hp.nic.in

Ban Oak (*Quercus leucotrichophora* A. Campus ex. Bahadur) is an important fodder tree species of Himalaya. Its natural pure stands occur on the southern aspect in the outer ranges of western Himalaya. Besides ecological significance, it is a principal source of firewood, charcoal and agricultural implements to the hill people. The species seeds abundantly and the mature healthy seeds have a germination capacity of 80-90 per cent. Its seeds are heavily attacked by the insect-pests, birds and wild animals resulting into the significant seed loss. Reduced availability of sound seed on the forest floor thus, hampers the natural regeneration. Insect-pest infestation is the principal contributory factor towards the loss of sound seeds. Seed losses due to pest infestation, its impact on natural regeneration, and germination capacity have been studied and the results obtained from 12 different locations covering the entire ban oak zone of Western Himalaya are given in this paper.

The mature seeds of ban oak start falling on the ground during the month of December and continue till February. Studies on the proportion of sound seed to the infested ones fallen on the forest floor have amply shown that infested seeds were more than double the quantity of sound seeds. Out of three distinct groups of insects viz; nut weevils, moth larvae and gall forming cynipids, the maximum damage was due to nut weevils, *Curculio sikkimensis*. The adults lay eggs on the young acorns above the cupule by making a puncture with the help of a long snout during July-

August. One to many larvae develops inside the acorn by making galleries. This leads to the death of seed in many cases. The per cent seed infestation on tree crown remained between 15-35 per cent, except at one location (up to 60%) and on forest floor it was more than 50 per cent. Per cent germination of the total fallen seed on the forest floor varied from 0.5-4.5 at all the 12 different locations. Healthy and infested acorns each weighed about 490 and 740 number of seeds in one kilogram. The extent of insect damage to the seed influenced the per cent germination. Seeds infested to the extent of 25, 50, 75 and 100% showed upto 45, 30, 8 and no germination, respectively. The per cent germination in sound acorns ranged between 80 to 96 per cent.

The Introduction of *Pauesia juniperorium* (stary) (*Hymenoptera: Branocidae*) into Malawia for the Biological Control of *Cinara* Sp. NOV: (*Homoptera: Aphididae*)

C. Z. Chilima, S.T. Murphy
Forestry Institute of Malawia, Zomba, Malawia
Email: s.murphy@CABI.org

From 1986, the cypress aphid, *Cinara* sp.nov. was reported causing extensive damage to erotic and native cypress stands an Malawia. Since 1991, the Forestry Research Institute of Malawia (FRIM), with technical support from CABI Bioscience, has been undertaking a classical biological control project against the pest.

In 1994 and 1995, the parasitoid *Pauesia juniperorum* Stara, collected from western Europe and screened at CABI Bioscience, UK, was shipped to Malawia for rearing and direct field release. The field releases were made in cages containing aphid ingested branches during the months August to early October. Parasitoids released in 1994 did not establish. However, in 1995, females released in cages provided a large number of progeny with an evenly balanced sex ratio. These were allowed to disperse naturally from the cages. Regular branch samples taken later in the year showed that the parasitoid has dispersed several hundred meters from the cages. Mean parasitism on branches was 48 per cent. The parasitoid is now widely distributed in the south and centre of the country. The impact of the parasitoid on the cypress aphid is discussed.

Factors Influencing the Mortality and Health Trends of the Sessile Oak in Hungary

György Csoka
Forest Research Institute, Department of Forest Protection
Email: gycsoka@mail.datanet.hu

The large scale decline of the sessile oak (*Quercus petraea* MATT. LIEBL) was one of the most spectacular and important forest health problems both in Hungary and the neighboring countries (Austria, Romania and Slovakia) in the last two decades.

Experimental plots with individually numbered trees (ca. 300 trees/plot) were established in 1982 all over Hungary to study the process of sessile oak decline. 27 of these experimental plots are located in NE-Hungary. The health condition of the sample trees at the experimental plots has continuously been scored on a 4 degrees scale (5-4-3-2), twice a year (late May and mid September) since 1983.

This survey evaluates the autumn scores of more than 4500 sample trees at these 27 plots in NE Hungary recorded between 1983 and 1998. The social status of the sample trees (Kraft classes) was also recorded. The following indices were calculated based on the health scores recorded tree by: mortality index, mortality trend index, health index, health trend index. These indices were correlated with the drought index, and the yearly population level of the geometrid caterpillars. The drought index is defined as the average temperature of the growing season (in Co) divided by the weighted sum of the precipitation in the growing season (in 100mm).The population level of geometrids is expressed by the forested area damaged by them.

It is clear that the drought index and the mortality index follow a highly similar pattern. Between 1983 and 1989, when the drought index showed a decreasing trend, the mortality index also decreased. The rates of mortality between 1989 and 1992 were hardly more than 1%, and occurred mainly among the suppressed trees, so it can be considered as natural self-thinning. After 1991 when several seriously dry years followed each other the mortality index started to increase significantly, and mortality was recorded among the dominant trees too. The mortality index reached its peak in 1995 with value of 4.6%. Following 1995, when the drought index decreased significantly again, the values of the mortality index dropped too. This is also evident that the mortality index shows a delayed (ca. 2 years) response to the change of the drought index.

There are significant positive correlation between the yearly values, 2-, 3- years moving averages of the drought index, and the yearly values of the mortality trend index. Reverse correlation was found between the drought indicating variables (yearly values, 2-, 3-years moving averages of the drought index) and the health index. When a given year or a 2-3 years long period was extremely dry the health conditions of the sample trees got significantly worse.

Significant positive correlation was found between the population level of geometrids (yearly values, 2-, 3-years moving averages) and both the mortality index/mortality trend index. In the years when the geometrid population was high in the spring higher and increasing tree mortality was recorded in the autumn. Significant negative correlation was found between the population levels of the geometrids and both the health index and the health trend index. When the geometrid population level was high in spring, the health status of the sample trees got significantly worse in autumn.

Sphaeropsis sapinea: An Important Pathogen in Exotic Pine Plantations

Juanita de Wet, Michael J. Wingfield, Teresa A. Coutinho, Oliver Preisig, Jolanda Roux, Henk Smith, & Brenda D. Wingfield
University of Pretoria, Forestry and Agricultural Biotechnology Institute (FABI), 74 Lunnon Road, 0002 Pretoria, South Africa
Tel: +27 12 4203938, FAX: +27 12 4203960, Email: juanita.dewet@fabi.up.ac.za

Sphaeropsis sapinea is an opportunistic pathogen of conifers, world-wide. This pathogen posses a serious problem, especially in areas where it has been introduced, while it is not considered to be of great importance elsewhere, where pines are native. In South Africa, New Zealand and Australia, *S. sapinea* is one of the most important pathogens of exotic *Pinus* spp. The fungus can persists in pine tissue as a dormant endophyte until physical or environmental predisposition initiates a pathogenic response and the appearance of disease symptoms. Disease symptoms include die-back, stem cankers, stem malformations, collar rot, root disease and blue stain. In South Africa, timber losses due to post-hail associated die-back of *P. patula* and *P. radiata* trees have been estimated at more than half the potential value and about a quarter of the potential volume of wood produced. Effective control measures to reduce losses caused by *S. sapinea* in exotic pine plantations, necessitates an understanding of the biology and population genetics of S. *sapinea*.

The population structure of *S. sapinea* on native trees differs from the situation on exotic trees. The degree of diversity has recently been determined from a South African and Indonesian population using vegetative compatibility groups (VCGs). A larger number of VCGs were found in the exotic South African population in comparison to the population from Indonesia where native *Pinus spp*. are known to occur. This finding contradicts the general assumption that a lower degree of diversity exists in introduced populations, compared to well-established native populations. The higher degree of diversity determined for the South Africa population can probably be attributed to multiple introductions of the pathogen with pine seed into the country.

Sphaeropsis sapinea isolates can be characterized in three distinct types based on RAPD analysis, size of conidia and virulence. These different types are referred to as the A, B and C morphotypes. Isolates of the C morphotype have significantly longer conidia and are more virulent than those of both the A and B morphotypes. Based on cultural characteristics, texture of conidial walls and ITS sequences, isolates of the A and C morphotypes are more closely related to each other than to those of the B morphotype. Isolates belonging to the A morphotype were the most common, and include those from South Africa. The C morphotype has recently been reported for the first time and includes isolates from Indonesia. The differences in virulence among isolates of the three morphotypes will influence effective management and quarantine practices.

Two dsRNA mycoviruses, SsRV1 and SsRV2, as well as various other dsRNA fragments, ranging in size from ca. 8 kb to 1.6 kb, have been isolated from world-wide collection of *S. sapinea* isolates. The complete genome sequences of both SsRV1 and SsRV2 has been determined and these viruses have accordingly been classified as belonging to the Totiviridae. No conclusive evidence has thus far been found to link the presence of these dsRNA fragments to changes in the normal phenotype of the pathogen. The *S. sapinea* isolates screened, either had multiple infections by more than one dsRNA fragment, or single infections.

Mycoviruses have potential to be used to reduce the impact of pathogens such as *S. sapinea*. This is called hypovirulence, which is a spontaneous reduction in the virulence of the pathogen, as has been shown for the chestnut blight fungus, Cryphonectria parasitica. Hypovirulence-conferring genes of *C. parasitica* or synthetic hypovirus transcripts could potentially be incorporated into the SsRV-viral genome in order to induce hypovirulence in *S. sapinea*. We envisage an integrated disease management approach in order to reduce losses due to *S. sapinea* infection, especially in exotic plantations. Such an approach would include breeding and selection for resistance, the manipulation of dsRNA associated with *S. sapinea* and careful site selection to minimize mechanical damage and stress.

Arthropod Diversity of Exotic vs. Native *Robinia* species in Northern Arizona

Thomas E. deGomez, M. R. Wagner
Northern Arizona University, Box 15018, Arizona, 86011 Flagstaff, USA
FAX: (520) 523-1080, Email: ted3@dana.ucc.nau.edu

Commercial forestry worldwide depends upon the use of exotic tree species because of the benefits that can be gained from improved production. However, the use of exotic trees in plantations has been rife with misconceptions from both supporters and opponents of their use. Many foresters tend to discourage the use of exotics predicting that the exotics would have higher numbers of insect pest species than the native trees. However, there are many examples when exotics have had fewer insect pest problems than natives of similar taxon.

This study was a comparison of arthropod species data sets for species of woody plants in their native and exotic range. Data sets comprised 26 pairs of arthropod species lists; the paired data sets consisted of the number of arthropod species in the native range of the plant and a corresponding data set from where the plant grows as an exotic. Plants in the study came from many genera such as: *Pinus, Robinia, Abies, Chamaecyparis, Cupressus, Picea, Pseudotsuga, Thuja, Tsuga, Prosopis, Tamarisk, Cytisus,* and *Schinus.*

Preliminary results indicate that there is greater arthropod species colonization on woody plants in their native range. We further analyzed whether the number of arthropods are influenced by the time a plant species has been growing in a non-native range, and whether the area of plant cover influences arthropod colonization of the native and the exotic plant species.

The Buffering of Acidifying Nitrogen and Sulphur Deposition in the Soil on the ICP Forests Intensive Monitoring Plots in Finland

John Derome, Antti-Jussi Lindroos and Kaarina Niska
Finnish Forest Research Institute, Rovaniemi Research Station, P.O. Box 16, FIN-96301 Rovaniemi Vantaa, Finland
Tel: +358-16-336 4640, Email: John.Derome@metla.fi

Acidic deposition, resulting from the emissions of sulphur and nitrogen compounds, is a potential stress factor for forest ecosystems by accelerating soil acidification. The capacity of podsolic forest soils to neutralise and buffer the anthropogenic inputs of hydrogen ions is dependent on a number of processes, e.g. cation exchange, silicate mineral weathering and Fe and Al buffering systems. As a result of the buffering and neutralisation reactions, the chemical composition of rainwater changes as it passes down through the soil profile. Monitoring the chemical composition of the soil solution is therefore a key indicator in estimating soil acidification and the buffering capacity of the forest soil.

The capacity of the soil on 16 ICP Forests intensive monitoring plots to buffer acid inputs has been monitored since 1997 on the basis of bulk deposition, stand throughfall and percolation water samples collected during the snowfree period. The plots were located in Norway spruce and Scots pine stands. Zero-tension lysimeters were inserted at depths of 5, 20 and 40 cm measured from the ground surface, with 5 replications per depth.

At all the sites, the input of protons in stand throughfall has been effectively buffered or neutralised by the time the percolation water has reached a depth of 40 cm. The pH of percolation water at this depth depends on the neutralising and buffering properties of the subsoil. There was considerable variation in the pH increase in percolation water at depths of 5 and 20 cm, because the rate of buffering or neutralisation depends on a number of soil properties, e.g. thickness of the organic layer and E and B horizons, the soil texture, which determines the percolation rate of the water and the degree of interaction between the percolation water and the soil, and the base saturation of the organic layer and uppermost mineral soil layers.

There was a clear increase in sulphate concentrations in percolation water with increasing soil depth. The main reason for this is that sulphate is a relatively mobile ion in the soil; the sulphate-adsorption capacity of the organic layer and underlying E horizon is relatively low, and most of the sulphate is adsorbed by the Al and Fe sesquioxides precipitated lower down the soil profile in the B horizon. The amount of water percolating down the soil decreases with increasing soil depth as a result of evaporation from the soil surface and evapo-transpiration by the tree stand. This results in an increase in the sulphate concentration with increasing soil depth.

The nitrate concentrations in percolation water were extremely low. Nitrogen in a plant-available form is the primary factor limiting tree growth on forest soils in Finland, and it is clear that a nitrogen input (e.g. as nitrate) will be rapidly taken up by the roots of the trees and ground vegetation. These results also support the conclusion that the nitrogen status in the soil on these plots has not reached so-called nitrogen saturation. Furthermore, the C/N ratio in the organic layer on all these plots was well above 25, and there is not likely to be a risk of nitrification and nitrate leaching into the ground water.

In conclusion, according to the change in rainwater/soil water acidity as it passes down through the soil profile, the buffering capacity of the soil on the ICP Forests (level II) monitoring plots was relatively high. The sulphur concentrations in bulk deposition, stand throughfall and percolation water were the highest on the plots located in southern Finland. The nitrate concentrations in percolation water on all the plots were extremely low as a result of efficient nitrogen uptake, and the risk of nitrate leaching into the groundwater appears to be negligible.

Zinc Mobilisation in Forest Soil Near the Harjavalta Cu-Ni Smelter, SW Finland

John Derome, Tiina Nieminen
Finnish Forest Research Institute, Rovaniemi Research Station, PB 16, FIN-96301 Rovaniemi Vantaa, Finland
Tel: +358-16-336 4640, Email: John.Derome@metla.fi

Introduction

Zinc is a micronutrient that is essential for the metabolic functioning of higher plants and animals, but in high concentrations it is one of the trace metals potentially most hazardous to the biosphere (Kiekens, 1995). A number of studies have been carried out on the detrimental effects of Zn emissions from Zn smelters on soils and surface waters, but relatively little attention has been paid to the fact that many other nonferrous smelters (especially Cu-Ni smelters) also emit considerable amounts of Zn into the environment. For instance, up until 1991 the smelter at Harjavalta, SW Finland, emitted more Zn than Cu or Ni, even though it is generally referred to as a Cu-Ni smelter. Although heavy metal emissions from the smelter have been considerably reduced during the past decade (Helmisaari et al. 1995), in 1995 there were signs of an increase in the Cu, Ni and Zn concentrations in percolation water (20 cm depth) in the immediate vicinity of the smelter. The aim of this report is to present long-term (1992-98) trends in percolation water Zn concentrations close to the smelter, to assess whether Zn leaching is likely to affect ground water quality, and to determine whether liming agents could be used to counteract this potential hazard.

Materials and Methods

Percolation water samples were collected during 1992-1998 at a depth of 20 cm on one control and two treated plots in a severely damage Scots pine stand located 0.5 km from the Harjavalta smelter. The experimental layout and the pre-treatment and analysis of the water samples are described in detail in Derome and Nieminen (1998). Mg-rich limestone (2 t/ha) was applied to one of the plots, and a correction fertiliser (1 t/ha) consisting of slow-release powdered minerals (including 20% calcium and magnesium carbonate) and a mixture of fast-release, water-soluble salts (including Cu and Zn, 0.8 kg/ha) to the other.

Results and Discussion

The uppermost soil layers at the site are severely contaminated with a range of heavy metals including Zn (Derome and Lindroos, 1998). Despite the strong reduction in Zn emissions from the smelter, during 1995-98 there was a clear increase in the Zn concentrations in percolation water on the control plot (Fig. 1) in 1996. The deposition of Mg, K, SO4 and Ni within the stand increased strongly during 1995-96, but there was no increase in Zn deposition. In addition, during 1992-96 there was a net loss of Zn from the 0-40 cm soil layer down into deeper layers, i.e. the output of Zn in percolation water (40 cm depth) was greater than the input to the soil in throughfall (Derome and Nieminen, 1998). The corresponding fluxes for Cu and Ni were negative, i.e. the pools of Cu and Ni are increasing in the 0-40 cm soil layer. Zinc is more mobile than Cu or Ni in the soil: it forms soluble complexes with chloride, phosphate, nitrate and sulphate, and soluble complexes and chelates with organic matter (Geering and Hodgson, 1969), and has a lower affinity for cation exchange sites than Cu and Ni. The increased deposition of Mg, K, SO4 and Ni in

1995-96 appears to have increased Zn mobilisation from the organic layer in 1996. The liming and correction fertiliser treatments reduced the Zn concentrations to about half the level on the control plot. The initial increase in 1992 was presumably due to the displacement of Zn in the overlying soil layers by the added cations (primarily Ca2+, Mg2+, K+), and to the small addition of Zn in the CF treatment. The subsequent decrease in the Zn concentrations was presumably due to the immobilisation of Zn caused by the increase in soil pH values resulting from liming (Kiekens, 1995).

Fig. 1. Effect of liming (LT) and correction fertilisation (CF) on the Zn concentrations in percolation water (depth 20 cm) at a distance of 0.5 km from the Harjavalta smelter during 1992-1998. O = control. The bars indicate the standard error of the mean. (not shown)

Conclusions

Despite the considerable reduction in emissions from the Harjavalta Cu-Ni smelter, there is strong evidence to suggest that the large amounts of Zn that have accumulated in the surface soil of the forest ecosystems surrounding the smelter during the past 50 years are susceptible to mobilisation and may be carried deeper down into the soil. This poses a potential threat to groundwater quality in the area. Liming at suitable doses will help to prevent this problem.

Evaluation of Chemicals For the Control of Sapstain on Rubber Wood

E.J. Maria Florence
Kerala Forest Research Institute, Division of Pathology, 680 653 Trichur, Kerala, India
FAX: +487 782249, Email: libkfri@md2.vsln.net.in

As soon as the tree is felled it is prone to microbial degradation. Mould fungi and sapstainers are the primary colonies of the felled tree. So far numerous preservative chemicals have been evaluated for the effectiveness against mould and sapstain. But only a very few have been found to possess all the requisite of a good preservative. In late 1960s Sodium pentachlorophenoxide (NaPCP) was introduced as an antisapstain chemical throughout the world. However, over the years, the growing concern regarding the toxic compounds and their related environmental problems has brought down the use of NaPCP. At present the ban on the use of Pentachlorophenol and NaPCP in most countries has led the search of an alternative antisapstain chemicals which are effective and environmentally safe Study conducted in Kerala Forest Research Institute revealed that sapstain caused by *B.theobromae* is a serious problem in the proper utilisation of rubber wood in Kerala. Different chemicals were screened for their efficacy in controlling sapstain caused by *B theobromae* on rubber wood. The fungicides evaluated were Captafol, Busan 1009, Hylite extra and Chlorothalonil. The efficacy was first evaluated on wood blocks, then in the field. Different concentrations on the Fungicides were also tested. Busan 1009 (1% a.i) in combination with boric acid (1%) was found to be effective in controlling sapstain.

Chlorothalonil, was also found to be effective in controlling sapstain . Among the two different types of stacking tested, open stacking found to reduce the fungal infection on the wooden planks. During rainy seasons, the concentration of the fungicide has to be increased for better control of fungal growth. The details of the fungicidal evaluation will be highlighted in the paper.

A Comparative Study on the Abundance and Diversity of Ichneumonid Wasps (*Hymenoptera: Ichneumonidae*) in Selected Forests and Non-Forest Habitats in Peninsular Malaysia

Idris Abd. Ghani
Universiti Kebangsaan Malaysia, Department of Zoology, Faculty of Life Sciences, 43600 Bangi Selangor, Malaysia
Tel: 6-03-8292973, Email: idrisgh@ukm.my

A comparative study on the abundance and diversity of Ichneumonidae wasps in the selected forests and non-forest (agriculture) habitats of Peninsular Malaysia was conducted from July to November 1998. The forest or non-agriculture habitats selected were Kuala Lompat Wild Life Reserve Forest (Primary and undisturbed forest) in Pahang, and Universiti Kebangsaan Malaysia-Permanent Forest Reserve (secondary forest) and Bush areas around Univerisiti Kebangsaan campus in Bangi, Selangor. Whilst the agriculture habitats were an orchard of star fruit and sapodilla of the Malaysian Agriculture Research Institute of Malaysia in Serdang, Selangor, and Rubber and Oil Palm plantations of the New Labu Estate in Nilai, Negeri Sembilan. The insect wasps were caught using four Malaise traps per habitat per week for three months period. Insects caught were brought back to laboratory, sorted and identified up to subfamily levels.

Result showed that Bush areas had the highest numbers of Ichneumonidae's subfamily recorded and Ichneumonidae individuals per subfamily collected compared to other habitats including the

Kuala Lompat Wildlife Forest Reserve. The Universiti Kebangsaan Permanent Forest Reserve recorded the least number of Ichneumonidae subfamily (10), which is much lower than that of agriculture habitats.

Overall, the highest and lowest number of individual Ichneumonid collected was from the Kuala Lompat Wildlife Forest Reserve and rubber plantation habitats respectively. The number of Cryptinae individuals was the most abundance in all habitats followed by the Pimplinae and Ichneumoninae. There was strong and significant relationship between the number of Ichneumonid individuals collected and the subfamilies and habitat types. This suggests that the abundance of Ichneumonid wasps influenced by the subfamilies and types of habitat.

This study had successfully collected 49% (17) of the Ichneumonidae subfamilies recorded worldwide (35), indicating that Ichneumonidae diversity is high in Malaysia. The Shannon Weiner diversity index value (H') indicated that the diversity of Ichneumonidae subfamilies was significantly different among the habitats. Although the KLFR is the primary forest, the value of H' of Ichneumonidae subfamilies of the Kuala Lompat Wildlife Forest Reserve was significantly lower that that of bush areas. Interestingly, the bush areas had the highest H' value than that of other habitats, suggesting that it has plenty of resources such as food and host for the wasps to survive and reproduce. The availability of food and resources in any particular habitat could increase the number of individual (abundance) per subfamily, and this would indirectly increase the H' value of the Ichneumonidae subfamily. Results of this study also indicated that better understanding on wasp biology and ecological needs can increase their diversity in disturbed habitats (forest or agriculture). High diversity of these wasps is very important to us as they could act as biological control agents of insect pests of economic trees or crops. Further study with longer sampling periods and increase number or types of habitat use should be conducted. This would give better estimation and view of Ichneumonidae population abundance and diversity in Malaysia.

Biochemistry and Molecular Biology of Interaction between Phytoplasmas and *Paulownia* Related to the Pathogenic Mechanism

Tian Guo-Zhong, Luo Fei, Zhu Sui-Fang, Zhang Xi-Jin, Xiong Yao-Guo, Huang Qin-Cai, Qui Wie-Fan
Research Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, 100091 Beijing, China
FAX: 86-010-62884972

Paulownia infected with phythoplasma displays unique exteior symptoms, witches' broom (loss of apical dormancy) and phyllody (abnormality of floral organs) as well as interior symptoms, ans abnormal accumulation of callose in the affected sieve tubes. The *in vitro* cultured healthy and graft-transmitted plantlets of several *Paulownia* clones were used for study related metabolic changes to phythoplasma infection. It was found that the level of free indole-3-acetate acid (IAA) and catechol decreased significantly in the diseased plantlets and change of IAA is also consistent with the decline of catechol. This strongly suggests that auxin degradation is directly involved in the symptom development of the disease. The activities of peroxidase and IAA oxidase increased distinctly in the infected plantlets. The isoenymes of both enzymes were analyzed by means of native acidic and basic polycrylamide gel electropherensis (PAGE) as well as isoelectric focusing on agrose and PAGE gels. Findings showed that there is stronger activity of IAA oxidase on the basic (cationic) peroxidase isozyme bands, whereas acidic (anionic) peroxidase isozymes have weak IAA oxidas activity. The tissue print of peroxidase and IAA oxidase on nitrocellulose filter revealed that the main alteration of both enzymes occurred in the affected vascular tissues, the areas of the phythoplamsa colonization. A peroxidase isoenzyme with high IAA oxidase was purified by (NH4)2SO4 precipitation and a series of chromatolography onto Sephadex G-25, cellulose CM-52, Sephadex DEAE-A50, and Sephacryl-2000HR columns. The partial amino acid composition, molecular mass, pl value, porphyrin and gycosylation of the purified enzyme ere characterized. The immunological property of the enzyme was evaluated through western blotting with the use of commercial antihoseradish peroxidase antibody. By using a pair of specific primers to the ipt gene Agrobacterium iumefanies and blunt ligation technique, a 427 bp fragment of ipt gene originated from the poplar stem gall pathogen was cloned and the cRNA probe was prepared, the hybridization of the phythoplasma

DANN with cRNA probe was conducted. In addition, the abnormal acculmulation of callose in the affected sieve tubes was shown to be correlated with the severity of the witches' broom symptoms. The sythesis and decomposition of the callose in response to the pathogen infection were also investigated by analyzing ß-1,3-glucan synthase and ß-1,3-glaucanase activities and its isozymes. Based on this finding, an IAA oxidation hypothesis which explains the symptom development of *Paulownia* caused by phytoplasmas is propsed. The treatments of infected *in vitro* cultured plantlets with various plant growth regulators, phenolic compounds antioxidants as well as tetracyclines also supported the proposed mechanism.

Paulownia Witches' Broom Disease in China, Present Research Status

Tian Guo-Zhong, S.P. Rachaudhuri
Research Institute of Forest Ecology, Environment and Protection
Chinese Academy of Forestry, 100091 Beijing, China
FAX: 86-010-62884972

As a widespread disease which has been found in almost every *Paulownia*-growing area of China, *Paulownia* witches' broom disease caused by phytoplasma has been one of most serious problems that Chinese artificial timber industry is faces with. The present research on this disease in China is introduced and evaluated in this paper. It covers the geographical distribution and damage done by the disease, symptomology, etiology, histology, physiology and biochemical changes of infected plants, pathogen localization and distribution, pathogen transmission, factors influencing disease epidemic, and control measures. The recent progress in the area of the propagation and application of phytoplasma-free seedlings by means of *in vitro* culture technique, the molecular detections od pathogen using DNA hybridization and polymerase chain reaction based on the 16S rRNA gene conserve sequence, and approaches on the pathogenic mechanism related to the unique symptom development associated with phytoplamas infection are discussed in more detail. Based on the analysis to the key factors of influencing disease prevalence in China, a new phytoplasma infection cycle model and enovating control strategies are proposed.

Damping off Pathogeny of *Pinus merkusii*

Achmad Hadi, Soetrisno Hadi
Institut Pertanian Bogor, Fakultas Kehutanan, 16310 Bogor, Indonesia
Tel: +62-251-504734, Email: adhat@bogor.wasantara.net.id

Damping-off incited by *Rhizoctonia solani* and *Fusarium oxysporum*, is one of the problems associated with the production of *Pinus merkusii* seedlings in seedbeds for the establishment of forest plantations in Indonesia. The pathogens are able to cause damping-off of seeds and seedlings younger than 7 weeks old. *R. solani* is more aggressive than *F. oxysporum*. The older the seedlings, the lower the incidence of the disease, indicating that the older the seedlings the more resistant they are to damping-off.

F. oxysporum and *R. solani* produce adaptive C1-cellulase as well as pectinase. The C1-cellulase activity of *F. oxysporum* is stronger than that of *R. solani*. Conversely, the polygalacturonase - a component of pectinase- activity produced by *R. solani* was higher than that produced by *F. oxysporum*. The higher activity of pectinase produced by *R. solani* is suspected to make this pathogen more aggressive than *F. oxysporum* because polygalacturonase plays an important role in the host tissue maceration and in the exposure of cellulose to cellulolytic enzymes leading to the cell wall degradation.

In the stem tissues the peroxydase activity increases with the age of the *P. merkusii* seedlings and reaches its peak when the seedlings are 3 weeks old. Thereafter, the peroxidase activity gradually decreases with age. Unlike the peroxidase activity, the polyphenol oxidase activity is very low, fluctuates, and there is no consistent pattern related to the seedling's age.

Lignification is a natural process in plant cell development. The lignin content of hypocotyl seedling tissues gradually increases with age. The increase is suspected to make older seedlings more resistant to damping-off. Lignin could increase the host resistance by structural and/or biochemical defence mechanisms. In the case of damping-off of *P. merkusii*, lignin content in the root collar tissues is suspected to directly increase the seedling's resistance to damping-off, mainly by structural defence mechanism.

Peroxidase is thought to be the main enzyme that oxidizes monolignol to initiate the lignin synthesis in plant tissues. The increase of peroxidase activitty tends to be followed by the higher increase of lignin content in the tissues.

The Impact of *Sirococcus* Shoot Blight on the Development and Growth of Norway Spruce (*Picea abies* [L.]Karst) in Young Plantations.

Erhard Halmschlager, A. Gabler, F. Andrae
University of Agricultural Sciences, Billrothstraáe 53/l/4, A-1190 Vienna, Austria
Email: halmi@edv1.boku.ac.at

The mitosporic fungus *Sirococcus conigenus* (DC.) P. Cannon & Minter causes shoot blight and seedling mortality on many conifer hosts in the northern temperate zone. The disease occurs in nurseries, young plantations, natural regeneration and sometimes in mature stands. In middle Europe the most common species damaged by this fungus is Norway spruce. The most recent outbreak started in the early eighties. The primary damage is to the current shoots which affects growth. Young trees suffering from multiple infections may show crown deformation or even die.

The aim of our study was to investigate the impact of *Sirococcus conigenus* shoot blight on the development and growth of Norway spruce in young plantations, by examining the increment losses due to various intensities of infection. Investigations were carried out at Schöneben (920 m eve, Upper Austria) in a 0.75 ha plantation that was established in 1978 on former farmland. Trees originally had been planted with a 2 by 1.5 m spacing. Within this area, infestation occurred mainly in four patches. A systematic sampling design, 20 by 15 m was used, establishing 19 plots, each having a plot radius of 3.6 m. Within each sample plot the diameter at breast height (DBH) of each tree was measured and classified into four damage classes (0=no damage, 1=light, 2=moderate, 3=severe damage). From all trees classified, five trees of each damage class were randomly chosen, their height was measured and stem disks at 0.3 m and 1.3 m were taken for further analysis. Using this data, plus an additional 35 heights representing all DBH classes, height diameter curves were constructed for each *Sirococcus*-damage class. Tree ring analysis was carried out using the Johann`s Digitalpositiometer.

Results of this study clearly indicates that *Sirococcus* shoot blight significantly affects radial and height growth of infected trees. Average DBH of lightly damaged tree class was 80% compared to the average diameter of the healthy class, moderately and severely damaged tree classes were 72% and 55% respectively. Taking the annual radial increment of the healthy trees as a reference (100%) the relative development of radial increment of the damaged trees over time was studied. The light and moderate damage classes showed lower but constant relative radial increment over time. Damage class 3 (severe damage) is lower and constant for several years then the growth rate declines visibly. Additionally, comparisons of the ratio between increment at DBH and the increment at 0.3 m for classes 0,1 and 2 show similar relationships, while for the severe damage class, this ratio is higher. This may be a result of multiple infections and dieback of terminal shoots found on severely damaged trees. The DBH/DH 0.3 m ratio of trees from all other damage classes, however, indicate a similar radial increment at breast- and stump-height.

The different *Sirococcus* damage classes of shoot blight also reflected different height growth. Heights of healthy trees had a range from 4.7 m (DBH 5c m) to 11 m (DBH 19 cm), while heights of severely infected trees ranged from 2.9 m (DBH 3 cm) to 5.8 m (DBH 9 cm). The diameter height curves of the lightly and moderately infected trees appear between the two.

In summary, *Sirococcus* shoot blight had a dramatic impact on the growth of Norway spruce in young plantations. This research was conducted as part of the Special Research Program "Forest Ecosystem Restoration (SF008)" , funded by the Austrian Science Foundation and the Ministry of Agriculture and Forestry.

Physiological and Biochemical Effects of Methanolic Extracts of Neem and Chinaberry Seeds as Natural Insecticides

M. Hashem, Sawsan M.El-Mesieri; I.A.Rawash and Fatma A. El-Meniawi
Alexandria University, Dept. Economic Entomology, Faculty of Agriculture, Alexandria, Egypt
FAX: 00203-5972780, Email: hussein@safwa.com.eg

Insecticidal effects of ethanolic extracts of neem trees seeds (*Azadirachta indica* A.Juss), chinaberry tree seeds (*Melia azedarach* L.) and damsisa plant (*Ambrosia maritima* L.) against different developmental stages of the cotton leafworm, *Spodoptera littoralis* (Boisd.) were previously evaluated and their physiological effects on its reproductive activities were investigated in our laboratory. In the present study the effects of the critical concentrations, the least sublethal concentrations which exhibited significant reduction in the reproductive activities, of ethanolic extracts of the above mentioned plant materials on the protein and free amino acids (FAAs) contents of the male reproductive organs and spermatophores (SPs) of *S. littoralis* were investigated by both larval treatment, by oral application method and adult treatment, by oral application method.

Critical concentrations of such three extracts significantly reduced the fresh weight and protein contents of the male accessory glands (MAGs) and SPs by both methods of treatment. The reduction in the fresh weight and protein contents in the testes was significant. Sixteen FAAs were detected in the MAGs as well as in SPs. In the untreated males the FAAs contents were found to be higher in the MAGs than in SPs . Treatment of larvae or adult male moths by neem seed extract strongly and significantly reduced the total FAAs contents in both MAGs and Sps since reductions were about 62% and 36% by larval treatment and about 55% and 41% by adult treatment, respectively.

Injection of MAG substance extracted from treated males, with the critical concentrations of the three plant extracts, into newly emerged virgin females caused lower stimulation of egg laying when compared with the MAG substances extracted from untreated males. Moreover, the female ovipositional activities were significantly reduced by the injection with MAG substances extracted from treated males. Feeding *S. littoralis* larvae on caster leaves on male moths on sucrose solutions treated with the critical concentrations of such plant extracts reduced the toxicity of the extracted MAG substances to the injected female moths. However, in all of the above-mentioned results the neem seed extract exhibited the highest potency followed by the chinaberry seed extract and then the damsisa plant extract.

Studies on the Effects of Nutrition Management on the Recovery of Damaged *Pinus massoniana* in the Air Polluted Area

Shang He, Ma Guangjing, Wang Weiping, Luo Qixuan, Yang Shengyuan, Cai Bing
The Chinese Academy of Forestry, The Research Institute of Forest Ecology, Environment and Protection, Wan Shou Shan, 100091 Beijing, China
Email: shanghe@fee.forestry.ac.cn

In this paper, the effects of nutrition management on recovery of damaged *Pinus massoniana* lamb forest were studied. Based on the comparison of nutrient contents in conifer of damaged *Pinus massoniana* lamb before and after nutrition management, the way for supplying content of lack elements in and developing nutrition balance were explored and concluded. The results showed that nutrition management could promote the recovery of damaged forest in polluted areas. According to nutritional diagnosis, the lack of Mg in all of nutrient elements was serious and universal phenomenon in experiment plot of Guangzhou, which only accounted for 52.8 of healthy *Pinus massoniana* lamb. The N/Mg value was far from it on relevant nutrition condition. The degree of base saturation was quite low, which was only 2.5% on layer of 0-10 cm, and 1.8% on layer of 20-30cm. The highest value of Mg/Al and Ca/Al was only 0.011 and 0.019, respectively. The acidity of soil was serious. After nutrition management, the content of Mg in conifer was increased generally, of all of treatments, the B treatment was the most effective, since the Mg content in conifer were increased by 37.1% in comparison with before, and the N/Mg value was much closer to the state of nutrition balance. The degree of base saturation of soil was increased, which was increased to 8.3% on the layer of 0-10 cm and to 7.4% on the layer of 20-30cm, respectively. The highest value of Mg/Al was 0.104. The tendency of acidity for soil was preliminary controlled, the chlorosis extent of conifer was obviously relieved as well.

Entomological Monitoring in Boreal Forests

Alexander S. Isaev
Centre for Ecological Problems and Productivity of Forests, Novocheremushkinskaya Str. 117418, 69 Moscow, Russia
Email: postmaster@spepl.msk.su

The consequences of mass outbreaks of destructive insects in the boreal forests are comparable with those observed after forest fires. Russia accounts annually for 2,200,00 ha of the pests`nidi. The outbreaks of such insect species as *Dendrolimus sibiricum, Ocneria monacha, Bupalus piniarius, Monomachus urussovi* are observed every year over the vast areas, doing great harm to virgin forests of Siberia and Far East. Therefore, we consider entomological monitoring as a significant constituent of forest health monitoring, ensuring, if done properly, conservation of the most important resource and the ecological functions of forests.

The monitoring program envisages the following main tasks to be solved: 1) study of forest health and insect populations under specific ecological conditions; 2) forecasts of the dynamics of insects`numbers and their impacts on the forest ecosystems; 3) timely detection of insects`outbreak nidi; 4) making optimal decisions on forest protection, with allowance for the resource and environment-forming functions of forests.

The monitoring information base shall be compiled by several ways. On the one hand, forest account and field data provide the ecological information on numerical and structural parameters of insect populations, their relations with feed-plants, and on the other hand, the insect habitats`database can be compiled. The predictors of forecasting the pest numbers are distributed into the four blocks allowing assessment of: a) site conditions; b) climatic and weather situation; c) forest conditions; d) basic parameters of interactions between insects, feed-plants, competitors and natural enemies at different stages of pest outbreaks.

The monitoring methodology is based upon modeling the gradation processes, extensive application of mathematical methods for substantiation of the optimal methods for sampling and processing of source ecological data, as well as for making practical decisions. The important constituent of entomological monitoring is the application of remote sensing methods based upon the data collected over many years with respect to the number s of main destructive insects, as well as upon a landscape-ecological approach for analysing spatial distribution of pests`nidi. The structure and distribution of pests`nidi, derived from satellite photographs, can be used as physiognomic indicators of the natural territorial complexes. This allows predicting the extent of potential forest damage as well as to select the key sites for the pest surveillance during the period between successive outbreaks.

The spatio-temporal dynamics of pests`outbreaks shall be studied by using a specialised GIS Protection of Forest against Destructive Insects. Depending on the target tasks of entomological forest monitoring, we distinguish between regional, subregional and local levels of data aggregation.

At a regional level that is based on singling out landscape zones, mountain and altitudinal belts, landscape provinces, the combined analysis of spatial data shall be carried out for detecting the insect species areals and the probable mass outbreak zones, as well as for the development of long-term forecasts and optimal forest-protection strategies. At a subregional level, the nidi`s structure and typology, forest resistance to pest attacks shall be studied, and the middle-term forecasts of the nidi`s development shall be made, within the bounds of separate landscape units. At a local level, the short-term forecasts of the nadir development shall be made, the models to describe spatio-temporal population dynamics shall be constructed, and the results of forest protection measures shall be evaluated.

To improve the forest -pathology interpretation methods, we need to have a wider set of survey facilities. In this connection, the combined utilisation of national security systems and civil satellite photographs of low and medium resolution (NOOA, LANDSAT, SPOT, and RESURS-F) has been very promising. Each type of survey makes it possible to derive a certain information concerning spatial distribution of pests`nidi, their location within a relief, extent of stands`damage, efficiency of forest protection, as well as other important parameters describing insect epidemics. The use of satellite photographs that reflect time series of long standing is of particular significance. Such photographs retaining the tracks of past outbreaks can be extremely useful when compiling a data base to describe forest damage cycles and nidi’s natural structure. The use of those data is very promising for a long-term forecasting of the spatial dynamics of insect populations, as well for the assessment of insect damage and insect influence on forests within a region. The developed system based on the research results over a long term of years, proved to be highly efficient when carrying out forest protection measures against *Dendrolimus sibiricus* Tschv. in 1994-96, covering more than 1 million ha of dark conifer forests in the Krasnoyarsk Territory.

Pathogenic Fungus Associated with the Mass Mortalities of Oak Trees in Japan.

Shinichiro Ito, T. Kubono & T.Yamada
Mie University, Department of Forest Resources, Faculty of Bioresources, Kamihama-cho 1515, 814-8507 Tsu, Mie, Japan
Tel: +81-59-231-9517, Email: ito-s@bio.mie-u.ac.jp

Keywords: mass mortality, *Platypus quercivorus*, *Raffaelea* sp., *Quercus* spp.

Recently, mass mortality of oak trees has been discovered in several coastal areas along the Japan Sea; more than fifty-thousand oak trees were killed in one year. No severe diseases like oak wilt disease in America, or pests, have previously been observed in oak trees in Japan. Many of the trunks of the dead trees had been attacked by ambrosia beetles, *Platypus quercivorus*, which belong to the *Platypodidae*, but the biotic and abiotic mortality factors have not yet been explained. Several similar studies that examined the cause of mass mortality in the southern beech, *Nothofagus cunninghamii*, in southern Australia, found that the death of the trees was strongly associated with attack by *P. surgbranosus* and infection by *Chalara australis*. Field studies, conducted in deciduous stands in several areas where more than twenty percent of the oak trees had died, observed the following characteristics of mortality. The first symptom, wilting, was observed in early July. The foliage of wilting trees turned red during the summer, and fifty percent of the trees then died between late August and the middle of September. Dead trees were infested by many *P. quercivorus*, but infested trees were not always killed. Identical dark brown discoloration was observed in the sapwood on the crosscut surfaces of the trunks of infested trees. Death was observed only in two species of oak trees, *Quercus serrate* and *Q. mongolica* var. *grosseserrata*. To clarify whether a pathogenic fungus was associated with the mass mortality, isolation and inoculation tests were conducted. *Phialophora, Cryphonectoria, Graphium,* and *Raffaelea sp*. were isolated from the discolored sapwood, necrotic inner bark, and gallery walls of dead and wilting trees. Of these, *Raffaelea* sp. was most frequently isolated from the discolored sapwood. *Phialophora, Fusarium,* and *Raffaelea* sp. were also isolated from body surfaces of larvae, pupae, and adult *P. quercivorus*, and *Raffaelea* sp. was isolated from the mycangia of females. Only *Raffaelea* sp. was isolated from both the trees and the insects. An inoculation test using the fungi that were frequently isolated indicated that only Raffaelea sp. could kill both *Q. serrata* and *Q. mongolica* var. *grosseserrata*. The results of the isolation and inoculation tests strongly suggest that *Raffaelea* sp. is associated with the mass mortality of oak trees in Japan and *that P. quercivorus* is the fungus vector. This is the first report of mass mortality of oak trees caused by *P. quercivorus* and *Raffaelea* fungus anywhere in the world.

Impact of Diseases in Nurseries, Plantations and Forests in Central India

Jamaluddin, N. S. K. Harsh
Tropical Forest Research Institute, Forest Pathology Division, Post Box # R.F.R.C, 482021 Jabalpur, India
Tel: 091-761-84746, FAX: 091-761-321759, Email: tfrilib@x400.nicgw.nic.in

Diseases are known to be the most destructive agents affecting the planting stock in forest nurseries and consequently the plantation yield thus affecting the forest productivity. However, the losses due to diseases are not so apparent in plantations and natural stand till partial or total death of trees occurs or the expected growth rate is not achieved. Pre- and post-emergence damping-off, wilt and root-rot diseases have been found quite common in forest nurseries of Madhya Pradesh in central India, in moist as well as dry climates, affecting most of the species being raised, causing severe losses to emergent crop which have been estimated up to 70% mortality. Progressive reduction in seed germination, seedling growth, biomass and survival has been estimated due to these root- diseases. Plantations are being intensively managed to increase productivity by reducing genetic variation, eliminating competing vegetation, maintaining optimum stand density and other silvicultural operations and thus exposed to risk of atack by diseases due to drastic change in the ecosystem. *Ganoderma lucidum* has been found to cause more than 50% mortality in an Acacia arboretum raised in a reforested site in Madhya Pradesh. Charcoal root-rot by *Macrophomina phaseolina* in tropical pines and some hardwood species and particulary in coastal areas of Orissa, has been observed as one of the major deterrents to the expected yield. Heart-rot damage in *Tectona grandis* (teak) and *Shorea robusta* (sal) has been assessed which affect 38-88% trees in the former and 58-77% trees in the latter species in natural stands, entailing a loss of about 11-12% in the wood volume, accounting for about 30 million rupees annually. Increased urbanization and industrialization is responsible for polluting of air and in turn causing stresses on trees growing in and around such areas. Air pollution from thermal power plant has been found to reduce the vigour of trees and to increase their susceptibility to root pathogens, canker fungi and insect pests.

Endophytic Fungi in the Needles of Austrian Pine with Particular Reference to *Cenangium ferruginosum* Fr.

Maja Jurc
University of Ljubljana, Department of Forestry and Renewable Forest Recources, Vecna pot 83, 1001 Ljubljana, Slovenia
Tel: +386 61 123 11 61, FAX: +386 61 271 169, Email: maja.jurc@gozdis.si

Research on endophytic fungi in needles of Austrian pine was conducted on two autochtonous and six alochtonous growing sites of Austrian pine in the period of three years. Contents of nutrients (N, P, K, Ca, Mg), sulphur (S) and lead (Pb) in the needles of sampled trees were analysed. Samples of 1-8 years old needles were taken from lower branches of 15-60 years old trees six times (in four months intervals: March, July, October). Suitable method for isolation of endophytic fungi was chosen and adapted. Altogether 99 fungal taxa were isolated and 56 fungal species were determined. Dominant species were: *Cyclaneusma niveum* (Pers.:Fr.) DiCosmo, Peredo & Minter (17,2%*), Cenangium ferruginosum* Fr. (15,4%), *Phialophora hoffmannii* (Beyma) Schol-Schwarz (7,8%), *Cyclaneusma minus* (Butin) DiCosmo, Peredo & Minter (5,2%), *Lophodermium conigenum* (Brunaud) Hilitz. (4,5%) and *Hormonema dematioides* Lagerberg & Melin (4,2%). The whole sample was infected 39% (2187 isolations from 5592 segments of 1864 needles). It was established that there exists specialisation of certain endophytes on the level of hosts genus (*Pinus*). There are differences in the growth of mycelia of five most frequent endophytes on different temperatures: 100 C, 200 C, 250 C, 300 C, 350 C, on different amounts of available water in growing media: aw1 = 0,98, aw2 = 0,96, aw3 = 0,94 and on acidified growing medium pH = 4,5. The occurrence of endophytes was different in trees growing on sites with different ecological conditions. There are no significant differences in number of isolations from trees from natural and artificial origin of stands and no differences regarding the age of trees. The species composition and the number of endophytes depend on the time of sampling, they are diminished in more polluted areas. Significant differences in species composition and in the number of isolated dominant endophyte species exist among isolations from the base, from the midst and from the top of the needles and with some fungal species between young and old needles. The content of ergosterol in buds and needles was determined (it was in the range from 0,006 up to 0,15 µg mg^{-1} d.w. of needles) and also in five most frequent endophytes (it was from 0,064 to 0,57 µg mg^{-1} d.w. of the fungi). Ergosterol content is only partially suitable measure for quantification of fungal endophytes in needles. It was established that stored seed, fresh seed and callus of Austrian pine do not contain endophytes. Fungus *C. ferruginosum* destroys the callus in double cultures.

Keywords: endophytic fungi, Austrian pine (*Pinus nigra* Arn.), biology of endophytes, ecology of endophytes, double cultures, latent infection, pathogenicity, mutualistic symbiosis

Chestnut canker - From Doom to Reflourishing of Sweet Chestnut in Slovenia

Dusan Jurc
Slovenian Forestry Institute, Vecna pot 2, 1000 Ljubljana, Slovenia
Tel: +386 61 123 13 43, FAX: +386 61 273 589, Email: dusan.jurc@gozdis.si

Chestnut blight (*Cryphonectria parasitica* /Murrill/Barr) was introduced to Slovenia in the year 1950. Up to the year 1960 the disease has spread over the whole range of sweet chestnut (*Castanea sativa* Mill.) which comprise nearly 25% of forest area (232.000 ha). All the quarantine measures to eradicate the disease were in vain and sweet chestnut was gradually disappearing from the forest.

In the beginning of eighties hypovirulent forms of chestnut blight were discovered also in Slovenia. They were frequent in western part of the country near the Italian border but in continental part of Slovenia they were not found. In the nineties the apparently hypovirulent forms of the disease gradually spread in varied frequency to the whole growing area of sweet chestnut.

The pathogenicity tests revealed that the virulence of isolates from apparently hypovirulent infections varied from avirulent to normal virulent forms of the disease. It seems that besides known viral inducer of hypovirulence the conditions of the environment and mostly the vigour of the host influence the expression of hypovirulence.

The hypovirulent infections appear mostly as superficial infections of bark in regions where it is present for a long time and as healing necroses of bark in areas where it has appeared recently. The frequency of virulent, typically hypovirulent and intermediate forms of chestnut blight differs among regions.

Temporal observations showed unexpected and unexplained fast dissemination of hypovirulent forms of the disease. Death of old sweet chestnut trees because of chestnut blight occur infrequently. It is confined to young trees, mostly sprout stems from stumps. The intensity of the disease diminished and with changed tending practices, with promoting and preserving high population of hypovirulent strains of chestnut blight fungus, the perspective of sweet chestnut is promising.

Forest as an Indicator of Regional Environmental Changes Lithuanian Case Studies

Loenardos Kairiukstis
Lithunian Forest Research Institute, State Scientific Programme ECOSLIT, Liepu 1, Girionys, 4312 Kaunas reg, Lithuania
Tel: 370-7-547775, FAX: 370-7-547446, Email: miskinst@mi.lt

Keywords: environment, pollution, biological indication, tree, human, animal.

Biological assessment of environmental changes in changing world is of paramount importance.

Over the last ten years multidisciplinary research on interacting components of regional system "Lithuania" (65.6 th. km^2, 2.02 mil.ha forests, 3.7 mil. population) and pollution load has been conducted. Increase (1960-1990) and a two-fold decrease (1991-1995) in the concentrations of different ingredients of pollutants in the air, water and soil has been assessed. Biological indication of these drastic pollution changes according to the physiological reaction of tree and its increment, according to the state-of-art of forests in the screen of regional monitoring (4x4 km), according to the mutagenic effect of pollution on animals and humans, their immunity systems, according to the spreading of malignant tumours and mortality of humans has been investigated. The investigation was carried out by 162 scientists of different specialities from 30 research institutes and universities united into state scientific Programme ECOSLIT.

It has been ascertained that cumulative effect of pollution (increase, decrease) influences negatively and positively the whole vital chain of the regional system, respectively: affects the state-of-art of forests (physiological stress of trees, defoliation, increment) immunogenetic changes in humans, cattle's, field voles, the spreading of cancer diseases and life duration of humans. It has been proved that trees are a susceptible bioindicator of pollution changes. In accordance with the state of art of trees it is possible to determine the chronology of environmental changes and its geographical location. Changes in biopotential of tree, electric conductivity in growing tissue, K+ion transport via cellular membranes, appears at once (hour, day, month the some year) following the environmental change. The concentration of proline in needles increase in 1-2 year while changes in tree damage and its effect on crown defoliation transformed through internal structures of an individual appears 3-4 years later. Also changes in mortality of human population and spreading of viral infections in animals noticeably appears 3-5 years later following the environmental changes. Changes in the immunity systems of humans and cattle organisms depending on the reaction investigated slightly differs, but appears depending on age group within 1-4 years. Changes in the anomaly of the heads of spermatozoa and the mortality of the embrions of grey voles (*Microtus arvalis*) appear within 2-3 years. Economic losses or profit for separate components of regional system is discernible after 4-5 years after the environmental changes and in Lithuanian case comprise about ±10% of GDP.

In conclusion it should be stressed that significant abatement of (air, soil and water) chemical pollution in the regional system activates reparation process with certain delay in the whole chain of life:

- K^+-ion transport via cellular membranes, proline concentration in the needles and crown defoliation of trees in forest diminish;

- Chromosome aberration frequency in humans and animals becomes lower, the human and animal immunity systems restore noticeably, the spreading of viral infections and diseases of cattle dicrease.

Is Resistant Variety of Japanese Cedar to *Semanotus japonicus* (*Coleoptera: Cerambycidae*) Also Resistant to *Epinotia granitalis* (*Lepidoptera: Tortricidae*)?

Kazutaka Kato
National Forest Tree Breeding Center, Okayama 709-4335 Shoo, Japan
FAX: 0868-38-5139, Email: katoka@ap.cc.affrc.go.jp

It is well known that not only sugi bark borer, *Semanotus japonicus* (Coleoptera: Cerambycidae) but cypress bark moth, *Epinotia granitalis* (Lepidoptera: Tortricidae) are the most important wood-boring pests against Japanese cedar, *Cryptomeria japonica* (L. f.) D. Don, and Japanese cypress, *Chamaecyparis obtusa* (Sieb. et Zucc.) in Japan. There have been several *C. japonica* resistant varieties against *S. japonicus*. To detect whether those resistant varieties were also resistant to *E. granitalis*, firstly I studied boring period and boring system of the 2 pests in the laboratory or in the field. Boring period of *E. granitalis* was early April to mid-May, whereas that *of S. japonicus* was late April to October, suggesting that the boring period was earlier and shorter on *E.granitalis* than on *S. japonicus*. At the beginning of boring in the bark, larval body weight was larger on *E. granitalis* than on *S. japonicus*, whereas, at the time just before pupation, the larval body weight was much larger on *S. japonicus* than on *E. granitalis*, suggesting that, while boring in the bark, *S. japonicus* larvae ingested more nutrition than *E. granitalis*. *E. granitalis* selected boring system as repeating the boring in the bark and escaping from the bark for several times to the pupal stage, whereas *S. japonicus* selected the boring system as boring in the bark all the time until pupation.

Secondly, I released *E. granitalis* larvae into trunks of *C. japonica* trees that were regarded to be highly resistant to *S. japonicus*. On the contrary to the prediction, most of *E. granitalis* larvae grew to adult stage, suggesting that even though resin flow from inner bark which was regarded to be most important to protect the attack of *S. japonicus* larvae was available for protecting the attack of *S. japonicus*, the resin flow could not protect the attack *of E. japonicus*. The reason was assumed by the difference of boring period boring system between the 2 pests: *E. granitalis* larvae bored before metabolism of host trees become active, the boring period of *E. granitalis* was shorter because of small ingestion of nutrition and *E. granitalis* larvae could escape from wood if the resin flow deterred the course of boring.

Effect on Cement Dust on Physiological Attributes of Some Selected Tree Species

Parvinder S. Kaushal
Parmar University of Horticulture and Forestry, Regional Center, NAEB, 173 230 HP Nauni-Solan, India
Tel: +91 1792 52487(O), FAX: +91-1792 52242, Email: pkaushal@yspuhf.hp.nic.in

Interest in air pollutant injury to tree species of economic importance is increasing in developing countries. Cement dust is an important pollutant witch affect vegetation in the vicinity of cement factories. The present study was conducted in the adjoining areas of one of the cement factory, The Gagal Cement Works, Himachal Pradesh . Fifteen econo,ically important tree species were selected for the study. The species were *Toona, Dalbergia, Cassia, Eucalyptus, Popular, Bombax, Mangifera, Citrus, Litchi, Psidium, Rosa, Bpugainvillea, Acacia, Pinus* and *Ficus*. Cement dust was found to increase the leaf temperature from 31,3øC (control) to 35.2øC. The effect was more prominent in case of *Citrus, Dalbergia* and *Bomax* species.

The rate of photosynthesis was influenced significantly by the cement dust. The average rate of photosynthesis under control condition was 17.5 mol m^{-2} sec-1. The average rate observed in the vicinity of the factory was 6.5 mol m^{-2} sec-1. The photosynthesis was affected more in *Mangifera, Citrus, Toona* and *Cassia*. The rates of transpiration and stomatal conductance were drastically influenced by the cement dust and impact was observed more prominently in case of *Citrus, Litchi, Dalbergia, Cassia* and Poplar. The average rate of tranpiration and stomatal conductance observed under the control conditions were 18.6 mol m^{-2} sec-1, respectively. The same when observed in the vicinity of the factory were 6.7 mol m^{-2} sec-1 and 0.48 mol m^{-2} sec-1, respectively. *Pinu***s** was observes to be the last affected tree species by the cement dust.

The Frosty Mildew in *Quercus acutissima*: A Serious Foliage Disease in Japan

Mikiko Kawai, Yasuo Suto, and Daisuke Ougi
Shimane Prefecture Forest Research Center, Shinji-cho, Yatsuka-gun, 699-0401 Shimane, Japan
FAX: +81-852-66-0302, Email: ringisen@joho-shimane.or.jp

Quercus acutissima bed logs are most valuable for cultivation of the shiitake mushroom and the tree has been grown in nurseries and planted in forest stands in several districts of Japan, although in small amounts. Since 1986, the occurrence of a foliage disease has been a problem in the southwestern districts. Suto (1993) described it as a new disease named “Frosty mildew”. In the present study, the damage, the symptoms and signs, and the causal fungus of the disease, pathogenicity of the fungus, and chemical control of the disease are reported.

In Shimane Prefecture, the disease occurred in several nurseries and young planted stands of *Q. acutissima* up to 15-year-old. The infection of the disease started from a limited part and expanded to a whole nursery or stand. In some epidemic areas, 50% or more leaves of the trees were infected and shed. In 1993, it was unusually cold and rainy in July and August, and in one stand almost all the planted trees were heavily infected. The disease occurred repeatedly in the stand infested in the previous year.

From early September, brown to red-brown spots appear on the leaves and rapidly enlarge circularly or irregularly, often spreading to the leaf margins and becoming confluent. The infected leaves are prematurely shed. Occasionally the tips of the young shoots are infected with the fungus, and become brown to die. Conical white to yellowish tufts, propagules of the causal fungus, are scattered on the adaxial surface of the infected leaves and on the shoots, being visible with the naked eye. Small black discoids, sclerotia of the fungus, are produced on the fallen leaves.

The propagule is multicellular, conic, white to yellowish, 480-830 µm high, 200-630 µm wide, consisting of a detachable subglobose stroma-like base and 1-2 conical bundles of hyphal appendages. The propagules are dislodged at a slight touch and disseminated. Sclerotia are orbicular, black, thin, 3-4mm in diameter. The fungus could not be identified because true conidia and the ascogenous stage were not observed on the sclerotia.

Mycelial agar disc and single propagule of the fungus were inoculated onto the leaves in June and October. Of several species of *Quercus, Q. acitissima* was infected most heavily, and *Q. dentata* and *Q. serrata* slightly. The inoculation on the abaxial leaf surface caused the symptoms of the disease, but the inoculation on the adaxial surface did not. The propagule of this fungus is considered to be an infection source and to infect the leaves by penetrating through stomata. In the screening test of 11 fungicides *in vitro*, benomyl and thiophanate-methyl completely suppressed mycelial growth of the causal fungus at 0.1 ppm and 1 ppm, respectively. The propagule of the fungus was inoculated on the leaves onto which the test chemicals had been were applied. Benomyl, thiophanate-methyl, and chlorothalonil prevented the symptom appearance even when the fungus was inoculated three weeks after the chemical application. These fungicides, therefore, are considered to be useful for the practical control of the disease in the field.

Les insectes et nos Forêts de chênes

Mohamed Ghazali Khous
University USTHB, Institut of Natural Sciences,
Laboratory of Entomology, BP 32, 16 111 El Alia,
Algiers, Algeria
Email: mkhous@hotmail.com

Le présent travail tente d'hiérarchiser les agressions des insectes sur les peuplements de chênes en Algérie et de relativiser ces derniers eu égard des autres contraintes que subissent ces écosystèmes. Les résultats des recherches entreprises par une équipe de recherche sur l'ensemble du térritoire national montreront l'importance des problèmes sylvicoles et écologiques et les insectes importants au plan économique qui s'attaquent à ces peuplements feuillus.

This present work of synthesis recapitulates realized observations these last years in the oak forests of height, by scientists and engineers forestiers. This attempt tempts of the impact of insects on the future of populatings oaks considered problems sylcicoles and those bound (connected) to the bad exploitation of the forested products. This work is the outcome of numerous years of extensive searches and observations on ground within the framework of the diagnostic of the pn‚nomŠne of decline the oak forests in Algeria very important these last years. Finally, we give imperative measures to be set to protect the natural forests of oaks of height.

Are Exotic Plantation Tree Species More Susceptible to Termite Attack than Native Species?

Laucence G. Kirton, Valerie K. Brown
Forest Research Institute Malaysia, Kepong, 52109
Kuala Lumpur, Malaysia
Tel: +60-(0)3-6302118, FAX: 60-(0)3-6365531, Email: laurence@frim.gov.my

Keywords: Isoptera, termites, *Coptotermes curvignathus*, hosts, attack, plantations, susceptibility, resistance, exotics

Termite attack is a problem that has had a significant impact on plantation forestry in Southeast Asia. The pest responsible for the damage is Coptotermes curvignathus Holmgren, a termite species capable of killing living trees within a short period of time. It has often been said that exotic plantation tree species are more susceptible to attack *by C. curvignathus* than native species. In the early years of the planting of rubber (*Hevea Brasiliensis*) in Peninsular Malaysia, it was suggested that the reason for the abundance of *C. curvignathus* in plantations was that the tree species was not naturally selected to resist attack. Subsequent authors commented that the termite tends to affect exotic tree species more than native species, citing rubber and conifers as examples of susceptible exotics. Indeed, the severity of *C. curvignathus*, as a pest in plantation forestry in the peninsula, was felt most greatly with the planting of exotic conifer species, such as *Pinus caribaea* and *Araucaria cunninghamii*. The belief that exotic trees are more susceptible to attack has been reiterated in reviews on termite feeding relationships and the importance of *C. curvignathus* in forestry. It has, additionally, been suggested that, besides possible acquisition of resistance by native plants, the termite may be unable to recognise toxic foreign trees.

The evidence used to suggest that exotic tree species are more susceptible to attack is somewhat circumstantial and there is evidence of equal, if not greater, susceptibility of some native tree species. In Papua New Guinea, a closely related termite species, Coptotermes elisae, occurs in natural conifer forests of native *Araucaria hunsteinii* and is known to prefer this species over the exotic Australian *A. cunninghamii* grown in plantations. There are also a number of introduced tree species grown on a plantation scale in parts of Southeast Asia, which have not been reported as being particularly susceptible to attack by *C. curvignathus*, among them *Gmelina arborea* (Verbenaceae) and *Acacia mangium* (Leguminosae). Studies showed that the termite was present on up to about 5% of 4 year-old

Acacia mangium trees, but that tree mortality was relatively low. Attack was usually confined to the heartwood, which was accessed through pruning wounds, leaf abscission scars or wood damaged by other insects.

Many native tree species in Malaysia appear to be more susceptible to attack than *Acacia mangium*. In the present study, all trees in a 50ha plot (1.0 x 0.5 km) of natural dipterocarp forest were examined for symptoms of attack by *C. curvignathus*. The termite was found to be capable of killing a large number of species of native trees, but also had clear preferences. Tree species that were susceptible to attack were *Canarium* spp. and *Dacryodes* spp. (*Burseraceae*), *Buchanania sessifolia* (*Anacardiaceae*) and *Koompassia malaccensis* (*Leguminosae*). Among the very abundant species that were never attacked was *Gironniera parvifolia* (*Ulmaceae*). The susceptibility of some native tree species to termite attack is also apparent from a number of early reports, notably *Koompassia malaccensis* (*Leguminosae*), *Shorea spp*. (*Dipterocarpaceae*) and *Campnosperma auriculata* (*Anacardiaceae*). These hosts are common in peat soils and, thus, it has been suggested that the high incidence of *C. curvignathus* on peat soils is due to the abundance of suitable hosts rather than soil characteristics. Other native species said to be commonly attacked are *Styrax benzoin* (*Styracaceae*), *Myristica* sp. (*Myristicaceae*) and *Macaranga* (*Euphorbiaceae*). We, therefore, conclude that native tree species can be as susceptible to attack as exotic species, and that the affinity of the termite for species such as conifers and rubber bears no relation to the fact that they are exotic.

Bark and Wood Boring Insect Pests of Scots Pine in Czechia

Milos Knizek, Petr Zahradnik
Forestry and Game Management Research Institute
Jiloviste-Strnady, CZ-156 04 Praha 5-Zbraslav, Czech Republic
Email: knizek@vulhm.cz

Long history of human intervention has resulted in the following composition of forest trees in Czechia: 54% spruce, 18% pine, and the rest is composed mainly of oak and beech. Even though the pine stands play a minor role in our forestry, in certain areas they represent the dominant part of forest stands. Drastic change in ecological structure of forest ecosystems and weather conditions has favored the development of forest insect pests which play limiting roles in the development of forest stands. During the first half of this decade, the abundance of pine insect pests increased rapidly due to very warm and dry summers in several consecutive years. In combination with neglect of forest protection in pine stands and inadequate control methods, we recorded considerable damage to pine forests. From 1993 to 1996 224 thousands m^3 of infested trees were cut down, which resulted in high economic losses for our forest industry. Because of the necessity to solve these problems our research program in the department of forest protection in FGMRI was developed. We focused our activity on the main wood and bark boring insect pests of pine, especially *Ips acuminatus*. Our project combined basic research on the biology as well as developing methods for forest protection. As a result of our research we prepared methods for the control of *Ips acuminatus* which is established on the basis of using trap trees baited with pheromone dispensers. The pheromone dipsenser containes a mixture of racemic ipsdienol, ipsenol and S-cis-verbenol. For greater effeciency in the pheromone traps it is better to substitute racemic ipsdienol with +ipsdienol. Prescriptions of control strategies and monitoring systems were published in leaflets for single pests. Publishing of the final results as a whole is being prepared. Results of our research were introduced in the field and are now commonly used.

Tree as Indicator for Determination of Alteration in Environmental Conditions (by Use of Enzymes, Cations and Anions Studies)

Iranian remote sensing scientists in 1998, after examining 1267 satellite pictures estabilished the widespread distribution of smoke and soot over Iran and penetration of oil slicks into the coastal habitats of the Northen coasts of Persian Gulf.

As such, a study was designed to trace the pollution strees in Mangroves and other tree species of Iran in the impacted regions. In order to gather scientific evidence for damaged inflicted on natural resources of Iran, several different approaches have been taken. For example, penetration of smoke and soot and oil slicks has been validated by remote sensing technology and mathematical modeling approahes; deposition and distribution of contamination has bee confirmed using field sampling and factual obeservation; degree and kind of damage has been determined using reliable scientific methods.

This research was done seven years after environmental pollution that casued by Persian Gulf War. Sampling was done from annual growth rings (1990-1998) of *Ziziphus spina-christi* and *Avicenia officinalis* in a large region of Iran (south and southwest). Annual growth rings of 1990 and 1998 were selected as control for before and after pollution, respectively. Tree were selected from GuatrBadar-e-Abbas, Boushehr and Shoushtar. Guatr had the most distances from pollution center but Shoushtar and Boushehr were in the center of pollution. Enzymatic and isoenzymatic alterations (peroxidase, estrase and amylase), cations contents (K, Na, Ca, and Pb) and sulfur contents were detemined.

Quantitative and qualitative alteration of peroxidase, amylase and estrase were determined. All trees (from any location) showed reaction aginst pollution, but level of reaction was different that depends on characters of trees (species and genotype) and ecological parameters. Results indicated all of trees reacted against air pollution and acid rain. Dependend on physiological characters on species of trees, reactions are different (enzymatic patters as well as enzyme activities). Alterations of amylase was more than perocidase and estrase. Probably stress had the most effect on sugar compound. The alterations of enzymatic patterns are stable or unstable. Peroxidase enzymes activity is affected regularly by ecological parameters (for example altitude and latitude) too.

Cationic (K, Na, Ca and Pb) and anionic (sulfur) alterations were shown in all of trees by environmental pollution as stress. These alterations are seen with differing ecological parameters (altitude and latitude), too. Quantitative and qualitative studies of enzymes were done by spectrophotometers and gel eletrophresis methods. Sodium and potassium were mesaured by flamephotometer. Calcium and sulfur were determined by titration and turbidometery methods.

Induced Resistance of Pine Trees Against Pine Wilt Disease by Avirulent Nematode Inoculation

Hajime Kosaka, Aikawa, T., Ogura, N., Tabata, K. and Kiyohara, T.
Forestry and Forest Products Research Institute, Nematology Laboratory, 1 Matsunosato, Kukizaki, 305-8687 Ibaraki, Japan
Tel: +81-298-73-3211 ext. 407, FAX: 81-298-73-1543, Email: hkosaka@ffpri.affrc.go.jp

Keywords: pine wood nematode, Japanese pine sawyer, disease control

Pine wilt disease caused by the pine wood nematode, *Bursaphelenchus xylophilus*, is a most serious forest disease in Japan. The disease has also been spreading in some areas of Eastern Asia in a last decade. Recently, environmentally friendly control procedures against the disease have been required besides the use of pesticides and nematicides. In such situation, it is known that prior inoculation with an avirulent isolate of the pine wood nematodes induced the resistance of young pine trees in the nursery against the disease. Delayed symptom development of the disease was also observed in mature pine trees on a country side forest by the prior inoculation with avirulent nematodes. These studies, however, needed post inoculation of the virulent nematodes as challengers because the pine wilt disease did not occurred naturally in the research fields. The pine wood nematodes are transmitted to the healthy pine trees by the Japanese pine sawyer, *Monochamus alternatus,* in nature. Further studies have been needed under natural condition.

We report here that the result of the avirulent nematode inoculation to the pine trees on a forest where the pine wilt disease is an epidemic naturally. The Japanese red pine, *Pinus densiflora*, and the Japanese black pine, *P. thunbergii*, on a forest stand at Chiyoda experimental station of Forestry and Forest Product Research Institute were inoculated with an avirulent strain of the nematode, OKD-1. 20,000 nematodes were inoculated to the pine trees on 27 May 1998 as treatment, but nothing was inoculated to the trees as control. Survival rates of the pine trees, the marks of vector insects on some dead trees and nematodes isolated from the trees were observed at may 1999. 94% of *P. densiflora* was alive in the treatment but 88% in the control. 92% of *P. thunbergii* was alive in the treatment, but 85% in the control. Larval frass of the Japanese pine sawyer and *B. xylophilus* were observed from some dead trees in the control. This observation indicated the pine wilt disease occurred naturally in this forest. Percentages of living trees were higher in the treatment than in the control. This result suggests that inoculation of avirulent nematodes prevent rapid spread of the disease in the natural condition. Furthermore, these differences in the survival rates of the pine trees between the treatment and the control might be larger after the treatments over several years though the differences were not large values in this experiment. We still consider that the inoculation of the avirulent nematodes should be one of the possible control procedure of the pine wilt disease and continue the studies.

Heart-rot in Japanese cypress - Damage of Japanese Cypress Forests Caused by Butt-rot and Stand Conditions at the Foot of Mt. Unzen -

Takashi Kubayashi
Nagasaki Agric. & Forestry Exp. Stn, 795-14, Masaki-oho, Isahaya-shi, 884-0043 Nagasaki, Japan
FAX: +81-957-25-1981, Email: kubayash@nagasaki-noc.ne.jp

Keywords: butt-rot, Japanese cypress, volume lose, *Tinctoporellus epimiltinus*, stand condition

The forests of Japanese cypress (*Chamaecyparis obtusa* (Sieb.et Zucc.) Endl.) at the foot of Mt.Unzen were investigated for the damage caused by butt-rot. The diameter of butt-rot at the cut end (D), and the heights (H) and volume (V) of butt-rot were measured in 118, 97 and 84 trees suffering from butt-rot in stands 25, 35 and 50 years after planting, respectively, and their relationship determined. In the 25-year-old stand, H = 15.095+7.2076xD, and V = -367.41+36.587xbasal butt-rot area at the cut end. In the 35-year-old forest; H = 17.131+8.5007xD, and V = -3004.70+ 71.888xbasal butt-rot area at the cut end. In the 50-year-old forest; H = 62.749+9.352xD, and V = -5188.70+112.93xbasal butt-rot area at the cut end. The volume of butt-rot in the 25-, 35- and 50-year-old forests was 0.1438, 1.006, 1.433m3 per 100 trees, respectively. The older tree, the higher was the butt-rot and the larger was the volume of the butt-rot.

In the 35-year-old stand, the influence of butt-rot on yield volume was investigated. The volume of rotten part was 0.9169m3, 6.95% of the expected yield volume. The volume of logs that were cut off and left in the forests was 4.1569m3. The loss was about 4.5 times larger than the rotten part in volume. The lost volume was 31.5% of the expected yield volume.

In the 25-year-old stand, the pathogen was isolated from 64 trees, 52% of trees suffered from butt-rot. Among the isolated fungi, *Tinctoporellus epimiltinus* (Berk. et Br.) Ryv., which is a tropical or subtropical fungus known as the pathogenic fungi of butt-rot, accounted for 15.6%. Some unidentified Basidiomycetes fungi were also isolated.

The age of the stand and gradient of the land seem to influence the degree of the damage of Japanese cypress trees caused by butt-rot. The soil condition also seemed to affect the damage. This damage is not a problem for non-commercial thinning, but is a serious problem for commercial thinning and final cutting because of loss of commercial value. We should take into consideration this damage when we operate on long-term rotations.

The Role of Bark Beetle Species (Col., Scolytidae) in the Hungarian Coniferous Forests

F. Lakatos
West Hungarian University, Institute of Forest- and Wood Protection, PO Box 132, H-9400 Sopron, Hungary
FAX: +36-99-311103, Email: flakatos@efe.hu

Hungary is a small Central-European country with a forest coverage of 18.2% (1640000 ha). Besides of the different broad leave tree species (*Quercus, Fagus, Robinia, Populus*), 15.1% of the Hungarian forest stands consist of coniferous tree stands. Aside from a few natural *Pinus sylvestris* and *Taxus baccata* stands most of those are close-to-nature to man created monoculure. The three most important coniferous species are *Pinus sylvestris* (9.1%1, 48243 ha), *Pinus nigra* (4.2%, 68666 ha) and *Picea abies* (1.5%, 24336 ha). The pine stands concentrate to the south-west and central part, till the spruce stands to the western Hungary. Both genus are either economically (wood production) or ecologically (soil and landscape protection) important.

In the last ten years the mass outbreak of bark beetles has been caused enormous economic losses in all parts of Hungary. The attacked area varied from 3000 to 7000 ha/year and altogether 33000 ha was attacked, which plead nearly 14% of the total coniferous area.

In our long term study through several field investigations and labour experiments we assessed the health conditions of the Hungarian coniferous stands and the reasons of the mass outbreak, started in the late 80's. The use of felled trap trees allowed us to define the species abundance. On *P. sylvestris*

34 bark beetle species live, but only a couple of them cause economic losses: *Tomicus piniperda*, *T. minor, Ips sexdendatus* and some *Orthotomicus* sp. On *P. nigra* there were 22 species detected, but no one could be characterised as economically important. On *P. abies* are 28 scolytids living, and the most important species are *Ips typographus, Pityogenes chalcographus, Polygraphus poligraphus* and in some special cases *Dendroctonus micans*.

The spatial analysis of the felled timber after bark beetle infestation and the presence of bark beetle species allowed us to make the right adjudication about its real economic importance. The results were converted into a GIS based map as well.

Effect of VAM Fungi on Growth and Root-Knot Resistance of Taiwan *Paulownia*

Ming-Jen Lee, Kuen-Yih Ho
National Chiayi Institute of Technology, Department of Forestry, Chiayi, China-Taipeh
Tel: +886-5-271-7200, FAX: 886 5 271 7016, Email: mjlee@rice.cit.edu.tw; mjlee@mail.ncyu.edu.tw

Keywords: Taiwan *Paulownia*; root-knot nematode; VAM fungi

Taiwan paulownia (*Paulownia x taiwaniana*), a natural hybrid of *P. fortunei* and *P. kawakamii*, which produces high quality timber, is an important fast-growing tree species for artificial plantations in Taiwan. However, it is susceptible to root-knot nematodes (*Meloidogyne incognita*), which infest roots of Taiwan paulownias, and cause severe damages to root tissues. Tree growth is seriously retarded. Subsequently, trees are more susceptible to other pathogen infections, and root rot or even death may occur. Thus, effective growth promotion of trees and biocontrol of root-knot nematodes are of great importance in sustainable management of Taiwan *Paulownia*.

In this study, VAM fungi, *Glomus etunicatum*, *Gl. fasciculatum*, and *Gl. mosseae*, were inoculated onto roots of 5-month-old Taiwan *paulownia* seedlings with 96±5 spores per seedling. One month later, Each seedling was inoculated with 50±6 root-knot nematodes. Then, seedlings were maintained in a growth chamber with photo-intensity of 340-400 umol·m^{-2}·s^{-1}, photoperiod of 12-hour light and 12-hour dark, and temperature of day 25±1 and night 20±1 for 2 months. The results revealed that the average height of seedlings inoculated with VAM fungi, VAM fungi + root-knot nematodes, root-knot nematodes, and control were 42.6 cm, 36.1 cm, 22.7 cm, and 29.5 respectively. The average number of root knot of seedlings inoculated with VAM fungi, VAM fungi + root-knot nematodes, root-knot nematodes, and control were 0, 82, 315, and 0 respectively. The average endomycorrhiza formation rates of seedlings inoculated with VAM fungi, VAM fungi + root-knot nematodes, root-knot nematodes, and control were 43.9%, 42.5%, 0, and 0. Results of seedling nutrient analysis with inductively coupled plasma atomic emission spectrometer showed that content of phosphorus and potassium was the highest in seedlings inoculated with VAM fungi among all treatments.

The Monitoring of Forest Condition in Finland

Martti Lindgren, Raitio, H.
The Finnish Forest Research Institute
Tel: +358 9 857051, FAX: +358 9 85705569, e-mail:,
Email: martti.lindgren@metla.fi

Keywords: forest condition, monitoring

Since 1985, Finland has been participating in the International Co-operative Programme on the Assessment and Monitoring of Air Pollution Effects on Forests (ICP Forests), which was established by the United Nations Economic Commission for Europe under its Convention on Long-range Transboundary Air Pollution. In 1986 the European Union adopted the Scheme on the Protection of Forest against the Atmospheric Pollution.

The Finnish Forest Research Institute (Metla) has been responsible for the monitoring of forest condition in Finland since 1986, carrying out an annual large-scale survey of the crown condition on a network comprising 460 permanent sample plots (Level I) using internationally harmonised methods. A survey of needle chemistry was started on the same plots in 1987, and a soil survey carried out during 1985-89 (supplemented in 1995).

The Pan-European Programme for Intensive and Continuous Monitoring of Forest Ecosystems (Level II) was initiated in 1995 in order to gain a better understanding of the effects of air pollution and other stress factors on forests. By the end of 1997, 17 Scots pine (*Pinus sylvestris*) and 14 Norway spruce (*Picea abies*) sample plots had been established for intensive monitoring purposes in different parts of Finland.

The forests in Finland are less defoliated than those in most of the other European countries. In the first years of the monitoring programme, during 1986 to 1989, defoliation increased in all tree species. Since then the tree crowns have recovered. However, a slight increase in the defoliation of broadleaves in 1992-1993 and in pine in 1993 was observed. No essential changes have been

observed in the defoliation level of any tree species in recent years. In 1999 the average degree of defoliation on Scots pine (*Pinus sylvestris*) was 9%, on Norway spruce (*Picea abies*) 18%, and on broad-leaved tree species (mainly *Betula* spp.) 11%. High stand age and unfavourable climatic and weather conditions greatly affect defoliation in Finland. No clear connections have been found between air pollution and tree crown condition at the national level.

The causal relationships between forest condition and environmental factors have been studied since 1995 on the Level II plots. Defoliation on the Level II plots was slightly higher than that on the Level I plots, apparently to be due to differences in the stand structure. The stands were characterised by a lack of nitrogen and low phosphorus concentrations, and potassium deficiencies were apparent on peatlands.

There were clear relationships between the concentrations of many nutrients in the needles and the organic layer of the soil. The strong South-North climatic gradient in Finland appears to be main reason for the S-N gradients in the total nitrogen and sulphur concentrations and C/N ratio in the organic layer. There is also a strongly decreasing S-N gradient in the deposition of nitrogen and sulphur compounds, and an increasing gradient in the average pH of bulk precipitation. It is very difficult to separate, with any degree of certainty, the effects of deposition on the soil chemical status from those attributable to climatic conditions. However, the strong correlation between the geographical location of the plots and the deposition and soil parameters indicate that both the climatic conditions and deposition should be taken into account when evaluating the chemical properties of forest soil.

Fifteen Years of Monitoring Forest Condition in Europe - Scientific and Political Implications

Martin Lorenz
Federal Research Centre for Forestry and Forest Products, Programme Coordinating Centre of ICP Forests, Leuschnerstr. 91, D-21031 Hamburg, Germany
Tel: +49-40-73962-119, FAX: +49-40-73962-480,
Email: lorenz@aixh0101.holz.uni-hamburg.de

Keywords: Europe; Monitoring; Forest condition; ICP Forests; Air pollution

For 15 years, forest condition in Europe has been systematically and continuously monitored by the International Co-operative Programme on Assessment and Monitoring of Air Pollution Effects on Forests (ICP Forests) of the United Nations Economic Commission for Europe (UN/ECE) and under the Scheme on the Protection of Forests against Atmospheric Pollution of the European Union (EU). Using harmonized methods laid down in a manual, 34 European countries have been assessing crown condition and to a great extent participated in soil and foliage surveys on a large-scale grid comprising about 5 700 sample plots. On 774 per-manent observation plots, inten-sive monitoring is performed, comprising assessments of crown condition, foliar condition, soil condition and soil solution chemistry, tree growth, ground vegetation, air quality, atmospheric depositions and meteorological conditions.

Results show that forest decline on the large scale developed far less dramatically than feared in the early 1980s. However, a general deterioration of crown condition is shown for the most frequent coniferous and broadleaved tree species, which can hardly be explained by natural stressors alone. Defoliation is particularly evident in those areas of central Europe where air pollution is highest. A recent recuperation of *Pinus sylvestris* in some of those main damage areas has been attributed to favourable weather conditions and improved air quality. There are indications for a spatial coincidence of air pollution, soil acidification, nutritional imbal-ances and defoliation of trees. On the large scale, however, these relationships are rather weak, and drought, insects and fungi are thought to be the primary factors influencing the temporal and spatial variation of crown condition. Air pollution is con-sidered to act as a pre-disposing, accompanying and locally triggering factor. More specific large-scale results are expected from ongoing integrative evaluations of crown, soil and foliage data, as well as from the planned upscaling of processes identified at the intensive monitoring site.

First results of the intensive monitoring indicate that nitrogen depositions are twice as high as sulphur deposi-tions, with nitrogen depositions dominating in western Europe and sulphur depositions dominating in central and eastern Europe. On 45% of the plots, nitrogen depositions exceed a critical level of 1000 mol_c/ha/yr, beyond which nitrogen leaching and an adverse impact on ground vegetation may occur. On 15% of the plots, acid depo-sitions (sulphur and nitrogen compounds) above 1500-3000 mol_c/ha/yr were found, which are thought to cause nutrient depletion and increased aluminium concentrations in the soil. Critical levels for nitrate in the subsoil threatening the filtering function for water resources are exceeded on 18% of the plots.

Impacts of Insect Outbreaks on Forest Sustainability: Spruce Budworm Decision Support System Use in Canada

David MacLean
Canadian Forest Service, Atlantic Forestry Centre, Post Box # 4000, NB E3B 5P7 Fredericton, New Brunswick, Canada
Tel: 506-452-3580, FAX: 506-452-3525, Email: dmaclean@fcmr.forestry.ca

Spruce budworm (*Choristoneura fumiferana* Clem.) outbreaks are natural disturbances that cause heavy spruce (*Picea* sp.) and balsam fir (*Abies balsamea* (L.) Mill.) mortality in eastern Canada and thereby result in large uncertainty in forest structure and productivity. These outbreaks are a natural component of forest succession, but must be taken into account in forest management planning, if plans are to be accurate.

Managers need tools to predict outbreak occurrence and effects on forest development, to ensure that expected timber supply/stand types will be present at the expected time of harvest/other usage, and to utilize silviculture and management planning to reduce the severity of future outbreaks. The Spruce Budworm Decision Support System (SBWDSS) was developed by the Canadian Forest Service from 1992-95. The SBWDSS links prediction and interpretation models to the ARC/INFO GIS, under an ArcView graphical user interface. It assists forest managers to predict budworm outbreak effects on forest structure and productivity, forecast forest growing stock and sustainable harvest levels, optimize protection (biological insecticide use) programs, and use silviculture and harvest scheduling to restructure forests to reduce future damage.

From 1996-99, the DSS was operationally implemented, on a cost-shared basis with industry and the provincial government, on all 8 million ha of forest in New Brunswick, Canada; it is also being implemented for test landbases in Alberta, Ontario, and Quebec. The SBWDSS models marginal timber supply benefits (m^3/ha) and the forest structure consequences of alternative management actions and facilitates incorporation of effects of insect damage into forest management planning. A defoliation-based stand growth model (STAMAN) and a timber supply model (Woodstock or FORMAN+1) are used to forecast forest development with and without defoliation. Volume loss (m^3/ha) is then calculated for each stand based on both direct (stand-level) and indirect (harvest queue disruption) marginal timber supply impacts associated with applying protection. The SBWDSS permits evaluation of cost/benefits and consequences of management, optimizes pesticide use (if desired), and improves visualization of the consequences of pest outbreaks and management strategies on forest performance indicators.

Strategic planning analyses evaluating the consequences of budworm outbreak occurrence, protection policy, and of protection exceeding the target foliage retention level of 60% or of part of the landbase not being protected have been conducted. Analyses for a 532,000 ha landbase in New Brunswick indicated that "normal" and "severe" budworm outbreak scenarios, defined based on future defoliation, would result in total losses of 4.7 million and 13.3 million m^3 of spruce-fir timber. Simulations indicated that sustainable harvest levels 20-30 years in the future were very sensitive to reductions in yield caused by defoliation. If insecticides were applied but defoliation exceeded the foliage protection target by 20% on 20%, 40%, or 60% of the landbase, harvest level reductions in years 15-20 of 370,000, 735,000, and 1.1 million m^3 would be necessary.

Geochemical Mapping of Elements in the Carpathian Mountain Forests Using Foliar Analysis of White Fir (*Abies alba* Mill.)

Blanka Mankovska, A. Bytnerowicz, D. F. Karnosky
Forest Research Institute, Masarykova street 2195, 960 92 Zvolen, Slovakia
Tel: +421 855 5314169, FAX: +421 855 5321883, Email: Blanka.Mankovska@fris.sk; mankov@fris.sk

Keywords: Air pollution; Foliar analysis; *Abies alba*; Carpathian Mountains

The Carpathian forests represent unique reservoirs of many endemic, rare, and unusual plant and animal species in Central Europe. White fir (*Abies alba* Mill.) is well distributed in the Carpathian Mountains. This species has attracted significant attention of scientists because of its decline and reduced genetic diversity caused by air pollution. Research sites were established in Slovakia, the Czech Republic, Poland, Ukraine and Romania in December 1995. Altogether 483 trees of predominant or dominant class in the second age category (21-40 years old) were sampled. Samples of needles were analyzed unwashed. Concentrations of elements were determined with atomic absorption spectroscopy: Al, Ba, Ca, Cu, Fe, Mn, Mg, Na, Sr, Rb, Zn (Perkin-Elmer model

3030B); Co, Cd, Cr, Be, Ni Pb, V (Perkin-Elmer model 3100, HGA-600); As, Se (AAS 3030B, MHS-20 Perkin-Elmer); Hg (trace mercury analyzer TMA-254, Tesla Holesovice). Concentrations of F were determined colorimetrically by (SPECOL 11 Carl Zeiss Jena), of S with a LECO SC 132 analyzer and of N with a LECO SC 228 analyzer. Observations of fir needle surfaces were performed with a Scanning Electron Microscope JEOL 840 A and by using an EDX analyzer LINK 10000. Particles deposited on surface and in stomata were assessed according to their morphology and EDX spectra. Particles deposited on fir needles were assigned into 4 basic categories (biological, mineral, coal-oil ash, and industrial particles) The accuracy of data was verified by comparison of the analysis of standard plant samples with results obtained in 109 laboratories within the IUFRO quality assurance working group. The samples were evaluated by common statistical methods.

Based on foliar analyses of *A. alba* the greatest load by air pollutants is in Slovak part of Carpathian Mountains, namely in the surroundings of industrial plants where also the highest values of studied elements were found. Between concentrations of Al, Be, Ca, Cd, Co, Cr, Cu, Fe, Hg, K, Li, Mg, Mn, N, Na, Ni, Pb, S, V a Zn in the needles of *A. alba* we found statistically significant difference between all study countries except for Sr and Rb. Evaluation of metal concentrations in needles was discussed in relation to pollution of the forest environment with heavy metals and limit values of the studied metals for plants. The highest values of the studied elements were found in Slovak portion of the Carpathian Mountains in the vicinity of industrial sources. The highest values of Al, Ba, Cd, Cr, F, K, Mg were found near to the Termal Power Plant ENO Zemianske Kostoóany and the Aluminium Plant in Ziar nad Hronom. The highest concentrations of Cu, Fe, Hg, Zn were determined in the localities influenced by the Non-ferrous Metallurgic Plant in Krompachy and the Mercury Processing Plant in Rud•any. High concentrations of As, Fe, Mn, S, and V occurred in the vicinity of the Ferrous Metallurgic Plants in Podbrezov and Kosice. Elevated above normal concentrations of Be, Cr, Na, Ni and Pb in fir reflect regional pollution of the environment with these elements. Elevated concentrations of Co, Se and Li, in the absence of Slovak sources of these elements indicate effect of a long-range transport from the heavily polluted areas in Poland and the Czech Republic. Liming of the pollution-weakened forest stands was a probable reason for increased concentrations of Ca in fir needles. This study proves that fir needles can be used as bioindicators of contamination of the environment with heavy metals.

Stomata of observed needles of *A. abies* contained aluminium as a part of minerals, ashes (Al- Si) and particles Al_2O_3 (vicinity of aluminium plant); iron as a part of particles of minerals, ashes and Fe_2O_3 (vicinity of metallurgy complex and thermal power plant); potassium as a part of mineral and biological particles and Mn, Na, V, Ni, Zn, Cr, As, Ba and Cu were found in the vicinity of non ferrous plants. This fact is especially important in the assessment of elements with significant nutritive value.

Chemical Composition of Deciduous and Coniferous Vegetation, Mosses and Humus as Environmental Indicator in Slovakia

Blanka Mankovska
Forest Research Institute, Masarykova street 2195, 960 92 Zvolen, Slovakia
Tel: +421 855 5314169, FAX: +421 855 5321883, Email: Blanka.Mankovska@fris.sk; mankov@fris.sk

Keywords: air pollution, foliage, mosses, humus

Effects of high concentrations of pollutants have resulted in large-scale dying. 85% of forests in Slovakia exihibited symptoms of damage. Concentrations of Al, Ba, Be, Ca, Cd, Co, Cr, Cu, F, Fe, Hg, K, Li, Mg, Mn, N, Na, Ni, Pb, Rb, S, Se, Sr, V and Zn in the foliage of five forest tree species (*Picea abies* Karst., *Pinus sylvestris* L., *Abies alba* L., *Fagus sylvatica* L., and *Quercus* sp.) three mosses (*Pleurozium schreberi*, *Hylocomium splendens*, *Dicranum* sp.) and humus from 3063 plots are completed with their contents related to the limit values and composition of individual particles in stomata of leaves.

The foliage, mosses and humus were not washed before analysis. The samples were taken by monitoring specialists in August 1994 and mosses also in August 1991, in accordance with international methodology. Concentration of elements was determined with atomic absorption spectroscopy: Al, Ba, Ca, Cu, Fe, Mn, Mg, Na, Sr, Rb, Zn (AAS Perkin-Elmer, model 3030B); Co, Cd, Cr, Be, Ni, Pb, V (AAS

Perkin-Elmer, model 3100, HGA-600); As, Se (AAS Perkin-Elmer, model 3030B MHS-20); Hg (TMA/254, Tesla Holesovice). F was determined colorimetrically (Spekol 11, Carl Zeiss Jena), S with LECO 132 analyser and N with LECO SC 228 analyser. Analytical data published in paper were verified and tested. The foliage was evaluated by scanning electron microscope JEOL 400 A and X-ray analyser LINK 10000. The particles deposited in the stomata of foliage (external content) were assessed as to their morphology and EDX spectra. The samples were evaluated by common statistical methods.

The average of element concentrations in the foliage of forest tree species was (in mg.kg-1): Al(151), As(0.57), Ba(65), Be(0.02), Ca(11021), Cd(0.20), Co(0.18), Cr(0.80), Cu(7.3), F(6.2), Fe(159), Hg(0.10), K(7503), Li(0.18), Mg(1458), Mn(1121), N(18165), Na(42.0), Ni(3.44), Pb (2.42), Rb(10.8), S(2163), Se(0.06), Sr(25.9), V(0.81) and Zn(42.7). The equilibrium of individual elements in plants is a precondition of their normal growth. Surprisingly, in contrast to data presented by Markert (1993), only highly positive correlation pairs (r>0.9) of locally emitted elements were found. External concentration and higher standard deviation in industrial areas confirm an effect of polluted air.

Concentrations of elements are higher compared to literature values. More than 75% of foliage surface contained Fe, Ca, Al, K. The highest values of Al, Ba, Be, F, K, Li were found in the vicinity of aluminium plant; Co, Mg, Rb, V of magnesite plant; As, Cu, Hg, S, Se, Zn in the region of non-ferrous metallurgy +mercury plant; Cd, Fe in the vicinity of ferrous metallurgy; N, Sr from military area and Ca, Cr, Ni from the National Park Low Tatras. In comparison with the content of heavy metals excluding of Cd- cover humus always contained more such elements than mosses. In comparison 1991/94 the content of Cd, Pb, Zn was reduced and the contents of Cr, Cu, Fe, Ni were increased.

The State of Health and Intensive Monitoring of Forests in Croatia

Forest Research Institute, Cvjetno naselje 41, 10450 Jastrebarsko, Croatia
Tel: +385-1-628-1022, FAX: +385-1-628-1493, Email: ured@jaska.sumins.hr

The state of forests in Croatia have been monitored since 1987 according to the International Co-operative Programme on Assessment and Monitoring of Air Pollution Effects on Forests (ICP Forests) at 87 bioindicative level 1 plots, located according to a 16 x 16 km network. It has been established that their state of health has, since monitoring began, continually declined. That is, the falling of needles and leaves and changes in their colour has increased since 1995, after which period there has been major improvement. In 1987, there was considerable damage of 7,9% in Croatian forests, 27.7% in 1995 and 19.6% in 1998.

Intensive monitoring of the state of forests is also undertaken according to ICP-Forest methods on 7 permanent level II plots, which are located in various regions in Croatia in various phytocenoses. On the plots, the state of the crowns is assessed and the electric resistance of the tree`s translocation system measured. Trees that do not have any visual signs of crown damage, i.e. healthy trees that fall into the class 0 of damage, have lower electric resistance than trees that fall into classes 1,2,3 of damage. For example, the Fir species (*Abies alba* Mill.), healthy trees (defoliation 0 class, needle loss up to 10%, degree of defoliation "none") have an average electric resistance of 9.2 KΩ, class 1 trees (10-25%, slight defoliation) have 9.8 KΩ, class 2 trees (25-60% moderate def.) have 12.4 KΩ, while class 3 trees (>60%, severe def.) have 17.3 KΩ. Measurements were undertaken in August 1997 and 1998. For class 4 trees (dead) electric resistance was not measured, as the translocation system was inactive.

To determine the state of crowns in level II plots, besides the ICP Forests methods, a unique method of the Forestry Institute is utilised. This method is the interpretation of aerial photographs of top crown details. Aerial photographs are taken with a special portable device, by which a capsule with a mounted camera is launched vertically from the ground, and within the scope of the upper point of movement, automatically photographs a particular motif and returns to the ground in a free fall. On aerial photographs, the degree of defoliation and discolloration in the upper isolated section of the tree crown is assessed, rather than being measured. Through the use of this method, objectivity of research as well as visibility of the most physiologically active crown parts that are not visible from the ground is attained.

Aerial photos show fir trees on Medvednica mountain on permanent sample plot No 103 (in proximity to the city of Zagreb) with different scales of damage and an oak tree on plot No 102 (in proximity to the city of Jastrebarsko).

Cylindrocladium blight a new disease of *Syzygium cumini* from India and its Management

Arushi Mehrotra, M.D. Mehrrptra
Forest Research Institute, Dehra Dun, Dehradun, India
FAX: 0135-756865, Email: icfre-dg@x400.nicgw.nic.in

Leaf spotting and blight, a new disease of *Syzygium cumini* caused by *Cylindrocladium quinqueseptatum* was recorded at New Forest, Dehra Dun in India in 1988. The disease appeared in the second week of September as small spots on leaves on two months old seedlings raise in root trainers containing the potting mixture consisting of one part soil and two parts each of sand and farm yard manure. The disease continued progressing as was evident from increase in number of spots on the leaves and more and more leaves being infected following precipitation amounting to 83.5mm on 12th September. However, the disease escalated with leaf spots turning into leaf blight and subsequently leading to seedling blight following fairly good rains amounting to 156mm in the fourth week of September. Data recorded on 23rd September showed that the disease incidence was 100% whereas defoliation and mortality were 63.8% and 24.5% respectively. The disease further escalated with more precipitation and assumed serious proportion by the first week of October when defoliation increased to 83.5% and mortality of seedlings to 63.5%.

The x and brought within the economic injury level by spray at weekly intervals starting from the 10th of September. Five applications of the fungicides were found effective. Though the disease incidence in treated seedlings was 100%, it remained restricted to development of only a few spots on the leaves. Moreover, none of the leaves was blighted and shed prematurely and there was no causality unlike control seedlings in which defoliation and mortality were to the extent of 83.5% and 63.5% respectively. A comparison of the biomass between treated and untreated seedlings in November end showed reduction in biomass to the extent of 772% in the latter. On the other hand, when Blitox (0.2%) was applied similarly, the mortality of seedlings was dipped to 9.8% and the seedlings were defoliated to the extent of 30%. Premature defoliation and blighting of leaves in large number in Blitox treated plants had adverse impact on plant growth as was evident from reduction in plant biomass by 671% as compared to seedlings treated with a mixture of Bavistin and Dithane M-45.

Some Important Nursery Diseases of Tropical Forest Trees, Their Impact and Management

M. D. Mehrotra
Forest Research Institute Dehra Dun, Dehradun, India
FAX: 0135-756865, Email: icfre-dg@x400.nicgw.nic.in

During the last 8 years xxx in forest nurseries established under social forestry and agro forestry xxx Pradesh, India to detect new disease outbreaks, evaluate damage xxx of economically important diseases. The following diseases hither xxx recently recorded and described. New diseases included damping xxx spot caused by *Rhizoctonia solani*, *Sclerotium rolfsii* and xxx top flagging of *Pinus kesiya* and leaf web blight of 23 hardwoods by *R. solani*, xxx hardwoods by *Phytopthora nicotianae*, *P. citrophtora* and *P. palmivora*, leaf blight of *Azadirachta indica* and *Pongamia pinnata by Coletotrichum dematium*, leaf and seedling blight of *Syzygium cumini by Cylndrocladium quinqueseptatum*, leaf blight of *Bombax ceiba* by *Ascochyty* sp.; set rot of *Populus deltoides* by *Phomopsis* sp., an exotic pathogen intercepted at New Forest, wilt of *Cupressus torulosa* by *Fusarium* sp.; root and basal rot of *Paulownia fortunei* by *R. solani* and *Fusarium* sp.; root and collar rot of *Bauhinia purpurea* by *R. solani*, leaf rust of *P. deltoides* (65/27 clone) by *Melampsora larici- populina*. Besides the above new diseases, three known rusts namely *Maravalia achroa, Ravenelia sessilis* and *R. elemensiae* were found highly damaging to seedlings of *Dalbergia sissoo*, *Albizia stipulata* and *A. procera* respectively Root knot nematodes ocurred commonlyy in nurseries and high nematode infestation on roots was recorded on *Pongamia pinnata, Olea glandulifera, O. europea, O. cuspidata* and *Paulownia fortunei*.

Study on the impact of the above diseases showed that damping-off *in H. integrifolia* accounted for 40% loss of seedlings whereas seedling blight by *S. rolfsii* caused 50-80% mortality and Phoma leaf spot damaged more than 50% of leaf tissues resulting in perceptible impairment in growth of plants. Rhizoctonia top flagging of *P. kesiya* wiped out 60-80% of the seedling stock whereas Rhizoctonia leaf web blight was particularly damaging to *Albzia lehhek, Melia azedarch* and *Asdiracta indica* causing 30-90% defoliation and rendering the plants unfit for planting in high humid areas. Though *Phytophthora* leaf blight was recorded on 8 hardwoods it was particularly damaging to *M. azedarach* and *H. integrifolia* causing 65-85% and 30% defoliation respectively. Ascochyta leaf blight of *B. ceiba* accounted for premature defoliation by 72%. Root and basal rot of *P. fortunei* caused 30% mortality of seedlings whereas it accounted for 40-95% death of saplings in experimental plots. Cylindrocladium seedling blight of *S. cumini* caused 83.3% defoliation and wiped out 63.5% of seedlings. Loss in biomass was estimated to be around 772% on comparison of Dithane M-45 + Bavistin treated seedlings with untreated surviving ones. Verticillium and Fusarium wilts resulted in 26% and 23% mortality in *M. indica* and *C. torulosa* respectively whereas Phompsis set rot of poplar resulted in 46% loss of cuttings and Rhizoctonia root and collar rot accounted for 68% loss of seedlings *of B. purpurea*. Maravalia leaf and twig rust of *D. sissoo* impaired considerably the growth of seedling besides causing 20% mortality whereas *R. sessilis* damaged the entire seedling stock of *A. stipulata* and mortality rose to more then 85% *and R. clemensiae* adversely affected plant growth due to heavy infection on foliage. Heavy infestation by root knot nematodes particularly in *P. forunei* and *Acacia catechu* had perceptible adverse impact on plant growth.

Majority of nursery diseases caused by soil borne pathogens were controlled by integrating cultural practices with fungicidal application in order to make disease management effective, economical and less hazardous. However, Cylindrocladium and *Phytophthora* blight, set rot, collar rot and rusts were effectively managed by fungicidal treatment alone. Application of coiled neem cake, an eco-friendly nematicide, not only reduced considerably root knot nematode infestation but also improved appreciably the growth of *P. fortunei* whereas moderate improvement in plant growth was recorded in *A.catechu* over control.

Alders Selection for Polluted Areas

Leon Mejnartowicz
Polish Academy of Sciences, Institute of Dendrology, PL-62-035 Kornik, Poland
FAX: +4861 8170166, Email: idkornik@rose.man.poznan.pl

In the Europe only two alders, namely the European black alder (*Alnus glutinosa*) and speckled alder (*Alnus incana*) are of importance for reforestation purposes in strongly polluted areas by emissions from copper industry, where air contains not only many toxic fumes, primarily SO2 , but also large quantities of heavy metals Cu, Pb, and Zn are being accumulated in the soil.

Alders are fast growing trees, with nitrogen-fixing root nodules occurring on moist and bogy soil. Between black (Ag) and speckled alder (Ai) there are natural hybrids (Aixg). The result of investigations presented below concern of half-sib progenies collected from 3 provenances of Ag one half-sib family of Aixg and a random common seed sample of 5 trees Ai. The main purpose of the experiment established in a region under the influence of emission from a copper smelter, was to see whether those exist difference between black alder families in their growth reaction to the emission from the copper smelter, and also to see which is more resistant black alder or speckled alder which faster growing and less demanding on site conditions. Evaluation of hybrid progeny is lesser importance for the needs of recultivation in view of the rather rare occurrence of these hybrids in nature. However results obtained for this progeny may perhaps be of indicator value for the utility of artificial interspecies alder hybrids.

It is generally believed that well growing seedlings in the nursery have also a greater resistance to a polluted environment. During the nursery investigations it was decided to test what influence is exerted by covering of the beds wit a polyethylene plastic tent (PT) on the growth of individual progenies. The planting material was obtained in two stages: 1.) seed sowing in PT and tending the first year, 2.) Seedlings after overwintering was divided into two groups, one of which was still cultivated in PT in a single-tree-plot test designated and the second was planted in the open nursery (ON). Both groups received the same soil preparation. With two year seedling (1+1) was established an experiment in the region of emissions from a copper smelter.

RESULTS

1. Cultivation of black alder (1+1) in a PT permits the attainment of much larger seedlings then when after 1 year in PT the plants are kept for second year in ON.

2. For the needs of outplanting in the zone of emission from a copper smelter it is better to produce nursery material in the regime, 1 year under PT and 1 year in the ON.

3. Alders which in the nursery period have developed very large leaves suffer later much more than alders with small leaves when grown in the zone emissions from a copper smelter. Their leaves undergo substantial injuries and the main leader dies at first and later grows much slower than the small-leaved trees. However the best results are obtained with alders having leaves which do not differ substantially from average size in dimensions.

4. Ai has better growth increments in the conditions of the polluted environment than Ag or Aixg.

5. Progeny of natural hybrid Aixg growth better than the parental species in unpolluted environment but in the zone of emissions from a copper smelter they have poorer increments than both parental species.

6. It is possible to make the tentative conclusion that both black and speckled alders are useful

species for planting in the areas polluted by emissions from a copper smelter.

Review Advance in Integrated Control of Larch Sawfly in China

Li Menglou, Guo Xinrong Tang Guanghui
Northwest Forestry College, 712100 Yangling, Shaanxi, China
Tel: +86-29-7082125, FAX: +86-29-7082293, Email: syq [suyinq@public.xa.sn.cn]

The results of research about biological and ecological character of larch sawfly *Pristiphora erichsonii* (Hartig): Influence of elevation on the vertical distribution and ecological type, deferring to the even spatial distribution. Life table parameters of experimental population, rm=0.04914, Ro=9.9881, average generation period T=46.7924d. Influence of temperature to sawfly growth and development, the suitable temperature range is 7-24°. Needle stock and timber volume loss intensity of infected larch forest is 10.32-100.00% and 4.625-5.946m3/ha. The control technique is as follows: Control tactics, control threshold value, population dynamics and prediction model sawfly-resistance larch species, chemical control methods and the way of natural enemy utilization.

Keywords: *Pristiphora erichsonii*, larch sawfly, ecology, control.

Importance of Management of Tree Seed Pathogens for Sustainable Forestry

R. K. Mittal
Vivekananda Parvatiya Krishi Anusandhan Sansthan, Room No. 401, 110001 New Delhi, Krishi Bhawan, India
Tel: (0) +91 11 3388808, FAX: +91 5962 31539, Email: rkm@icar.delhi.nic.in

Successful forest management has to be based on the complimentary principle: multiple use and sustained yield. Expansion of reforestation programmes, more silviculture and better forest protection are its chief components. Although foresters and forest pathologists have been aware of the seed health problems since past several decades, the increasing demand of seed of high quality and genetic potential for germplasm conservation and as reproductive material; development of new cultural systems such as container production and intensively managed nurseries, and the high cost of producing the quality seed and planting material, have made it imperative to manage them. Considerable savings can be accomplished by reducing fungal damages to seeds.

Yields of viable seeds can be increased, thereby increasing the seed: seedling efficiency, reducing the costs and extending the acreage of land to be seeded. Healthy nursery stock will increase the probability of successful reforestation and, will avoid economic losses resulting from the subsequent seedling mortality in the field. This however, requires a better understanding of the characteristics and behaviour of tree seed pathogens, more so for reducing the use of pesticides or replacing them by the biocontrol agents or improved silviculture. Tree Seeds are both suscept and vehicles of pathogens and may carry them as contaminants or infections. The pathogens include bacteria and viruses but predominantly the fungi. Several fungi have been reported on tree seeds world-wide; some even cause considerable reduction in seed germination, decay and loss of viability of seeds during storage, and diseases like damping-off wilt, blight and others of the seedlings in nurseries. Inoculation and establishment of infection of the host depend on conditions favouring pathogen's development, the pathogen that differs from one another in selection of the point of entry and the colonisation of seed, and the anatomy of seed which varies from one host plant genus or species to another. Tree seeds are exposed to many conditions during their collection, handling storage and germination which differ from those for the seeds of agricultural crops, and are conducive for fungal infection.

Management of the fungi therefore, requires integrated approach including timely seed collection from healthy sites, use of proper methods of collection, handling and storage of seeds including seed treatments with physical methods, chemicals and biocontrol agents. The paper is a synthesis of available information. It emphasizes the importance of characterization and management of tree seed pathogens and identifies the researchable issues for sustenance of reforestation programmes.

Disease Management in Eucalyptus Plantations for Solid Timber Production in Tasmania, Australia

Caroline Mohammed, Barry K., Pearce R., Milgate A., Yuan Z.Q., Battaglia M., Vaillancourt R. Mollon A., Eyles A
CSIRO, Forestry and Forest Products, Post Box # 252-12. Hobart 7001, Australia
Tel: +61 362 267954, FAX: +61 362 267901, Email: Caroline.Mohammed@ffp.csiro.au

Both on an international and domestic level Australia has a strong commitment to the role of forestry in sustainable development. The forest industry in Australia is therefore increasingly applying more intensive silvicultural regimes to timber production, involving thinning in native forests and establishment of plantations. Of the approximately 200,000 ha of eucalypt plantations established in Australia to date, most are intended for production of pulpwood on short rotations of 15 to 20 years.

Between 1991 and 1996 in Tasmania more than 7000 ha of *Eucalyptus nitens* plantations were established for saw-log or veneer on rotations of 30-plus years. The Tasmanian Regional Forest Agreement signed in November 1997 by the Federal and State Governments has provided further funding for solid wood plantation development to compensate for losses of production forest to reserves. Under it, another 20 000 ha will be planted - with *E. globulus* as well as *E. nitens* - over 5 years.

The major eucalypt species grown in plantations retain rather than shed dead branches which results in severe wood quality problems. Trees develop large knotty cores that make them unsuitable for the production of sawn timber and veneer. The only way to counteract these problems is 'green pruning', the removal of live branches. To minimise the diameter of the knotty core, pruning begins early in a tree's life and must extend as high as possible to maximise the length of good quality log that can be recovered. The high cost of both pruning and thinning operations means the impact of fungal stem degrade or foliar pathogens could be very significant.

Research in Tasmania focuses on developing management strategies to avoid or reduce the impact of fungal pathogens. Surveys have been conducted to identify fungal pathogens present in newly established plantations. Special emphasis has been given to the identification of the different species of *Mycosphaerell*a (leaf blotch), scoring damage and assessing resistance levels.

Pruning of live, especially large diameter, branches carries a higher risk of establishing decay than the pruning of dead branches. Management strategies for controlling branch size and minimizing pruning associated decay are considered essential. Studies, in both *E. nitens* and *E. globulus*, are being carried out to investigate antimicrobial defence and understand factors influencing its effectiveness both in the short and long term. A wide range of parameters involved in xylem defence in both the initial and later stages of wounding and decay infection of *E. nitens* have been examined; water content at the decay interface with NMR imaging and gravimetric sampling techniques, constitutive and novel compounds in the reaction zone, free radicals and mineral concentration. *E. nitens* does not appear to show certain defence responses typical of many other angiosperms. Ongoing research is comparing antimicrobial defence in *E. nitens* and *E. globulus* and the role of kino formation in the latter species.

Population Trends of *Hyblaea puera* Cramer in a Large Teak Plantation at Nilambur, Kerala, India

K. Mohanadas, KSS Nair
Kerela Forest Research Instiute, 680653 Trichur, Kerala, India
FAX: +487 782249, Email: libkfri@md2.vsln.net.in

Population trends of the teak defoliator *Hyblaea puera* Cramer (Lepidoptera: Hyblaeidae) was studied by sampling in a 1000 ha teak plantation area at Nilambur in Kerala, India. In addition to three permanent study plots containing about 200 trees, moving plots were used to sample shifting populations. Sampling was done at weekly intervals almost continuously during a three-year study period.

The study showed that during each year, while only two to three generations of the insects appeared in each of the study plots, seven to nine generations appeared in the total study area. During the early part of the season, outbreaks were characterised by synchronous development of the insect, with the dominance of one instar throughout the developmental period. However, in the later part of the infestation period almost all stages were present in each of the populations sampled, but the population was small. This was followed by a period of six to seven months months when the population although present, was very small and almost undetectable, until the out-breaks appeared again next year, following the pre-monsoon rains between late February to late May. If there was a shift in the time of arrival of the pre-monsoon rains.

Diseases and Disorders of Bamboos in Asia

Choran Mohanan
Kerala Forest Research Institute, Peechi, 680 653
Kerala, India
FAX: 0487 782249, Email: libkfri@md2.vsnl.net.in

Of the three major regions of bamboo distribution in the world, Asia is the largest with about 18 million ha of bamboo growing lands and having more than 800 species and varieties of bamboos belonging to 45 genera. However, economically important bamboos of Asian region belong to relatively few species of the genera, *Bambusa, Cephalostachyum, Dendrocalamus, Gigantochloa, Melocanna, Ochlandra, Phyllostachys, Schizostachyum* and *Thyrsostachys.* The productive potential of bamboo stands in most of the bamboo growing countries in Asia is affected by various biotic and abiotic factors including pests and diseases.

About 170 species of bamboos belonging to 26 genera in this region are found affected by various diseases and disorders. A total of 440 fungi 3 bacteria 2 viruses, a phytoplasma and a bacteria-like-organism have been reported from India, China, Japan, Thailand, Philippines, Bangladesh, Indonesia, Taiwan, Vietnam, Pakistan, Singapore, Sri Lanka and Malaysia as associated with various diseases and disorders of bamboos .Among the diseases only a few are identified as potentially serious one which affect the culm production as well as stand productivity. These include (i) culm blight caused by Sarocladium oryzae in village groves in Bangladesh and in coastal belts of Orissa State, India (ii) rot of emerging and growing culms of industrially important species in India caused by *Fusarium* spp. (iii) witches' broom incited by *Balansia* spp. in different species of bamboos in Japan, China, Taiwan and India (iv) little leaf of *Dendrocalamus strictus*, an economically important species in India, caused by a phytoplasma (v) culm mosaic caused by bamboo mosaic virus in Taiwan, (vi) culm rust caused by *Stereostratum corticioides* and (vii) top blight of *Phyllostachys* spp. caused by *Ceratosphaerea phyllostachydis* in China. From an economic point of view a disease impact assessment becomes difficult due to lack of sufficient quantitative data on disease damage and rate of spread of the disease.

Bamboo culm blight, culm rust, top blight and culm mosaic are spreading at a very fast pace in bamboo stands in the respective countries and occasional new outbreaks are common which affect the bamboo industry as well as the rural economy as a whole. Disease management measures practised against the diseases in the respective countries have relied mainly on silvicultural measures and to a lesser extent on chemical treatment. Etiology and epidemiology of most of these diseases are little investigated and often control measures adopted are proved inefficient.

Decay and biodeterioration of culms in storage is an important problem confronting the bamboo based industry in modern as well as traditional sectors in most of the countries in Asia. Natural durability of the bamboo culm is very low. A large number of decay and staining fungi have been recorded on bamboos under storage in different countries. The severity of the problem depends on duration of storage, bamboo species, environmental as well as storage conditions. Hence, appropriate storage techniques to minimise the hazards have to be developed. Although effective preservative chemicals and treatment techniques for bamboos are available, more emphasis should be given to develop low cost, locally available preservatives and economically viable as well as environment friendly treatment methods.

A concerted effort to study the potentially serious diseases of bamboos in this region and develop appropriate measures to check further spread of the disease in stands as well as safeguarding against the inadvertent introduction of disease in new areas in the region have to be made. Disease management strategies of both short-term as well as long-term measures including broadening the genetic base of bamboos, development and introduction of disease resistant species/provenances are suggested.

Biological Pesticides for Sustainable Management of Teak Pests

K. Murugan
Bharathiar University, Dept. Zoology, CBE-46, 641 046
Combatore, India
FAX: 091 422 422387, Email:
murugan@as250.bharathi.ernet.in

Insect pests cause severe damage to forest plantations, and lead to considerable economic loss. Teak is one of the very important commercial timber species found in India. Of the various insect pests infesting teak plantations, teak defoliator, *Hyblaea puera*, teak leaf skeletinizer, *Eutectona mechaeralis* and teak trunk borer, *Cossus cadambae* are of major importance. Application of synthetic pesticides has resulted in ecotoxicity, insecticide resistance, pest resurgence and secondary pest out-breaks. Due to these and other concerns there is a need for effective biodegradable pesticides with greater selectivity. Neem, *Azadirachta indica* A.Juss-Meliaceae, is indigenous to India. Neem derivatives comprise a complex array of novel compounds with profound behavioural and physiological effects on insects such as repellence, phagodeterrence, growth distruption etc. Application of neem seed kernel extract (NSKE) mixed with nucleopolyhedro virus (NPV), *Bacillus thuringiensis* (Bt) and fungi, *Beauveria bassiana*, showed promising control measures of *H. puera*, *E. mechaeralis* and *C. cadambae* on five year old teak plantations. Higher population reduction and larval mortality were observed after application of NSKE and Bt toxins on teak plantations. Combination of NSKE, NPV and fungal extracts brought out larval deformities and reduced oviposition of moth in the field. Laboratory experiments also showed significant reduction in feeding and fecundity of the insects. Bioefficacy of plant compounds with potentiating effect on microbial pesticides in relation to practical field management of forest pests have been discussed.

Biodiversity of Ganoderma a Stem Rot Infection in Tamil Nadu South India

K. Murugesan, K. Perumal, P.S. Sudhakar Gandhi, and P.T. Kalaichelvan
University of Madras, Centre for Advanced Studies in Botany, Guindy Campus, 600025 Chennai, India
Email: ptk@unimad.ernet.in

Ganoderma lucidum and allied species are widely occurring polyporous white rot fungi causing the heart rot disease on many angiosperms and gymnosperms. Though these fungi generally cause only decay of dead wood and stumps and also attack aged and declining trees. Severe infection by these have been reported in a variety of trees like Tamarind, *Delonix, Acacia, Casuarina, Prosopis, Citrus*, Silk cotton, Oil palm, Mango, Coconut and teak in Tamil Nadu. Therefore a servey on the incidence of this disease was conducted in the hilly areas of Nilgiri, Anamalai hills and Kodaikanal as well as in the plain of the east coast of Tamil Nadu.. In general the incidence of this disease was more in the plains than in the hilly forest areas. While about 55% of all the diseased trees in and around Chennai have been infected by *G. lucidum*, only about 5-10% had severe infections in Kodaikanal and Nilgiri forests. However, the disease incidence was slightly higher at about 25% in the Anamalai hills. Detailed studies on the isolates of the fungus *G. lucidum* showed that this fungus produces macroscopical aerial basidiocarps and cause extensive delignification, dissolution and Š disintegration of cell walls of tamarind wood by the secretion of the lignolytic enzyme lignin peroxidase, laccase, carboxy methyl cellulase and xylanase were observed. Similarly among the different cell wall components of wood namely lignin, cellulose and hemicellulose, *G. lucidum* showed preferential utilization of lignin for growth. The basal stem rot of *Tamarindus indica* caused by *G. lucidum* is a serious problem in and around Chennai and other areas of Tamil Nadu. The biological control of *G. lucidum* was also studied under *in vivo* and *in vitro* conditions. The details on this study will be presented.

Ganoderma Diseases of Evergreen Forest Trees in Anamalai Hills South India

K. Murugesan, P.S.Sudhakar Gandhi, P.T. Kalichelvan
University of Madras, Centre for Advanced Studies in Botany, Guindy Campus, 600025 Chennai, India
Email: ptk@unimad.ernet.in

An assessment of wood rot fungal infection in evergreen forest carried out periodically from July '97 to October, '98 in Anamalai hills, Western Ghats South India. *Ganoderma lucidum* and other species cause severe root rot and heart rot infection in many of the economically important tree species including *Mesua ferrea, Hopea parviflora, Vataria indica, Palaquium ellipticum, Amoora canarana, Aglaia rouxburghiana* and *Machilus macrantha* etc., Macroscopical survey made in one hactare of 448 trees by observing the disease indicators in Anaikunthi shola showed that 25.67% of trees were infected by *Ganoderma* species. An attempt made on biological control of *Ganoderma lucidum* in nurseries of forest tree species with *Trichoderma viride* and *T. harzianum,* were found to reduce the disease incidence.

Blister Bark of *Casuarina*

Chaendaekattu Narayanan, J.K. Sharma and V. Mohan
Institute of Forest Genetics and Tree Breeding, R.S. Puram Coimbatore, 641 002 Tamil Nadu, India
FAX: 91 0422 430549, Email: sfsc@giasmd01.vsnl.net.in

Wilt or blister-bark is a seriuos disease affecting *Casuarina equisetifolia* (Butler, 1905; Narayanan & Sharma, 1996; Mohan, Narayanan & Sharma 1998) and *Casuarina hybrid* (*C. equisetifolia* x *C. junghuhniana* Miq) (Narayanan, Sasidharan & Sampathkumar, 1998). Blister-bark disease particularly affects monoplantations of *Casuarina* and has attained global quarantine significance as it has been recorded from India, Vietnam, Thailand, Mauritius and Ceylon (Narayanan et al., 1996; Narayanan, 1998). The paper discusses findings on epidemiology and management of blister-bark disease. Detailed symptomatological studies in blister-bark affected *Casuarina*s showed that, age of the trees and prevailing environmental factors of the sites, significantly influenced field symptom expression and disease severity. Further studies on various provenances of *C. equisetifolia* showed significant differences with reference to blister-bark disease incidence. Cell free culture filtrate of the pathogen, induced differential phytotoxicity in shoots of *Casuarina equisetifolia*, which can be utilized for preliminary in-vitro screening of numerous genotypes for further disease resistance breeding.

Spatial Distribution of *Lepidoptera* species in the Forest Stands in the Lugar Nuevo State Woodland (Jaén, Spain)

Antonio Notario, Luis Castresana
Universidad Politécnica de Madrid, Departamento de Ingeniería Forestal de la E.T.S. de Ingenieros de Montes, Ciudad Universitaria, s/n 28040, Madrid, Spain
Email: anotario@montes.upm.es

In the Lugar Nuevo State woodland there are forest stands of *Pinus pinaster*, *P. pinea*, *Quercus ilex*, *Q. faginea*, *Q. suber* and *Arbustus unedo* mixed with *Quercus coccifera*. In each of these stands some plots are chosen, with the aim of collecting examples of Lepidoptera. When the examples are taxonomically identified, a study is carried out of their spatial distribution and behavior in relation to the vegetation species under consideration. 126 *Lepidoptera* species were detected, 34 of which can be considered as potential pests. The highest biodiversity was found in the stand of *A. unedo* mixed with *Q. coccifera*, followed by the *Q. ilex, Q. faginea, Q. suber, P. pinaster* and *P. pinea* stands.

Natural Enemies and Biological Control of Elm Leaf Beetle in Tehran, Iran

Rasoul Omid
Research Institute of Forest & Rangelands, P.O.Box: 13185-116, Tehran, Iran
Email: rifr@jsis.neda.net.ir

Elm Leaf Beetle (ELB) is the most important pest of elm trees in Tehran and other big cities of Iran. Larvae of this pest cause the main damage by feeding on the leaves of elm trees and skeletonizing them. Investigation for potential natural enemies of this pest was carried out from 1993, and several species of arthropod predators and parasitoids were identified in Tehran. These species include Mantis, Ladybirds, Wasps and Spiders, but the main natural enemies were two species Wasps and one Ladybird as follow: * *Tetrastichus gallerucae* (Fonscolmbe) (Hym. Eulophidae) is an egg parasitoid of ELB and the percentage of its parasitism was 25-45% in different times and places of the city. *T. brevistigma* Gaham (Hym. *Eulophidae*) is larval-pupa parasitoid of ELB. This wasp cased 18-25% parasitation. These two species of wasps were reared in laboratory condition, LD 14:10, 25+_1 Degree C. and RH 65+_5% . Under this condition a single generation of the *T. gallerucae* and *T. brevistigma* were completed in 14-18 days and 13-15 days respectively. *Oenopia conglbata* L. (Col. *Coccinellidae*) is predator of ELB. Both larva and adult of this ladybird feed on eggs and first stage larvae of ELB.

Shoot Borer: *Hypsipyla robusta* Moore (*Lepidoptera; Pyralidae*) Damage to Growth and Survival of Native *Meliaceae* (African Mahogany)

Emmanuel Opuni-Frimpong, Cobbinah, J. R.
Forestry Research Institute of Ghana, P. O. Box 63, U. S. T. Kumasi, Ghana
FAX: +233-51-60121, Email: forig@africaonline.com.gh

African mahogany namely *Khaya, Entandrophragma, Guarea* and *Lovoa* species (meliaceae) are considered among the most valuable Tropical timbers worldwide. These species are found naturally throughout the Wet semi-deciduous and Dry forest zones of West and Central Africa Timber trade in Ghana began in the last quarter of the nineteenth century and was initially focused on the mahoganies. Currently, timber from the native mahogany is earning approximately 12% of total timber exports. The percentage stocking of the mahoganies in the forest, using forest inventory data is reported to be 2.6%. The domestic and international markets depend heavily on these species. This has led to excessive exploitation of these species in the natural forest. It is observed that the annual over-exploitation of the mahogany species is approximately 53% and most of the species in the meliaceae family are predicted to go commercial extinction by the year 2004. Continuous over-exploitation has prompted a proposal to list all mahoganies on Cites appendix II. As a result its exploitation will require a permit from the Forestry Department. However legal restrictions and/or depletion of the Reserves will further restrict supply and export revenue. The Government of Ghana in response to the dwindling resource of the mahogan put in place measures to guarantee their sustainable production in the natural forest. The measures include establishment of the mealiaceae in plantations and the reduction in yield allocated to contractors for felling in the natural forest. Most of the plantations that were established failed due to shoot borer *Hypsipyla robusta* Moore attack. *Hypsipyla* has been recorded on Khaya species, Entandrophragma species, Carapa species, *Lovoa* species indigenous to Africa and *Swietenia macrophyla* exotic mahogany, in West Africa.

Recent reviews on the mahogany pest problem emphasize an integrated pest management strategy based on the incorperation of pest tolerant planting stock in silvicultural systems which encourages natural biological control. The search is on for sociologically and economically acceptable, sustainable and environmentally safe integrated pest management (IPM) strategies for these major timber species (African mahogany).

The principal damage consists of borers feeding on and killing the apical shoot. The *Hypsipyla* attack reduces vigour and repeated attack on the leading shoot causes stunted growth. The excessive branching as a result of the death of the death of the terminal shoot affects the quality and quantity of wood that can be recovered. Thus reducing the commercial value of the timber.

There seems to be regional differences in the life cycle of *Hypsipyla*. While four larval instars were recorded in Nigeria, five or six larval instars have been recorded in Ghana. Regional differences in life cycle and probably in the host plant preferences on the species of hypsipyla has prompted the need for intensive local biological investigation which can be incorporated into IPM of *Hypsipyla* in a Coordinated Action Network.

The different species of *Meliaceae* have different mechanisms and different levels of tolerance to *Hypsipyla* attack. A study to identify the extend of seedling growth following *Hypsipyla* attack in three African mahogany species is currently going on at the Forestry Research Institute of Ghana. This study aims at identifying plant characteristics associated to tolerance which will help formulate appropriate IPM strategies for control of the pest of the mahogany.

Tree Defoliation as the Environment Quality Assessment

Remigijus Ozolineius
Lithuanian Forest Research Institute, Girionys 1, 4312 Kaunas reg., Lithuania
FAX: (370-7) 547446, Email: miskinst@mi.lt

It has been clarified that not only different damage agents (fungi, insects, wildlife, snow, wind, etc.) but biological factors (species, crown form, branching habit, tree age, social class, soil humidity, etc.) also determine crown defoliation. For example, defoliation of narrow-crowned trees is slightly more significant than that of wide-crowned trees (28.8±0.6 and 22.2±0.8%, respectively). In comparison to crown defoliation of trees Norway spruce of comb branching (32.7±2.7) or plate (30.5±1.6%) type, that of trees of irregular comb (22.5±0.7%) or brush (23.8±0.5%) branching type is less. Crown defoliation of younger trees is less as compared to that of older trees (up to the age of 20 years crown defoliation of conifers is only 11.1±1.0% and that of trees older than 80 years - 27.3±0.5%). Trees of Kraft class III and IV were defoliated considerably more than these of Kraft class I-II (crown defoliation of conifers of Kraft class I-IV is 21.0±0.8, 23.4±0.3, 27.9±0.6, and 28.4±3.3% respectively). Crown defoliation of trees growing on sites of normal humidity (N) and swamps (P) (in case the index of their fertility is identical) is more significant than that of trees growing on wet sites (U) or these of temporary surplus of moisture (L) (for instance, defoliation of spruces on sites "c" in hydrotopes N and P is 11.2±0.2 and 39.8±3.5%, respectively, while that in hydrotopes L and U is 8.7±0.2 and 6.2±0.9%, respectively. Consequently, it is necessary to standardise data on crown defoliation for assessing the ecological situation (quality of environment) in different districts of the Republic. The standardising of the data has been performed according to defoliation of the upper part of a crown. Trees of Kraft class I and II without visual indication of damage have been selected.

It has been determined that in a certain hydrotope the correlation between age (A) of a tree and defoliation (DF1.3) is best described by the equation DF1.3=aAb. For instance, for pine in hydrotope N DF1.3=10.35 A0.294 (R2=0.88), for spruce in hydrotope L DF1.3=4.51 A0.572 (R2=0.73).

Since crown defoliation depends upon the hydrotope and age while site fertility does not essentially influence it. Crown defoliation of pine in hydrotope N equals 1.0. The coefficients of standardisation have been calculated in other hydrotopes (DFst.=KDF1.3, here Dfst. is standardised defoliation, K - the coefficient of standardisation).

By applying such data the quality of the environment in different administrative districts of the Republic has been assessed. Environmental quality was evaluated as the best in the districts where air pollution is the lowest.

The Forest Damage Documentation and Information System of the Federal Forest Research Centre

Bernhard Perny
Federal Forest Research Center, Institute of Forest Protection, Seckendorff-Gudent Weg 8, A-1131 Vienna, Austria
Tel: +43-87838-1145, FAX: +43-87838-1250, Email: Bernhard.Perny@fbva.bmlf.gv.at

- An Introduction and First Experiences

In 1996 the Institute of Forest Protection started to elaborate a comprehensive Forest damage documentation system for pests and diseases occurring in Austrian forests. The basis data therefore are written expert opinions, which date back up to more than 40 years. The reasons therefor were the preservation of scientific knowledge, support of a comprehensive database, and a more comfortable elaboration of damage diagnosis. The damage documentation and information system consists of two major parts:

- the database: containing a great number of information of the samples send in and about the symptoms found. At the beginning it has been configured as a relational Filemaker database. Now it is transformed into an Oracle-database. The goals were a facilitated data input and improved possibilities for requests as well as the compatibility to the internet.

- The photo documentation: consisting of a large slide database with more then 10.000 slides and an analogue Video documentation system which allows to take images as well as video sequences even at high magnifications. The photo documentation system allows joint analytical and diagnostical work of several scientists as well as the visual documentation of pests/diseases and damage during the analystic and diagnostic work.

Perspectives: In the next future the parts of database will be opened for public use in the Internet. The main goals of the performance in the world wide web are;

- providing a helpful knowledge in form of this database for authorities and private clients and
- the possibility of independent input of environmental and stand data by authorities and other clients.

Study of Performance of Different Attractants for *Ips typographus* (L.)

Bernhard Perny
Federal Forest Research Center, Institute of Forest Protection, Seckendorff-Gudent Weg 8, A-1131 Vienna, Austria
Tel: +43-87838-1145, FAX: +43-87838-1250, Email: Bernhard.Perny@fbva.bmlf.gv.at

In studies regarding pest control the different pheromones for Ips typographus which are commercially available showed very different catching performance. In the course of these tests, beetles were taken from 4 different pheromone agents (Pheroprax, Ipsowit, Pheroplates, and Etokap IT) and used for further investigations in addition to the electrophoresis. In laboratory reproductive tests in sprucelogs, their fertility and fecundity was assessed. Those of the beetles that were analysed by electrophoresis were submitted to a detailed dissection the data of which were also evaluated.

Considering all investigated factors and parameters, there is a basis for the assumption that different pheromones (pheromone formulations) do not only cause different catch quotas but also catch different beetles. A pheromone which is less effective (such as Etokap IT, which was then available on the market) does not only have significantly lower catch quotas; also the reproduction rate in the above-described reproductive tests in spruce and the electrophoretic splitting of isoenzymes distinguish this substance (more or less clearly) from the other products. On the other hand, it was not surprising that the difference between Pheroprax and Ipsowit is minor taking into consideration that, according to informations during a later phase of this project, they differ chemically only by a different degree of purity of the applied substances.

Insect Factors Effecting Seedling Establishment in Second Rotation *Pinus radiata* Forests in New Zealand

Stephen D. Reay, Walsh, Patrick J., Roberta L. Farrell and Arvina Ram
Forest Research Associates (FRASS), 32 Cambourne Rd, Sandringham, Auckland, New Zealand
Tel: 0064 9 815 5427, FAX: 0064 9 445 6955, Email: sreay@clear.net.nz

Keywords: *Hylastes ater*; *Pinus radiata*; mortality; sub-lethal attack; sapstain fungi

Background

Hylastes ater (*Coleoptera: Scolytidae*) is a European bark beetle that was first recorded in New Zealand in 1929. It is now well established in all exotic pine plantations. *H. ater* breeds in stumps, roots and logs of *Pinus* spp. The adults attack and can kill young pine seedlings. Despite initial concerns, *H. ater* has been disregarded as a pest in New Zealand until recently. However, unpublished surveys indicate that attacks on *P. radiata* seedlings by *H. ater* are common in second rotation forests.

Objectives

The main objectives of this study were to evaluate the extent of *H. ater* attack and mortality in second rotation *P. radiata* forests and to investigate the effects of sub-lethal feeding on seedlings.

Methods

Sites were chosen to cover a variety of site types and logging histories. One hundred seedlings were sampled along a randomly located transect in each site. Every dead seedling encountered was removed and examined for evidence of *H. ater* attack. In addition, every fifth seedling encountered was removed from the soil and examined. Evidence and severity of *H. ater* attack was recorded as follows, no evidence, evidence of attack, moderate attack and severe attack.

Results and Discussion

Attack by *Hylastes ater* is the dominant cause of seedling mortality in the first year of establishment in second rotation *Pinus radiata* forests. *H. ater* emerges from stumps and attacks surrounding plantings during maturation feeding. Seedling mortality is usually less than 20%, although mortality may reach 50%. Mortality differs with site and is strongly correlated with logging history. Those seedlings planted in sites soon after logging are most at risk from *H. ater* mortality.

Of serious concern is the amount of sub-lethal attacks by *H. ater* seedlings. While mortality may be considered low, the extent of sub-lethal feeding attack is much higher. Two thirds of one-year old plantings showed evidence of 60-90% sub-lethal attack by *H. ater*. The proportion and severity of sub-lethal attack differs between sites and shows a strong relationship to logging history. Sites with the greatest proportion and most severe sub-lethal attacks are those planted soon after harvesting.

While sub-lethal feeding does not effect seedlings growth in the first two years of planting, longer-term effects of sub-lethal attack are not known. The seedlings in this study were examined to determine whether a relationship between *H. ater* attack and the presence of sapstain fungi existed. Preliminary results indicate a highly significant relationship between severe sub-lethal *H. ater* attack and the presence of sapstain fungi.

Integrated Pest Management Approaches in Forest Nurseries: Alternatives to Methyl Bromide

Maria Isabel Salerno
Facultad de Ciencias Agrarias y Forestales, Lab. Proteccion Forestal, UNLP-CIC 60 y 119 CC31, 1900 La Plata, Buenos Aires, Argentina
Tel: 03 806 32, Email: salerno@epoisses.inra.fr

Afforestation represents a major environmental effort around the world. High quality seedlings supply is a critical issue in the recultivation process. Pests have a negative impact in seedling health in forest nurseries. Among them *Fusarium* diseases cause the main losses in *Eucalyptus* spp. and *Pinus* spp. nurseries. Disease incidence being generally considered to be related to the high population levels of the *Fusarium* species. Methyl bromide is still an important control measure available in forest nurseries in Argentina. Environmental concerns on the use of this chemical continously encourages the development of alternative methods. Integrated pest management (IPM) programmes are powerful and effective tools. As a first step in order to develop an IPM program, suitable IPM approaches were considered for the management of *Fusarium* diseases. Field trials were carried out in order to (i) monitor the *Fusarium* population in the nursery field soils for predicting the expected damage to forest seedlings, (ii) evaluate the effect of soil solarization to decrease the population levels of *Fusarium* species and (iii) compare the effects of solarization with the use of methyl bromide, dazomet and fungicides. These studies have shown that nursery field soils in Argentina have few *Fusarium* taxa. Cultural practices such as the incorporation of organic matter amendments increased the diversity of *Fusarium* species as well as the population levels. Solarization effectively reduced the *Fusarium* population levels and this behaviour was related to deceased incidence. Solarization treatment was as effective as the methyl bromide treatment while dazomet was less effective. The use of fungicides decreased the population levels of *Fusarium* species only partially. In conclusion solarization represents an alternative method for the control of *Fusarium* diseases in forest nurseries preventing the risks of the methyl bromide use. Moreover, this treatments should be combined with appropriate cultural practices avoiding the addition of potential pathogens that might increase disease incidence.

Variation in Resistance of *Casuarina* Provenances to the Stem Borer, *Indarbela Quadrinatata* Walker (*Lepidoptera: Metarbelidae*)

K. R. Sasidharan, A. Balu, B. Deeparaj, R.V. Varma
Institute of Forest Genetics and Tree Breeding,
Coimbatore, 641 002 Tamil Nadu, India
FAX: 91 0422 430 549, Email: ifgtb@satyam.net.in

Casuarina equisetifolia is an important tree species used for coastal afforestation in India. It was introduced to the country in nineteenth century.

Because it is a growing short rotation tree, having multiple utility from fuelwood to poles for construction, *C. equisetifolia* has been the farmer's favorite species. Since it is compatible with many agriculture crops, the farmers in Southern India grows, *C. equisetifolia* under agroforestry system, especially in the coastal areas.

Though *C. equisetifolia* is almost free from major pests in its places of origin, it is encountered with many severe problems in countries where the species has been introduced. In India there are about 56 species of insects reported to feed on live Casaurina, among which the stem borers are very serious. The bark feeding borer, Indarbela quadrinotata attacks *C. equisetifolia* plants above two years age. The larva remains inside the borer hole made on the main stem or branches during day time and comes out during night time for feeding on the bark. The borer holes made on the stem not only obstruct the condition of nutrients and foot materials, but also invite invasion of pathogens into the attacked trees, ultimately resulting in die-back. The problem of the stem borer has been very severe in the semi-arid Casaurina growing tracts of the east coast, especially in Tamil Nadu.

In order to find out provenance's resistant to the stem borer, studies were conducted in an International Provenance Trial of *C. equisetifolia* laid out in 1992, at Neyveli area of Tamil Nadu State. The trial contains plants raise from twenty provenance's, in Queensland, Egypt, Kenya, Vietnam, Malaysia and India and a local seed source (control).

The study shows that among the 21 seed sources, one provenance, Kilifi is completely resistant to the borer and another provenance, Watamu is highly resistant. The four provenance's rated as resistant are: Ela Beach, Kenyatta Beach, Pantai Dalit and Tanjung Aru. Eight provenance's viz. Bako Borneo, Pantai Moyog, Darwin *Casuarina*, Montazah Alexandria, Nine Chu, Phl., Wangetti Beach and Non Nuoc are susceptible and seven provenance's, Mamorah Alexandria, Chadipur/Balasore, Peempur/Kujaug, Haingara/Balukhand, Local, Mariana Island and Cua longhi Loc are highly susceptible.

Beta-1,3 Glucanases Confer Resistance to European Chestnut against *Phytophtora cinnamomi*

R. C. Seabra, Sebastiana, M.; Ramalho, J., Martins, A. and Pais, M.S.
Laboratory of Plant Biotechnology-ICAT., Edificio ICAT, Campo Grande, 1749-016 Lisboa, Portugal
FAX: 351 1 7573625, Email: maria.pais@fc.ul.pt

European chestnut orchards were drastically reduced as a result of ink disease, caused by *Phytophtora cinnamomi*. All over the world, problems of ink disease were mainly solved by establishement of *C.sativa* x *C.crenata* orchards. This expected good solution now being confronted with problems due to the high susceptibility of these hybrid clones to virus diseases and to the production of fruits and wood with lower quality.

It is urgent to find new approaches to minimise world chestnut disease problems. In an attempt to create new alternatives, for chestnut improvement, a program for molecular identification of selected clones was established. This program aims the correct discrimination between *C. sativa* and hybrids and between resistant and susceptible clones. These resistant clones were obtained following a breeding program, started in the forties, and have been shown, until now, resistance to ink disease after inoculation tests with *P. cinnamomi*.

The analysis by RAPD enabled the molecular separation between *C. sativa* and *C.sativa* x *C.crenata* hybrids, and proved to be adequate for the molecular characterisation of the ink disease resistant clones.

Sequencing of the ITS regions was also performed, in order to compare the results with those obtained by RAPD analysis and to establish molecular tools which can be used for the large-scale screening of genetic diversity of *Castanea* populations.

It is commonly accepted that resistance against fungi can be the result of expression of ß-1,3 glucanase and chitinase genes. Following the studies on resistant chestnuts, it was verified that they present much higher levels of ß-1,3 glucanases in leaves than the susceptible *C. sativa* clones. These levels are comparable or even higher (in some cases) to those observed for mycorrhizal plant leaves. Otherwise, the leaves from mycorrhizal plants present much higher ß-1,3 glucanases activities than those from non-mycorrhizal plants. These results have been cross-linked with those from studies on resistance to *Phytophthora* of susceptible plants mycorrhized with different mycorrhizal fungi. The results obtained revealed that susceptibility of chestnut plants is reduced at least by 40%, depending on the mycorrhizal fungi species used.

Insect Outbreaks in North West of Russia

Andrey Selikhovkin, Mikhail Kozlov
Russia
Email: Andrew@forest.spb.ru

Forestry is a major economic sector in north-western Russia, including Murmansk and Arkhangelsk districts, Komi Republic, and northern part of Karelia Republic. Forest pests were generally considered to have low importance in these regions. However, comparison with respective areas of Finland and Sweden, for which the information on pest outbreaks is readily available, suggests that damage from pests and pathogens may well affect economy of Northern regions.

The information on forest damage was classified in the former USSR, and there was a common tendency not to report any loss or damage. Therefore we assumed that the official data of the Russian Federal Forest Service are unrealistic, and should be used with discretion.

The goals of our study were (1) to locate primary information on forest pests and pathogens, which is generally stored in archives of local forest enterprises and forest protection organizations, (2) to evaluate its reliability by cross- check of different sources, including interview of local people, (3) to summarize the reliable data in a form suitable for statistical analysis, and (4) to reveal spatial and temporal patterns which may be related to environmental changes during the past decades.

By searching over 1,000 sources and interweaving of ca xx forest pathologists in the region under study, we discovered an information on outbreaks of 38 insect species between 1950 and 1998. The total area of the outbreaks during this period was about 1 mln ha. Total losses of timber or other forest products (for instants seeds) for the same period were about 18,5 mln USD. Since a number of outbreaks had surely not been recorded (or reported) for this sparsely populated territory, we believe that forests in >2 mln ha was damaged during insect outbreaks, resulting in losses of >20 mln USD. We concluded that forest pests have caused much more problems in northern forests of Russian part of the Europe than it was yet believed.

We detected an increase in frequency and severity of outbreaks between 1955 and 1998, and proved that this increase was not due to changes in intensity or quality of forest health monitoring. We suggest that this pattern may have resulted from either industrial development of the region (due to increases in pollution etc.) or climate change.

The Loss of Pine Stand Stability in the Northwest of Russia

T. A. Semakova, Shabunin D.A., Maslakov E.L
St.-Petersburg Forestry Research Institute, Institutsky pr., 21, 194021 Saint-Petersburg, Russia
FAX: (812) 552-80-42, Email: spb330@spb.sitek.net

The loss of pine stands stability in the National Park "Sebezhskij" (Pskov region) is a particular example of the great problem of pine stands degradation in the series of regions in the Northwest Russia.

The National Park was organised some years ago on the territory of the industrial (intensive) forestry. Mature and maturing pine stands prevail in the National Park now. The part of the stands were tapping for 10-15 years ago. The great disturbances of tapping rules have been placed at that time.

The expansion of disease caused *Heterobasidion annosum* (Fr.) Bref. in pine stands produces a large amount of declining trees which infect by pine shoot beetles.

Some years ago there happened unfavourable weather conditions (drought and snow-fall). They caused snowbreak in young-growth stands. As a result pine shoot beetles (*Blastophagus piniperda* L. and *Blastophagus minor* Hart.) outbreak took place there. This species are the most aggressive ones for pine stands in this region. Numbers of another aggressive pests, such as *Ips acuminatus* Gyll. and *Pissodes pini* L., is not significant. *Tetropium* spp. are typical for declining trees. As a result, pine shoot beetles outbreak expanded in the surrounding woods (tapped and virgin ones). The pest outbreak developed at the background of *Heterobasidion annosum* (Fr.) Bref. infection. The disease caused by fungus *Peridermium pini* is also widely spread.

The pine shoot beetles harmful activity, which lasted for some years, caused the loss of pine stands stability in the National Park. The data obtained showed that the average health category of the stands is now about 2-3 (by the six-number scale that is usual in Russia for describing pathology conditions of individual trees or whole stands). In other words, the stands, investigated are "depressed" and "high grade depressed". It is necessary to carry out the clear sanitary felling in the woods, which have a great portion of died trees (16-53%), because the selective cutting leads to the formation of sparse stands. Besides, the selective cutting changes the light regimen and the next outbreak of pine shoot beetles will be provoked. It is necessary to leave the seed trees, but the harmful activity of pests leads to the decrease of their seed productivity. The combination of the fungi *H. annosum* and pine shoot beetles creates the great hazard of a new pests outbreak in the future.

It is very useful to realise the long-term pathology monitoring for prognostication of the convertibility of pathological processes in the injured stands. The regeneration of the lost pine stands requires to develop special forestry measures and new recreation regimen. Though, the expansion of disease caused by *H. annosum* in pine stands doesn't make it possible to look forward to full regeneration. Probably birch stands will replace lost pine stands.

Pro-ecological model of forest ecosystems protection in Poland

Zbigniew H. Sierota, Andrzej Kolk
Forest Research Institute in Warsaw,Bitwy Warszawskiej 1920 No.3, 00-973 Warszawa, Poland
Email: z.sierota@ibles.waw.pl

The need of a new model of managed forest protection, based on ecological principles, raised recently due to the condition of forests in Poland, existing threats as well as society's expectations.

Forests in Poland cover the area of 8800 thousands of hectares, what makes the country forestage of about 28%. Stands are characterized by the simplified age and species structure (with the domination of coniferous – 77,3%, mainly Scots pine – about 70% of total forested area) as well as severe endangerment of biotic, abiotic and anthropogenic stressing factors.

The most important threats are insect pests and pathogenic fungi. It was demonstrated in the period of 1970-1998 by the mass occurrence of over 60 species of pests, among which 46 were controlled on the area of about 9 million of hectares. In 1982 the nun moth (*Lymantria monacha* L.), most danger species of pine and spruce stands was chemically treated on the area of 2,3 million of hectares. Additionally, forests in Poland on over 1 million of hectares are potentially threaten by the pathogenic fungi, mostly *Heterobasidion annosum* root rot. The damages associated with the occurrence of all kinds of fungi caused infectious diseases are reported on the area of 0,55 million of hectares each year.

Intense management practices that had been applied in the forestry since the second half of the 19th century have essential impact on the health condition and sustainability of forests in the present. This is the reason of forest ecosystem transformation from natural communities towards the artificial, plantation-like forms with the timber production as a most important goal of cultivation. As a result, the lasting changes of the soil properties, site degradation as well as simplification of species composition and age structure had occurred. The plantations of low biological variability and decreased sustainability replaced the natural forests, adjusted to the site and local climate condition.

The health status of forests in Poland is also determined by such factors like country geographic location in the zone of interaction of two major climate types in Europe: continental and Atlantic or fragmentation of forest site types resulted from the influences of 3 glacial ages. In addition, industrial air, soil and water pollution, radioactive contamination and global climate change affect the forest condition. That is why it is so important to limit the destructive impacts on forest ecosystems and to increase their biological resilience and stability.

Pro-ecological model of forest resources protection is based, first of all, on prevention. It may be expressed by the holistic approach towards the forest management manifested by the merged forest sylviculture, protection and exploitation practices to minimize harmful human impacts on natural processes.

The basic features and goals of pro-ecological forest ecosystem protection may be listed as follows:

Complex approach towards the forest ecosystem protection.

Spreading protection on large spatial units such as ecosystems, physiocenosis or mezzo-regions and on all living natural resources.

Early detection and recognition of potential threats and their limitation by the application of the biological, bio-technical and hylo-technical methods of forest protection.

application of methods and technologies safe to the environment

evaluation of the forest ecosystem disturbances by use of biological indicators such as average specimen biomass of *Carabidae*, primary insect outbreak sites or coefficients of phytopathological monitoring

The fundamentals of the pro-ecological model of forest protection are sustainability and multi-function forest management, what oblique foresters to comply such rules as follows:

Protection and extend of diversity of forest ecosystems by preservation of most valuable stands and endangered species of fauna and flora

Preservation of vitality and health condition of forest ecosystems by preference of silvicultural an protection treatments encouraging forest sustainability (promotion of genetic and species diversity, native and resistant ecotypes, species-site concordance etc.)

Turning back the degraded forest elements to its primeval state and protection of their further existence in the forest environment in spite of anthropopressure and threats.

Plant Derivatives from Oil Yielding Forest Species: Their Utility in Pest Control

Neelu Singh, Alka Bhargava
Tropical Forest Research Institute, Chemistry of Forest Produce Division, Post Box # RFRC, Mandla Road, 482021 Jabalpur, India
FAX: 91-761-321759, Email: alkamit@envfor.delhi.nic.in

In recent years environmental pollution has been increasing at an alarming rate due to indiscriminate use of synthetic pesticides. High levels of pesticidal residue in foodstuffs which is neither within permissible limits nor conforms to international standards, have directed studies towards use of environmentally safe, biodegradable phytochemicals. Oil seeds are a major source of biologically active compounds. There are about 93 such species available in India. These, however, remain badly under-utilised, only 7% of the total potential being tapped. In the present study, the bio-efficacy of natural products from non edible oil yielding seeds of some forest species viz. *Azadirachta indica, Jatropha curcas, Madhuca indica* and *Pongamia pinnata* have been studied for assessing their potential against some key insect pests of tropical forests.

Terpenoidal fractions isolated from *A.indica* kernels were screened for their feeding deterrancy against 3rd instar larvae of *Ailanthus excelsa* webworm, *Atteva fabriciella*, at different concentrations. Chloroform and aqueous isolates exhibited promising feeding deterrancy of 37.4% even at a low concentration of 0.03%. Five chromatographic fractions (FA-FE) and phorbol derivatives from *J.curcas* were screened in the laboratory and field against 3rd instar larvae of *Hyblaea puera* (teak defoliator), *Eutectona machaeralis* (teak skeletoniser) and *Plecoptera reflexa* (sissoo defoliator). Seed oil constituents showed significant deterrancy which varied between 43.37-100% at concentrations from 0.01-2%. Two component fractions FD and FE showed larvicidal activity (76.66-100% mortality) at the tested concentrations. Phorbol derivatives showed 60-80% antifeedancy at 1-5% under field conditons. Test solution of 1% concentration showed 100% feeding inhibition on seed insects of Bambusa arundinaceae and *Acacia nilotica*. Seeds from *M .indica* were collected from ten different localities and their bio active saponin glycosides estimated gravimetrically, giving a yield of 3.4 to 10%. Their biological activities were evaluated against insect pests of *Tectona grandis, Dalbergia sissoo, Dendrocalamus strictus* and phytonematodes *Meloidogyne incognita* and *Rotylenchus reniformis*. Emulsifiable concentrates of these concentrates showed antifeedancy in the range 20-80%, insecticidal (100% mortality at 1% concentration) and nematicidal properties (17.65-100% at 0.01 to 1% concentration) under laboratory conditions. Karanjin, 3-methoxyflavone-7,8-furan, separated from seed oil of *P.pinnata* was tested against teak defoliator *Hyblaea puera* and *Dalbergia sissoo* defoliator, *Plecoptera reflexa*. It was found to be effective in affording leaf protection against larvae, over the control. 1% and 2% concentration provided a leaf area protection of 67.5 and 92%. The e/g masses of phytonematode, *Meloidogyne incognita* treated with different dilutions of karanjin (2%, 1%, 0.5% and 0.1%) exhibited promising effects on larval emergence and mortality, 85.54%, 64.5%, 55.86% and 45.44% as compared with the control. Thus it may be postulated that the pesticidal potential of these oil constituents, which is technically and economically feasible, but still under utilised can be exploited for the preparation of eco-friendly protection chemicals.

Cono- and Spermatophagous Insects of Norway Spruce *Picea abies*/L./Karst.

M. Skrzypczynska
Academy of Agriculture, Dept. Forest Entomology, Listopada 46, 31-425 Kraków, Poland
Email: rlzabeck@cyf-kr.edu.pl

In Poland, Norway spruce *Picea abies* /L./Karst. is an important forest tree species in the mountains. Cono- and spermatophagous insects of *P. abies* have been studied in Poland for almost 25 years. The objectives of these studies were:
/l/ to evaluate qualitatively and quantitatively, the cono- and spermatophagous insects of *P. abies*;
/2/ to assess the impact of these insect species on seed production, and
/3/ to identify the parasitoids of these pests.

As a result of these studies, the following conophagous insects were obtained:

Cydia strobilella L./Lep., Tortricidae, *Dioryctria abietella*/ Den. et Schiff./Lep., Pyralidae, *Eupithecia pini* Retz. Lep., Geometridae, *Kaltenbachiola strobi*/Winn./Dipt., Cecidomyiidae, *Strobilomyia anthracina*/Czerny/Dipt., Anthomyiidae/ and two spermatophagous insects *Megastigmus strobilobius* /Ratz./Hym., Torymidae/

and *Plemeliella abietina* Seitn. /Dipt., Cecidomyiidae/. The major pest, *C. strobilella*, destroyed 20-96% /average 25.4%/ of the Norway spruce seeds. *P. abietina* infested 2-13% /av. 8%/ seeds, while attacks by *M. strobilobius* were rare. Losses to other insects were less than 2%.

During investigations parasitoids of these insects were noted. Hymenopterous parasitoids of *C. strobilella* included: *Elachertus .geniculatus* /Hart./, *E. nigritulus* /Zett./, *Tetrastichus strobilanae* /Ratz.//Eulophidae/, *Liotryphon strobilella* L., *Nemeritis transf* /Grav./, *Scambus calobatus* /Grav.//Ichneumonidae/. Parasitism reached almost 60% with 35% caused by *L. strobilellae*. These parasitoids should be evaluated as biological control for *C. strobilella*.

I. typographus f. *japonicus* Niijima (Col., Scolytidae): A Genetic Analysis by Allozymes and Mitochondrial Sequence Data

Ch. Stauffer, Lakatos F.
Universität für Bodenkultur Wien, Pathology and Forest Protection, Hasenauerstr. 38, A-1190 Wien, Austria
FAX: +43-1-3686352-97, Email: stauffer@ento.boku.ac.at

Ips japonicus was first described by Niijima (1909) on Yezo spruce, *Picea jezoensis* and Sachalin spruce, *Picea glehnii* in Japan. Kono & Tamanuki (1939) described *I. japonicus* as a form *of I. typographus*, *I. typographus* f. *japonicus*. Wood (1992) stated that even the status as subspecies is doubtful. However, studies of associated antagonists like mites and like the associated blue stain fungi revealed differences between the *European I. typographus* and the Japanese *I. typographus f. japonicus*. This study was designed to analyse the phylogenetic relationship of *I. typographus f. japonicus* in relation to other European Ips species, particularly *Ips typographus*.

I. typographus f. japonicus was collected from Hokkaido (Japan) and Changbai County (China), infesting *P. jezoensis*. Two regions of the mitochondrial genome and several isozyme loci were screened. A nucleotide divergence of 1.71% estimated by the gamma distance following the Tamura & Nei (1993) model was detected. All the substitutional sites were on the third codon position and transitions, thus not changing the amino acids. Further a species specific non coding region between COI and tRNA-LEU showed no difference between *I. typographus* and *I. typographus f. japonicus*. The European *I. typographus* populations, and the two Asiatic populations formed two significant monophyletic clusters.

Ecosystem Management of Forests In Russia: Strategy Of Forest Protection

Valentin V. Strakhov
All- Russian Research and Information Centre for Forest Resources, Novocheremushkinskaya Str. 117418, Moscow 69 Moscow, Russia
Tel: 7-095-332-5338, FAX: 7-095-331-0533, Email: aricfr@aha.ru

The analysis of interaction humans-forest ecosystems in Russia over of the 20th century does not reveal an essential evolution of forest protection strategy. Its development has not left frameworks of improvement of fire fighting measures and of controlling pests and diseases. We can state that - in force of diverse reasons - an inertia of political, instead of ecological priorities continues to exist in forest policy as concerns forest fires, outbreaks of insects pest and forest diseases, and their consequences for forest ecosystems, when justifying and developing active measures. The fire protection of forests and the control of pests and diseases are traditionally considered as a subsystem of forest management that should carry out organisational, sanitary and active (destroying) measures in order to protect forests and other forest economic objects from harmful organisms and negative man-made and natural influences and thus to maintain and increase the efficiency of forest biogeocoenoses. So, the definition of this subsystem highlights its understanding as a service of emergency reply on already happened events in forest ecosystems. Continuing of such understanding of forest protection leads to preserving paradigm (that became obsolete) of interrelations between humans and with forest ecosystems as antagonistic: all that deprives humans to use forest resources, first of all, wood, refers to as negative factors (fires, outbreaks of insects, diseases, etc.). This stereotype in public consciousness has proved to be tenacious enough in life and its conception at each new generation successfully begins in schools and universities, then proceeds through professional dialogue, textbooks, normative documentation and mass media. A dismal view of forest fires and burnt, nidi of outbreaks of forest insects and diseases of damaged leaves, branches, wood, etc. firmly secures this stereotype.

The transition to the ecosystem-minded forest management in Russia demands a differentiated approach to economic and ecological assessments of role and functions of forest fires, pests and diseases in various landscapes' elements.

The strategy of forest protection for an ecosystem-minded forest management demands to recognise that the laws of Nature have priority over those of economic development. The humans should be considered within the framework of forest ecosystems, and not as their supreme manager.

The said strategy proceeds from principles of adaptational ecology and adaptational management, that predetermines differentiated approach to organisation of the inventory and planning works, forest protection, use, restoration and forest area arrangement. It means that there is necessity to restructure enterprises and institutions, delimiting different patterns of ownership for various specialised kinds of activity, reducing at the same time the number of forest management units and increasing their equipment.

Recently Appeared Fungal Diseases on Forest Trees in Hungary

Ilona Szabo
West Hungarian University, Institute of Forest and Wood Protection, PO Box 132, H-9401 Sopron, Hungary
Tel: +36-99-311100, FAX: +36-99-311103, Email: szaboi@efe.hu

In Hungary situated in the Carpathian-basin, Central Europe, the rate of forest covered areas amount to 18%. The Hungarian forests are dominated by stands of broad-leaved tree species: oaks *(Quercus cerris, Q. petraea, Q. robur*), black locust (*Robinia pseudoacacia*), beech (*Fagus sylvatica*), poplars (*Populus* x *euramericana, P. alba, P. canescens*). Conifers are represented mostly by Scots and Austrian pine (*Pinus silvestris* and *P. nigra*). During the 1990s the appearance of some dangerous diseases, new for Hungary have been observed on most frequent cultivated forest tree species. Since the ratio of forests and the assortment of tree species are limited by climatic and topographical conditions, these diseases caused by fungi have a major significance for the forest practice in Hungary.

On *Quercus cerris*, especially in young stands of thinning age an abnormal swelling and cancer deformation of the collar region of the trees is frequent. The bark becomes abnormally thick, cracked and decays on some portions of the stem circumference. In the bark cracking the black stromata of the *Ascomycete Botryosphaeria stewensii* can be seen. At first the pycnidia develop that produce one celled and hyaline conidia becoming dark and two celled after their evacuation from the pycnidial cavities. The other factors can occasionally contribute to the disease syndrome, especially the frost and the attack of honey fungus (*Armillaria* species, most frequent *A. gallica*).

On *Robinia pseudoacacia* some bark canker and necrotic diseases have been recently investigated. In the summer 1998 the total death of the above ground parts of young trees was observable in 1-3 year old plantations. In other cases and on the somewhat older trees the lens shaped bark necroses were frequent mostly at the basis of lateral branches. The causal agent was the fungus Diaporthe oncostoma, anamorphe Phomopsis oncostoma. Further fungi as *Cucurbitaria elongata, Massaria anomia* were found frequent on the diseased twigs and branches as secondary colonizers.

Another symptom also has been frequent on young tress as well as on older ones at the bifurcation of the branches: swelling, deformation and fissures. This kind of canker proves to be caused by *Fusarium* species, namely *F. lateritium* and *F. avenaceum*. Their ocher colored sporodochia often can be observed on the swelled deformations. They infect the trees through injuries of different origin, in most cases caused by frost.

On hybrid poplars (*Populus* x *euramericana*) bark necroses caused by *Fusarium* species have been observed in relation to attack of poplar borers. In a stand of clone I 214 the bark decay has started from the larval galleries of *Agrilus populneus* and extended on large bark areas causing the death of the trees. In this case *F. solani* was isolated. At another clone the galleries of *Melanophila picta* were the starting-points. The margins of the necroses were healed in this case.

The *Phytophthora* root and collar rot of alder reported for the first time from southern Britain in 1993 has been recently observed in Hungary on *Alnus glutinosa*. The mass death of the trees became conspicuous in 1999, but the annual ring analysis of the stem basis of decaying trees shows that the epidemic has started three to four years earlier. The pathogen is close related to *Phytophthora cambivora*. It is morphologically variable, our isolates form smooth oogonia and two-celled amphigynous antheridia.

A Survey for *Bursaphelenchus* spp. in Conifers in Austria and Implications to Austrian Forests

Christian Tomiczek
Federal Forest Research Centre, Seckendorff-Gudentweg 8, A-1131 Vienna, Austria
Email: christian.tomiczek@fbva.bmlf.gv.at

Wood samples from more than 400 coniferous trees (*Abies alba* Mill., *Larix decidua* Mill., *Picea abies* L., *Pinus sylvestris* L., *Pinus nigra* ARN., *Pinus cembra* L. and *Pseudotsuga menziesii* FRANCO), showing decline symptmos, taken from 200 different sites all over Austria, were investigated concerning the occurrence of *Bursaphelenchus* spp.. 62% of wood samples contained sapwood nematodes out of which 27% belonged to *Bursaphelenchu*s. The most abundant species was *B. mucronatus*. *B. hofmanni*, *B. sexdentati*, *B-leoni*, *B. eggersi* and *B. new* spec. were observd less frequently. So far, the pine wood nematode (*B.xylophilus*) could not be found in Austrian forest.

Pathogenicity test with *B. mucranotus* and *B. sexdentati* on 3 yr. Old seedlings (*P. sylvestris* L., *Abies alba* Mill., *Picea abies* L. and *Larix decidua* Mill.) in climatic chambers (250C) and under outdoor conditions caused at least 30% mortality. Mortality increased in climatic chambers when additional water stress was induced (200ml per pot and week). The results indicate that *Bursaphelenchus* nematodes seem to be involved in the decline of coniferous forest in Austria, especially after drought periods.

Assessment on The Distribution of Wood-Inhabiting Macrofungi in Peninsular Malaysia

Salmiah Ujang, P.Thillainathan and Steve Moss, FRIM, Kepong, 52109 Kuala Lumpur, Malaysia
Tel: +603-6342633, FAX: +603-6367753, Email: salmiah@frim.gov.my

A total of 327 samples of wood-inhabiting macrofungi were studied with regard to their distribution from forest reserves at Kepong, Pasoh and Jeram Lenang and from plantation forests at Kemasual, Mata Ayer and Ulu Sedili. The highest number of species was collected form Pasoh forest reserve and the smallest number came from Mata Ayer plantation forest. Altogether, 52 species were identified. Common species found were *Earliella scabrosa* (Pers.) Gilb. & Ryv., *Trametes feei* (Fr.) Pat., *Lentinus sajor-caju* (Fr.) Fr. *Lenzites elegans* (Fr.), Kuntze, *Pycnoporus sanguineus* (Fr.), Murr. and *Schizophyllum commune* Fr. Similarity indices (Jaccard and Menhinick) showed the highest species diversity occurred at Pasoh forest reserve. Comparison between forest reserves and plantation forest showed that there is greater species diversity in forest reserves and lowest in plantation forests.

Termite Damage and its Management in Tropical Forests

R. V. Varma
Kerala Forest Research Institute, Division of Entomology, Peechi-680 653 Trichur Dist, Kerala, India
FAX: +487-782249, Email: rvvarma@kfri.org

Keywords: Eucalypts, Termitidae, Kalotermitidae, termite control, tropical plantations

In the tropics, subterranean termites cause serious damage to saplings and young trees of some species and often pose a threat to afforestation programmes. In general, exotic tree species are more prone to termite attack than the native species. In addition, dampwood termites of the genera, Kalotermes and Neotermes, cause damage to older living trees of some species.

In all the tropical countries, the exotic eucalypts are seriously damaged by several species of subterranean termites during the first year of establishment, and in some cases, during subsequent years also. Most common are species of the genera, *Macrotermes*, *Microtermes* and *Odontotermes* in Africa and Asia, and Nasutitermes in South America, all belonging to the family, Termitidae. The economic damage caused by termites to eucalypt plantations is substantial. If prophylactic measures are not adopted, over 80% of the transplants are liable to be killed by termites. In the past, control measures were generally based on soil treatment with organochlorine insecticides. Prophylactic spot treatment with aldrin, heptachlor or chlordane proved very effective and was practiced widely for establishment of eucalypt plantations. However, the use of the highly persistent organochlorine insecticides has now been phased out, on environmental considerations. Therefore research on the use of less persistent insecticides and other alternatives has become necessary. The organophosphate, Chlorpyrifos and some pyrethroids have shown promise and are currently being used. Controlled-release formulations of carbosulfan, carbofuran and chlorpyrifos have also been found effective, but are not being used widely as they are costlier. Although a number of non-chemical alternatives have been tested, none have proved operationally successful yet. However, this is a field which requires serious investigations and evaluation.

Three species of the genus *Neotermes* (Kalotermitidae) attack living trees of the exotic mahogany (*Swietenia macrophylla*) in Fiji, causing serious damage, and *N. tectonae* causes economic damage to plantations of the exotic teak (*Tectona grandis*) in Indonesia. There are no practically effective control methods against them.

Estimation of Conifer Resistance against Pests and Fungal Diseases

V. P. Vetrova, Polyakova G.G., Stasova V.V., Pashenova N.V., Konstantinov M.Yu.
Kamchatka Institute of Ecology of Far, Eastern Branch of Russian, Academy of Sciences, Petropavlovsk-Kamchatsky, Russia
Email: Institute of Forest [dndr@ifor.krasnoyarsk.su]

The current ecological situation conditions the priority of working out methods for forest protection against pests and diseases. In this context the problem of early diagnostics of woody plant resistance loss becomes pressing, since decrease of resistance is one of the reasons of outbreaks of pest insects and fungal diseases transmitted by these insects, that cause widespread mortality of forest stands or significant reduction of their economical value.

Inoculation of pathogenous fungi, associated with xylophagous insects is known to promote hypersensitive reaction in infected tissues of conifer stem phloem. This reaction is characterised by prompt development of necrosis in infected and adjacent cells and activation of terpenoid and phenolic metabolism (Reid et al., 1967, Paine et al., 1977).

A number of researches, devoted to defensive response in conifers to inoculation with pathogenic fungi, are concerned with study of resinosis, induced by pathogen effect (Reid et al., 1967; Wong, Berrymann, 1977; Cook, Hain,1987). The role of various phenolic compounds in induced defence response of conifers is studied insufficiently, while this group of substances is widespread in woody plants and is well known for its antimicrobic activity. Therefore it is necessary to extend investigations of physiolo gical and biochemical parameters of defensive response to fungal pathogens as well as simultaneous anatomical studies of tissues, involved in defensive response. This very approach will make it possible to devise methods of early diagnostics of resistance loss, when exterior symptoms of decline don't make its appearance.

In this paper the data on biochemical and anatomical parameters of stem phloem defence reaction, induced by fungi or their mycelium extracts are presented. The study was carried out in natural stands of some main siberian forest conifers, where trees of *Abies sibirica*, *Picea sibirica* and *Larix sibirica* were influenced by some biotic and abiotic environmental factors of different intensity. A number of experiments were conducted to establish defensive response parameters suitable for the characteristics of conifer resistance to pathogenous fungi and pest insects.

Our results show that trees, irresistable to fir sawyer beetle (*Monochamus urussovi* Fisch.) colonization, are very sensitive to the fungi, transmitted by this beetle. The level of fir tree resistance to the fir sawyer beetle and associated fungi was found to be characterized by the rate of lignin and proanthocyanidins accumulation in stem phloem reaction zone.

Decrease of spruce trees resistance under flooding of their root systems may also be estimated by the dynamics of lignin and proanthocyanidin concentrations in stem phloem after inoculation.

Strong correlation was shown between degree of fir tree defoliation by Siberian *moth (Dendrolimus superance sibiricus* Tschetvr.) and resistance of these trees to fungal invasion. The resistance of trees was evaluated by dimensions of necrotic lesion and other anatomical features of defence reaction zone.

In casebearer (*Coleophora laricella* Flkv.) damaged larch trees a defensive response to fungal infection involves an increase of necrotic lesion in stem phloem and decrease of infested phloem mass in comparison with non-damaged intact trees. From biochemical point of view the stem phloem response was shown to be systemic and non-specific. The systemic pattern of the response was indicated by tannin accumulation in stem phloem in reply to casebearer damage of needles. The non-specific character is suggested by the same tannin accumulation in response to insect damage of needles and fungal inoculation of stem phloem.

The method of single inoculation of stem phloem with pathogenous fungi usually vectored by xylofagous insects is shown to be simple and convenient technique for defensive response study and in the end for determination of mechanism of woody plant resistance to pathogens.

The risk of occasional spread of infection in forest stand during experimental inoculation may be avoided by substitution of fungal preparation by their mycelium extracts. The induced alterations in defensive response after these extracts application were found to be the same as after fungal inoculation. The advantages of diagnostics of conifer tree resistance by single inoculation method are its sensitivity and multi-utility. The method sensitivity results from capability to evaluate the resistance decre ase when no exterior signs of decline appear yet. The multy-utility is concerned with possibility to estimate effect of any unfavourable environmental factor, bringing tree resistance down. So, anatomical and biochemical parameters of conifer stem phloem defensive response induced by pathogenous fungi invasion are related with the level of resistance to pathogenous fungi and pest insects and may be used for characteristics of conifer resistance to these pathogens.

Insects as Indicators of Forest Health in Ponderosa Pine Forest in Northern Arizona

Jaime Villa-Castillo, G. Sanchez-Martinez and M. R. Wagner
Northern Arizona University, School of Forestry, Box 15018, 86011 Arizona Flagstaff, USA
FAX: (520) 523-1080, Email: jvc@alpine.for.nau.edu

Forest health in northern Arizona ponderosa pine forests has declined since European settlement. Reintroduction of fire and thinning are the main practices suggested to return forest to healthy conditions. However, a major gap exists in understanding how broad landscape-level management practices may affect forest health (i.e. biodiversity, NPP, tree growth efficiency). We are examining ground beetles (Carabidae), bark beetles (Scolytidae), and wood borers (Cerambycidae) as potential indicators of forest health in relatively large stands (20-40 ha) subjected to different management regimes in Northern Arizona. Although rarely referred to as ecological indicators, these insect guilds have most of the desirable attributes such as high sensitivity to environmental change and stressing factors. We hypothesize that the composition and community structure of these insects is linked to specific stand structural and functional attributes.

Four stand conditions with four replicates are being evaluated: 1) thinned plus prescribed burned, 2) thinned, 3) unmanaged, and 4) wildfire burned stands. Standard trapping techniques are being used to sample insects on each guild. The study will include two growing seasons to determine insect guild abundance. Insects are being identified to the species level when possible. Predictive indexes based on selection of functional groups will be used to characterize the differences in stand conditions.

Preliminary results on the ground beetle guild indicate that species richness and evenness differed significantly among treatments. Unmanaged and thinned sites had lower Shannon diversity index than wildfire burned stands and thinned plus prescribed burned stands. Also, the number of species was consistently higher on wildfire burned sites. Differences on species assemblage were found among treatments. Unmanaged and thinned stands were consistently dominated by one species of the genus *Synichus*. Although this species was recorded on wildfire burned stands, the abundance of two species of genus *Calathus* was more characteristic on these stands. Several species of genus *Amara* were abundant on wildfire burned stands but rare on thinned stands and prescribed burned stands.

There were differences in bark beetle and wood-borer diversity among treatments. Wood borer diversity was consistently higher than bark beetle diversity in stands other than wildfire burned stands. Bark beetle diversity was higher than wood borer in wildfire stands. There were stand specific beetle species as well. The red turpentine beetle (*Dendroctonus valens*) was present in all the four stand types; however, other Dendroctonus species were found in wildfire burned stands only. The Cerambycidae *Acanthocinus obliquus* was found in wildfire burned stands and unmanaged stands, whereas Arthopalus rusticus was found in unmanaged stands only.

These findings are encouraging because they suggest that selected insect guilds can be used to characterize stand condition. The presence and relative abundance of specific insect species could be used to indicate healthy or unhealthy conditions of ponderosa pine forests, based on documented insect behavior.

Integrated Pest Management to Sustain Iroko Production in Ghana, West Africa.

Michael Wagner, Joseph R. Cobbinah, S. Adu-Bredu, V. Agyeman, J. Appiah-Kwarteng, P. Bosu, J. D. Nichols, D. Ofori
Northern Arizona University, School of Forestry, Post Box # 15018, Arizona 86011-5018 Flagstaff, USA
Tel: 520-523-6646, FAX: 520-523-1080, Email: Mike.Wagner@nau.edu

Milicia spp. (*M. regia* and *M. excelsa*), referred to as Iroko in West and Central Africa, are valued commercial timber species because of their natural durability and good working properties. Because of this high value, Iroko exploitation has exceeded regeneration throughout much of its range. Regeneration of the species is poor because of several factors including attack by a gall-forming psyllid *Phytolyma lata*, low incidence of overstory trees, high seedling mortality, limited dispersal of fruits, and narrow environmental conditions that are suitable for seedling survival. *Phytolyma* attack is followed by dieback of the foliage down to the woody tissue, which disrupts physiological processes, causes growth reduction, and in many cases kills seedlings. Repeated attacks by *Phytolyma* are common, resulting in decimation of seedlings in plantations. All attempts to grow this species in West African plantations have failed. For the past 8 years an integrated team of ecologists, geneticists, and entomologists have developed a comprehensive integrated pest management (IPM) system to manage this insect. Components of the IPM system include:

1) Identification and clonal trials of genotypes of Iroko that tolerate *Phytolyma lata* attack resulting in a number of clones of Iroko that show considerable potential as insect resistant stock.

2) Development of improved cultural practices such as vegetative propagation, seed collection and storage procedures, nursery production, and improved planting techniques. Experimental trials of Iroko in mixed species plantations with both native and exotic species has demonstrated the potential of some significant pest impact reduction in mixtures when compared with pure stands. Thechoice of companion species may be important as may be the sequence of planting various species

3) Enhanced understanding of regeneration of Iroko and the role played by the psyllid in natural forests: including determining the light conditions suitable for regeneration, seedling survival relative to the parent tree and the influence of gap size on seedling survival and *Phytolyma* attack.

4) Identification of factors influencing natural enemy regulation of *Phytolyma lata*. Four parasitoids from two families were identified: *Psyllaephagus phytolymae* (Encyrtidae), *Aprostocetus salebrosus*, *A. roseveari*, *and A. trichionotus* (all Eulophidae) were identified. Percent parasitism was low, between 4 and 16% with higher rates in drier months (November through February). A negative relationship was discovered between parasitism and the size of the galls. *Psyllaephagus phytolymae* did not occur on seedling galls, even though it has been cited in the literature as one of the primary parasites on *Phytolyma lata*. The absence of this important parasite from the seedling galls may explain why the worst cases of *Phytolym*a damage occur in nurseries and young plantations.

This IPM program has the potential to resurrect Iroko as a major West African timber species if effectively implemented in suitable growing sites.

Study on the Relationship between Morphological and Dissection Characters of Bark and Its Resistance to Longhorn Beetles (*Anoplophora nobilis* Ganglbauer and *Anoplophora glabripennis* Motch)

Fugui Wang
Chinese Academy of Forestry, Research Institute of Forest Ecology, Environment and Protection, 100091 Beijing, China
FAX: 0086-10-62884972, Email: fugui@prot.forestry.ac.cn

Bark is the only reproduction place of longhorn beetles, and is very important for their population cycle. The different species and clones of tree resistance to longhorn beetles are highly correlated with the physics, chemical and morphological characters of bark. In this paper, olefin sections of 49 species and clones of bark were made, and 19 indexes of micro-characters of cortex, periderm, primary phloem and secondary phloem were observed and described in quantity and quality. The rough degree and thickness of bark were measured. The quality indexes were quantified by Quantity Theory I, and all 57 variables and 1 constant (population density of longhorn beetles (Y)) were analyzed by Stepwise Regression. Finally, 7 factors, namely, rough bark (x1), light rough bark (x2), sclereid in cortex (x3), small cubic crystal in primary phloem (x4), fibre surrounded crystalloid in secondary phloem (x5), organic compound in periderm (x6), distribution way of fibre in secondary phloem (x7) were proved to be related to the tree resistance to longhorn beetles. The regression equation was Y=-2.559+13.531x1+4.676x2+3.654x3+1.992x4+.293x5+3.050x7-1.499x6 , r=0.713, and the difference was significant. Among 7 factors, 2 concerned bark morphological characters, 3 concerned the chemistry characters, 2 concerned the structure characters. These above indicated that tree resistance to longhorn beetles depends on the synthetic element.

Antioxidant Enzyme Activities to Air Pollution of *Alnus firma* in Yochon Industrial Complex, Republic of Korea

Su-Young Woo, Don Koo Lee, Dong-Sup Lee and Dong Geun Kim
Sangju National Univ., Dept. Forest Resources, 742-711 Sangju, Korea R.
Email: swwoo@samback.sangju.ac.kr

This study measured the seasonal changes of physiological characteristics and antioxidants of Alnus firma to compare several enzyme activities (Rubisco, Superoxide dismutase (SOD) and Glutathione Reductase(GR)) between resistant and sensitive Alnus firma trees in Republic of Korea. Resistant and sensitive Alnus firma individuals near Yochon industrial complex were selected to conduct this study.

Photosynthetic capacity, stomatal conductance, transpiration, Rubisco, SOD and GR activities of resistant trees which had no visible damages to air pollution were higher than those of sensitive trees in same area. All physiological results supported that biochemical process to be one of the important key features to understand resistance to air pollution. Increases of photosynthetic capacity and antioxidant enzyme activity in resistant trees in response to air pollution were the results of biological compensation to stress.

Relationship Between Fungal Spread and Defensive Responses in Japanese Cedar Sapwood Inoculated with *Guignardia* Dieback Fungus

Toshihiro Yamada, Nakashima, T. and Ito, S.
Forestry and Forest Products Research Institute, Forest Pathology Laboratory, P.O. Box 16, 305-8687 Ibaraki, Japan
Tel: +81-298-73-3211 ext. 404, FAX: +81-298-73-1543, Email: yamari@ffpri.affrc.go.jp

Keywords: *Cryptomeria japonica*; *Guignardia cryptomeriae*; sapwood; wood discoloration; defensive response; phytoalexin

To determine the relationship between fungal spread and defensive responses in the sapwood of Japanese cedar, *Cryptomeria japonica*, a canker and dieback fungus, *Guignardia cryptomeriae*, was inoculated into excised stem lengths and standing trees of *C. japonica*. Then, spreads of wood discoloration and fungal hyphae were measured, and defense responses were analyzed chemically and anatomically.

Fungal hyphae spread quickly in autoclaved stem lengths and freeze-treated stem lengths. In spring inoculation test, fungi spread longitudinally in the excised stems as fast as on potato dextrose agar. Therefore, constituents of sound sapwood prior to the infection are thought not to inhibit fungal spread in the wood. Fresh excised stem lengths, in which intensity of the defense response was weakened, interfered with fungal spread except in the case of spring inoculation with virulent isolates. Fungal spread was most retarded in living trees. Sapwood of fresh excised stems responded more intensively to avirulent isolates than to virulent isolates, and the rate of retardation of fungal spread was higher in avirulent isolates than in virulent isolates. These results indicate that active defense responses play an important and definitive role in the inhibition of fungal spread in the sapwood of *C. japonica*. Axial-tangential ratio of fungal colonization was higher in living trees and fresh excised stems than in both autoclaved stems and freeze-treated stems. This suggests that active defense mechanisms are also involved in the determination of the shape of wood discoloration.

Wood discoloration and fungal hyphae spread quickly during the first 2 weeks of inoculation in the standing trees. The spread of both virulent and avirulent isolates was inhibited between 2 weeks and one month postinoculation, though the size of wood discoloration and fungal colonization varied depending on the virulence of inoculated fungal isolates.

Within one week postinoculation, oil droplet-like deposits containing norlignans (e.g. hinokiresinol, agatharesinol and sequirin-C) and terpenes began to be secreted. Extractives content increased between 2 weeks and one month postinoculation. Antifungal compounds, hinokiresinol and a few unidentified compounds, accumulated quickly as phytoalexins. Agatharesinol, sequirin-C and several terpenes, which had little antifungal activity, accumulated slowly in the reaction zone barrier. These results suggest that accumulation of inhibitory substances contribute to the retardation of fungal spread within 2 weeks after the infection and the complete prevention thereafter.

Intensity of the defense response, evaluated from the concentration of phytoalexins and secretion of oil droplet-like deposits, did not differ between standing trees inoculated with isolates of different virulence. Concentration of phytoalexins accumulated in the reaction zone barrier, however, were higher in inoculated trees than in wounded trees, suggesting the enhanced induction of defense responses by the existence of pathogenic fungi. Concentration of phytoalexins in the reaction zone barrier was higher in fresh excised stems inoculated with avirulent isolates than ones inoculated with virulent isolates. This fact suggests lower induction level of the defense response against virulent isolates under stress.

The Land Leech, *Haemadipsa zeylanica japonica* (Gnathobdellida: Haemadissidae), Study of Biology to Control its Biohazard.

Ikuo Yamanaka, Akiomi Yamane
University of Tokyo, 299-5503 Chiba, Japan
Email: akyamane@brs.nihon-u.ac.jp

Key word: land leech, biology, biohazard, population increase, change of forest management, shika deer

The land leech, *Haemadipsa zeylanica japonica*, is a common blood sucking land leech, and distributes widely from subtropical to warm-temperate zones of Japan, but each distribution area is usually localized, and its density is usually low. However its range and density have increased since 1985 in the southern Boso Peninsula, Chiba Prefecture in Japan. Now it often causes biohazard by attacking forest worker, hiker. resident, as well as companion animals not only in the forest but at the home garden in rural village. It is not dangerous among the animals inhabiting in the forest, because it does not transmit any harmful pathogen, but it is thought to be one of the most uncomfortable ones which causing bleed of human being unconsciously during working, hiking, and walking. This causes some undesirable impact on tourist industry by decrease of visitors there. To establish safety control measures against it, studies on biology and environmental factors affecting population increase of the land leech have been made.

Based on laboratory observation, the life span is about 9 to 19 months, and after sucking blood 4 or 5 times it becomes mature enough to deposit cocoon of which average number of eggs was about 6, maximum was 13. Deposition of cocoon and hatching from cocoon occurred at the temperature above 15°. Sucking and mating were observed above the temperature of 10°, that means the activities during winter stopped, but even in winter when it was warm enough it may become active in sucking blood. The amount of blood sucked by a land leech from host human being was six times as much as its body weight . During blood -sucking it exhausted excessive water from its body surface of which weight was about twice as much as the body weight. Total amount of blood sucked was about eight times and grand total of bleeding from host including loss of blood after it left was about nine times as much as its body weight.

The reasons why expansion of distribution and population increase have occurred were considered to be due to the population increase of the shika deer, and change of forest management in which the ever-green broadleaf trees have not been harvested for production of charcoal and fuel wood for long time resulting in overcrowded forest and providing suitable environmental conditions such as rich in litters and wet on forest floor for the land leech. At present the most convenient way to avoid attack by the leech is use of effective repellents available commercially.

Diseases and Disorders of *Azadirachta excelsa* in Peninsular Malaysia

Maziah Zakaria
Forest Research Institute Malaysia, Kepong, 52109 Kuala Lumpur, Malaysia
Tel: 603-6302110, FAX: 603-6365531, Email: maziah@frim.gov.my

Keywords: *Azadirachta excelsa*; Diseases; Nursery; Plantation

During the last decade, the rapid establishments of forest plantations in Peninsular Malaysia are based on fast growing exotic species. However in recent years, the trend has shifted to indigenous species. One of the species chosen is *Azadirachta excelsa* locally known as sentang. Since this species has never been planted in large scale, its introduction as monoculture provides opportunity for the emergence of new disease problems. There has therefore, been an increase in demand in recent years for information regarding this problems.

Disease surveys conducted at forest nurseries and plantations in all the states in Peninsular Malaysia revealed that seedlings of *A. excelsa* are resistant to disease, since there are very few diseases occurring at the nursery stage compared to the plantation. The only nursery disease outbreak observed was wilting of *A. excelsa* cuttings due to *Sclerotiu*m sp. In the plantation root disease and multiple leader phenomena are the two most common occurrences. Apart from this, foliage and stem diseases are also observed but they are less common.

Root diseases such as root rot and collar rot occurred in most of the areas surveyed. The associated pathogens are Basidiomycetes, namely *Phellinus* sp. and *Rigidoporus* sp. At the moment they are the most important threat to young *A. excelsa* in plantations. There are also occurrences stem diseases such as canker, shoot lesion and dieback but incidence are generally low. The occurrences of foliage disease such as leaf spots and lesions, curled leaves and yellowing of leaves are very minor that it did not cause any significant damage to the trees. The fungal pathogens most commonly associated with these diseases are *Lasiodiplodia theobromae, Fusarium* spp., and *Colletotrichum gloeosporioides*.

Multiple branching phenomena have been observed occasionally at several sites in Peninsular Malaysia. It was observed to occur on one a half to two year old trees planted on poor lateritic soil, where no tending is done. Until now no specific fungus has been found associated with this symptom.

Apart from fungal problems *A. excelsa* is also susceptible to a number of known abiotic factors and conditions. The abiotic factors include water-logging, drought, nutrient poor sites and hard pans. In addition, factors such as site preparation and site history also play an important role in increasing disease incidence especially root diseases.

Incidence du complexe des ennemis naturels intervenant à la fin du cycle de larvaire de *Thaumetopoea pityocampa* Denis et Schiffermüller (Lep., Thaumetopoeideae) dans une région subsaharienne (Djelfa-Algérie)

M. Zamoum, G. Demolin
INRF, Laboratoire d'ecologie Forestiere, 84340 Malaucene, Algeria
FAX: 2531097, Email: m.zamoum@lcmel.fr

La processionnaire du pin, *Thaumetopoea pityocampa* (Lep., Thaumetopoeidae), défoliateur des essences résineuses à travers le bassin méditerranéen est en phase de culmination permanente, depuis plus d'une décennie dans les reboisements à *Pinus halepensis* Mill. du "barrage vert" en Algérie. Les attaques massives de ce ravageur sont apparues dès 1970, après les grands efforts entrepris dans le cadre du projet intitulé "barrage vert" qui a pour objectif la reconstitution des formations forestières à travers toute l'Algérie et plus particulièrement celles localisées le long de l'Atlas Saharien. Une monoculture exclusive, celle du pin d'Alep, a engendré une explosion démographique des populations de *T. pityocampa* qui, par ses défoliations répétées, mettait en péril ces reboisements qui évoluaient déjà dans les conditions contraignantes d'une région semi aride. Cette dernière est connue pour ses déficits hydriques (moins de 400 millimètres d'eau par an) et par la pauvreté de ses potentiels édaphiques.

L'étude a été menée durant les cycles de développement 1993/1994 et 1994/1995 dans la région subsaharienne de Djelfa dans des peuplements artificiels non encore fermés avec des arbres ne dépassant pas trois mètres de hauteur. Ces reboisements font partie du "barrage vert" et correspondent à la limite sud de l'aire de distribution de *T. pityocampa.* Cette étude a permis d'inventorier et d'évaluer l'aptitude parasitaire des ennemis naturels de ce ravageur, notamment les parasitoides intervenant à la fin du larvaire.

Parmi les traits d'adaptation phénologique qui ont été observés dans la nature, nous avons les rythmes des dépôts et ceux des processions de nymphose, qui marquent la fin du cycle larvaire. A Djelfa, il apparaît que les pontes ont lieu avec 30 jours de retard par rapport à des biotopes similaires du point de vue altitude comme Chréa (nord de l'Algérie) et le Mont-Ventoux (sud de la France) alors que les processions de nymphose interviennent à des époques similaires à celles des deux autres biotopes cités.

Les résultats obtenus montrent que les espèces clefs du complexe des parasitoides ont été retrouvées à Djelfa mais la diversité spécifique de ce complexe est faible par rapport à celle observée dans le littoral algérien et le sud de l'Europe. Il ressort des résultats de l'inventaire que se sont les parasitoides polyphages qui n'ont pas été rencontrés dans les stations d'étude. Cela est vraisemblablement liée à l'artificialisation abusive du milieu découlant de la monoculture pratiquée dans le projet du "barrage vert".

L'efficacité des différents parasitoides intervenant à la fin du cycle larvaire a varié d'une station et d'une année à l'autre et s'est montrée dépendance de la densité de l'hôte et des possibilités de coincidence phénologique avec ce dernier. Des élevages des parasitoides des chenilles dans les conditions semi-naturelles et l'observation des rythmes de dépôts de pontes et des processions de nymphose dans la nature ont permis de constater dans certains cas, un désynchronisme entre la présence de l'hôte avec celui des parasitoides qui se développent dans des microclimats différents.

Concernant les parasitoides larvo-nymhphaux, *Erigorgus femorator* (Hym., Ichneumonidae), peu abondant en règle générale dans l'aire de réparition du ravageur, a été constamment observé. Son action a été dans certains cas plus importante que celle du parasitoide spécifique *Phryxe candata* (Dipt., Tachinidae)

Les résultats ont permis d'apporter des éléments biologiques sur le déterminisme des gradations et d'asseoir une stratégie de lutte intégrée pour contrôler, autant que possible, les populations de cet insecte dans les conditions du "barrage vert".

The DCPV Virus Used for Long-lasting Control *of Dendrolimus punctatus* (Lepidoptera: Lasiocampidae) in China

Yongan Zhang, Chen Changjie, Wang Zhixian, Chen Jiawen and Wang Yuzhu
Chinese Academy of Forestry, Research Institute of Forest Ecology, Environment and Protection, 100091 Beijing, China
FAX: 86-10-62884972, Email: Zhangyab@prot.forestry.ac.cn

Satisfactory results were obtained by using the compound formulation of *Dendrolimus cytoplasmic* polyhedrosis virus (DCPV) with *Bacillus thuringiensis* Berliner (Bt) to control *Dendrolimus punctatus* Walker (D.p.) (Lepidoptera: Lasiocampidae)in Masson pine forests in south China. At the condition of 27°, the compound of DCPV (1-105CPB/ml) with Bt (2-107spores/ml) against 4-instar larvae made 70% mortality, and infected 50% the survivors as well. Within the compound of the two biocontrol agents, Bt could quickly reduce populations D.p. larvae and DCPV could spread and preserved in the colony of the defoliator generation by generation. Meanwhile, the dosages of the DCPV and Bt were reduced to 20% and 40% respectively, compared with being used alone. There were still 78.5% individuals containing DCPV (determined by ELISA), and thus, the pest was maintained at a low population, since its spraying in 1983 in certain forests.

Ecological Pest Management and its Practices of Forest Pest Management in China

Zhang Zhen
Chinese Academy of Forestry, Research Institute of Forest Ecological Environment and Protection, 100091 Beijing, China
FAX: 86-01-62884972, Email: zhangzhen@prot.forestry.ac.cn

There are only 134 million ha. of forest with the coverage rate of 13.92%. To solve the problem, Chinese government has made effort to develop plantations in recent years. With the increase of the plantation area the damaged area increased year by year from 1 million ha. in 1950s to 11 million ha..

Because of the limitation of existing IPM strategy and the limited application of biological control, the occurrence area of forest pests is still increasing and the situation will last at list for a period of time. To solve the problem sustainable pest management must be taken as a guideline. To meet the need of Sustainable Development and Sustainable Pest Management, ecological pest management “EPM”¸ is proposed to replace IPM in future.

EPM uses many elements of integrated pest management “IPM”¸but it is based on keeping and supporting the natural stability of the ecosystem and suppressing pest outbreaks at the very beginning when the population density is still low. With a special system of collection and processing of information, the frequent detection and estimation of pest, predator and parasite population density, biological control decision making is made according to the threshold when pest is slipping away from the control of the natural enemies. EPM can be cheaper than IPM because both costly uses of chemical pesticides and mass inundation by artificially reared parasites or predators are rejected.

There are some successful practices in forest pest management of EPM technology in China. For example, suppress the pine caterpillars through mountain closure, control the longhorn beetles by diversification of forest structure, use pine caterpillar CPV (*Dendrolimus punctatus*) and the inoculative release of Beaureria bassiana to control of pine caterpillars. However, at the present level of knowledge and technology, EPM cannot be elaborated thoroughly. More efforts should be made in researches of the ecology of ecosystem and the relevant techniques.

Population Crash Threshold of *Paulownia* Bagworm *Clania variegata* Snellen (Lepidoptera: Psychidae)

Sun Zhiqiang, Qiao Jie Fu Jianmin
Paulownia Research Center of China, 3 Weiwu Rd., 450003 Zhengzhou, China
Tel: +86 371 5944534, FAX: 86-371-5953628, Email: prdcc@caf.forestry.ac.cn

Keywords: Population crash threshold; *Cryptothelea variegata*; Spread rate; Parasitism

Data of paulownia bagworm [*Cryptothelea variegata* Snellen (Lepidoptera: Psychidae)] population development, management, and parasitism from 1985 to 1995 in Lankao county, Henan province, P. R. China were analyzed. The hypothesis of population crash threshold was therefore put forward and the index of the threshold was calculated based upon the analysis. The result could theoretically explain the sudden breakdown of bagworm population in large area of pure paulownia plantation.

The development of bagworm population, on account of the attacked area, could be divided into spreading stage (1985-1990) with average spread rate of 115% annually, peak stage (1991-1992) with spread rate of nearly zero and breakdown stage (1993-1995) during which the pest population crashed sharply.

Control operations of *C. variegata* were effective for foliage protection but they could not prevent the pest from dispersing due to incomplete control of trees with living larvae, it was not the means to lead the population to crash either. Reliable data also showed that *C. variegate* cycles were more likely to be the result of interaction with parasitoids. Furthermore, parasitoid is one of the facilitation factors to promote the breakdown of bagworm population but not the key element.

Population of *C. variegata* will extinct under condition of population crash threshold Tcr=355 larvae per hundred leaves of insect density or above, and spread rate should be or near zero. The intensive high density caused severely interspecies competition and under such condition the environmental carrying capacity was shortage to support the whole population.

Mass Rearing of *Chouioia cunea* (*Hymenoptera: Eulophidae*) and Applying for Biocontrol of Fall Webworm in China

Yang Zhong-qi
Research Institute of Forest Protection, Chinese Academy of Forestry, Beijing, 100091 , China
FAX: 86-10-62884972, Email: yangzq@nic1.forestry.ac.cn

The effective endopupal parasitoid, *Chouioia cunea* Yang (Hymenoptera, Eulophidae: Tetrastichinae), of *Hyphantria cunea* (Drury) was studied on its starting development and effective accumulated temperatures, as well as mass rearing technique. By experiment of different defoliators selected for substitute hosts, 12 of them showed good result, and especially substitute host I and II were the best hosts for mass rearing the parasitoid for the number 5270 and 468 reared from one host respectively). After releasing for biological control of fall webworm in three Provinces and one city in China, the pest was significantly controlled. The parasitic ratio usually reached over 80% by the wasp itself, plus other parasitic natural enemies, the total parasitic ratio of the pest was over 90%. It was indicated that the biocontrol technique has a bright prospect to supression the pest under control.

Impact of Pine Wood Nematode on Pine Forest Sustainability in Taiwan

Ming-Jen Lee
National Chiayi Institute of Technology, Department of Forestry, Chiayi, China-Taipeh
Tel: +886-5-271-7200, FAX: 886 5 271 7016, Email: mjlee@rice.cit.edu.tw; mjlee@mail.ncyu.edu.tw

Keywords: Pine wood nematode; Pine sawyer; Taiwan red pine; ecosystem

Pine wood nematode (PWN), *Bursaphelenchus xylophilus*, has caused severe damage to pine forest in Taiwan since its first occurrence at a small tree farm of 0.3ha at Shimen village in 1982. It is recognized that the pine wilting disease at Shimen village was the starting point for PWN disaster in Taiwan. Pine sawyer (PS), *Monochamus alternatus*, was discovered to be the most important insect vector of PWN. From 1985 to 1990, outbreak of severe pine damage spread rapidly from northeast to north and then southward to Taoyuen pref., and the disease became epidemic. During this period, two pine species, i.e., *Pinus luchuensis* and *P. thunbergii*, were severely attacked and destroyed.

Since 1991, the disease spread through north to central part of Taiwan. Although Taiwan red pine (*P. taiwanensis*) was claimed as resistant species, PWN damage has spread to the main stands of Taiwan red pine in central Taiwan. It was discovered that the PWN recovered from the diseased Taiwan red pine coincided morphologically with *B. mucronatus*, which can mate with *B. xylophilus*.

Recently, the disease was discovered in Taiwan red pine plantations in southern Taiwan. The infested areas have been increased to more than 3,500 ha.

Fortunately, up to the present, PWN damage does not occur in plantations of five-needle pines, such as Taiwan armand pine (*P. armandii*) and Taiwan white pine (*P. morrisonicola*). Control measures such as felling of diseased trees, burning, chemical spray and fumigation treatment, and biological control, as well as attractants application were conducted to eradicate PS and PWN. Quarantine regulation has been set up to prevent disease expansion. Reforestation with PWN resistant tree species, salvage cutting, thinning, breeding for resistance, and establishment of multi-story forest, as well as forest ecosystem management strategy are adopted to ensure sustainability of pine forest in Taiwan.

The Background of Insects - Defoliators Outbreaks Prediction in Ukrainian Forests

Valentina L. Meshkova
Ukrainian Research Institute of Forestry & Melioration, Pushkinskaya str. 86, 310024 Kharkiv, Ukraine
FAX: (+ 0 380572) 43-25-20, Email: zahist@u-fri.kharkov.com

Pest prediction must answer the questions - what pest, when and where can form the outbreak, what will be the influence to the stands. This will allow to make the decision about necessity of control measures planning. The foliage-eating insects cause the main injury in the considerable part of Ukrainian forests, especially located in the forest-steppe and steppe zones. The main defoliators of deciduous trees are *Tortrix viridana* L., *Lymantria dispar* L., *Euproctis chrysorrhoea* L., *Operophtera brumata* L., *Erannis defoliaria* L. The main needle-eating insects are *Diprion pini* L., *Neodiprion sertifer* Geoffr., *Dendrolimus pini* L., *Bupalus piniarius* L., *Panolis flammea* Schiff. Population parameters, site and stand characteristics in the foci and out of them as well as weather indices during outbreaks, before and after them in different regions of Ukraine for more than 50 years were collected in computer databases. There are also databases with ecological and population indices of the main defoliators, critical population density in different conditions, phenological data for pests and their hosts in the different regions of Ukraine. All these data were processed using statistic methods, multivariate, principal component, discriminant and GIS-analysis to obtain some quantitative characteristics of conditions in which pest outbreaks occur.

Investigations of outbreaks history show that pest-defoliators outbreaks are cyclic and have high correlation with sun - spot activity. Special attention was paid to development of meteorological factors analysis methods, which allow to determine the zones of different outbreak frequency and injury, to predict the weather conditions unsuitable for stands resistance and suitable for pests, to systematize the information about critical periods for pests and to plan in time protecting measures using phenologic indicators. Statistic analysis allows to conclude that duration, intensity and spreading of outbreaks vary in the different foci and depend on site conditions, initial forest state. The state of stands may be both the cause and the result of this process. To predict the probability of outbreak realization in the given site conditions we tried to take into account the totality of relief, soil, stand indices and state, water availability in analysis of the pest history for different forest enterprises. The mean characteristics of above said parameters and their statistics were calculated for the stands with outbreaks and without them. Simultaneously damage history was analyzed. It was stated that equal pest density can cause different damage in different region, site, stand, weather conditions. Thus foliage consumption by pest depends on foliage quality and weather. Weather influence both on the foliage quality and feeding rhythm of the larvae. Pest damage influence to tree vitality also depends on numerous factors which characterize site conditions, weather, previous damage and stands state, as well as stand composition, biological peculiarities, number and population state of insects. The spring damage is more dangerous than the autumn one because shoots do not develop and reserve substances do not accumulate. The middle-aged trees are more resistant to damage than young and old ones. Oppressed and desiccated trees decline more quickly than healthy ones. Healthy trees foliage is less favorable for insect development because of large contents of protective substances in the leaves or needles. The trees in the favorable site conditions recover more quick after damage. At dry weather more trees die than in the wet seasons. Sudden frost in autumn can cause the pest mortality or shoot mortality if they are not yet woody.

The Effects of Simulated C2H4 Alone and Synergic Stress with SO2 and NO2 on Several Woody Plants

Shang He, Shang He, Liang Jingsen, Li Baizhong, Yuan Gongying, Liu Zeng
The Chinese Academy of Forestry, The Research Institute of Forest Ecology, Environment and Protection, Wan Shou Shan, 100091 Beijing, China
Email: shanghe@fee.forestry.ac.cn

Ten species of woody plants: *Pinus tabulaeformis*, *Platycladus orientaliscl*.Franco, *Sabin*a, *Populus tomentosa, Salix capitata* carr., *Sophora japonica* L., *Robinia pseudoacacia* L., *Amorpha fruticosa* L., *Fraxinus sogdiana* Bunge, *Ailanthus altissima* Swingle, were exposed to simulated C_2H_4 alone and combination of it and SO_2, and NO_2 by using open-top chamber. The responses of their some physiological metabolism as chlorophyl content, K^+ leaching concentration, free amino acid, ascorbic acid, to these gaseous pollutants, were investigated in this paper. Based on the responses, the evaluation of resistance for the experimental plants through cluster analysis method were made in this paper as well. The results showed that the resistance of several species such as *Platycladus orientalis* cl. *Franco, Sabina, Fraxinus sogdiana*

Bunge, and *Amorpha fruticosa* L. were stronger among all of experimental tree species, whereas *Ailanthus altissima* Swingle was weaker.

Threats to Armenia's Forest Biodiversity

Armen Nalbandian
Moskovyan 35, 375002 Yerevan, Armenia-
FAX: (3742) 531 861, Email:
hayantar@antar.infocom.amilink.net

Armenia is a landlocked mountainous country situated in the north-eastern part of the Armenian Highland and bordered from the North by Georgia, on the East by Azerbaijan, on the South by Iran, and on the West by Turkey. It covers an area of 29.8 thousand square kilometres and has a population of 3.7 million. The capital of Armenia is Yerevan. Armenia is a typical mountainous country, 90% of the territory of which is situated on 1000 m above the sea level, including 40% at 2000 m above the sea level. The average altitude of the territory is 1830 m, the highest point is 4090 m high and the lowest is 390 m high.

The geographical situation of the country and complex mountain terrain as well as its vertical zonality have created conditions for a unique biodiversity of resources and natural conditions. The forest area of Armenia is 4,599 km^2, including 3,341 km^2 forest cover (or 11.2% of Armenia's territory). The forest cover area per capita is 0.1 ha. More than 200 species of trees and bushes are grown in trees. The main tree species of oak, beech and hornbeam. The forests of Armenia are characterized by rich biodiversity, the great number of endemic flora and fauna species. In the mentioned forests there are 24 species of endemic plants registered, most of which are wild relatives of cultivated plants, for example Armenian pear tree, Meghri plume, etc. Among invertebrate animals, beetles are particularly well studied whose total quantity in the forest zone reaches almost 2,300 species, including 30 endemic species. The species of vertebrate animals in forest zones is also rich in biodiversity. Here 2 5 species of mammals, 90 species of birds, 11 species of reptiles and 1 specie of amphibians are registered. Rare and threatened species are the Caucasian endemic, for example Caucasian birth mouse, Black sea mole. In the mentioned forest zones a rare population of Syrian bear exists.

In Armenian forests such organisms are widespread (insects, diseases, etc.), which during their mass reproduction period defoliate trees and bushes in vast areas and cause desiccation. Before the breakdown of the USSR prophylactic aviation combat measures were implemented against these problems, yearly on 15,000-25,000 ha. These measures prevent the current damage as well as further spread of the damage. After the collapse of the Soviet Union, the mass cut down of trees because of the energy crisis created favorable conditions for the mass reproduction and expansion of these diseases. In recent years 9,000 to 15,000 forest cover areas are being defolia ted. For 1999-2003 a projection of the expansion of those areas has been done using computer models. According to this projection if no measures are taken until 2003 the infected area will reach 62,000 ha, and lost of yearly growth will be 179800 cbm. At present in the situation of economic crisis, the volume of implemented measures d o not exceed 10% of the necessary measures. For this reason the infected areas increase each year and a great number of desiccated trees can already be noticed, namely 3-10%. If a tree defoliates for three years in a row, consequently it is desiccated. Thus, there is an urgent need tor developing and implementing modern methods of pest control in the forests of Armenia.

Study on Fermentation Engineering of *Bacillus Thuringiensis*

Ziwen Yang, Yue Shukui, Currier, Thomas, C.
Northeast Forestry University, China

This paper was dealing with research on the fermentation engineering of *Bacillus thuringiensis* (Bt.). The main subjects of the research were about the highly toxic Bt strain isolation and characterization, genetically engineered Br construction, medium optimization, fermentation metabolism, downstream technology, high cell density cultivation and application.

Highly toxic Br strain, MP-342, was isolated from naturally died insect. It was more than toxic to *Pluttella xylostella* and *Helioverpa armigera* than the production strains of main Bt preparations of European and American, such as Xentari©, Dipel©, Agree©, Cutlass©, Delfin©, 1S057A and Javelin©. MP-342 strain belonged to *B. thuringiensis sups. kurstaki*, and had flagella serotype H3a3b3c. It carried six genes of insecticide crystal proteins, which were crylAc, crylAc-3, crylla, crylAa, cry2Aa and cry2Ab; and owned 7 plasmids with molecular weight of 152Md, 45 Md, Md, 7.2Md, 5.5Md, and 5.2Md respectively. The cryl genes located on plasmids with molecular weight of 152Md and (or) 48 Md., while the cry2A and cryl Ia genes located on 152Md plasmid. MP-342 strain produced 133kD and 71 kD proteins. It differed from Bt HD-l strain, which was the production strain of Dipel in plasmid profiles, insecticidal crystal proteins, gene types and gene locations. The main proteins expressed by MP-342 strain were CrylAc, CrylAc-3 and Cry2Aa, and lacked CrylAb, to which resistance had been developed by some insects. CrylAc-3 was also highly toxic to *Spodoptera exigua*.

MP-342 produced water-soluble potentiator in the supernatant of fermentation broth, which showed low toxicity to neonate of *H. armigera* (LC50 was about 20ug/ml), could increase the toxicity of spore and crystal complex about 3 fold. Potentiator in supernatant was stable during pH2-10, and good thermostability. There was no significant effect on potentiation activity when supernatant was boiled for 15min. But the activity of supernatant lost when autoclaved at 121°C for 20min. And this supernatant had no lethal and teratological activity against larvae and adult of housefly. It demonstrated that this potentiator was not á-exotoxin and also different from protein toxin, which was not thermostable. And it was similar to Zwittermicin A and Ia. This water-soluble potentiator made MP-342 strain more toxic than HD-l. Efficacy of fermentation beer of MP-342 was over 4000lU/ul. The technical powder of MP-342 was obtained through spray-drying process. The average efficacy and toxin content were 55744lU/mg and 10.4% respectively. Technical powder of MP-342 was very stable during storage. When treated at 54°C for 7 days and 14 days, the activity decreased 7.1% and 15.1% respectively. But liquid formulation was unstable during storage, of which the efficacy decreased 60-70% after 6 months storage.

The water-soluble poteniator in the discard supernatant from technical powder production process was recovered through vacuum evaporation and spray-drying process. The maximum solid content in concentrated supernatant could reach 45%. The proper spray-drying condition was 300°C at entrance, and 80°C at exit. The vacuum evaporation and spray-drying process showed no significant effects on the activity of potentiator. 700kg potentiating powder could be obtained out of the production of 1000 kg technical powder. The potentiator powder composed of 10.58% carbohydrate, 5.82% total nitrogen, 1.15% fatty acids and plenty of amino acids and inorganic salts.

Liquid formulation with efficacy of 8000lU/ul and 16000lU/ul was made by mixing concentrated supernatant with fermentation beer and sludge. Efficacy of the mixture was highly correlated with crystal concentration and index of supernatant concentration. The correlation formula was: Y (efficacy, lU/mg) =-1582.9+1500.4X1 (crystal concentration) +1435.2X2 (index of supernatant concentration). r=0,983. The toxicity to Spodoprera exigua could increase 11.14 fold when mixed MP-342 technical powder with potentiator powder at the ratio of 1:10. 32000lU/mg and 64000lU/mg powder preparations were obtained at the mixing ratio of 1:2-4. Powder potentiator was more stable than liquid potentiator. The powder potentiator was relatively stable, it maintained 70% of original activity after 3 days' treatment at 54øC, and no decrease any more. The potentiation activity of supernatant in liquid formulation decreased 48.2% after 13 months storage at room temperature.

MP-342 strain was transformed with plasmid pHT3lOl carried crylCa gene by electroporation, and 41 transformants were obtained in erythromycin selected plate. MP-342 lC-15, one of the transformants, was proved to carry crylCa gene, recombinant plasmid and express Cryl Ca protein. The percentage of CrylCa protein in this recombinant was 35% of Cryl proteins and 29% of total crystal proteins.

Recombinant plasmid showed a rather good genetic stability. Reservation rate of recombinant plasmids was 94.6% after 22 generations of propagation. LC50 of MP-342 IC-15 to neonate of *S. exigua* was 21.65ul/ml which was one fold lower than that of parent strain, MP-342. Toxicity of MP-342 IC-15 to *P. xylostella* was similar to that of parent strain. Potentiator produced by MP342 IC could increase the activity 2 to 3 fold against *S. exigua* and DBM in some extent.

A new model was set up to optimize Bt fermentation media. This model included four selection procedures. Single factor selection test was used for the selection of suitable single carbon and nitrogen ingredients. Combination test was adopted to select factors with combination effect. Steepest ascent method was used to determine optimizing region. The response surface method was used to wok out mathematics equation which was used to predict optimization medium recipe. This model could be used to treat various ingredients, and experiment factors could be controlled with easily handle number, through step by step selection, optimum recipe could be got at the last experiment. By using bioassay toxicity as parameter, the model above was adopted to optimize MP-342 medium. An optimized medium YM-2S was achieved. The toxicity of fermentation beer reached 5016.5lU/mg (*H. armigera* as testing insect). LC50 to *P. xylostella* was 85.3ppm. It was

5.16 fold (*H. armigera* as testing insect) and 4.38fold (*P. xylolstella* as resting insect) higher in toxicity compared with that of HD-l strain in its production medium and continuous cultures (μ_{max} = 0.69 l/hr, Ks = 0.5mg/ml, Yx/s = 0.75g dry cell weight/g glucose). The middle of log growth phase was determined as appropriate feed time. pH value was a good parameter to predict the log growth phase. By using constant fed-batch culture strategy, the fermentation level was correlated with substrate Consumption rate when the total glucose concentration was lower than 76.6g/l. Higher feeding concentration of glucose would cause the accumulation of substrate and limit of oxygen supply. By using the variable feeding speed fed-batch culture, the residual glucose was easily controlled within 10.0g/l and higher biomass and spore count could he got. Medium with low C/N ratio in growth stage was helpful for spore formation. Of fed-batch 19#, maximum biomass, crystal concentration, bioassay efficacy and spore count were 65.2g/l, 10.11 mg/,l, 0.28ug/ml diet and 1.29 X 1010/ml respectively. In fed-batch culture of 19#, low C/N ratio medium was fed at earlier growth stage while high C/N ratio medium was fed at later growth stage. Compared with batch culture 3#, its glucose Consumption was 2.76 times higher, whereas maximum biomass, crystall concentration, bioassay efficacy and spore count were 3.08, 3.25, 2.79, and 3.39 times higher respectively. Feeding at spore and crystal formation inhibited spore formation, caused the variation of morphology of crystals and expression of crystal protein with abnormal molecular weight.

Niche of Bark Beetles within *Pinus armandi* Ecosystem in Inner Qinling Mountains

Chen Hui, Yuan Feng
Northwest Forestry University, Faculty of Resouces,
Yanglinng, Shaanxi, 712100, China
FAX: 029-7082093

The bark beetles of damaged *Pinus armandi* Fr. and their niche were investigated in middle areas in Quinling Mountains. The result showed tat 19 species of bark beetles infected and damaged Pinus armandi in pine ecosystem of Quinling Mountain, but only 11 species of bark beetles were obviously competitive for the spatial and trophic niches. *Dendroctonus armandi* Tsai et Li was a precursor of bark beetles to attack the healthy host, which brought through blue stain fungi to infect host trees, and their symbiotic fungi prior to *Dendroctonus armandi* ward overcame the resistance system of host trees. In the Quinling Mountains bark beetles are depentaed on different times to infect host trees. Competition of bark beetles for the spatial and trophic niches can competitively coexist, and thus the ecosystem could be steadily maintained.

Ökologischer Wandel als Grundlage und Triebkraft einer zukunftsorientierten Waldbewirtschaftung

Siegfried Anders
Institut für Forstökologie und Walderfassung, Bundesforschungsanstalt für Forst- und Holzwirtschaft, Alfred- Möller -Str. 1, 16225 Eberswalde, Germany
FAX: +49-3334/65-354, Email: anders@aixh.holz.uni-hamburg.de

Eine zukunftsorientierte Waldbewirtschaftung begreift den Waldel der ökologischen Bedin-gungen aufgrund von Umweltveränderungen sowie sich ändernden gesellschaftlichen Anforde-rungen an einen mehrfunktionalen Wald als Herausforderung.

Voraussetzung für Nachhaltigkeit in Ressourcennutzung und Landschaftsschutz, für die Bewertung der umweltrelevanten Leistungen der Wälder ist die Bündelung und Strukturierung vorhandenen Wissens und die Einordnung neuer Erkenntnisse über Waldökosysteme in be-herrschbare, ökologisch begründete Elementarheiten des Waldes, die wir als Wald- bzw. Forstökosystemtypen bezeichnen. Diese werden über Wirkungszusammenhänge von Bio- und Geosystem in Raum und Zeit durch ökologisch bzw. ökologisch-ökonomisch determinierte "Fahrrinnen" geführt.

Bei einer im Rahmen der Waldformation einmaligen Merkmalskonfiguration sind sie (über Schlüsselfaktoren quantifizierbar) in sich weitgehend homogen in wesentlichen strukturellen Merkmalen, wie Zusammensetzung und Mengenanteile der Baumarten, Schichtung und Schichtenaufbau, Arten- bzw.Artengruppenzusammensetzung der Bodenvegetation und deren Mengenentfaltung, durchschnittliche Anzahl der in den jeweiligen Entwicklungsstadien beteiligten Pflanzenarten, in Qualität und Quantität wuchsbestimmender ökologischer Faktoren, wie Bodennährkraft, Luft- und Bodenfeuchte, Strahlengewinn und Wärme, in wesentlichen Prozeßabläufen, wie geochemischen Stoffflüssen (C, N, H2O u.a.), Nettoprimärproduktion, inter- und intraspezifische Konkurrenz, Regeneration. Sie grenzen sich von anderen Wald- bzw. Forstökosystemen durch qualitative und quantitative Unterschiede im Zustand und in der Ausprägung o.g. Merkmale ab. Daraus resultiert für die Einheiten eine definierbare waldgeographische Stellung, eine in sich ähnliche genetische Ausstattung, eine gleiche Entstehungsgeschichte (natürlich=Wald, halbnatürlich=Halbforst, künstlich=Forst).

Forstpraktisch sind Wald- und Forstökosystemtypen flächenkonkrete Informationsträger zu ökologischen, biologischen, ökonomischen sowie sozialen Leistungen und Funktionen der Wälder und Forsten. Wald- und Forstökosystemtypen in der Einheit von Standort und Betand sind in der Forschung anhand relativ weniger, sorgfältig ausgewählter und hinsichtlich Struktur, Ökologie und Prozeß intensiv untersuchter Ökosysteme (Fallstudien) zu determinieren und zu parametrisieren. Die dabei erkannten Beziehungen zwischen (nur aufwendig quantifizierbaren) wuchsbestimmenden ökologischen Faktoren sowie Prozeßabläufen auf der einen und (vergleichsweise einfach erhebbaren) Strukturmerkmalen auf der anderen Seite erlauben eine flächenhafte Verallgemeinerung von Forschungsergebnissen. Dies wird beispielhaft dargestellt, indem verschiedene Wald- und Forstökosystemtypen hin-sichtlich ihrer wasserwirtschaftlichen Leistungen (pflanzenverfügbare Bodenfeuchte, Tiefenver-sickerung, Grundwasserneubildung), ihrer Produktivität (Kohlenstoffbindung und -speiche-rung) sowie ihrer Naturnähe (biologische Vielfalt) verglichen werden.

Ziel dieser Vergleiche ist, über die Bereitstellung fundierten Wissens die Zukunftsfähigkeit naturnaher Wälder zu sichern. Über das Konzept einer dem natürlichen Standortswandel fol-genden potentiell-natürlichen Vegetation wird dabei der Grenzbereich bestimmt, bis zu dem eine differenzierte Naturabweichung im Sinne eines ökologisch-ökonomischen Kompromisses zugelassen werden und jenseits dessen nicht mehr toleriert werden kann, weil sie zum Schaden wird.

Spatial aspects of forest management-landscape ecological perspective

Bostjan Anko
University of Ljubljana, Dept. of Forestry, Ljubljana, Slovenia
Email: bostjan.anko@uni-lj.si

Keywords: landscape ecology; forest management; sustainability; environment; ecological function.

As long as (or wherever) timber production has been considered the only or at least the principal forest function, the spatial considerations of forest management have been limited primarily to the percentage of forest complexes, proximity to the market or at least to the means of transportations (from rivers to railways). Considerations of site productivity were of secondary importance - particularly in cultural landscapes where forest lost in this regard invariably to just about any other land use.

Thus, timber grows everywhere if only given a chance and this forest function (so important in itself) rarely, if ever, influences the forest distribution patterns in cultural landscapes.

Sustainability is said to have three components: ecological, social and economic one. The same could be said about the role of forest in modern cultural landscapes. As a landscape component forests perform three major groups of functions: the ecological/environmental, social/culturally conditioned and economic/production ones.

Managing forests for the said three groups of functions from a spatial point of view clearly requires different approaches. Production functions by and large require only sufficient forest area of reasonable site quality and proximity to the market is only of secondary importance. Social functions (e.g. recreation, aesthetic) are much more dependent on the proximity of the beneficiaries (visitors). As such they are subject to changes in the growth of cities and industrial areas. Losses of forests within such »catchment areas« can be only replaced in a given radius - depending on the willingness of the people to accept certain costs in terms of time and/or money.

Contrary to the above, majority of the ecological forest functions (e.g. antierosion, climate, water, habitat etc.) are not as flexible in the time and space. Largely they are natural givens - depending on natural conditions cannot be shifted around at will - they require a thorough knowledge of landscape ecology in the broadest sense of meaning.

Conserving biodiversity has recently become one of the most important (hopefully not just fashionable) forest functions. In many parts of the world forest is, indeed, some kind of Noah’s ark, conserving and saving many forms of life and natural processes.

In order to conserve such biodiversity not only large areas of diverse forest habitats are required. Conserving biodiversity on gene, species, ecosystem, landscape and higher levels of ecological integration requires quite clearly different principles of modern forest management for other forest functions; it is only that managing for biodiversity stresses that forests in space (landscape, region, even continent perhaps) need to be managed as a connected, functioning ecological system, considering of archipelagoes of forest complexes (patches) that are in distances that render possible functioning communications and are in addition connected with corridor systems (networks).

Application of this view of forests in management for all the other (particularly ecological) forest functions may bring a novel view of forest into the classical forest management. New questions will be asked and new solutions sought - particularly if we consider such (new?) forest management in the context of the three imperatives of modern forestry - i.e. of multiple use, close to nature and sustainable forest management.

Flora vegetation and conservation of forest gene resources of the National Park Conguillio, IX Region Chile

Cesar Arrigada Escamilla, Contreras Fernández, Domingo
Universidad de Temuco, Escuela de Ingeniería Forestal, Avenida Menéndez Pidal s/n. Apartado Correos 3048, Temuco, Chile
FAX: 34-957-218563, Email: ir2aresc@uco.es

Keywords: forest gene resource; abundance and importance of species; phytogeographic origin; life form.

The flora, vegetation and conservation to the millenarian forest resources of the National Park "Conguillío", located east of Temuco IX Región, Chile was studied.

Using the methods of the Zürich-Montpellier school of phytosociology, 59 vegetation samples were analyzed. Size and distribution of the samples were defined according to criteria of floristic, physiognomic and ecological homogeneity, and minimal area requirements. A floristic list was first obtained from the vegetation samples and then from herbaria collections, 248 vascular species. From the obtained vegetation table the frequency, abundance and an importance value of each species were determined. The phytogeographic origin and their life forms were obtained from other authors, associate with the descriptions of theirs, and were also determined.

It was concluded that the low homogeneity of the phytosociological table confirmed the presence of an alto diversity floristic among the sample analyses. Most important plant taxa include families Compositae and Papilionaceae. In the biological spectrum, Phanerophytes and Hemicriptophytes are abundant, indicating with it that the phytoclimate of the park is Hemicriptophyties. Principal components analysis revealed that dampness and temperature were the likely main factors in the distribution of the species in a park studied.

A most detail about to structure of the vegetable associations was studied, give these multivariate statistical analysis. The first, appears like if it to be a strong influence on the dynamic of vegetable analysed.

In the park and "Cordillera de los Andes" there is a scheme of retrograde succession from community climax of *Araucaria araucana* (Mol.) Koch.-*Nothofagus pumilio* (P et E) Krasser., to the condition of the continued steppe in zone ecotonal of *Araucaria*, Steppe and *Nothofagus pumilio* in the most humid conditions. At the same that other research, was determined the following process of secondary succession for the park.

Harvest and Fire

Gramineae

Pernettya Sp - *Escallonia Sp*

Chusquea Sp - *Berberis Sp* - *Escallonia Sp*

Araucaria araucana - *Poa tristigmatica or*

Araucaria araucana - *Nothofagus antarctica or*

Araucaria araucana - Nothofagus dombeyi or

Araucaria araucana - *Nothofagus pumilio*

In this way was observed that *Araucaria araucana* takes part in many kinds of communities in agreement with the kinds of soil, height and humid available in the zones was studied. Nevertheless the general standard shows a defined relation between the composition of different stand and the humid and height over at sea level. *Araucaria araucana* begins to grow at 1050 m.s.n.m., mixed with *Nothofagus antarctica* (G Forster.) Oerst., *Nothofagus alpina* (P. et E.) Oerst and *Nothofagus dombeyi* (Mirb.) Oerst. At the 1.230 m.s.n.m, only with *Nothofagus dombeyi*, at the 1.350 m.s.n.m., the forest is compound for *Araucaria araucana and Nothofagus pumilio* and at the 1.600 m.s.n.m., *Araucaria araucana* to disappear.

Through the phytosociological study, the following wooded associations *Araucarietum araucanae*, *Araucario-Nothofagetum pumiliae*, *Araucaria araucana-Poa tristigmatica*, *Araucario-Nothofagetum dombeyosum*, *Nothofagetum pumillionis and Chrysosplenio-Nothofagetum dombeyosum and Austrocedrus chilensis-Nothofagetum dombeyosum*.

Jointly, to these wooded masses, in the forest was founded bioindicators species with which was determined among others. The conditions of richness or poverty of nutrients, humid, degradation of soil. Finally, the forest resources, the flora and the ecosystems of the park are real banks of genetic pool, since into them are preserve species with problems of conservation, in addition they have a millenarian species in which the forest science don't still to dedicate it a real importance.

Climate change: some evidence from a tropical forest experimental watershed in the Philippines

Santiago R. Baconguis, Liza I. Canete-Ranes
Ecosystem Research and Development Bureau,
Department of Environment and Natural Resources, 4031 Laguna, Philippines
Tel: (63-49)536-2229, FAX: (63-49)536-5820, Email: erdb@laguna.net

Keywords: global warming; climate change; evidence; monitoring; tropical forest; the Philippines.

Global warming, or climate change in general, and its consequences are among the pressing issues today. For example, the global average surface temperature has increased by 0.3-0.6°C over the last century (Lasco and Pulhin, 1998). The changes have been attributed to the rise in concentration of greenhouse gases (GHGs) in the earth's atmosphere. GHGs like carbon dioxide, methane, nitrous oxides and chlorofluorocarbons absorb thermal radiation emitted by the earth's surface. Hence, rising concentration of GHGs in the atmosphere could lead to a change in energy balance and consequently the world's climate.

To monitor the climate changes, data from an experimental catchment in the Philippines was made. Analysis was made for the daily rainfall (1970-1997) and air temperature (1974-1997) records at the dipterocarp forest catchment of the Angat watersheds in San Lorenzo,Norzagaray, Balkan, Philippines. The area is considered a representative of the evaluation of dipterocarp forests in the country and belongs to Climatic Type I based on the Coronas'(1920) system of classification.

Data shows that there is an increasing trend in temperature, an evidence of warming during the recent years. The mean annual temperature during the intervening years (70s, 80s, 90s) is 26.9°C, 27.1°C and 27.5°C with 1997 being the hottest with an annual mean temperature of 28.2°C. The 1997 value is 1.0°C higher than the 1974-97 mean annual temperature and 0.7 ohigher than the mean annual temperature in the 90s.

Annual rainfall varies from year to year with an annual average of 3,198.0mm. The 1997 rainfall is about 32% below the annual average. During the study period, there were twice as many El Nino years than La Nina.

Relationship of soil nutrients to occurrence of *Shorea curtisii* in two hill dipterocarp forests in Peninsular Malaysia

Mohamed Basri bin Hamzah
Universiti Putra Malaysia, Department of Forest Production & Bicomposite Technology Centre, Malaysia
Email: basri@forr.upm.edu.my

Keywords: dipterocarp forest; soil nutrient; species occurrence; regeneration; soil acidity; Malaysia.

Shorea curtisii (Seraya) is the most important timber species in the hill dipterocarp forest (HDF) of Peninsular Malaysia. A study was conducted to gauge the influence of soil nutrients on Seraya's occurrence in two contrasting virgin HDF ecosystems; an isolated hill on the western coastal plain with clinal species distribution pattern (Selandar Forest Reserve, Melaka State) and a foothill of an inland mountain range with patchy or mosaic pattern (Senaling Inas F.R. in Negri Sembilan State). Seraya, a normative HDF species was compared with *S. leprosula* (Meranti Tembaga), a normative timber species of the lowland dipterocarp forest with which it overlaps in its lower altitudinal limits of distribution. Plots measuring 10x10 m were laid out using stratified random and systematic designs respectively in Selandar (n=40) and Senaling Inas (n=70). As species abundance measures all trees (dbh >10cm) were identified, enumerated and dbh measured and regeneration (1.5m height to dbh <10cm) similarly identified and enumerated. Soil samples were augured (0-30cm depth) at five points per plot, bulked, processed and analysed for total nitrogen, phosphorous, potassium, magnesium and CEC, available phosphorous and pH. Data was analysed using Canonical Correspondence Analysis with strong canonical correlation between species and environmental axes taken as $r^2>0.70$. Results indicate overall strong influence of soil nutrient factors on species occurrence in both study sites. Total phosphorous, potassium and soil pH were strongly influential on species with variation between sites, vegetation type and abundance measures. In Selandar, tree frequency was affected by soil acidity alone and regeneration by acidity and potassium. In Senaling Inas, tree frequency and basal area were influenced by both acidity and potassium while regeneration by acidity and total phosphorous. Tree vegetation appear more responsive to soil nutrients in the more complex Senaling Inas stand. But regeneration appears uniformly sensitive in both sites. Biplot analyses showed greater Seraya tolerance for lower fertility and more acidic soils compared with Tembaga. The tolerance was however more marked among regeneration in Selandar but less so in Senaling Inas. The possible influence of soil nutrients on Seraya occurrence and distribution pattern in the HDF was discussed with implication on its post-harvest regeneration.

Estimation of biomass and nutrient extraction through forestry interventions in natural *Nothofagus pumilio* forests in Magallanes, Chile

Juan Caldentey, Magni Carlos
Universidad de Chile, Departamento de Silvicultura, Casilla Postal 9206, Santiago, Chile
FAX: 56-2 -541 79 55, Email: jcaldent@abello.dic.uchile.cl

Keywords: forest; biomass; nutrient; *Nothofagus pumilio;* forest management; productivity; Chile

The use of a forest ecosystem under sustainable assumptions implies the need of evaluating the distribution and total amount of existing products feasible of being extracted from a forest with each forestry intervention. The productive capacity of a forest site may be determined through quantification of existing biomass (dry weight unit/surface unit). This information may be supplemented with the study of nutrient accumulation in trees to optimize forest resource use.

In order to estimate the effects of natural *Nothofagus pumilio* forest management on biomass and nutrient extraction, two stands - one pure, uneveraged of the species, and another one mixed, uneveraged with *Nothofagus betuloides* - were studied, both located in the Province of Magallanes, Chile.

In order to estimate existing biomass in each stand, allometric equations providing the dry weight of the different tree components were adjusted using BHD and their total height as predictive variables. Nutrient accumulation was estimated by weighing biomass amount with nutrient concentrations determined in tissue subsamples. Forestry intervention in each stand was simulated using extraction rates accepted under Chilean legislation, estimating biomass and nutrient amounts extracted, to remain standing, and to remain as waste on the forest floor, comparing two treatments: one with and the other without barking.

Total accumulated biomass in the pure stand was 421.8 t/ha (85.1% boles and 14.9% crowns). Total estimated aerial mineralomass reached 5,572 kg/ha (96% accumulated in woody tissues and 4% in leaves), with percentage distributions of 55.2, 29.2, 6.7, 4.4, 2.2, 1.6, 0.3, 0.4, 0.7, and 0.03 in Ca, N, K, Mg, P, Mn, Fe, Zn, B, and Cu, respectively.

The mixed stand exhibited a total accumulated biomass of 322.2 t/ha (81% boles and 18.6% crowns). Total estimated aerial mineralomass was 3,480.2 kg/ha distributed on a percentage basis in 52.9, 27.2, 9.7, 4.5, 3.6, and 1.1 of Ca, N, Mg, K, P, and Mn, respectively. The remaining 1% corresponds to Cu, Fe, Zn, and B.

When simulating application of a protective felling (shelterwood system) on the pure stand with a 49.6% reduction in the basal area and a protective canopy of 161 trees to remain standing, 129 t/ha of biomass would be extracted and 79 t/ha would remain as harvesting waste. An amount of 521 kg/ha of mineralomass (97.9% macro-nutrients and 2.1% micro-nutrients) would be removed. A figure of 1,935 kg/ha of nutrients in the waste would remain on the forest floor. If extracted boles were barked on site, extracted biomass would descend 7.2% and the removed mineralomass amount would be 422.5 kg/ha.

When simulating application of a protective felling on the mixed stand, with a 45.2% reduction in the basal area and a protective canopy of 176 trees to remain standing, 146.2 t/ha of biomass would be extracted and 30.4 t/ha would remain as harvesting waste. Development would remove 1,125 kg/ha of mineralomass (98.2% macro-nutrients and 1.8% micro-nutrients). A figure of 564 kg/ha of nutrients in the waste would remain on the forest floor. If barking is considered, extracted biomass diminishes 9.6% and exported mineralomass amounts to 462 kg/ha.

Certification of forest reproductive material

Lorenzo Ciccarese, Davide Pettenella
Agenzia Nazionale per la Protezione dell'Ambiente, Via V. Brancati 48, 00144 Rome, Italy
Tel: 06 50072277, FAX: 06 50072313, Email: ciccarese@anpa.it

Keywords: forest reproductive material; national and international standards; plant varieties; labelling system; material source identification.

Several national and international standards for Forest Reproductive Material (FRM) have been developed, for example by the Organisation of Economic Cooperation and Development (OCSE, 1974) and the European Economic Commission (CEE, 1967). Their objective is to ensure that anyone establishing a plantation for forestry purposes is supplied with healthy planting stock, genuinely of the provenance or origin chosen by the customer; in addition, certification maintains and makes available to customers high quality FRM of superior crop plant varieties and enable the forest industry to export FRM around the world.

Over recent years, considerable changes have occurred in the forest nursery stock demand, the more important of these being summarised as follows:
1. a growing request of a wide variety of species, for a wide range of uses (multi-purpose forestry);
2. an increasing demand for plants and seeds of native species, broadleaves rather than conifers, and local provenances in forest practice;
3. an increasing performance potential requirements for planting stock.

Because of these changes, the OCSE and EEC schemes are inadequate, as confirmed by the fact that the demand for certification of FRM under these schemes has dramatically decreased. In particular, for the EEC scheme, it depends on the fact that it covers only few species (mostly conifers) and considers appearance and size for evaluating plant quality. Today, such parameters are considered inadequate indicators of survival and growth, while the main determinant of tree seedling capacity to perform well after outplanting is their physiological condition.

As far as the contents of FRM standards, there are three main set of issues that should be considered: inherent genetic quality (i), material attributes (ii) and performance attributes (iii).

(i) Nurserymen must keep accurate records that explain in detail the history of the FRM, taking into consideration that use of local provenances, varieties or ecotypes is preferred and encouraged by national and international resolutions.

(ii) Material attributes, that can be measured directly. They include both morphological attributes, such as height, collar diameter, dry weight, volume; and physiological attributes, such as bud dormancy, water status, mineral nutrition, carbohydrate status, levels of growth regulators and enzymes.

(iii) Performance attributes, which are measures of the performance of the whole seedlings when subjected to specified test conditions. They include a wide array of tests, such as root growth capacity, vigour test, frost hardiness, infrared thermometry, chlorophyll fluorescence, ethanol analysis.

Moreover, for an effective guarantee of the FRM, not only good standards are requested, but also a third-party independent system of certification based on international well established rules. This is the only way certification can guarantee that FRM has been collected, handled and produced according to a known set of standards. Process and product certification should be associated to a labelling system to be used to mark FRM traded in the international market.

The introduction of certification programme in forest nurseries is very likely to improve plantation establishment, preventing the use of not source identified seeds or the planting of poor quality seedlings. In addition, it can be beneficial to nursery personnel in developing new stock types or nursery cultural regimes; enhance confidence between nurserymen and customers, field foresters and reforestation scientists.

Towards priorities of biodiversity research

Hans de Iongh
The Tropenbos Foundation, Post Box # 232, 6700 AE Wageningen, Netherlands
Tel: 31-317-426262, FAX: 31-317-423024, Email: e-mail Iongh@IAC.AGRO.NL

Keywords: biodiversity research; policy and management focus; management objective**.**

In 1996 the Tropenbos Foundation published the policy document ‘Towards Priorities of Biodiversity Research’ (Biodiversity Policy Document: BPD). The BPD proposes:
1. A procedure to identify research priorities for biological diversity, and
2. A preliminary and partial application of this procedure.

Starting point of the procedures are main policy and management objectives of the Tropenbos programme:
1) Land-use planning for conservation and sustainable forest land use
2) Designation and management of totally protected natural forest areas
3) Protection and reintroduction of endangered species
4) Documentation and adoption of indigenous management of tropical rain forests
5) Use and valuation of non-timber forest products
6) Sustainable timber production
7) Rehabilitation and productive use of secondary forests

The information needs related to the different policy and management objectives have been listed and categorised into site specific information needs and generic information needs.

Also considered are the three dimensions of biodiversity research:
1) spatial patterns
2) temporal patterns(short-, medium- and long term)
3) functional relationships

Based on the seven objectives, the information needs and the three dimensions of biodiversity research, information was gathered as to the availability of research methods that would produce the results necessary to fulfil these objectives. This process resulted in an ‘information matrix’, which can be used in various ways, as a basis for selecting the most urgently needed research:
1. The matrix facilitates the identification of repeated needs for similar types of generic information.
2. The matrix shows research areas where methodological improvements are most needed.
3. The matrix provides a means for a critical review of the relevance for policy and management of ongoing or planned biodiversity research.

Tropenbos will follow the procedure outlined in this paper to further develop the biodiversity component in its own research programme. The policy and management focus of each site will be matched with the policy and management objectives described in this paper. Research proposals will be assessed on the basis of a comparison with the information matrix.

A preliminary ranking of research priorities lists:
1. Indicators for monitoring biodiversity
2. Criteria to identify forest land suitability
3. Criteria to evaluate the results of biodiversity monitoring/land suitability rating
4. Distribution of forest types/species
5. Taxonomic studies Taxonomic studies

The transfer of timber line to higher altitudes in the conditions of Kopaonik

Milosav Filipovic
National Park Kopaonik, 36354 Kopaonik, Yugoslavia
Tel: +381 36 71 098, Email: inszasum@EUnet.yu

Keywords: timber line; spatial distribution; forest; anthropogenic factor; national park; Yugoslavia.

The National Park Kopaonik extends over the highest parts of the mountain Kopaonik which is situated in the central part of the Balkan Peninsula, at the altitude of 2017 m. The flora of Kopaonik consists of 1350 taxa, and alpine flora in the National Park includes 825 species and subspecies, of which 91 are endemic, 82 subendemic and 3 stenoendemic plants. The region of the National Park Kopaonik influenced by biotic, abiotic and especially by anthropogenic factors in the past, suffered numerous transformations which affected the composition, abundance and distribution of wildlife. Unfortunately, many plant and animal species are extinct in this area. A significant, often decisive influence on the flora and fauna was exerted by the anthropogenic factor reflected in daily mining by which this mountain was named, forest clearing, pasturing and, more recently, the expansion of tourism with all the accompanying activities (traffic, water engineering, visitors' circulation, etc.).

This paper analyses the issues of timberline translocation. It proves that the upper tree line gradually changes to higher altitudes, "occupying" the previous communities of juniper and blueberry (*Vaccinio-Juniperetum*). This phenomenon is proved in three ways:

By comparing the photographs made 40-50 years ago with modern photographs of the same sites.

By comparing actual forest maps with old forest maps.

By observation and records at several sites where the gradual disappearing of juniper and other vegetation is evident, due to invasion and gradual formation of spruce forest canopy at higher altitudes.

Field observation is accompanied by measurements and attempts to assess the velocity of spruce-forest upper tree line change. The explanation of this phenomenon should be sought in the three significant reasons:

1) small-scale but still present artificial afforestation of the area, 2) drastic reduction of livestock which used the grazing land in this area, and probably the most significant reason: 3) global, as well as local climate changes, especially the process of mean annual temperature increase.

Impact of silvicultural treatments on monospecific stands of *Aucoumea klaineana* Pierre

Marc Fuhr, Delegue Marie-Anne
Campus international de Baillarguet, BP 5035, 34032 Montpellier, France
FAX: 33 4 67 59 37 33, Email: fuhr@cirad.fr

Monospecific (or monodominant) forests dominated by long-living pioneer species are a frequent stage of secondary successions in tropical areas. These long-living pioneer species (*Terminalia superba, Triplochyton scleroxylon, Aucoumea klaineana*, etc.) are often of great economic value and forest logging operations have heavily relied on them in Congo, Gabon since the turn of the century. However, nowadays other values of these species and of the associated vegetation are more and more taken into consideration: biodiversity, carbon sinks, non timber forest products, etc. Secondary forests in the coastal forest-savanna mosaic of Gabon are mainly even-aged monospecific *A. klaineana* stands developed on areas abandoned after shifting cultivation. *A. klaineana*, a typical long-living pioneer tree, represents about 80% of the logged volume and is, therefore, of tremendous importance for the Gabonese forest sector.

Sustainable management of such monospecific forests should not only improve growth and yield of the dominant timber species but also ensure its regeneration while delaying or stopping the natural evolution of this secondary vegetation towards a possible climacic or more mature forest devoid of the interesting long-living pioneers.

The continuous monitoring since 1987 of 34 permanant plots of natural pure *A. klaineana* stands, ranging from 5-10 to over 60 year-old, in the coastal forest-savanna mosaic of Gabon is a precious tool to quantify the impact of silvicultural operations including commercial logging on growth, regeneration and mortality. In 1989, 13 plots (from 7 to 45 years old) were selectively thinned in order to promote the growth of dominant *A. klaineana* designed as plus trees. In 1995, two 50 year-old plots were commercially logged to assess logging damages and post-logging regeneration.

Natural mortality of *A. klaineana* did not substantially increase after the silvicultural operations. Recruitement between 1987 and 1997 (individuals with a diameter at breast height reaching 10 cm) was favourable to *A. klaineana* if the stands were thinned before reaching 35 years old : the species accounted respectively for 57 and 49% of the recruited trees in the thinned and control plots. Three years after logging, *A. klaineana* is the most abundant species (11%) of the natural regeneration (individuals higher than 30 cm with dbh < 30 cm) in the most intensively harvested plots. In spite of large open areas due to a considerable harvesting intensity (more than 15 stems/ha), the density, higher than in treefall gaps (1%), is much lower than in fire-protected savannas (31,5%). Interspecific competition appeared favourable to the establishment of *A. klaineana* seedlings in situations where both early pioneer and shade-tolerant species were excluded: moderately damaged areas (lightly open canopy and damaged soil) or large open areas temporarily flooded. The relevance of the silvicultural treatments in order to delay the disappearance of *A. klaineana* is discussed.

Efecto de la tala en la estructura de un bosque autóctono del Uruguay (Sudamérica).

Iván A. Grela, Romero, Fernanda; Brussa, Carlos
Universidad de Agronomía Montevideo, Facultad de Agronomía-Area Forestal, Av. Garzón 780, Montevideo, Uruguay
Tel: (00598 2) 3072201, FAX: (00598 2) 3093004

En el Uruguay existe muy poca información sobre la dinámica de las comunidades leñosas, a pesar de lo cual han sido explotadas fundamentalmente para la obtención de energía (evidentemente sin los planes de manejo silvícolas adecuados). Gran parte de las mismas se han regenerado, aunque no hay datos que establezcan si han habido cambios importantes en su estructura.

Con el objetivo de determinar el comportamiento de un "bosque de quebradas" (formación vegetal caracterizada como selva subtropical empobrecida) luego de la tala, se determinó la estructura fitosociológica de dos sectores contiguos del mismo en las nacientes del Río Lunarejo, Uruguay, (Originalmente toda la zona tenía las mismas características, sin embargo en el año 1982 un sector fue talado (tala selectiva de especies maderables) para la obtención de madera de aserrío. Posteriormente no hubieron talas lo que posibilitó la regeneración del bosque. Esto permite comparar la estructura fitosociológica actual con la original y por lo tanto establecer los efectos de la intervención.

En este caso se entiende por estructura fitosociológica la composición florística, la cantidad de individuos por superficie, la distribución horizontal y cobertura de cada especie presente, resumido en un índice jerárquico de las especies que componen la comunidad.

Se establecieron cinco parcelas de 500 m^2 en sitios considerados característicos de cada sector, se censaron los ejemplares arbóreos, calculándose para cada especie los parámetros: Abundancia (Ab), Frecuencia (Fr), Dominancia (D) y Regeneración Natural (RN). A su vez con estos parámetros se calcularon el Indice de Valor de Importancia (IVI) e Valor de Importancia Ampliado (IVIA) con los cuales se caracteriza la estructura de cada comunidad.

No se encontraron diferencias florísticas ni fitosociológicas importantes entre las comunidades. En cada caso cinco especies representaron alrededor del 60% del IVIA, siendo tres de ellas comunes a ambas. Esto quiere decir que luego de la regeneración se mantienen como más importantes las mismas especies que en la situación original. Sin embargo si se consideran los valores absolutos de los parámetros se observa que la comunidad intervenida presentó aproximadamente el doble de ejemplares por unidad de superficie, y la mitad de Dominancia que la situación original (tanto para el total de la comunidad como para cada una de las especies más importantes), es decir se trata de una comunidad con el doble de individuos pero estos son de mucho menor tamaño, lo cual demuestra que la regeneración se debió al rebrote de cepas cortadas (como en otras situaciones) sino por nacimiento de nuevos individuos.

Site quality estimation of *Pinus roxburghii* Sargent stands in India

B. Gupta, R. K. Sahu
Dr. Y. S. Parmar University of Horticulture and Forestry, Nauni, Solan, H. P. -173 230 , Nauni, Solan, India
FAX: 91+1972+52242, Email: Guptab@yspuhf.hp.nic.in

Forests of chirpine (*Pinus roxburghii* Sargent) account for 8.3% of the total forests area in India and occur gregariously as pure crops in outer Himalaya and Shiwalik ranges at elevations ranging from 600 to 2100 m, otherwise it is found in a continuous belt belt between latitudes 27^o to 35^o N and longitudes 70^o to 92^o E. The present study was conducted in Solan Forest Division of Himachal Pradesh in India with the aim to classify sites under chirpine due to its differential growth pattern on different sites. The direct method of site quality estimation viz., height intercept method was followed, since it is a time saving method, after selecting all the 19 years old plantations and natural stands under Solan forest division. In all there were seven such sites viz., Dharampur natural stand, Kandaghat plantation, Sabathu natural stand, Bauhli natural stand, Barog natural stand, Sultanpur plantation and Oachghat natural stand. Total tree height and height intercept viz., mean internodal lengths of 3, 4, 5, 6 and 7 internodes from breast height were recorded for the selected trees in each site. Linear, log linear and curvilinear models were tested for different height intercepts in order to find out the best mean internodal length (height intercept). Six years mean internodal length was found as the best indicator of site quality. The 5 years height intercept was also found to be quite significant but its significance was less than 6 years height intercept. The model finally developed by 6 years height intercept was:

Height19 = 3.0493 + 0.1419 HI - 0.0007 HI2 (adjusted R^2 = 0.54) (0.0223) (0.0002)

HI = Height intercept (6 years mean internodal length)

Figures in parentheses are respective standard errors.

On the basis of 6 years height intercept classification of different sites was done as : the site with less than 30cm height intercept was graded as poor site (Dharampur natural stand), sites with height intercept between 30-50cm were considered as average sites (Kandaghat plantation, Sabathu natural stand and Bauhli natural stand), sites with height intercept between 50-70cm were called as fair sites (Barog natural stand, Sultanpur plantation) and the site with height intercept more than 70cm was rated as good site (Oachghat natural stand).

The present calssification was then compared with the standard site quality classification given by Forest Research Institute (FRI), India for chirpine stands. The good site quality site was equivalent to site quality I/II given by FRI and poor site quality sites was equivalent to site quality III. Thus, the findings suggested that the height intercept method can be reliably used for estimating growth of young chirpine stands and can be taken as an indicator for their future management.

Regional forest monitoring in Latvia

Dzidra Hadonina
Ministry of Environmental Protection and Regional Development of the Republic of Latvia, Peldu icia 25, LV-1494 Riga, Latvia
FAX: +371 7820442, Email: jana@main.vvi.gov.lv

Keywords: forest health; ecological monitoring; Scotch pine; Norway spruce; common birch.

Regional forest monitoring in Latvia was started at 1990 according to International co-operation programm methodic ICP Forests (International Co – operative Programme on Assessment and Monitoring of Air Pollution Effects on Forests 1 st Level). The objective on the ICP Forests Programme is to ensure a long – term and systematic observation, assessment and forecasts health condition in Latvia.

The main tasks are:

- to carry out a general assessmsnt of forest condition;
- to determine the changes and trends in forest health;
- to detect the main factors influencing forest health.

The annually observed national grid in Latvia is 8 x 8 km and comprises 379 observation plots with 9005 trees in 1997. Most the assessed trees are conifers – Scots pine (47,1%) and Norway spruce (26,3%); the most represented broadleaf species is common birch (20,9%). In general about 90% of broadleaves and 80% of conifers observed are considered to be none or slightly damaged.

The mean defoliation of Scots pine in 1997 reaches 22,8% and shows a statistically significant inprovement since 1996. About 74% of trees observed are none or slightly damaged; moderately damaged – about 25% of trees. Regarding forest monitoring data in 1997, insect attacks on Scots pine have diminished, associated with total population dynamics of insect species. The main factors influencing Scots pine health in 1997 are diseases (mainly *Cronartium flaccidum*) and bark insects (*Tomicus* spp., *Pissodes* spp., etc). The hard winter of 1996/1997 has also caused widespread snowbreaks, as well as different indirect effects.

The mean defolation of Norway spruce is 17,2%, being very close to the value in 1996 (17,1%). About 85% of Norway spruce observed are supposed to be undamaged or slightly dameged; only 14,4% are moderately and 0,5% severely damaged. In comparison with 1996 the changes in defoliation classes are slight. The main direct factors influencing Norway spruce in 1997 are game and insect attacks (*Ips typographus*). Changes in water availability (destroyed amelioration canal system, activities of beaver – *Castor fiber*) have also negative impact of sprucee health.

Regarding broadleaves the most widespread tree species is Common birch with the mean defoliation 16,7%, showing crown condition deterioration since 1995. Also crown condition of other broadleave species (aspen, Common alder, etc.) has become worse. The deterioration of tree condition of broadleaves is possibly associated with warm and dry summer of 1997.

Tree crown defoliation is significantly affected by phytopathological, entomological as well as mechanical damages, however, they explain only a part of crown damage. It is supposed that also meteorological conditions, air pollution and other factors directly and (or) indirectly influence forest health. The obvious impact of air pollution on tree condition is local and observed near stationary sources. In order to assess the effect of air pollution, meteorological and other factors, it is necessary to start a complex analysis of the forest condition, estimating the share of each of these factors in forest damage in Latvia.

Assessment of forest technologies and their impact

B. S. Hansra, N.R. Gangadharappa, G.T. Prasanna Kumar
ICAR, 110012 New Delhi, India

Keywords: deforestation; ecological equilibrium; assessment of forest technology; forest development.

Growing population competition for poorly controlled forest resources is intensifying huge pressure and accelerating deforestation. The proportion of forest to the total geographical area in India is not sufficient to maintain ecological equilibrium though several forest policies were formulated since 1894. In India, studies have shown that dense forest cover (crown density 40% and above) is only 11.71% even though a country should ideally have 33% of its areas under forest. The country also loses 1.3 million ha of forest area every year and soil loss due to degradation which is equivalent to the loss of 30-50 million tonnes of food grains. This had called for a major shift in the policies and approaches and ultimately new forest policy was introduced in the year 1988, which envisages people involvement and their movement in the development, protection, management, maintenance of forest and augmentation of the raw material production. This means dissemination of forest technologies among the people. The dissemination of forest technology is a complex process as exemplified by the research studies conducted in India. It is probably universally recognized that behavioral change among people and those in hierarchy of systems for promoting it-is one of the requisite component of forest development, in addition to the technological, physical, social economical, political and cultural factors. One of the research studies entitled "Diffusion of forest tree species among the farmers of Karnataka" (1998) revealed that adoption of simple technology like growing of *Eucalyptus*, *Casuarina* and Silver oak trees by all farmers of Bangalore district has taken over 52 years. The researchers also evaluated the technologies against the identified various dimensions. It has been revealed that people felt that growing of tree species on their farm lands either on boundaries or as block plantations is relatively advantageous, compatible to soil, temperature and rainfall, less complex, less trialable and the results and observable. Further, farmers indicated that the initial cost and the operational cost required for growing tree species is high and low respectively. The profile of farmers revealed that majority of them studied up to primary level, having small land holdings, poor economic condition, less innovative and less cosmopolite. Further, they have occasionally participated in the forest extension education activities. thus, the characteristics of forest technology coupled with socio-economic, cultural traits factors are the reason for the slow diffusion process. Another study conducted during (1998) in Karnatka also revealed that the involvement of the people right from the planning, implementing and evaluation of the forest improvement and protection, will able to bring consciousness and awakening about the ecology and environment. Therefore, the strategies like Joint-Forest Management should be implemented in right spirit. Research assessment on tree co-operative societies indicated that the member people are aware of the importance of forest, for meeting fuel fodder and timber requirement through the established community forest. Wherever there is wasteland, such lands can be used to establish community forest by involving people themselves.

Introduction d'espèces ligneuses dans la jachère en zone soudanienne du Cameroun: effets sur le cycle de l'azote et la séquestration du carbone dans le sol

Jean-Michel Harmand
CIRAD-Forêt Programme Arbres et Plantations Projet Jachère, BP 1386 Dakar, Senegal
Email: jean-michel.harmand@cirad.fr

En Afrique tropicale, la jachère, faisant suite à une période de culture, peut être considérée du point de vue agro-écologique comme une phase de stockage de carbone et d’éléments minéraux pour l’agrosystème. A la remise en culture, ces ressources sont plus ou moins mobilisables selon les modalités de la défriche (brûlage ou exportation des parties aériennes, dessouchage ou non).

En raison des besoins croissants en terres agricoles et de la lenteur des processus de remontée biologique, surtout en situation de surexploitation des ressources de la jachère, il est judicieux de trouver des systèmes accélérant la reconstitution des propriétés physiques, chimiques et biologiques du sol. Dans ce cadre, la jachère agroforestière qui permettrait d’accélérer la restauration de la fertilité du sol en agissant sur l’ensemble des cycles biogéochimiques et d’assurer une production végétale (bois, gomme arabique) apparaît comme une alternative intéressante.

L'objectif de la présente étude est de comparer à une jachère naturelle herbacée protégée contre le feu et le pâturage, des jachères plantées en *Acacia polyacantha*, *Eucalyptus camaldulensis* et *Cassia siamea*. La comparaison porte sur la production de biomasse, le cycle de l'azote et la fixation du carbone dans le sol. Quelques éléments sont donnés sur le comportement des cultures après jachère.

Dans la jachère à *A. polyacantha*, la fixation symbiotique de l'azote (de l'ordre de 630 kg/ha en 7 ans) et le fort recyclage qui l'accompagne, entraînent un stockage de l'azote plus important que dans les autres systèmes, à la fois dans la végétation et dans le sol.

L'important recyclage de l'azote par le sol est caractérisé par la grande quantité d'azote apportée par la litière, par la forte minéralisation de l'azote du sol et par le développement considérable en surface du système racinaire absorbant l'azote minéralisé. Le recyclage de l'azote est lié aux processus de minéralisation et fragmentation de la litière aérienne et racinaire qui donnent lieu à une incorporation de matière organique (MO) au sol sous forme de débris végétaux. Cette incorporation est responsable de l'augmentation significative en 6 ans des stocks de carbone du compartiment matière organique du sol sous *A. polyacantha* (MOS de taille < 2mm). Dans les autres types de jachère on n'observe pas de variation significative des stocks de C du sol pour la même durée. Chez *E. camaldulensis*, on observe à 6 ans une assez forte immobilisation de l'azote dans la biomasse aérienne et la litière au sol et pas d'incorporation de MO au sol sous forme de débris végétaux. *C. siamea* est une espèce exigeante en azote dont l'immobilisation rapide dans la phytomasse est suivie d'un fort ralentissement du cycle de l'azote caractérisé par une faible minéralisation de l'azote du sol, un arrêt de croissance et une baisse de production de litière à 4 ans. Cela correspond à une maturité précoce de l'arbre dont l'alimentation en azote est assurée par le recyclage par la litière. Néanmoins la faiblesse des flux d'azote correspond à une faible incorporation de MO au sol qui reste comparable à celle effectuée par la jachère naturelle herbacée.

La plus grande capacité d'*A. polyacantha* à stocker de l'azote facilement minéralisable, explique son effet supérieur sur le comportement des cultures suivantes après 5 ans de jachère.

Lorsqu'elle existe, l'augmentation du stock de carbone du compartiment MOS au cours de la période de jachère (+3,5 t/ha dans l'horizon 0-40 cm sous *A. polyacantha* de 6 ans) reste faible par rapport à la fixation du carbone dans les systèmes racinaires. Pour les systèmes *A. polyacantha, C. siamea, E. camaldulensis*, jachère herbacée et culture continue, cette dernière est respectivement de 9,8 t/ha, 6 t/ha, 5,7 t/ha, 1,3 t/ha et 0,5 t/ha si on exclut les souches. Cependant les systèmes racinaires se décomposent très rapidement après remise en culture, sous l'action de la macrofaune du sol en particulier les termites, et ce compartiment « racines » se montre très fugace par rapport au compartiment MOS qui demeure quantitativement stable après deux ans de remise en culture.

Age-related changes in forest communties of Lithuania

Stasys Karazija
Lithuanian Forest Research Institute, Girionys 1, LT 4312 Kaunas, Lithuania
FAX: 370 7 547446, Email: Miskininkyste@mi.lt

Keywords: forest types; community composition; biodiversity; Norway spruce; Scotch pine; broadleaved stands.

In the forests of Lithuania (its territory is in the zone of mixed forests of Europe) Scotch pine (37%), Norway spruce (23%) and various broadleaved (birches, asps, oaks, ashes, black alders etc.) stands prevail. Clear cutting frequently shifts the species composition from conifers to soft deciduous species and later vice versa. Age-related changes in the species composition of vegetation of lower storeys occur in pure stands. Their clarifying is necessary for accurate assessment of the changes induced by human activity.

With increasing age spruce communities are typical of the most intensive shift of the species composition. In spruce stands (depending upon their age) five stages of the development of communities have been singled out: stand restoration (cutovers), stand closing (forming), thicket (pole stand), self-thinning and stabilization (subclimax). At the stage of stand restoration the communities are characteristic of the greatest species diversity and abundance (projection cover) of vegetation. The species typical of cutovers appear and spread. At the stage of stabilization species diversity of vegetation is slightly less. The least species diversity and even complete decline of forest ground cover vegetation are observed at stage of thicket of spruce stands. With increasing age of stands grass cover changes most considerably, while moss cover less. Besides, its nature of a change largely depends upon the forest type. The most insignificant changes in the species composition occur in glade, although the tendencies of changes in abundance are the same.

Forest ground cover vegetation diversity has been assessed according to the Shannon's index. The lowest values have been determined in the communities at the stage of thicket whilst the highest ones at the stages of stabilization and stand restoration (in some forest types the place of maximum is different).

In accordance with the T. Sorensen (1948) coefficient (when projection cover of different species is used for calculation) assessment of the similarity of different development stages of forest communities has shown that the communities at different stages of age in the same forest type are less similar as compared to these of the same stage in adjacent forest types. Phyto-indication method by H. Ellenberg (1991) - indices of ecological demand of plants and that by L. Ramenskij (1956) - ecological tables of plants have been applied. It has been determined that with increasing age of stands changes occur in the ecological conditions. The index of light varies most considerably. Its highest value is at the stage of stand restoration, slightly lower at stabilization stage and the lowest value is at the stage of thicket. The index of moisture is also highest at the stage of stand restoration. It is an indication of bogging up. At later stages with increasing age of stand the value of index diminishes. However, in different forest types its decrease is different. The tendencies of changes in other ecological indices are not distinct. It implies that these communities belong to one type of ecological conditions. Also it proves that similarity indices (Sorensen) applied in geobotany formally do not express ecological similarity of the communities. Consequently, determination of plant indicators is of great significance. Since there are very few indicators typical of a concrete forest type, which remain at all stages of stand development, determinants have been assessed. They permit us to identify forest communities of different types by distinguishing them from ecologically close types.

In pine stands as well as in spruce stands the communities of young stand being formed are typical of the greatest plant diversity. The most scanty vegetation is found in the communities of thicket (pole stand). However, the differences between various stages in pine stands are by far less as compared to spruce stands. In cutovers destroyed moss cover is restored at the thicket stage of young stands. In comparison to spruce stands, on dry sites of pine stands assessment of ecological conditions by the method of phytoindication has demonstrated slightly different results. It has been noticed that the needs of the communities of young stands in light are somewhat higher. It holds for pine stands at other stages. In cutovers no increase in moisture has been detected.

The process of underwood development and its species composition enables pine stands to be divided into two groups - stands which develop devoid of changes in tree species and these where the species composition shifts from pine to spruce.

Age-related changes in broadleaved stands one by far less. The communities of young stands are also characteristic of the most significant plant diversity. However, with increasing stand age the species composition of vegetation in formed stands changes negligibly; it can be partially explained by the fact that during self-thinning of broadleaved stands underwood density increases. In these stands significant fluctuation of the species composition of vegetation has been observed. It causes new problems in delineating protected territories and in assessing changes in vegetation.

Root biomass and symbioses in a first rotation of an *Acacia mangium* plantation - the role of soil disturbance and burning

Anders Malmer, Peter Högberg Johan Wester and Louise Lindquist
Swedish University of Agricultural Science, Department of Forest Ecology, SE-901 83 Umeå, Sweden
FAX: +46 90 786 6617, Email: Anders.Malmer@sek.slu.se

Fine root biomass, A-mycorrhizal infection and root nodulation was studied in *Acacia mangium* plantations in Sabah, Malaysia. Samplings were made at 1 and 9.5 years after planting within a paired catchment study on environmental effects and production from plantation establishment at conversion from dipterocarp forest. The treatments covered were 1) minimised soil disturbance and no burning before planting, 2a) crawler tractor log extraction and burning before planting - outside tractor disturbance and 2b) like 2a but - on soil disturbed by tractors. Tree production in the less disturbed and unburned catchment was double compared to the normal practice including soil disturbance and burning. This difference have been ascribed the tractor soil disturbance which covered 25% of the area, but tree production differences were also clear between unburned and burned undisturbed soils.

Initially fine root biomass in disturbed soils above 45 cm depth was only 25% of that of undisturbed soils, but in the end of the rotation the differences were non significant. The only exception to this was clay top soils (opposed to sand top soils and the areal mean) where root biomass was still only 42% of that of undisturbed soils. Total fine root biomass developed from 1.8 and 2.0 t ha^{-1} after 1 year to 3.6 and 4.4 t ha^{-1} at 9.5 years for "minimum disturbance" and "normal practise" respectively in comparison with 4.0 for the previous rain forest (0-50 cm). Initially A-mycorrhizal infection was higher after "minimum disturbance" (84% of root length) compared to burned but undisturbed soil (71%) and disturbed soils (60%). In the end of the rotation all treatment had reached up to between 77-84% of root length infected. However, at 9.5 years chitin analysis of the roots revealed possible differences in quality (better developed mycelium) with 0.93 mg chitin per g of dry roots in "minimum disturbance" and 0.74 and 0.49 mg g^{-1} for "normal practise" with burned soil and disturbed soil respectively.

Root nodulation was recorded at the first investigation. No nodules were found in samples from disturbed soils and in 35% and 31% of samples from "minimum disturbance" and burned but undisturbed soils respectively. Nitrogen fixation could not be calculated according to the natural abundance method, due to lack of suitable reference species. However, ratios between nitrogen and other nutrients in leaves from *Acacia mangium* and other species indicate that nitrogen fixation have been apparent.

These results fit well with investigations on the natural rehabilitation of disturbed soils on tractor tracks. Within a time span of a decade the top soil organic content slowly increases and bulk density decreases. However, the development of soil structure and favourable porosity have been shown to take longer. That could explain that at the end of the rotation there were possibly less developed mycelia in disturbed soils and still lower fine root biomass in disturbed soils with more compact clay top soils. It should also be noted that initially the development of A-mycorrhizal infection was lower by 16% in burned but nondisturbed soils compared with the unburned soils. This difference may well be one of the keys to the doubled nutrient uptake by trees in the initial years. Avoidance of burning did not only stretch out nutrient release from residues (decomposition) in time, but also gave better circumstances for retention of nutrients in the site biomass.

Ecological and productivity characteristics of mixed endemic-relic pine forests in Yugoslavia

Krstic R. Milun, Ostojic R. Dragana
Forestry Faculty of Belgrade University, Kneza Viseslava 1, 11030 Belgrade, Yugoslavia
Tel: +381-11-553122, FAX: +381-11-545485, Email: sumeivode@sezampro.yu

Key words: mixed endemic-relic pine forests; enviroment conditions; stand characteristics; productivity; tree development

The research was carried out in the mixed forest of autochthonous pines: Macedonian pine (*Pinus peuce* Gris.) and Scotch pine (*Pinus silvestris* L.) with white-bark pine (*Pinus heldreichi* Christ.), beech (*Fagus moesiaca* Domin, Maly/Czeczott) and other species, in the National park ‘Sarplanina’in Serbia (Yugoslavia).

This intresting plant community of high mountain forest eco-systems is situated in the nature reservation "Jazinacko jezero". It is phytocoenologically classified as *Pinetum peucis-silvestris* prov. Macedonian pine and white-bark pine are nature rarities - Tertiary relics and subendemics of the Balkan Peninsula and this part of Europe. Their distribution is microdisjunctive, confined by the subalpine zone. Endemic character of these species and their representation in alpine forest ecosystems indicate the characteristic ecological requirements and biological features and the specific flora of the Balkan Peninsula.

The researched stand is situated in specific enviroment conditions: altitude 1,600-1,700 m, exposure southwest, and slope 25 degrees. It is over silicate parent rock and shallow acid brown soil. The mountain masiff of Sarplanina is the natural border with Macedonia and its geographic position conditions the specific climate characteristics - it is situated at the meeting point of Aegean, Adriatic and continental climate, which are modified by alpine relief, and can be characterised as submediterranean-continental mountain climate. Climatic conditions at this altitude (1,700 m) are characterised by mean annual air temperature about 5.4^{o}C, in the growth season (May-September) 12.4^{o}C and average annual rainfall 1,380 mm (in the growth season 45%). According to Thornthwaite's classification, the climate is perhumid; according to Koppen's classification, its group is Dfb.

The stand is even-aged, with complete canopy, aged 80-100 years. The number of trees is 1380 per ha, with diameter variation of 7.5-87.5cm. The percentage of tree number is: Macedonian pine 33%, Scotch pine 37%, white-bark pine 18%, and other species 12% (beech and sycamore). Mean diameter of Macedonian pine is 18cm, Scotch pine 27, white-bark pine 28.5cm, and beech 19cm. Tree number distribution in diameter classes is not typical for even-aged stands because of a greater representation of Macedonian pine, but also beech and maple in lower diameter classes, which may indicate a gradual invasion of these species in the forests of heliophilous pines. Macedonian pine and beech mean height is 14cm, Scotch pine 16.5m, white-bark pine 15m. Dominant trees attain the height of : Macedonian pine 22 m, white-bark pine 18 m and Scotch pine 24 m. Stand productivity is characterised by total volume 474 m^3ha: Macedonian pine 22%, Scotch pine 48%, white-bark pine 25%, and other species 5%. Mean of dominant trees (20% largest dbh trees) aged 80 attain the dbh of: Macedonian pine 31 cm, white-bark pine 28 cm and Scotch pine 37 cm. Current diameter increment of Macedonian pine culminates between the ages of 20 and 25 (6.8mm), white-bark pine between 30-40 (5.6mm), and Scotch pine about the age of 20 (9.4mm). Macedonian pine and white-bark pine diameters, about 50-70cm at the age of 80-100, and volume 474 m^3/ha, show that these (rare) forests may be regarded as highly productive in their natural site (high mountain habitats).

The structure development and maintenance of this intresting plant community of high mountain ecosystems should be supported by active protection. Natural regeneration of these autochthonous pines should be initiated and directed selectively, by the correspodending strictly controlled silvicultural treatments in the aim of extending the distribution and enabling the more abundant progeny of these species.

Nutrient budget of an agrosilvopastoral system - a case study from Kerala, India

M. Achuthan Nair, Jacob John
Kerala Agricultural University, Department of Agronomy, College of Agriculture, Vellayani, 695 522 Trivandrum, Kerala, India
FAX: 91-0471-480239, Email: kauvly@giasmd01.vsnl.net.in

Homesteads of Kerala present an excellent example of a tropical agrosilvopastoral system. However, quantitative information on the nutrient budget of the system are lacking. A field investigation was undertaken to assess the nutrient addition, biomass production and nutrient removal in a typical agrosilvopastoral system of Kerala, India. The study, which formed part of an ad hoc project of the Indian Council of Agricultural Research, was carried out in a homestead of 0.50 ha in southern Kerala, India for a period of two years extending from October 1994 to September 1996. The topography of the study site was undulating and the soil type sandy. The homestead was typically a coconut-based agrosilvopastoral system. The tree components in the system, besides 100 coconut palms, included four mango, six jack, one wild jack, one sapota, two cinnamon, three drumstick, six teak, one tamarind and one cashew. Annual crops cultivated in the interspaces were amaranths in the first year and banana in the second year. The system also consisted of three cows (2+1) in the first year, while in the second year it was four (2+2). The admixture of trees/crops resulted in a cropping intensity of 106.51 (I year) and 111.51% (II year). The amount of litterfall, stemflow and throughfall was quantified by means of suitable traps of known dimension placed below the canopy of trees. The N, P and K contents of collected samples were estimated by standard analytical methods. The nutrients added into the system through organic manure, recycling crop residues, and inorganic fertilizers were also quantified. The harvested biomass from the crops and trees were weighed and their nutrient contents estimated to work out the nutrient removal. The annual nutrient addition by way of litterfall amounted to 4.48, 0.85, 1.92 kg N, P and K (I year) and 3.76, 0.33, 1.51 kg N, P and K (II year) respectively. The addition of nutrients by stemflow was 0.03, 0.001, 0.08 kg N, P and K and 0.04, 0.001, 0.15 kg N, P and K in the first and second years respectively. Throughfall from trees resulted in a nutrient input of 0.53, 0.04, 2.40 kg N, P and K (I year) and 0.81, 0.04, 4.05 kg N, P and K (II year). The total nutrient addition through organic manure, obtained from the livestock component of the system was 28.28, 23.92 and 30.72 kg N, P and K (I year) and 21.42, 19.00 and 27.48 kg N, P and K (II year). Inorganic fertilizer mixtures of coconut resulted in an addition of 38.00, 19.00, 76.00 (I year) and 42.00, 21.00 and 84.00 kg N, P and K respectively. The pseudostem of banana was recycled during the second year resulting in a nutrient contribution of 3.04, 0.64 and 10.40 kg N, P and K respectively. The study further revealed that certain quantity of nutrients were permanently lost from the system by way of harvested biomass. The total biomass production from the system was 9484 kg dry weight (DW) and 9676 kg DW in the first and second years respectively. The corresponding N, P and K removal during the first and second years were 62.70, 11.83, 93.84 kg and 68.17, 11.40, 99.33 respectively. The nutrient balance sheet revealed that the nutrient loss from the system through harvested produce was counterbalanced by nutrient addition through various sources. The tree-crop-livestock integration was a special feature of the system. Plant nutrients were involved in a constant cycling within the soil and plant compartments of the system. Though various nutrient cycling processes tend to replenish the nutrient pool, pool, permanent losses occurring through harvest may need to be compensated through external input. Hence, in agrosilvopastoral systems dominated by annuals and bearing coconut palms judicious application of manure is necessary to sustain its productivity.

Effect of *Pinus roxburghii* Sargent on the nutrient contents of grasses in mid-hills of western Himalaya.

R. Nayital, B.Gupta and Vipan Guleria
Dr. Y.S. Parmar University of Horticulture and Social Sciences, Department of Silviculture and Agroforestry, Nauni, H. P. -173 230 Solan, H.P., India
FAX: 91+ 1972 + 52242, Email: Guptab@yspuhf.hp.nic.in

Keywords: pine; grassland; nutrient content; nitrogen; phosphorus; potassium; Himalaya**.**

The study was carried out in Solan district of Himachal Pradesh in India located between latitudes 30°&31°N and longitudes 76°&77° during the growing season (July to October) to determine the effect of chirpine (*Pinus roxburghii* Sargent) growing at different aspects on nutrient status (N, P & K) of grasses and soil. Two adjacent grassland sites each of 0.1 ha area, one having chirpine overstorey and other without chirpine (open grassland), were selected at three aspects namely: northwestern, northern and southwestern. All the sites were situated at the same locality. Chirpine trees in these sites had crown height ranging from 10.5-12.5m, crown diameter 7.7-8.7 m, crown surface area from 46.57-59.45 m^2. Density of trees at three aspects varied from 270 to 300 trees/ha. Relative solar influx under the trees ranged from 51.9-60%. Plant samples were collected by harvesting 12 quadrats each of size 50x50 cm from each site at monthly interval starting from 15th July. The plant samples were segregated specieswise and analysed for N, P and K. Composite soil samples from 0-30cm depth were collected from each site on each sampling date.

The important grasses recorded in these sites were : *Themeda anathera*, *Chrysopogon montanus*, *Heteropogon contortus* and *Panicum maximum*. Nitrogen concentration in aboveground and belowground ranged from 0.59-1.22% and 0.42-0.91% respectively. Phosphorus concentration ranged from 0.08-0.25% and from 0.04-0.16% in aboveand belowground biomass respectively. Potassium concentration was found to vary from 0.34-0.68% and 0.23-0.49% in above and belowground biomass respectively. Thus, the nutrient concentration was higher in aboveground biomass as compared to belowground biomass at all the sites. There was no significant effect of chirpine as well as aspect on the nutrient status of the grasses.

Soil pH varied from 6.8-6.98 and 6.92-7.20 under chirpine and open grasslands respectively. Organic carbon under chirpine was more (1.6, 1.47 and 1.37%) as compared to open grasslands (1.55, 1.45 and 1.15%). Available N ranged from 0.014-0.043 and 0.012-0.028% under chirpine and open grasslands respectively. Available P ranged from 15-31 ppm under chirpine and 19-30 ppm in open grasslands. Whereas, available K varied from 103-195 ppm and 115-330 ppm under chirpine and open grasslands respectively. Thus it was concluded that chirpine increased the Nitrogen contents of the soil but decreased the P and K contents.

Morphological indices of tree sustainablility

Remigijus Ozolineius
Lithuanian Forest Research Institute, Girionys 1, 4312 Kaunas reg, Lithuania
FAX: (370-7) 547446, Email: miskinst@mi.lt

Keywords: morphology; defoliation; increment; tree sustainability.

Sustainability of a tree can be defined as an its ability to transform one form of energy into another (for instance, to transform the solar energy into chemical etc.) despite any external disturbance.

Two levels of relative sustainability exist. That corroborated by:
- variation of tree growth in the process of dendrocoenosis (forest ecosystem) forming;
- the character of growth and morphological variation during the transition into the lower part of the storey;
- non-specific morphological responses, i.e. active and passive phases;
- threshold variation in the radial increment of a tree with increasing crown defoliation.

The first stable level is observed in limits of crown defoliation 0-35% while the second - in limits 60-85%. For each level of stability, specific morphological characteristics and changes in the inner morphological correlation have been clarified. Transition from the first to the second level is, by far, more rapid than “the moving” within a relatively stable state, i.e. decreasing of stem increment suddenly accelerates. The existence of the second unstable level is based on the fact that within increasing defoliation, approximately 85 to 100% of the increment of the tree does not decrease gradually - at a certain point it drops suddenly to zero and the tree dies.

Each stable level is characterised by three morphological states. In the first level, three morphological levels have been singled out: 1) the stable tree (the most complicated morphological structure - the highest rate of branching etc.; the morphological correlation is weaker than that of a relatively balanced tree; the largest foliage mass, defoliation 0-10% etc. in terms of coenosis they are open-grown trees or trees of Kraft class I); 2) the relatively “balanced” tree (more simple morphological structure, strong correlation of inner morphology, defoliation 10-15% etc.; in terms of coenosis they are trees of classes I-II), and 3) the “effective” tree (a tree “works” most productively; less foliage “creates” a similar stem increment, defoliation 15-20% etc.; in terms of coenosis they are trees of class II).

Transition from the first level to the second one is characterised as the state of high lability (crown defoliation ranges from 40-60%, trees are “sensitive” to the environmental impact; the trees are of class III).

The second stable level is also typical of three morphological states. At the first state is a tree of reduced liability (even sufficiently strong affirmative effect cannot transfer a tree to the first state of stability; for instance, trees of the lowest Kraft classes do not “recover” even after very intensive thinnings). The second state - a tree with disturbed morphological correlation (the size of different organs is independent of their position in a crown); and the third state - absolute collapse of morphological homeostasis of a tree.

An assessment of sustainable forest on environmental conservation in China

Daoli Peng
Beijing Forestry University, Box 117, 100083 Beijing, China
FAX: 0086-10-62338133, Email: dlpeng@ss2.bjfu.edu.cn

Keywords: forest conservation; sustainability; environment; ecological function of forest; China.

With the rapid economic development, much more international attentions have been paid to environmental problems. Forest plays an important part of ecology system, especially, in activities of environmental conservation. In china, natural forest conservation projects have been executed for three forest districts of northeast, northwest and southeast. The purpose of this study is to describe the expansion and decrease of forest distribution in the three forest district, and discuss factors causing such expansion and decrease from several points of view. This study reviewed land surface, site and contour of the different forest district and evaluated the environmental conservation functions of the forest. First we have build the forest resources environment database by geographic information system (GIS), and assumed that forests have three functions as follows: forest land conservation, sustentation of ecology system and landscape preservation, Then we evaluated quantitatively these functions of forests using GIS, Data from forest record, vegetation maps soil distribution maps and the results of analyses of GIS were used as factors of valuation, Each factor is divided into five categories, and each category is given a quantitative score, The results showed that natural forest plays a great part of the environmental conservation functions for China forest resources and environmental conservation.

Changes in forest ecosystem on drained areas

Jaak Pikk
Estonian Agricultural University, Forestry Research Institute, Kreutzwaldi 5, 51014 Tartu, Estonia
Tel: +372-7-421093, FAX: +372-7-421053, Email: jpikk@eau.ee

The large scale forest drainage in the vicinity of the Baltic Sea after the fifties has essentially improved fertility of forest soils, intensified growth of trees and increased percentage of forested lands. Probably that has leveled climate conditions as in Estonia (57030'-59049'N; 21046'-28013'E) during the last decade has been characterized the climate with relatively short cold periods with little snow in winters and generally cooler summers. Climate warming has caused distribution of till rarely presented tree species, wild animals and birds in the region.

Estonia is situated in the region of intensified paludification. Paludification decreases soil fertility and leads to the declination of the biodiversity of ground vegetation. Today, drainage of one forth of the forest lands has sufficiently bounded transgression of peat to the mineral lands and due to that the drainage is stopped. Ecological changes that become evident after the drainage should be taken into consideration in managing of stands.

Evolution of forest site types in the drainage areas develops towards more fertile types. Middle quality class (stand height degree in defined age) of stands has been arisen in State forests during 25 year analyze period in the all drainage stands, in spite of the dominate tree species: pine, spruce, birch or aspen. It also remarks intensified nutrient cycling, bigger biomass and oxygen production. More intensively change the plant communities in fens with thin peat layer. In alder fens and alder-birch fens mostly meadowsweet *(Filipendula ulmaria*) starts to dominate and after couple of decades it will substitute with goutweed (*Aegopodium padagraria*), if the soil parent rock is carbonate sandy loam. Domination of goutweed has become evident also in the drainage of palutified forests. Areas with deep peat deposition will be transformed into decayed swamps with different fertility where herbaceous plants, bilberry (*Vaccinium myrtillus*) or wood sorrel (*Oxalis acetosella*) will dominate.

Evolution of the new plant communities diversifies remarkably our forests and environment generally. Depending on botanical composition of peat deposit and on filtration of mineral horizon below peat layer, after drainage the thickness of the peat layer decreases 0,6-1,5mm per year.

A part of the nutrient elements that leaves during decomposition process will be used by plants and trees, the other part will be evaporated or leached to runoff waters. If the peat will disappear too quickly and the process of the soil genesis in mineral horizon is slow, the growth of trees may be stunted. For that reason the investigation of regeneration possibilities of the soil genesis using ground water regulation and other measures needs quick solution and implementation in practice.

Weakening cultural traditions and struggle of sacred groves for survival.

M. P. Ramanujam, D. Kadamban
Department of Botany, Centre for Post Graduate Studies, 605 008 Pondicherry, India
Email: drramanujam@hotmail.com

Keywords: sacred groves; religion; vegetation and forest preservation; biodiversity.

This paper traces the history of sacred groves in India and examines the conservation status of the groves in the Pondicherry bioregion.

Sacred groves are patches of vegetations or forests preserved on religious grounds. They were established in ancient days by ecosystem people inhabiting the hilly terrains when they attempted agriculture/cultivation as vocation. As clearing of forests became inevitable, such people adopted ecologically prudent ways to preserve environment. One was to leave patches of original vegetation totally undisturbed and the other was shifting cultivation. Expanding population and its inextricable dependance on natural resources for survival justified large scale deforestation. Hence it became necessary to retain at least the semblance of local biodiversity, as man, out of greed or need might wipe out the wood stands.

In order to deter people from desecrating the vegetational resource, the ancient people sanctified natural elements as sacred trees, sacred animals, sacred habitats etc. Sacred groves, dedicated to the local deity, are the most prominent of them. Unflinching faith in supernaturality and the fear of god are two vital elements that contributed to their survival. Slowly, the ecosystem people migrated to the plains and the society got fragmented. Yet the identification with nature and concern for conservation of natural elements were so deep that they revered and respected them, even as they disturbed, slashed, killed or consumed them. This was more acute in the plains in the face of large scale convertion of land for agriculture.

For the castes /communities for whom the respect for nature was the unifying force, the methodology /practices adumbrated in course of time was guided by cultural tenets and sustained by religious beliefs. As a result such conservational practices became woven intricately into the fabric of traditional cultures of those societies.

The advent of hinduism increasingly shifted the primacy from the forests to the deities, While in most of the interior/rural groves the idols of ancient gods lie in the open , construction of temples and erection of huge imagines of animals are strikingly evident in many groves in the urban and semi-urban settings. Infuence of western culture has also contributed to the decline of the groves by promoting the extention of temples structures and by adding colour and glamour to the worship patterns. Spread of literacy and modernism have further slackened the strangle hold of religions and the belief-systems which had been the guiding force in conservation.

Another factor that has accentuated the decline is the alienation of people from the conservational model as evident from the protected area networks. Wherever people are involved in the maintenance of the grove, and reciprocally drew tangible benefits, the groves survived. Nevertheless, the spread of modernism, absence of any tangible benefit, state control of temples have additively precipitated their decline.

Recent initiatives in Uttara Pradesh and Bihar where people are egged on to develop a kinship with the groves and in Karnataka where religious attributes are channelized through ecologically sustainable synthetic forests for benefits, have provided a glimmer of hope. Their revival, after realizing their ecological values as seen in Mizoram, is further reassuring, With the protected area network failing to deliver the goods, it is imperative that sacred groves, which symbolise the success of conservation through religious traditions and cultural practices, must be rediscovered and restored to their original glory. Their biodiversity is very vast, rich and impeccable.

The groves of India in general and the 15 major groves in and around the Pondicherry region in particular subscribe to most of these generalizations and crave for immediate conservational initiatives.

Contribution of forest research for an ecosystem in extinction: forest: the case of the Atlantic forest of the northeast of Brazil

G. M. Rego, Hoeflich V.A
Universidade Federal do Paraná, Setor de Ciências Agrárias-Pós-Graduação em Agronomia, Rua dos Funcionários, 1520-Bairro Juvevê, Curitiba, Brazil
Tel: (041)350.5601, FAX: (041) 252.3689, Email: ggiza@nutecnet.com.br

Keywords: Atlantic forest; genetic biodiversity; degradation; historical process; Brazil.

The Atlantic Forest is constituted, with certainty, in the threatened of Brazil bioma and, probably, of South America. As a result of its geographical location and with distribution along the Brazilian coast, the area was the first to be explored in the Country. The Atlantic Forest located in the Northeast of Brazil, has been desolated by man's action that already destroyed great part of the genetic biodiversity of that ecosystem, along the five hundred years of colonization of Brazil. The work had for objective to accomplish a rising of the contributions made for the best knowledge of the problems and potentials of the Atlantic Forest and with this to offer subsidies for best to become aware the Brazilian and world society on the prevalent processes of degradation of the remainders of the Atlantic Forest and its negative effects on the quality of the life of man of that area. The work presents an evolution of the historical process of the degradation of the Atlantic Forest since the beginning of the colonization of Brazil to the current days. They are suitable the desolated species of the primary Forest, and its substitution for agricultural cultures and agricultural exploration without there was any concern with the replacement of the desolated forest resources, with the conservation of the soil and with the environment. They are also suitable the consequence of the deforestation of the forest in this area on several environmental aspects (modification in the microclimate; disappearance of the rivers and ciliary forests and loss of the genetic biodiversity). The study indicates a group of actions of scientific and institutional character, that they should be developed, with extreme urgency, in way to avoid to such a pillaging of that important ecosystem and to lessen its impacts on the atmosphere and the populations that live in the areas preserved.

The vanishing palms of the forest ecosystems of India and their sustainable management

C. Renuka
Kerala Forest Research Institute, Peechi 680 653 Kerala, India
FAX: 0487-782249, Email: libkfri@md2.vsnl.net.in

The family *Palmae* (Arecaceae) is one of the most useful groups of flowering plants confined to the tropics. Their versatile use make them a preferable crop for wide cultivation even in the arid and semi-arid zones of the tropical regions. Palms are an important forest resource from ecological, social and economic viewpoints. In India 21 genera and about 106 species of palms occur in three major geographical regions; Peninsular India, Eastern and Northeastern India and Andaman and Nicobar Islands. A small number of palm species occur in the Gangetic plains and in the lower hill valleys of Northern India also. Apart from coconut (*Cocos nucifera*) and arecanut (*Areca catechu*), the major economic palms, cultivated as commercial crops, all other palms are seen in the wild or in semiwild condition. However, despite their frequent occurrence in forests, and the vast array of products derived from them, foresters have so far, dedicated little attention to palms when designing and implementing management plans. In India many palms are endangered. Natural populations of *Arenga*, *Pinanga* and *Bentinckia* have been severely affected due to habitat destruction. A combination of over exploitation and habitat destruction appears to have led many species of rattans to the endangered condition. *Corypha talifera*, an endemic species to West Bengal is reported to be extinct in the wild conditions. *Arenga, Borassus* and *Phoenix* are all multipurpose genera and over exploitation is adversely affecting their population size. In addition, some inherent botanic characteristics of certain palms also have contributed to retard their natural regeneration. In the absence of concrete efforts towards their replenishment, some of these wild palms are likely to face the threat of extinction. For ecologically sensitive palms like *Arenga, Pinanga, Calamus* and *Bentinckia* in situ conservation along with enrichment planting is needed. Plantations of presently over-exploited species and potentially useful species should be established on a large scale to boost their population for sustainable exploitation. In India, at present, the only palm included in the forest management plan under nonwood forest products is rattans. It is worthwhile to note that a number of wild palms have high potential for domestication and there is ample scope to improve upon the product range and commercial exploitation. Further, protection of wild palm genetic resources has practical application in genetic improvement of both wild as well as cultivated palm varieties.

Endemic plants of peninsular Malaysia: their conservation status and future prospects

L. G. Saw, L.S.L. Chua
Forest Research Institute Malaysia (FRIM), Kepong, 52109 Kuala Lumpur, Malaysia
Email: sawlg@frim.gov.my

Keywords: endemic plants; conservation; endangered species; scoring system; Malaysia.

Most of endemic trees species and palms in the Malay Peninsula (Peninsular Malaysia, Singapore and South Thailand) have been scored for their conservation status using the IUCN 1994 Red List Categories. Of the 814 endemic taxa scored, 348 species (42.75%) species are in the threatened categories while the remaining 466 species are in the lower risk. 52 taxa have been classified as criticallly endangered while 47 others are in the endangered category. No species have been categorised as extinct because there is a lack of information to correctly determine if species had gone extinct. However, most of the species that had only been recorded once are now considered in the critically endangered or endangered categories. In process of scoring the species, it also became evident that there are flaws in IUCN criteria used to assess the conservation status, in relation to endemic Malayan tree and palm species. The present scoring system employed for Malaysia has been modified from the IUCN criteria to suit Malaysian conditions. To ensure the continual existence of the rare, threatened or endangered plants, efforts are currently underway to locate these plants. A large number of these threatened species have narrow phytogeography and their populations are not necessarily protected in totally protected areas such as the National parks and Wildlife Sanctuaries.

The role of flood water control and desert afforestation in environment improvement.

Zieaoddin Shoaei
Soil Conservation and Watershed Management research Center, Post Box # 13 445, 1136 Tehran, Iran
Tel: (+98)-21-4905709, FAX: (+98)-21-4905709

Keywords: flood water control; afforestation; environment improvement; desert; water saving; Iran.

The meagre amount and uneven distribution of precipitation means that more than 90% Iran is designed as arid and semi-arid. It is estimated that more than 50 billion m^3 surface runoff out of total 413 billion m^3 (mean annual) precipitation drains into Caspian Sea, Persian Gulf and inland lake and swamps. If substantial amount of this flow could be saved, a major portion of our water demands would be satisfied. Flood water spreading is a method that follows numbers of purposes. Some example of these are: to stabilise drifting sand, to control erosion, to develop artificial forestlands, to make changes the environment of the belt zones around desert, to satisfy water requirement, to remove sediment carried by flood-water for changing the bare lands to farm lands, to control ground water quality by preventing the intrusion of saltwater into water bearing aquifer.

Following to a very successful integrated approach and ongoing research project in southern province of Iran that was started in January 1983 and has achieved its main objectives, the national large scale developing program was planed. This plan started in 1995 and consists of 20 stations. The major aims of these stations are; to develop a model for different condition of geology, climate, soils and hydrology, to extend such idea for inviting the people to participate and to develop this project in their own lands, to help the government for large scale planning for water utilisation in Iran. This paper will introduce the basics of this project and its successes since 1995.

Technological exploitation of polysaccharide - polysaccharide interaction

Purshottam L. Soni
Forest Research Institute, Chemistry Division, Dehradun (U.P.), India
Email: amrish_sharma@hotmail.com

Keywords: polysaccharide; galactomannan; gum; *Cassia tora; Leucaena leucocephala*; gum industry; India.

Most seeds contain starch as the principal stored food for use by the embryonic plant in its initial growth. Almost all food plants used by humanity produce seeds with starch as the carbohydrate reserve. However, a number of plant food reserve polysaccharides are based on structural polysaccharide from the plant cell wall. The most well known of such reserve polysaccharides, from an industrial view point, are the plant seed galactomannans, which are based on a β-1,4-linked D-mannan backbone which is solubilised by substitution of α-1,6-linked D-galactose residue to the mannan of the backbone. However, other β-1,4-linked structural polysaccharides also forms the basis for groups of plant reserve polysaccharides. Thus the food storage polysaccharides from tubers of the *Amorphophallus* genus are based on a β-1,4-linked D-glucomannan backbone. During the past several years, numerous cultivated crops and forestry species have been investigated for their galactomannan content to give a boost to Indian gum industry which is mainly exploiting guar (*Cyamopsis tetragonolobus*).

In view of the industrial importance of seed galactomannans, the seeds of Leguminosae family have been screened which reveals some genera like *Acacia, Albizzia, Erythrina* are found to be almost devoid of the gum whereas seeds of almost all the species of *Cassia*, *Crotalaria*, and *Indigofera*, occuring in India have been found to be very rich in galactomannan content.The investigations carried out at this institute have shown that seeds of *Leucaena leucocephala*, *Prosopis Cineraria* and *Cassia tora* yield 20-35% of the galactomannan which is invariably present in the endosperm of the seeds and therefore, easily separable by mechanical means. The *Cassia tora* Linn. is a common herbaceous annual occurring as a weed throughout India. A patented technology has been developed to produce the gum from *C. tora* (yield 30-32%) by dry method. The gum has been found to be excellent wet-end additive in paper making. *C. tora* gum on modification act as a flocculant for the treatment of backwater in paper industry and as a settling aid of mud in sugar industry. Non gelling concentration of Xanthan gum and *C. tora* gum interact in solution to give significant increase in viscosity and forms gel which can be exploited in food industry. Paper will be presented to describe the rheological behaviour with respect to their synergistic interaction, of a mixture of Xanthan and *C. tora* gum, the structure of which is different from guar and locust bean (*Ceratonia siliqua*) gums.

High technologies for Russian forestry

Vasiliy I. Sukhikh, Victor K.Teplyakov, Valentin S. Shalaev
International Forestry Institute, 69, Novocheriomushkinskaya Str., 117418 Moscow, Russia
Tel: +7-095-3311701, FAX: +7-095-3322917, Email: sukhikh@cepl.rssi.ru

Keywords: forestry; high technology; RS; GIS; GPS; administration management; Russia.

In transition to market economy Russia works on the problem how to make forest administration and management more effective. One of the ways is to design and implement modern and perspective, so-called “high”, technologies in forestry and multiple use of forest resources. To solve these problems it is necessary to change the system of getting information on forest state and dynamics. Most of the forest lands in Russia is difficult to access. There are also a variety of forest lands by designated use. All these make high technologies very effective Among these technologies are remote sensing by use of Russian and foreign satellites, GPS and GIS technologies, modern layers and sensitive materials for air-photography. All this attracts the attention of the country’s research, educational and industrial institutions. The paper deals with analysis of current state of the problem, and especially with it’s theoretical and methodological issues, staff training and practical implementation in forestry.

Utilization of aerobic sludge compost as a soil conditioner and fertilizer for plant growth

Ulvi Tolay, Yavuz Yavuzsefik
Abant Izzet Baysal University, Forestry Faculty, 14600 Düzce-Bolu, Turkey
Tel: 0374 514 11 43, FAX: 0374 523 22 83

Keywords: aerobic sludge; waste water; water treatment; composting; soil conditioner; plant growth; forestry and agriculture.

Sludge is a byproduct of industrial or municipal waste water treatment. The characteristics of sludge depend on both the initial waste water composition and the subsequent waste water and sludge treatment process used. Increasing volumes of aerobic sludge generated in industrial an municipal waste water treatments plants have resulted in making our solid waste disposal problems worse. It is possible to dispose of aerobic waste water sludge by land filling or incineration, or to reuse this sludge after proper composting. Aerobic waste water treatment sludge generally contains (on dry weight basis) 50-60% organic matter, 4-7% nitrogen,2-3% phosphate (as P2O5), potassium and other minerals.

The most beneficial and appropriate method for sludge resulting from food industry waste water treatment is composing with various kinds of bulking agents. Sludge is typically composted for 21-60 days, during the time pile temperature typically reaches 55^{o}C in a properly run operation. During composting, the organic material in the sludge is degraded to a humus-like material that makes an excellent soil conditioner. The bulking agent is also partially digested. The compost obtained through aerobic treatment can have several beneficial uses in forestry and agriculture.

In this study, sludge from yeast manufactured in Pakmaya-Düzce Plant has been composted with peat moss and corn stalk chips and used as a plant growing media in containers. According to the results obtained from investigation, 2 parts of composted corn stalk chips with sludge + 1 part of sandy loam soil 20% of agricultural prelate mixture gave the best growth for garden flowers (*Tagetes patula* Carolus Linneaeus, *Tagetes erecta* Carolus Linnaeus, *Zinnia elegans* Nicolaus Joseph Jacquin, *Malcolmia maritima* Carolus Linneaeus).

Observations on the mycorrhizal status in decaying and not decaying woodlands in Italy

Livio Torta
Università degli Studi, Istituto di Patologia vegetale, Viale delle Scienze 2, 90128 Palermo, Italy
Tel: 091422974, FAX: 091423238, Email: patveg@mbox.unipa.it

Keywords: mycorrhizal status; decaying and healthy trees; mycorrhizal index.

In order to assess the eventual associations that can occurs between the mycorrhizal and the fitosanitary status in decaying and not decaying Italian woodlands, a research was carried out in permanent stands delimited in Sicilian and Tuscanian areas. In some natural and artificial woods of *Pinus halepensis*, *Quercus ilex*, and *Q. suber* the number of mycorrhizal apex and the index of mycorrhizal infection in different plots with decaying or healthy trees were evaluated. For this purpose, samples of soil, roots, and seedlings were collected and observed, using a methodology for making easy the collection of data. In the same plots the presence and the number of mycorrhizal sporophores was detected, too.

The results of these observations, conducted for four years in Sicily and two years in Tuscany, seem to show a strict association between the mycorrhizal status and the health of both the plants and the studied environments. These results evidence that in the stands with healthy trees, the number of mycorrhizal apex, the index of mycorrhizal infection, the variety of mycorrhizal forms, and the number of both the species and the sporophores of mycorrhizal macromycetes are more abundant, in comparison with those observed in decaying ones.

In particular, it was observed that not decaying stands with healthy *P. halepensis* in Sicily, revealed an active mycorrhizal status (high index of mycorrhizal infection, many different mycorrhizal forms, and a lot of species and sporophores of mycorrhizal macromycetes as *Tricholoma terreum, T. scalpturatum*, *Lactarius vinosus*, *Hygrophorus limacinus, Inocybe fastgiata*, etc.). On the contrary, in the decaying stands, where *P. halepensis* showed evident symptoms of chlorosis, redden of needles, and blight of twigs and branches, the index of mycorrhizal infection was very low, as well the variety of mycorrhizal forms, and the presence of mycorrhizal macromycetes. In this stands the sporophores of saprotrophe species were much more represented (*Lyophillum* spp., *Clytocibe* spp., etc.).

The survey conducted in the stands with *Q. ilex* in Tuscany showed that the older woods were characterized by a low mycorrhizal index and few mycorrhizal forms, in comparison of the younger ones. Moreover it was noted that the old woods had a poor underwood and an high percentage of trees fallen down, with evident sporophores of *Phellinus torulosus* at the bottom; on the other hand, in the delimited stands in mature woods, it was found a lower number of species and sporophores of mycorrhizal macromycetes than in the stands with older or senescent trees.

Observations carried out in other Sicilian and Tuscanian environments, confirmed that high index of mycorrhizal infection are always associated with a good fitosanitary status, and permitted the characterization of some specific symbiosis, as the association *Lactarius cimicarius-Quercus suber*, in Sicilian woodlands.

Natural areas as baseline ecosystems for forest monitoring and research: the role of U.S. Forest Service research natural areas

Lucy E. Tyrrell, Tom Crow
USDA Forest Service, 5985 Highway K, WI 54501 Rhinelander, USA
FAX: (715) 362-1166, Email: ltyrrell/nc_rh@fs.fed.us.gv

Keywords: natural resource management; sustainability; biodiversity; indicator; monitoring.

Key to any natural area’s usefulness to natural resource management is its ability to provide information that is not available from more intensively managed landscapes. Effects of management are evaluated not only against the management objectives but also in comparison to a control area that did not receive the same treatment. How can we determine the effect of forest management on stream habitat unless we have an example of a stream in an area not managed for timber harvest? How can we evaluate the recovery of the ground flora after a timber harvest unless we have followed the floristic composition of an unharvested area over time for comparison? How can we study the impacts of silviculture on biodiversity, unless we can inventory biodiversity in unharvested sites? How can we assess the impacts of roads or forestry practices on soil erosion, unless we have areas in which soil erosion is measured in the absence of roads and silviculture?

Research Natural Areas (RNAs) established by the USDA Forest Service are managed to maintain the biological diversity and natural processes within representative national forest ecosystems. Forested RNAs can serve key roles as control or reference areas for monitoring or research that examines the effects of forest management on such ecosystems. A few large RNAs (1,000's to 10,000's of acres) are better able to represent landscape patterns and serve as control areas than many smaller RNAs.

Several examples of research and monitoring in RNAs will highlight the under-utilized potential of RNAs to contribute to the scientific understanding of forest characteristics and functions, and thus to forest ecosystem sustainability.

The Bowl RNA (White Mountain National Forest (NF), New Hampshire) is a relatively unmodified watershed of northern hardwoods. Many studies are using this area as a baseline watershed. One study compared patterns of lichen diversity in forests to show that ‘stubble lichens’can be used as indicators of ecological continuity. At The Bowl, 23 ancient forest indicator lichen species were found, confirming it as an intact old-growth site. Another integrated study of soil nutrients, foliar nutrients, and forest productivity at The Bowl (and a range of other sites that have different land use histories) has helped researchers use remotely sensed data to predict the impacts of forest management alternatives on nutrient cycling and productivity at a site.

Tionesta Scenic and Research Natural Areas on the Allegheny NF (Pennsylvania) have been surveyed for stream habitat, macroinvertebrates, and fish to compare with reaches of the same stream flowing through harvested areas. Bat species diversity at Tionesta (old growth) has been compared with bat species diversity in second-growth forests.

Research conducted at Memorial Grove Hemlocks and Tucker Lake Hemlocks RNAs on the Chequamegon-Nicolet NF (Wisconsin) compared diversity and abundance of birds, small mammals, and amphibians in these old-growth hemlock-hardwood forests to that of second-growth stands.

Monitoring the number of land snail shells (live, empty, and broken) in the leaf litter at Atwood Ridge RNA before and after a prescribed burn has enabled managers on the Shawnee NF (Illinois) to respond to concerns about possible effects of the Forests' prescribed fire program on land snail density and mortality. Results indicate that fire does not affect snail mortality as much as soil moisture.

Floristic inventories at The Cape RNA (Green Mountain NF, Vermont) are part of studies to determine management effects on biodiversity.

RNAs and other natural areas provide critically important baselines for forest resource management. Best management practices can be developed for intensively managed areas based on information obtained in reference areas if land is allocated to both uses within the same landscape.

Soil characteristics in common oak and common hornbeam (Carpino betuli-quercetum roboris Ht. 1938) forests in the Republic of Croatia

B. Vrbek
Forest Research Institute Jastrebarsko, Trnjanska 38, 10 000 Zagreb, Croatia
Tel: +1 611 33 72, FAX: +1 611 33 72, Email: borisv@sumins.hr

Keywords: soil characteristics; moisturisation; common oak; common hornbeam; Croatia.

In common oak and common hornbeam (Carpino betuli-Quercetum roboris Ht. 1938) forest stands, i.e. the ecological-managerial type (EGT) II-G-10, it has been found that hydromorphic class of soil types are present. Soils in this class are characterised by either periodical or permanent supplementary moisturisation. According to present research, there are ten soil types which belong to the EGT II-G-10: pseudogley on level terrain and pseudogley-gley (Gleyc luvisols), eugley (Gleysol) subtype hipogley and humic fluvisol (Fluvisol). Occasionally, some types from the automorphine soil class are also present: pseudogleyed luvisol (Orthic luvisol) and on some localities pseudogleyed cambisol (Eutric cambisol). The aforementioned soil types and sub-types in common oak and common hornbeam (Carpino betuli -Quercetum roboris Ht. 1938) forest stands in Croatia have a wide range of chemical and physical characteristics. The area or the pedoecological sub-divisions are called pedogeographic areas. According to recent research, the difference between them is the level and the presence of the main soil type or types, their parent soil and other chemical and physical characteristics. On 209 locations and sample plots, one pedological profile and two assisting profiles were excavated. A morphological description of the soil was undertaken on the main pedological profile and samples of their genetic horizons were taken for chemical and physical analysis. After processing the results, the soil type and subtype were determined as well as the main chemical and physical soil characteristics for the ecological-managerial type forest stand. According to the results of the chemical and physical analyses many of the differences were observed between the West Drava watershed and Cesma and Ilova watershed. In a pedological sense these are two extremes. The East Drava watershed and the Pokupsko basin have many common characteristics but differ in the genetic form of the soil profile and mechanical structure. The main difference is in the genetic form of the dominant soil pseudogley on the level terrain. In terms of the percentage share of particular soil types in the II-G-10 ecological-managerial type, these areas can be divided into four pedogeographics sectors. 1. The East Drava watershed with the dominant parent material alluvium of 80% and alluvial terraces of 20%, on which 40% is eugley-hypogley (Gleysol), 40% humic fluvisol (Fluvisol) and 20% pseudogleyed luvisols (Orthic luvisol); 2. The West Drava watershed where dominant parent material is also alluvium (40%) with alluvial terraces and swamp loess 20%. The dominant soil types are humic fluvisols 60% (Fluvisol), eugley-hipogley (gleysol) and pseudogleyed luvisol 10% (Orhtic luvisol); 3. The Cesma and Ilova watershed with part of the Sava watershed in which the dominant parent material is swamp loess which is 90% of the total and alluvial terraces is 10%. In these areas the dominant soil is pseudogley on the level terrain (Gleyc luvisol) with 80% of the share, pseudogley-gley (Gleye luvisol) with 10% and eugley-hipogley (gleysol) with 10%.

In The Pokupsko basin area with part of the Sava watershed, the dominant parent material (60%) is loam and clay in some parts mixed with swamp loess in the upper layer, alluvium 20% and alluvial terraces 20%. The dominant soil types are pseudogley on the level terrain of a primary origin i.e. with a heavier mechanical structure (Gleyc luvisol) taking up 50% of the total, pseudogley-gley (Gleyc luvisol) taking up 25% and eugley-hipogley (Gleysol) taking up 25%.

Comparison of tree composition in primary and logged forest

Mohamed Zakaria, Mohd Nordin
Universiti Putra Malaysia, Department of Forest Management
FAX: 603-9432514, Email: mzakaria@forr.upm.edu.my

Keywords: species composition, primary forest, logged forest, Euphorbiaceae, Dipterocarpaceae

The understanding of variations in species composition of primary and logged tropical rainforests requires detailed and intensive long-term observations. More recent studies conducted in primary forest showed that there were no dominant species in the forest (Kochummen et al. 1990; Manokaran and La Frankie 1990; Kamarudin 1986).

The most common families were Euphorbiaceae, Myrtaceae and Lauraceae. Members of the Dipterocarpaceae are the most abundant of the emergent and tall upper canopy trees (Anderson 1957; Ashton 1964; Wyatt-Smith 1952). This paper describes in detail the differences in species composition of primary and one-year-old logged forest in the Ulu Segama Forest Concession area in Sabah and considers the effects of logging on the recovery of tropical lowland rainforests.

The study was conducted at two sites, each representing a primary and one-year-old logged lowland dipterocarp forest. The primary forest study site is situated within the Danum Valley Conservation Area. The one-year-old logged forest study site is situated adjacent to the primary forest study site. Both study areas had a size of about 40,000 m² (20m x 2000m) or equivalent to about 4 ha each.

The study showed that the primary forest study site was very rich in Euphorbiaceae. This represented 15.3% of the total number of trees recorded. The second highest group was members of the family Dipterocarpaceae, represented 14.4% of the total. The four largest families - *Euphorbiaceac, Dipterocarpaceae, Meliaceae* and *Lauraceae* - were predominant in the study area. Their numbers add up to 1089 trees out of a total 2195 trees (49.6%). Altogether 49 Families were recorded in the primary forest study site. Of these, seven were represented by a single specimen. In addition, 23 families were represented by less than 10 individuals each. These accounted for less than 80 individuals, or 3.7% of the total.

In the logged forest study site the Family Dipterocarpaceae was marginally the family with the largest representation. It accounted for 14.8% of the total. The eurphorbs were a close second with 13.7% of the total number of individuals. As with the primary forest study site, the top four families (Dipterocarpaceae, Euphorbiaceae, Meliaceae, and Lauraceae) accounted for 727 individuals, or 45.5% of a total of 1599 trees. Altogether there were 44 families in the logged forest plot. Twenty of these were represented by less than 10 individuals each, and four were represented by a single individual.

Tree family composition between primary and logged forests showed that although the forest had been logged, 13 families had many more representatives in logged than in primary forest. This was especially true in the family Polygalaceae, with 51 individuals more in logged forest than in primary forest. However, the data clearly showed that many more families had higher numbers of representatives in primary than in logged forests. Marked differences in numbers of representatives were evident in the family Euphorbiaceae and Meliaceae.

There is a strong correlation in the ranking of plant Families between the two study site (Spearman's Rank Correlation; rs=0.89, n=43, p<0.01) suggesting that the ranking positions of each family in the two forest types were very similar. Also the tree composition in both forests was almost the same. However, there was a very highly significant difference in the number of individuals present in both forests (F=19.21, df=51, n1=2195, n2=1599, p<0.001). In primary forest there were 548.5 trees (i.e. trees bigger than 15cm dbh)/ha, while in logged forest there were only 399.8 trees/ha.

The result from species-area relationship clearly indicated that species richness in primary forest is much higher than in logged forest. Results from cumulative number of taxa encountered against increasing number of trees sampled also demonstrated similar patterns. A greater number of trees from the 4-ha area sampled in logged forest were missing particularly at the species level. This shows that selective logging has reduced the number of species due to the reduction in the number of trees left standing after logging. Poore (1968) suggested that even if a 20-ha area of logged forest were sampled, it would not necessarily include all the species in its vicinity.

Although it has been shown that logging affects all species at random, the most important difference between primary and logged forests was the lower number of families, genera and species in logged forests. There were 5, 3 and 17 lesser number of Families, Genera and Species respectively in logged than in primary forests. Many of the trees lost during logging were not only timber trees but also non-timber and important fruit-trees from the families Euphorbiaceae, Meliaceae and Lauraceae.

Forest grazing for sustainable forest management: a case study of China

Jiang Zeping, Xiao Wenfa, Meng Ping, and Sun Xiaomei
Chinese Academy of Forestry, Sustainable Forestry Research Center, Wan Shou Shan Hou, 100091 Beijing, China
FAX: +86 10 62872015, Email: jiangzp@rif.forestry.ac.cn

Forest grazing has been a tradition for thousands of years in China. In recent decades, however, overgrazing in forests have caused many forest to be degraded, especially in forestry-rangeland ecotones. At present the forestry/pastoralism issue has become a focus of public awareness, and has been treated as one of the priorities in sustainable forestry in China.

Based on case studies throughout China, it is recognized that forest grazing, which is often being considered as a silvicultural measure for plantations for controlling undergrowth and improving nutrient cycling, is one of the most serious factors inhabiting forest natural regeneration in dry zones, and usually induces water and soil erosion in humid zones, although its influence depends on the pressure and duration of grazing.

The paper consists of three major parts. Firstly, the practices of forest grazing were reviewed for typical ecozones, mainly for the arid and semi-arid zones, temperate humid zone, subtropical and tropical humid zones, and sub-alpine zone, with special reference to the resource conflict management. Secondly, strategies and measures were presented for better management of forest grazing for each ecozone, including capacity building, joint management of stakeholders, legislation, communication, training, extension systems, et al. Thirdly, the priorities of researches were listed. The role and its utilization of traditional knowledge were discussed.

It is concluded that, i) forest grazing is a vital part of sustainable forestry; ii) the balance between forest grazing and the limited restoration capacity of forests is possible, but it is a long-term task which requires improvements on related policy and institution, public participatory, forest management technology, investment, and etc; iii) it is crucial to satisfy all stakeholders' demands, otherwise, any attempts to protect and develop forests will not be practical, therefore, the first step to deal with the forestry/pastoralism conflict is to define scientifically their relationships in an integrated system of social, economic and cultural background in stead of in pure forestry or animal husbandry; iv) further researches are needed, e.g. the livestock load capacity of forest, rotation of rangeland, classification of grazer, monitoring technology and precaution systems; v) traditional knowledge are useful and effective in the improvement of forest grazing; and, vi) it is necessary to extend a new management model step by step, and the process can be greatly promoted by information communication.

Nature forest management and biodiversity conservation in Northeast China

Hao Zhanqing
Chinese Academy of Sciences, Institute of Applied Ecology, Post Box # 417, 110015 Shenyang, China
FAX: +86-24-23843313, Email: Lmdai@iae.syb.ac.cn

Northeast forest is the most extensive forest in China. Forest area is 36.57 million hm^2 and accounts for over 27.8% of the national total. Forest storage is 3 billion m^3 and accounts for 30.3% of the national total. Forest coverage is 54.8% ranking first in China. It is a major forest product base in China and supplies more than 1/3 of national commercial timber. The zonal vegetation is broad-leaved Korean pine forest. Compared with the vegetation of Europe and North America in the same latitude, this type of forest is significant for its complex composition and structure, high biodiversity, and specific dominant species. However, since the irrational utilization by clear-cutting, the area of virgin forests has decreased dramatically during the past 100 years. The patterns of species diversity have changed greatly and many species that closely depend on the old growth forests were disappeared.

Different forest management treatments have varied impact on biodiversity. Two kinds of timber logging way are commonly used in Northeast China: Clear-cutting and selection cutting and clear-cutting was a major way for timber logging before 1980's. The study results showed that the influences exerted by selection logging on avian or plant community were much less than those done by clear cutting. There were only 8 species of birds on clear-cutting site after 2 years recovery and all of them were shrub-grass birds. After 50 years recovery of clear-cutting, bird species increased to 15 and 12 of them were forest birds. But this value was much lower than that of virgin forest which had 34 species of birds and 33 of them were forest birds. In selection cutting forest with removal 40% in volume, there were 24 species of birds after 2 years and 72% of them were forest birds. It was much higher than that of secondary forest with an age of 50 years formed on clear-cutting site. For plants, study results showed same trend as birds. After 2 years of selection cutting, 90% of virgin species could be found in disturbed forest. Only abundance was little bit different between virgin forest and selection cutting forest. But in clear-cutting forest site, it needs 60 years for 90% of virgin species to recover when propagules are available. Otherwise, it needs longer for virgin species to recover.

Current state of forest ecosystems in the Urals

Vladimir N. Bolshakov
Institute of Plant & Animal Ecology, 8th March St. 202, 620144 Ekaterinburg, Russia
Email: vladimir.bolshakov@ipae.uran.ru

Keywords: population; forest; anthropogenic transformation; northern taiga; southern taiga

The Urals make a natural boundary between Europe and Asia, extending for more than 2,000 km from steppes in the south to the tundra zone in the north. But the major part of the whole territory of the Urals is covered by forests.

The current state of forests in the Urals is to a large extent determined by historical reasons. Intensive forest felling started immediately after the foundation of the very first plants which used woody charcoal as the main energy source for metals production. Situation with forests specially aggravated from the second half of the XVIII-th and in the following centuries, when the number of metallurgical industries exceeded a hundred. Significant loss of forests occurred also due to numerous fires.

Thus during the last 300 years, various types of human activities, namely mining and metallurgical industries, development of towns and network of roads, intensive agriculture, growth of population, lead to gradual decrease of the primary forest communities represented in the Urals mainly by dark and light coniferous forests, whereas the ranges of the derivative foliate forests were marked to increase.

The detailed analysis of the retained plant communities allows estimating the modern state of anthropogenic transformation of the region territory. Specialists consider that level of these changes not exceeding 10% corresponds to favorable ecological situation. 30% of the territory transformation shows that situation is still normal. But when these changes embrace about a half of the region forest stands, ecological conditions should be regarded as non-desirable. 70% of the disturbed area indicates to a situation of risk, whereas 90% and more reveal critical or disastrous ecological situation. This way of estimation shows that only in the very north of the Ural region ecological situation remains favorable for the vegetation state. On the contrary, in the south districts over 80% of the territories are disturbed, mainly due to agricultural development of lands and creation of agrocoenoses. About 11% of the whole territory now reveals disastrous ecological condition.

Proposing that modern ecological situation has developed during three centuries of the Ural flora exploitation, one can evaluate rate of transformation, the latter making ca 270 square km per year. If the process continues and with the same intensity, we can expect full disappearance of the primary north-taiga forests during the next 55 years, those of the south taiga - in about 60 years, and tree stands of the middle-taiga regions - in 140 years. At present, a critical situation is registered in pre-forest-steppe and pre-taiga regions.

Forest melioration of agrolandscapes

G. B. Gladun
Ukrainian Research Institute of Forestry & Melioration, Pushkinskaya str. 86, 310024 Kharkiv, Ukraine
FAX: +0 380572) 43-25-20, Email: root@u-fri.kharkov.com

Keywords: Afforestation; Agrolandscapes; Ukraine

The forest melioration in Ukraine is more than half-century, when the State has begun research and practical works. The most active period of forest meliorative stands creation was the second half of the XXth century, when the interests of land use and ecology had to be taken into account, especially when extensive agriculture development. So far as forest melioration objects were located mainly on the agricultural lands and size of works was more than on the other kinds of recultivated lands, in so far as the agrolandscapes have become the main area of it. Now more than 42,400,000 ha of lands (79% of total area) are in the agrarian sector of economy, 32,000,000 ha from them are arable ones. The land use is not always safe for ecology.

The agrosphere state causes alarm because of soil destruction. 18% of area is damaged by intensive ravine erosion; annual soil losses are 600-650 mln of tons, which include humus and necessary nutrients (K^+, Na^+, Ca^{2+}, P etc.). Deflation and suffusion bring to annual losses of arable lands. The area of such lands is more than 10 mln of ha. They need the immediate melioration, mainly by means of forest cultivation. In the modern conditions, forest melioration is acknowledged as universal, reliable and permanent. Unlike other approaches, forest melioration influence on the soil functions regime in some distance from the forest objects, on the microclimate parameters (heat and water) positive changes, superficial and ground water regime and other important characteristics of agrolandscapes. Forest melioration promotes the improvement of ecological situation and gradual restoration of ecological equilibrium. The last is one of the main conditions of evolutionary functions of landscapes regeneration that is self-regulating and self-rehabilitation with gradual increase of bioecological potential of their natural and changed by man structural components.

Forest melioration plays the main part in the restoration of disturbed relations between natural complexes (forests, arable lands, meadows, water objects), because different spatial forms of shelter belts and their density determine both the landscape structure and homeostasis on the whole. The main tasks of the forest melioration are: to determine the initial and the further notions about necessary and optimal participation of its objects in the site and area structure; to ground the quantitative parameters of the forest meliorative objects on the first stages of the landscapes restructurization; to develop the effective spatial, special, functional & purposal and other kinds of forest meliorative stands, which would promote the increase of biodiversity and saturation of landscapes; use of the forest melioration must take into account not only ecological & economical sense, but also social meaning and correspond to aesthetic demands.

It is already proved that meliorative stands with stable signs of system and with area more than several thousands of hectares can carry out the transgressive functions and regulate the climate. Particularly precipitation increases 15% and productivity of agrocenosis increases 15-35%. There is any alternative to forest melioration by its useful properties. Therefore in the conditions of climate aridization and global warming the meaning of forest melioration as a factor of agrolandscapes stability will grow significantly.

Effect of timber tree residue and its compost application on growth of some local trees in Egypt

Hussein Ibrahim Mahmoud Aly, H.A.Abou-Gazia, M.E.Saleh and M.A.M.Abd El-aal
Alexandria University, Forestry and Wood Technology Dept., Alexandria, Egypt
FAX: 00203-5446914, Email: hussein@safwa.com.eg

Keywords: compost; residues; eucalypt; *Casuarina; Acacia*; bark; leaves

The main objective of this study was to find the best way for using disposal wood wastes into organic manure (compost) for increasing the economical return. The experiment was designed to study the effect of different soil treatments which containing timber trees residues such as using wastes directly in cultivation, wastes with add nitrogen, and composted wastes.

Wastes were mixed with each of clay and sandy soils in the ratio 1:1 to study the effect of different soil treatment on plant parameters. The results can be concluded that the utilization of compost of sawdust, bark and leaves after mixing with sandy and clay soils for eucalypt, casuarina and acacia plantations as a growth media is recommended than sawdust, bark and leaves added directly or sawdust, bark and leaves with nitrogen (ammonium sulfat)

On the other hand, utilization of leaves after mixing with sandy or clay soil as a source of soil medium without any treatments for eucalypt, casuarina and acacia plantations is recommended because its superiority to the control.

Fertility status of hill forest soil of the south eastern part of Bangladesh

Mizanur R. Bhuiyan
Khulna University, Soil Science Discipline, 9208 Khulna, Bangladesh
Tel: 880-41-721791, FAX: 880-41-731244, Email: Dr. Khairul Azam [azamku@khulnanet.net]

Keywords: forest soil; soil fertility; soil degradation

The forest resources of Bangladesh have been severely depleted. There exists a high potential to increase forest resources in the hilly areas of the southeastern part of Bangladesh. The soils of hilly areas are being degraded and deteriorated with time and consequently the soils are becoming less suitable to support forest trees and agricultural crops. In order to prevent and limit the degradation of these hill soils and for keeping the soil fertility to its optimum level very limited soil study was done. For evaluating the present fertility status of the area recently (1998) a study on the physico-chemical properties of the soil was carried out. It has been found that the nutrient elements in the soil have decreased substantially from the previous study results. The pH of soils have decreased during the 10 years period (1988-1998) resulting higher acidity. The reasons responsible for increasing of soil acidity and lowering of soil fertility may be due to (a) destruction of forests and removal of vegetation resulting in exposure of the soil surface which is then oxidized and consequently increased the soil acidity and (b) soil erosion due to run off washed away the top soil containing high organic matter and nutrients.

Study of nutrient deficiencies of sandy soils in the Congo by pot experimentation: effects of the site

J. P. Bouillet, Safou-Matondo R, Nzila JD
CIRAD-Forêt/UR2PI, Post Box # 1264, Pointe-Noire, Congo
Tel: +242 943184, FAX: 242 94 47 95, Email: UR10@calvacom.fr

Keywords: *Eucalyptus*; coppice silviculture; production

Since 1978, 42,000 ha of clonal *Eucalyptus* plantations have been established in the Pointe-Noire region for pulp production. These plantations, owned by ECO sa (Eucalyptus du Congo Société Anonyme), are based on two natural hybrids (E.PFI and E.12 ABL* saligna). As felling age is 7 years, management of coppice appeared very early as a main issue. More than 10 trials focusing on this goal were therefore established since 1985. Moreover, complementary experiments were set up to compare coppice and replanted sites production.

Coppice silviculture: The trees can be cut at ground level, without impact on latter coppice production. From 4 months after cutting, there are marked differences in growth between coppice shoots. These differences increase with age: from 2-3 years, only the two bigger shoots per stump (70% of total basal area) keep on growing. Coppice reduction increases growth of the remaining shoots. This operation can be done during the first year, as soon as the dominant shoots can be identified (4-9 months old).

Optimal coppice reduction intensity depends on soil fertility and stump density: as observed with planted crops, the maximum production is obtained, between 600 stems/ha in the low fertility sites and 800 stems/ha in the best sites. As initial stand densities vary between 400 to 800 stems/ha, 1 to 2 shoots per stump are selected. Secondary coppice shoots have to be controlled, manually (bush knife) or chemically using glyphosate (Roundup®). This last manner allows weed control at the same time, and thus, lower costs. It provides the best results for shoot control and stem growth.

A fertilization of 200-250 kg/ha N-P-K (13-13-21) must be applied one year after the harvesting of the previous stand (planted crop or coppice).

Coppice vs replanted sites: Coppice stumps can be weakened with a 40% glyphosate solution (Roundup®). The solution must be applied by spray at a dose of 25-30 ml/stump, just after stem harvest (less than one hour). No return time is then necessary.

A site replanted with the previous clone exhibits about the same MAI as coppice. Moreover the loss of production during the period between harvesting and planting must be taken into account. It appears therefore that a plot may be replanted only if a much better vegetal material can be used (*E. urophylla * E. grandis* vs natural hybrid,…).

Conclusion

These results contribute to efficient management of the Congolese commercial plantations consisting at present of 13,000 ha of planted crop, 19,000 ha of coppice and 10,000 ha of replanted sites.

Forest regeneration utilizing mulching sheets and symbiotic microorganisms

Keywords: mulching sheet; symbiotic microorganisms; *Pinus thunberghii* Parl., *Pinus densiflora* Sieb. et Zucc., *Pisolithus tinctorius* Coker et Couch *f. tinctorius*; forest regeneration

In order to investigate the possibility of utilizing a combination of a mulchingsheet (MS) composed of polyester random fiber web as the main material and mycorrhizalfungi (MF), effects of their utilization were surveyed for 3-5 years on the growth of *Pinus thunbergii* Parl. and *P. densiflora* Sieb. et Zucc. at model and actual slopes.At plots where spores of *Pisolithus tinctorius* Coker et Couch *f. tinctorius* (Pt) were dispersed as MF and MS were applied after *P. densiflora* was seeded, the stem diameter at ground level and planting stock height showed greater values from the first year, compared with those at control plots.

The growth at the experimental site belonging to Ehime University where seeds of *P. densiflora* were incorporated into the MS showed greater values of stem diameter at ground level and planting stock height from the first year, compared with those at control plots. MS were stuck at the site where 5 years had elapsed after *P.thunbergiiwas* planted at Mt. Tanakami in Ohtsu, Shiga. An increase of 66-494% was shown in the stem diameter at ground level and tree height of *P. thunbergii*, compared with those of control plots during 5 years.

At the Nojiri River experimental site on Sakurajima Island in Kagoshima where *P.thunbergii* of a two year-old planting stock was planted after MS were stuck, *P. thunbergii* showed a strong tolerance against sulfurous acid gas (SO_2 gas). From these findings, it was estimated that MS and MF were effective forthe regene-ration of forests devastated by various causes.

Site productivity estimation using stand variables in neotropical secondary rain forests: methodological considerations and a case study

Bernal Herrera, José J. Campos Arce
University of Costa Rica (CIA), 2060 San José, Costa Rica
Tel: (506) 2243712, Email: bernalh@cariari.ucr.ac.cr

Keywords: site productivity; tropical secondary forests; *Vochysia ferruginea*; northern Costa Rica; neotropics

Secondary forests growing on abandoned agricultural lands are becoming an increasingly important part of the forest resource of many tropical countries. Several analyses have drawn attention to the potential of such forests for management for a wide range of products and services. One urgent need is to progress beyond simple estimations of the area occupied by tropical secondary forests, to determinations of forest area by categories of age and site productivity. In spite of the relevance of site productivity estimations to forest management in the neotropics, there have been very few experiences dealing with assessing site quality in broadleaved secondary rain forests.

We estimated site productivity and its variation for the dominant and commercially important tree species *Vochysia ferruginea*, in four secondary rain forest stands 16 to 28 years old in Northern Costa Rica. In the 28 years old stand, 36 sample plots (20x20 m) were installed in 1995 in such a way as to cover the whole range of substrate variation at the site. The stand was assumed to be even-aged and dominate height, estimated as the mean total height of the four tallest *Vochysia* trees in each plot, was used as the measure of site productivity. In a second part of the study, carried out between 1996 and 1999, site productivity and its variation, using the concept of site form (i.e the expected height of a 25 dbh tree) was evaluated in all four stands. 29 sample plots (20x20 m) were installed covering the whole range of soil variation at the sites. Site form was estimated for each plot using a linear model. Adjusted multiple regression models of dominant height and site form on soil variables were fitted by multiple regression procedures.

For the first part of the study, all plots showed low within-plot coefficients of variation for total height (four tallest trees), suggesting homogeneous site productivity conditions in the 400- m^2 sample plots. Dominant height of *Vochysia* was correlated with mean plot canopy height and stand basal area, and with its own basal area.% clay, % organic matter, P, Fe and Cu at soil depth 0-12 cm, were correlated with dominant height. The best fit was obtained using P, Mn, % organic matter and % clay as independent variables (R^2 = 79.5%; s.d. = 1.8 m).

In the second part of the study, site form showed a high between-plot variation (16.2-32.2 m), indicating high variation in terms of site productivity between the stands. Site form of *Vochysia* was significantly correlated with stand basal area and with 26 soil variables. Adjusted multiple regression models of site form on soil variables were fitted. The best fit was obtained using %sand at 12-30 cm depth as the independent variable (R^2 = 59.3%; s.d. = 3.0 m).

Dominant height appears to be a potentially useful indicator of site productivity in broadleaved neotropical secondary rain forests stands of similar age. Meanwhile, site form could be a potential indicator of site quality in situations when age is unknown and different between stands. This study suggests that there may be an important effect of site quality on timber production in this type of forest.

Effect of domestic sludge on the initial growth performance of *Samanea saman* (Jacq.) Mer. in the nursery

Mohammed Kamal Hossain, M. S. Haque and M. S. Hossain
Chittagong University, Institute of Forestry and Environmental Sciences, 4331 Chittagong, Bangladesh
Tel: 880-31-726310, FAX: 880-31-610004, Email: ifescu@globalctg.net

Keywords: soil; sludge; fertilization; *Samanea saman*; seedling growth

The treatment and disposal of industrial and municipal or domestic sludge is an environmentally sensitive problem. Since sludge constitutes organic and inorganic substances, it can be used as a soil amendment, either for land reclamation or for increased plant growth. Application of sludge to land has been practiced in an attempt to disposal of municipal and domestic wastes and to gain potential fertilizer value from the application. Most of the nurseries of Bangladesh use forest topsoil and cowdung or inorganic fertilizers as growing media of seedlings. This results degradation of the fertility of forest site as well as it costs much to transport the soil in the nursery site. So, it is necessary to find a suitable growing media of seedlings in the nursery as well as an alternative safe disposal route of municipal or domestic sludges. The present experiment was conducted in the nursery of the Institute of Forestry and Environmental Sciences, Chittagong University. *Samanea saman* seedlings were grown in 23cm x 15cm (9 x 6) sized polybags filled in with the soil:sludge mixtures in different ratios. Domestic sludge was prepared by composting vegetable wastes, straw, lawn clippings, weeds, used tea wastes, waste paper, discarded portions of fish and meat and other wastes generating form the kitchen. The seeds of *Samanea saman* were collected from the Seed Orchard Division of Bangladesh Forest Research Institute, Chittagong. Seedlings were raised in the polybags in a completely randomized design to see the effect of domestic sludge on the initial growth and biomass accumulation at the end of the experiment. One hundred and eighty seedlings taking thirty-six seedlings in three replicates were laid to grow in control (soil only) and soil mixed with domestic sludge in four different proportions (1:0.3, 1:0.5, 1:1 and 1:2). Height growth (cm) was collected at two weeks interval. The six months old seedlings were randomly selected for harvesting and the collar dia, root length and oven dried weight of leaf, stem and roots were measured. Root length, leaf weight ratio (LWR), root weight ratio (RWR) and root shoot ratio of the seedlings treated by sludges and soil mixes in different proportions were not found significantly different from control (soil only). However, growth parameters like height (cm), collar dia (mm), leaf, stem, root and total dry weight, stem weight ratio (SWR), specific stem weight (SSW) and quality index (QI) were significantly higher in sludge treated seedlings in comparison to the seedlings in the control treatment. In most of the growth parameters, seedlings grown in soil: sludge mixes in a ratio of 1:0.3 performed better and then followed by 1:0.5 and 1:1 mixes. A deleterious effect of sludge was observed in the seedlings when soil: sludge was mixes in a ratio of 1:2. The linear, quadratic, cubic and quintic polynomial trends were analyzed for growth and supporting growth traits of the seedlings in all the treatments. Considering the findings of the experiment, it may be recommended that the domestic sludge may be used in low doses to the seedling grown media

Soil and site classification for forest zoning in ITTO model forest management area (Sarawak, Malaysia)

Evelyn Jugi, R. Glauner, A. Gralla, B. Hahn-Schilling, J. Sabang
Forestry Department, Kuching, Sarawak, Malaysia

Forest zoning is prerequisite for the preparation of a medium-term forest management plan that divides forest management units of approximately 100,1000 ha in size according to forest functions; protection, production, and social. Forest zoning seeks a sound and feasible compromise between forest conservation, economic needs and societal demands. Thus, forest zoning encompassed a multi-disciplinary planning approach, comprising forest engineering, ecologoy, socio-economic, economy and site classification.

A production forest reserve of 166,000 ha's in Central Sarawak studied for site-related management restrictions; soil erosion hazard, soil compaction risk and nutrient status. Soil and site data were obtained based on a 1 x 1-km systematic grid survey of the area. The grid was based on the 1:50,000 topographic map of 100-ft. contour interval. Amount and pattern of rainfall of the area was extrapolated from data obtained from surrounding meteorological stations.

For soil erosion hazard, the universal soil loss equation was applied to models the annual soil loss under undisturbed conditions (primary forest), after ground-based skidding (reduced impact logging with crawler tractors) and off-ground logging (helicopter logging and cable crane system). Two relative thresholds (accelerated erosion is year one after logging and accumulated erosion over one cutting cycle) were used for the determination of the forest functions and prescribed yarding techniques. Soil compaction risk was assessed using soil texture classes up to 50 cm soil depth, classifying them into low, average and severe compaction risk. The local soil types were categorized into five classes of soil nutrient status based on averages for exchangeable bases to depth of 50 cm. Additionally the river buffer zones of 20 m width on each side of permanent watercourses were mapped. Spatial extrapolation and data overlay was done using GIS technology.

Hypothetical zones were derived and prescribed logging techniques to mitigate environmental impact. The postulated zonal areas are approxomately 34% for protection (no logging), 40% airborne yarding and 26% ground skidding. These results form a solid base for further decision making and incorporating other disciplines (socio-economics, biodiversity, etc.) to finally produce a forest function map as part of a medium-term forest management plan in line with the national and international forest conservation sustainability efforts.

Connection between site productivity and floristic composition in Slovenia's beech forests

Marijan Kotar, Dušan Robic
University of Ljubljana, Department of Forestry,
Vecna pot 83, 1000 Ljubljana, Slovenia
Tel: +386 61 1231161, FAX:
Fax: 386 61 271-169, Email: marijan.kotar@uni-lj.si

Keywords: *Fagus sylvatica* L.; site productivity; floristic composition; site index; total volume production

European beech (Fagus sylvatica L.) is the most important tree species in Slovenia. It is an essential component of forest stands in over 50% of the forests, while in 25% it occurs with other tree species in mixed stands.

Nowadays beech accounts for 29% of the growing stock, but the natural proportion would presumably exceed 58%. In future the share of beech in the growing stock will increase because Slovenian forestry is based on close-to-nature silviculture and natural forest structures. Among prerequisites for rational close-to-nature forest management the determination of performance of site capacity, or site productivity (SP) is of importance. The determination of SP is connected with two questions:

1) Which available method for establishing SP gives the most acceptable results with regard to sites overgrown by pure beech stands and to stands with prevailing beech?

2) What is the appropriate basic unit for determining SP?

The study, which was carried out in 18 locations of mature beech forest stands, includes different site types determined by means of recent floristic composition (Braun-Blanquet approach). Different syntaxa demonstrate presumably variety of site types. A site unit represents a group of forest plots occupied by phytocoenoses of similar floristic composition belonging to the same syntaxon (i.e. the most frequent subassociation, and association). Within each such site unit, scattered in 18 locations, five square sample plots 30 x 30 m in size were chosen as a base for the estimation of SP by means of site index (SI_{100}) and total volume production (TVP). These sample plots were carefully chosen in pure fully stocked beech stands. The mean age of the stands analysed ranges from 94 to 196 years. As site index (SI100) top height at 100 years was used (the average height of 9 largest trees per plot of 900 m^2). The results of the study show that SI_{100} (site index at the age of 100 years) indicates relatively well site productivity (SP). The differences between SP established on the basis of TVP and the maximum mean annual increment (MAIMAX) are very small. The differences between SP estimates for sample plots within the same syntaxon/site unit do not exceed mostly ± 1 m^3/ha/year. So in general we can use well-defined syntaxa as strata for the detection of site units used to establish site productivity (SP):

In some cases however, differences can be more distinct. An explanation can then often be found among statements of classification and ordination procedures of relevé and in ecological indicator values (according to Ellenberg) as well. In such cases we have to divide a syntaxon/site unit into subunits in accordance with definable microsite parameters. In relevé processing FITOSEZ program was used, as a similarity measure Horn’s(1966) modification of Morisita’s (1959) index for proportions was selected. A cluster analysis and principal-component analysis (PCA) were made by means of available general programs, and Ellenberg’s ecological indicator values were used.

Controlling landscape nutrient fluxes with agroforestry

Johannes Lehmann
University of Bayreuth, Department of Soil Science and Soil Geography, 95440 Bayreuth, Germany
Email: Johannes.Lehmann@uni-bayreuth.de

Keywords: agroforestry; nutrient fluxes; single tree effects

Reducing nutrient losses for maximum productivity of a land use system but also for minimum pollution hazard are a prime goal for regional land use management. Relations between nutrient input and output may be controlled by internal nutrient cycling. Landuse systems with trees may be advantageous by storing more nutrients within the biomass and by a more efficient nutrient cycling than annual cropping systems. The complementary of resource use by associated tree and crop species is a major determinant of the potential efficiency of agroforestry systems in controlling nutrient fluxes. The resulting spatial variability, however, poses difficulties in assessing those nutrient fluxes on an area or even landscape level. Strategies for the assessment of relevant factors for the determination of the nutrient output like single tree effects, plot experiments, extrapolation of point measurements and catchment studies are discussed using examples from a range of climatic regions, in order to both improve internal nutrient cycling and minimize off-site effects of landuse by agroforestry. Singletree observations are a viable method to assess the effects of tree species on ecosystem functions like nutrient fluxes. This function can be linked to properties of the tree, e.g. root distribution, biomass production, canopy architecture or chemical properties of plant tissues. Thus, the root activity and distribution could be showed to affect nutrient uptake and leaching: *Bixa orellana* with a rapid nutrient uptake and fast nutrient recycling through litter fall showed a superficial root system and was not useful for the retrieval of subsoil nutrients, whereas *Bertholletia excelsa* took up nutrients from greater depths and from a farther distance. This information can be used to design a land-use system that combines an accelerated internal nutrient cycling with lower leaching losses, if these two tree species are combined. Plot measurements are the classic way of landuse research, but may be only feasible in geometrically simple agroforestry systems like intensive fallow or alley cropping. Nitrogen leaching was 65% lower underneath a hedgerow of acacias than in a sorghum monoculture. By intercropping, nutrient losses from the annual crop could be reduced by 53%. These effects were related to a deeper and more continuous root system of the alley cropping system than the monoculture. Various examples are now available demonstrating that with agroforestry systems we are able to control nutrient fluxes. The methodology for the assessment of nutrient fluxes has to be adapted to the type of agroforestry system, in order to achieve conclusions on a landscape level.

Increasing nutrient use efficiency by mixed tree cropping in the humid tropics

Johannes Lehmann
University of Bayreuth, Department of Soil Science and Soil Geography, 95440 Bayreuth, Germany
Email: Johannes.Lehmann@uni-bayreuth.de

Keywords: nutrient use efficiency; mixed tree cropping; humid tropics; tracer

Available nutrient contents are often very low in strongly weathered soils of the humid tropics due to the low inherent nutrient levels and low retention capacity of the soils. Nutrient leaching is a common problem especially in cultivated fields when the soil organic matter content is diminished and additional nutrients are applied. In this contribution, we demonstrate that the nutrient use efficiency can be increased with a combination of different tree crops.

Using a variety of tracer techniques with stable and radioisotopes, the uptake of nutrients was studied in a mixed cropping system with indigenous tree crops for food and wood production. In the first experiment, ^{15}N was applied to *Theobroma grandiflorum* (Willd. Ex Spreng.) K. Schum.; *Bactris gasipaes* kunth.; *Bartholletia excelsa* Humb.&Bonpl.; and *Bixa orellana*. together with chemical fertiliser. The fate of the isotope was monitored during one vegetation period. In a further study, ^{32}P was injected at 0.1, 0.6 and 1.5 depth. The foliar P uptake was compared between the mentioned tree species and fallow vegetation and between dry and wet season.

The tree species showed largely differing magnitude and areas of nutrient uptake. *Bixa* and *Bactris* took up a higher proportion of the applied ^{15}N than *Theobroma* and *Bertholletia* since the former showed higher foliar $d^{15}N$ values. This coincided with a faster biomass production. *Bertholletia* took up only 29% of its total ^{15}N up taken from the fertilised area under the canopy compared to the fertilised areas under the canopies of the neighbouring species. *Bertholletia* seemed to obtain the majority of the fertiliser N from the area underneath the *Bactris*, which was planted at a 4 m distance. Therefore, *Bertholletia* profited more from the fertiliser applied to *Bactris* than around its own stem. Secondly, *Bertholletia* may serve as an important safety net for a cropping system.

Bertholletia, which took up less of their N from the applied fertiliser and more of their N from a farther distance from the stem, had a higher root activity in the subsoil as revealed by the ^{32}P application. By combining trees having an accelerated nutrient uptake with trees which acquire nutrients from a lateral area, it is possible to increase the nutrient use efficiency of a cropping system. This is especially important in the humid tropics were we have to cope with low nutrient reserves and low cation exchange capacities but high leaching rates.

Nitrogen fluxes in forest successions in the humid tropics

Johannes Lehmann
University of Bayreuth, Department of Soil Science and Soil Geography, 95440 Bayreuth, Germany
Email: Johannes.Lehmann@uni-bayreuth.de

Keywords: Amazon; dissolved organic nutrients; nitrogen; forest successions; subsoil

Under primary forest species of the central Amazon, large amounts of mineral N were found in the subsoil (2m). In contrast, it was shown that in a secondary forest which has been developed after forest destruction by natural or anthropogenic burning mineral N contents in the subsoil were low. It is not clear whether subsoil N is lost by leaching after forest destruction or if the secondary forest is able to use this subsoil N more efficiently than primary forest species. Furthermore, it is not known up to now, if and how fast the subsoil N pool may regenerate under secondary forest.

In this study, we were measuring throughfall, stemflow, and soil solution N (to a depth of 2m) and mineral and total soil N to a depth of 5m in secondary forest and under two primary forest species in three replicates. Solution N was analysed for hydrophilic and hydrophobic organic compounds, ammonium, and nitrate. All of the compartments are analysed for N isotope composition.

Preliminary results indicate that large amounts of nitrate are present in the subsoil solutions exceeding our sampling depth under secondary forest as well as under primary forest species. The amount of organic N decreased with increasing depth in both soil solution and mineral soil. Consequently, soil solution N had a higher proportion of nitrate in the subsoil than in the topsoil. Increasing $d^{15}N$ values in the subsoil show a strong N metabolization with increasing depth, especially under primary forest species.

These results suggest that during the initial phase of reestablishment of the forest cover N released in the topsoil is leached down to the subsoil generating a large available N pool. As nitrate is the major N compound in subsoil solutions, the anion exchange capacity is the most important determinant to conserve this N pool in soil. With further growth of the forest and increasing rooting depth this subsoil N pool may become an important source for forest regeneration.

Evolution de la fertilité des Sols, Trois Ans après Jachère Boisée Artificielle.

Dominique Louppe, N'Klo Ouattara & Robert Oliver
CIRAD-Forêt, BP 5035, 34032 Montpellier, Cedex 1, France
Tel: +33-4-67615800, FAX: +33-4-67593755, Email: dominique.louppe@cirad.fr

Mots-clés : jachère arborée, *Acacia auriculiformis*, *Eucalyptus camaldulensis*, *Gmelina arborea*, cultures, maïs, riz, évolution de la fertilité, Côte d'Ivoire.

Dans le Nord de la Côte d'Ivoire, trois espèces ligneuses (*Acacia auriculiformis* A. Cunn., *Eucalyptus camaldulensis* Dehn. et *Gmelina arborea* Roxb.) ont été plantées à très fortes densités : 5.000 pied.ha^{-1}. Le dispositif en blocs complets compte quatre répétitions. Après 6 années, ces plantations ont été exploitées. Elles ont produit respectivement 50, 63 et 71 T.ha^{-1} de bois sec qui ont été sortis des parcelles. Après exploitation des arbres, l'essai a été mis en culture de maïs. Chacune des 12 parcelles initiales a été divisée en quatre sous-parcelles auxquelles ont été appliqués deux fois deux traitements croisés: 1) résidus d'exploitation (brindilles et feuilles) laissées sur la parcelle ou brûlées avant la première mise en cultures ; 2) apport ou non d'engrais aux cultures chaque année. Des analyses pédologiques ont été faites au moment de l'abattage et après trois années (1996 à 1998) de culture (maïs, riz et maïs). Les rendements agricoles ainsi que les composantes agronomiques du rendement ont été mesurés.

Au moment de l'abattage, le sol apparaît plus riche en azote et en magnésium échangeable sous *Acacia*. Il est appauvri en azote et en potassium sous *Eucalyptus* et en magnésium sous *Eucalyptus* et *Gmelina*.

Près de deux années après exploitation, le taux de carbone organique est le plus élevé dans les parcelles fertilisées où les résidus forestiers n'ont pas été brûlés. C et N diminuent de *Acacia* à *Gmelina* et à *Eucalyptus* tandis que C/N augmente.

La flore adventice, pendant la période de culture, est modifiée ; certaines espèces indicatrices de sols fertiles sont fréquentes après *Acacia* et rares après *Gmelina* et surtout *Eucalyptus*, et inversement *Imperata cylindrica* devient envahissant après *Eucalyptus*.

Ces différences de richesse du sol permettent un meilleur rendement agricole après *Acacia*. En première année, le rendement du maïs passe de 1,7 T.ha^{-1} après *Acacia* à 0,9 après *Gmelina* et à 0,4 après *Eucalyptus*. En seconde année, les rendements de riz sont respectivement de 1,5, 1,1 et 1,0 T.ha^{-1}. Après trois années de culture, les productions les plus importantes sont toujours obtenues après *Acacia* et montrent que *Gmelina* et surtout *Eucalyptus* ne sont pas de bons précédents forestiers pour l'amélioration des sols agricoles. Les résultats agronomiques sont confrontés aux analyses pédologiques de fin de cycle de culture et commentés.

Phenolic induced nutrient imbalance in forest soils: implications for conifer regeneration

Azim. U. Mallik, Inderjit
Lakehead University, Department of Biology, P7B 5E1 Thunder Bay, Ontario, Canada
Email: amallik@gale.lakehaedu.ca

Keywords: Phenolic compounds; Soil changes; Ericaceous shrubs; Conifers; Regeneration

Phenolic compounds of understory shrubs have been linked to regeneration failure and poor growth of planted conifer seedlings. Water soluble plant phenolics may be leached from foliage as well as from degradation of lignins and tanins. Many phenolic compounds are attributed to allelopathic growth inhibition of forest trees. This may occur due to direct toxicity effect of the phenolics on seed germination and seedling growth, particularly root growth. The degree of inhibition is a function of the type, concentration and composition of phenolic mix in the substrate and the species of affected plant. Apart from the direct toxicity effect on conifers, phenolic compounds can also interfere with available soil nutrients by forming phenole-protein complex and thus can bring about long-term soil changes. This paper reports on several controlled experiments to test the resource-toxin hypothesis involving phenolic compounds and their role in soil nutrient changes. Selected ericaceous shrubs and their respective conifers were used as model plants. Soil amending experiments were conducted with leaf litter of *Kalmia angustifolia*, *Ledum groenlandicum* and *Gaultheria shallon* followed by soil analysis for pH, organic matter, PO_4G, N, K, Ca, Mg, Al, Fe, Zn, Mn, Cu, Ba, and total phenolics. Results showed that *Kalmia* and *Ledum* leaf amendments create significant soil nutrient changes by increasing total phenole and decreasing N contents but *Gaultheria* amendment resulted little change in soil nutrients. *Kalmia* and *Ledum* amended soils also had significantly higher concentrations of Fe, Mn, Al, and PO4G than control. Results are discussed in the context of ecological role of ericaceous plants in long-term habitat change that have implications for forest regeneration.

Anthropogenically induced fire and its effects on soil properties along a vegetation chronosequence in humid tropical ecosystem: a case of Hong Kong Country Park

Lawal M. Marafa, K. C. Chau
The Chinese University of Hong Kong, Department of Geography, Shatin, N.T., Hong Kong
FAX: (852) 26035006, Email: lmmarafa@cuhk.edu.hk

Keywords: fire; soil properties; soil nutrient status; humid tropical ecosystem; vegetation chronosequence; south China

There is no doubt that the ecological effects of fire are of great concern. The impacts of fire on ecosystems are variable across gradients in time and space. The current state of knowledge is typified by detailed characterizations of the impacts of particular fires on specific sites from which generalizable insights may not emerge. Although a number of research on the effects of fire on soil properties have been done in the Temperate, Mediterranean and Northern Circumpolar ecosystems, such in-depth study is scarce in the humid tropical ecosystems, particularly in the South China ecological region. This work examined the effects of hill fire on the soil properties, particularly soil nutrient status along a vegetation chronosequence that transcends a newly burnt, short grassland, tall grassland, mixed grass and shrub and woodland vegetation. A retrospective approach was used to study this chronosequence since areas with variable fire history are available in Hong Kong, where hill fires often devastate the country park environment. In a normal fire season, there could be as many as 300 fire outbreaks within the country parks which forms 40% of the territory.

The immediate effects of fire on soil properties were obvious. However, the effect appears to dissipate with successional development. Immediately after fire, soil pH increased with about 0.3 units, while exchangeable Al decreased, which subsequently resulted in the decrease of the total exchangeable acidity (Al + H). The soil gradually acidified along the vegetation chronosequence with the woodland site being most acidic. Soil organic matter reduced after fire and gradually build-up with vegetational successional development. On the woodland site, however, the value of the organic matter significantly reduced probably as a result of the quantity of the litter produced by the standing vegetation. Soil exchangeable cations along the chronosequence are very low, but a build-up of the divalent cations (Ca and Mg) and Na was observed as successional development progresses, while, on the other hand, K decreased with successional development.

N mineralization was positively affected by fire. The quantity decreased 3 months after fire and was subsequently immobilized. In the course of mineral N production, the process of ammonification predominated over nitrification. Both forms of N, however, were prone to seasonal immobilization. Discernible differences in the rates of N mineralization along the vegetation chronosequence were observed probably as a result of differences in vegetation cover. In addition, clear seasonal pattern was also observed. In general, N mineralization rates were consistently higher on the topsoil layers. In this study, the uptake of NH_4-N surpassed the uptake of NO_3-N.

The absence of fire for a relatively long period leads to a vegetational successional development that is probably unique to this environment, albeit gradually. As a result of this slow pace of recovery, fire therefore results in the lowering of the floristic potentials of this ecosystem. However, if fire disturbance is avoided for a period of 3 or more years, the ecosystem starts to recover and as succession proceeds through 6 years and more, shrublands gradually replaces grasslands and ultimately tree species begin to appear as a result of the nutrient replenishment of the soil after a long period of fire absence.

Heavy metal concentration of the rock, top soil and plant from the serpentine and adjacent area in Andong, Kyungpook, Korea

Ell-Sik Min, Myung-Hee Kim and Suck-Hwan Song
University of Joongbu, Dept. Forest Resource, Mt.2-25 Majeonri Chubumyun Keumsangun, 312-940 Chungnam, Korea R.
Tel: +82-412-753-7641, FAX: +82-412-753-7641, Email: esmin@joongbu.ac.kr

Keywords: Heavy metal concentration; Serpentine area; Rock; Top soil; Plant

The research for heavy metal concentrations of rocks, topsoils and vegetation in the serpentine area has been made for the amount of their distribution and absorption. The samples from rocks (the serpentinite: SP, gneiss: GN, granite: GR, blackshale: BS and redshale: RS), the top soils and their vegetation (*Pinus densiflora*; PD) in Andong, Kyungpook, Korea. The plant samples were divided into the shoot and root. The heavy metal elements such as Ni, Cr. Co, Fe, Zn and Sc were analyzed in ACTLABS, Canada. Most of heavy metal concentrations in SP rocks (Ni: 1162 ppm, r: 366 ppm, Co: 109 ppm; Fe: 7.48%, Sc: 8 ppm), except Zn (50 ppm), were much higher than those in any other rocks (Ni;65-22ppm, Cr;201-21ppm, Co;16-8ppm, Fe;3.30-0.94%, Sc: 8-1ppm, Zn: 71-20 ppm). All of the analyzed heavy metal concentrations in the serpentine soil (Ni: 2143 ppm, Cr: 232ppm, Co: 159 ppm, Fe: 5.91%, Zn: 56 ppm, Sc: 4 ppm) were much higher those granite soils (18 ppm, 20 ppm, 6 ppm, 1.94%, 45 ppm, 3 ppm, respectively). These supposed that the parent materials directly influenced on their own weathered soils and especially, Ni and Co concentrations of the serpentine soil greatly increased through the weathering of their own rocks. The average heavy metal concentrations of *Pinus densiflora* in SP Ni: 40 ppm, Cr: 71 ppm, Co: 6.75 ppm, Fe: 0.413%, Sc: 0.525 ppm) largely higher than those in granite. But Zn concentrations had the contrary. Also, the concentrations of root (Ni: 70 ppm, Cr: 130 ppm, Co: 12.0 ppm, Fe: 0.747%, Zn: 21 ppm, Sc: 0.9 ppm) were largely higher than those of shoot (10 ppm, 12 ppm, 1.5 ppm, 0.079%, 17 ppm, 0.15 ppm, respectively).

Keywords: Chamber method; Continuous measurement; Forest floor; Carbon dioxide flux

CO_2 flux from a forest floor is large component of the forest CO_2 budget. Although there are several methods we can select to measure soil CO_2 flux, each of them has both advantages and disadvantages. Traditional method is so-called the chamber method. It has some variation like as alkali trap technique, static chamber method, dynamic (flow through) method [closed or open system] etc. All of them has a problem that we measure flux in unnatural condition by using chambers, for example, placement of a soil chamber changes air motion. In addition, these methods are difficult to measure flux continuously and to integrate spatially. Although many researchers have reported on soil CO_2 flux from a forest floor, few of them reported diurnal or annual variation.

In this study, we select a closed system of dynamic (flow-through) chamber method with an infrared gas analyzer (IRGA, Li-6262, Licor). To open and shut covers of chambers and solenoid valves are controlled by a personal computer for measuring continuously.

Our site, Kawagoe is a flat land located 35°52'N, 131°29'E with the elevation of 30m. The experimental forest is a temperate deciduous forest (*Quercus serrata* Thunb., *Carpinus laxiflora* Blume, etc.). Mean tree height is about 15m and the maximum LAI is 6. Soil consists of Kanto Loam. Leaf litter is removed in winter, then the soil surface is bare from early spring to early autumn.

CO_2 flux from the forest floor is about 0.05 to 0.2mg/m^2/s. CO_2 flux above the forest canopy ranges -1 to 1mg/m^2/s, soil CO_2 flux occupies the major component of the total CO_2 flux. CO_2 flux of each chamber and soil temperature are mutually related, but the magnitude of the flux of individual chambers is different. The values from a forest floor vary widely. This spatial variety is one problem when we discuss soil CO_2 flux.

We could get diurnal variation of soil CO_2 flux using continuous measurement system. A few papers reported CO_2 flux increased in nighttime. In this study, similar tendencies were sometimes observed. Soil temperature wasn't related to CO_2 flux in this case. We need to measure continuously for clarifying a factor of this diurnal variation.

Characterization of soil temperature in forest gap at a tropical lowland forest

Ahmad Ainuddin Nuruddin, Lili Tokiman and Mohd. Basri Hamzah
Universiti Putra Malaysia, Faculty of Forestry, 43400 UPM Serdang Selangor, Malaysia
FAX: 603-943-2514, Email: ainuddin@forr.upm.edu.my

Keywords: soil temperature; forest gap; tropical lowland forest

Forest gap is one of the basic units in forest dynamics. Gaps when formed developed their own microclimate. However, few studies have been conducted to relate gaps sizes and their microclimate parameters. This study was conducted to characterize soil temperatures at three depths in two gap sizes and to relate soil temperatures with other microclimatic parameters. This study was conducted at Air Hitam Forest Reserve, Puchong, Selangor from September to December 1997. Two gap sizes were chosen; large (500m^2) and small (180m^2). Continuous measurement on soil and air temperature, light and solar radiation were made for seven days. Due to availability of only one data logger, measurements of both gaps could not be made simultaneously. Measurement of soil temperature at three depths were made at the center of the gap while measurement of soil temperatures along a transect were made at 5cm depth. The result show that mean soil temperatures at 1cm, 5cm and 10cm in the large gap were 25.51, 25.45°C and 25.45°C, respectively. The mean soil temperatures in the small gap at 1cm, 5cm and 10cm were 25.26°C, 25.51°C and 25.33°C, respectively. The soil temperatures were higher in the center of gap and change progressively to the edge of the forest. Simple linear regression analyses of soil temperature at three different depths with air temperature were made using the large and small gap data. In both gaps, there were strong relationship between 1cm soil temperature and air temperature with R^2 of 0.96 for large gap and 0.65 for small gap. A linear relationship was found with R^2=0.57 between soil temperature of 1cm depth and solar radiation in the large gap. The study concludes that soil temperatures in the center of the gaps were higher at the center than the edge of the gap. Magnitude of soil temperatures differs with gap size in which larger gap shows higher values compared to smaller gap. The study concludes that soil temperature in the center of the gaps was higher at the center than the edge of the gap. magnitude of soil temperature differs with gap size in which larges gap shows higher values of soil temperature compare to smaller gap. This study also shows that air temperature can be used to predict soil temperature in forest gaps.

Sustainable central European forest management, forest soils and productivity. Shall we be scared from global warming influence on properties of forest soils? A general view

Klement Rejsek
Mendel University of Agriculture and Forestry, Faculty of Forestry and Wood Technology, Zemedelska 3, 613 00 Brno, Czech Republic
FAX: 00420 54521 1422, Email: kr@mendelu.cz

Keywords: soil science; acidification; mountain forests; soil analysis

Global acidification caused by man activity play an important role in current discussions within natural science. Soil scientific data from 63 deep soil pits obtained from research founded in 1931-1935 in Eastern Carpathian Mountains served as a level for reavaluation after 65 year in the area not affected by local sources of air pollution. The new data was obtained from five study plots at 1272-1550 m above see level characterised by 2130-2380 mm average precipitation and 0.6-1.8°C mean annual temperature. Spodo-Dystric Cambisol on phyllitic schist, Dystric Cambisol on schistic gneiss and Histo-Humic Podzol on phyllitic schist were described on plots covered by Norway spruce (*Picea abies* /L./Karsten) and European beech (*Fagus sylvatica* L.) either pure or mixed forest stands.

Results of the kind can be part of other investigations giving a green light to pondering a likely influence of global acidification on sustainable forest management from soil scientific points of view. General features of effects of acid precipitations on terrestrial ecosystems, their patterns and origin and a development of its evaluation are presented.

The laboratory data was obtained by the same methodology as in the thirties. Loss on ignition, total nitrogen, soil reaction in water, soil reaction in potassium chloride, base content, cation exchange capacity and base saturation was measured. The very complex nature of forest soil formation and the character of the soil forming factors (parent material, organisms, relief, climate and time) were discussed.

The facts lead to an opinion that the real changes in forest soil productivity as a result of acid deposition and the acification of forest soils in the sites with primarily very low base content, naturally extremely weak base saturation under the humid climate are of great importance. Decreasing pH level causes changes in the other characteristics in both surface and subsurface horizons.

Forest clearcutting and site preparation on a saline soil in east Texas: impact on soil chemical properties

Alexander K. Sayok, Mingteh Chang
KTA Consulting Engineers, KTAC Sdn Bldg, Lot 8650-3, Section 64, Box 1312, 93726 Kuching Sarawak, Malaysia
Email: Katas@po.jaring.my

Keywords: clearcutting; soil chemical properties; southern pine; saline soil; east Texas

Changes in soil chemical properties of a saline soil in the Davy Crockett National Forest near Apple Springs, Texas, were monitored under three forest conditions over a two-year period (October 1988 to September 1990). The three conditions were: 1) undisturbed mature southern pine forest, 2) clearcutting without site preparation, and 3) clearcutting with site sheared and windrowed. Regrowth of vegetation in the sheared plot was clipped during the entire period. Soil samples of three slope positions and six depth levels in each 0.2 ha plot were collected two months before and at five different times within 18 months after treatments for laboratory analyses of 14 elements and derivations of six parameters. It was a part of our efforts to investigate why artificial pine regeneration was so difficult to establish on the saline soils in East Texas.

The results showed that although the variations in most parameters seemed to correspond with seasons of the year, they also exhibited significant differences due to various degrees of forest disturbance. Shearing increased soil salinity by increasing the concentrations of total exchangeable cations and Na, total soluble ions Na, SO_4, HCO_3, and Cl, and the levels of ESP (exchangeable Na percentage), SAR (Na absorption ratio), and EC (electrical conductivity). Shearing also increased the concentrations of soil toxicity elements Al, Fe, and Mn, with Al being the most excessive. On the other hand, organic matter content was decreased by shearing, so were TKN and available P slightly. Increases in salinity and toxic parameters were usually significant at the 0-60 cm depths under the sheared plot. Due to low absolute values, none of the increases were above the harmful limit. However, the great increase of soluble Na, especially at the surface horizons, may be responsible for the poor soil drainage in the sheared area. The excessive increases in exchangeable Al may have reached a level affecting root development, nutrient uptakes of N,K, P, or other elements, and seedling growth of southern pine species in the study area. Further studies on the Al toxicity are required. In areas where Al may be a limiting factor in pine regeneration, the soil be limed to rise soil pH or treated with organic matter to provide buffer effects.

The effects of forest treatment on other elements and parameters were in orders of magnitude most unlikely to reach harmful limits or caused deficiencies in nutrient supplies. Clearcutting with all undiserable species and debris left intake is a better harvesting method than clearcutting and shearing in areas with saline soil problems. The regrowth of native vegetation in sheared areas such as oaks and hickories help minimize soil salt concentration, nutrient leaching, and soil water saturation level, providing an better soil environment for pine regeneration.

Influences of spruce stand phases on ground cover vegetation and the microrelief on soil conditions at the Pokljuka Plateau Moraines in the Julian Alps

Mihej Urbancic, Lado Kutnar
Slovenian Forestry Institute, Vecna pot 2, 1000 Ljubljana, Slovenia
Tel: + 386 61 200 78 09, FAX: +386 61 273 589, Email: lado.kutnar@gozdis.si

Keywords: mixed moraine; Rhytidiadelpho lorei-Piceetum; Podzolization

The Pokljuka plateau lies in the Slovenian part of the Julian Alps. Forests cover about 20 km^2 of its calcareous and mixed moraines. The prealpine fir-beech (*Homogyno sylvestris-Fagetum*) and subalpine spruce forests (*Piceetum subalpinum* s. lat.) predominate, both with a high wood productivity. On moraines with a typically very heterogeneous, undulating micro-relief, very heterogeneous micro-site conditions have been found.

On the carbonate moraines composed of limestone and dolomite materials, the dominant FAO-Unesco soil units are different kinds of Eutric Leptosols, Rendzic Leptosols and Eutric Cambisols that are covered with various species of mainly calciphilic undergrowth. Apart from limestone and dolomite debris, the mixed morraine is composed of marl, cherts, shales, and sandstone. This parent material is covered with predominantly dystric soils with mainly acidophilic ground cover vegetation.

In 1997, on the mixed moraine at the permanent 1 ha research plot near the bog Sijec, we systematically disposed 106 research square subplots (0.25m^2) overgrown with the plant community Rhytidiadelpho lorei-Piceetum in four groups. We chose 25 subplots from the serried spruce stand of mature trees and 15 from land cleared in 1996, 33 from the spruce young growth and 33 from the spruce thicket.

On all subplots the micro-relief was evaluated and the ground cover vegetation was inventoried. The average coverage ranged from 35% in the mature stand to 85% in the spruce thicket. The total number of plant species did not essentially change from the clearing to the thicket, but there were changes in the combinations of plant species and in the coverage of the individual plant species.

Under the canopy of mature spruce trees there were extremely few plant species. Due to felling, growth conditions changed and the number of species rose. After felling and because of the changed light conditions., grass vegetation was exuberant. The frequency and coverage of *Luzula pilosa* and *Luzula luzoloides* had increased. Some other species of the grass (Poaceae) and the sedge families (Cyperaceae) also appeared in the clearing. *Picea abies* coverage in the undergrowth was least among mature trees, increasing from the clearing to the young growth and was largest in the spruce thicket. The Shannon index showed an increase in biodiversity from the group of mature trees up to the young growth, where it reached its peak. In the spruce thicket the level of diversity decreased because of the extreme predominance of spruce in the undergrowth. The soil of each subplot was sounded at 5 points to a depth of 1 m. Most soil bores showed signs of podzolization. Only 9 (8.5%) subplots had non-podzoled soil. These were classified as Dystric and Ferric Cambisols. Eighteen (17.0%) subplots had partly podzoled soil with interlacement of Cambisols and Podzols. On the 79 (74.5%) subplots we found only different kinds of Podzols. Thirty-one subplots had initial to weakly podzoled soil (all bores had a spodic Bsp horizon and the thickness of the albic E horizon is 2 to 10 cm); 29 subplots had moderately podzoled soil (E is 10 to 20 cm) and 19 subplots had strongly podzoled soil (E is over 20 cm).

8.03.00 Forest Hydrology and Water Quality

Sustainable Management of Hydrological Functions of Main Forest Ecosystems in China

Gabriel Schiller, Yehezkel Cohen and Shabtai Cohen
The Volcani Center, Department of Agronomy and Natural Resources, Post Box # 6, 50250 Bet-Dagan, Israel
Tel: +972-3-9683678, FAX: +972-3-9669642, Email: vcgabi@agri.gov.il

Studies were conducted in the late 60s and early 70s on the hydrological balance of areas under various vegetation covers, in Thermo-Mediterranean climatic conditions. Interest in these studies resulted from concern about the hydrological balance of Israel's aquifers as influenced by large scale afforestation and reclamation of devastated natural oak scrub communities. The studies failed to produce accurate data due to calibration problems of the different methods used, and the extremely large spatial variability in site conditions, which prevented the determination of the water storage capacity of the bedrock-soil complex.

One of the ways to determine the water balance of forest areas is to use plant physiological parameters as an indicator of water availability in the bedrock-soil complex. Of the several parameters available, we selected the sap flow velocity, which provides a direct measure of the transpiration rate of the tree.

Sap flow was measured continuously over periods of several days 8 to 15 times during a year on 8 or 16 trees, whose diameter distribution represents the diameter distribution of all the trees growing in a plot situated either in *Pinus halepensis*, *Quercus calliprinos*, *Q. ithaburenis*, *Phillyrea Iatifolia* and *Tamarix aphylla* forests (all native species); and in *Eucalyptus camaldulensis* plantations, an introduced species. Results of these measurements were used to scale up the single tree water use to stand water use in a given environment.

The relationship between water availability (rainfall), and the estimated amount of water used by the forest vegetation should be regarded as a major factor in forest management.

Water use by fast-growing *Eucalyptus* plantations in southern China

John Collopy, Bai Jiayu, Zhou Guoyi and Jim Morris
Centre for Forest Tree Technology, Post Box # 137, Victoria 3084 Heidelberg, Australia
Tel: 61 3 9450 8697, FAX: 61 3 9450 8644, Email: j.collopy@nre.vic.gov.au

Key words: Eucalypt plantations, water use, heat pulse technique.

Eucalypt plantations make up more than half of the 600 000 ha forest estate on the Leizhou Peninsula and neighbouring areas of western Guangdong in southern China. Water uptake by eucalypt plantations may contribute to the depletion of scarce groundwater resources, and soil moisture shortage as a result of high water use may also limit tree growth during the dry season. Litter removal and whole-tree harvesting are common practices, although they are believed to contribute to fertility decline, soil crusting, increased runoff and severe erosion. However, there is little quantitative information on water use or water balance of plantations in southern China.

A new project sponsored by the Australian Centre for International Agricultural Research aims to measure stand water use for eucalypts and other species on the Leizhou peninsula subject to various site conditions and management options, and quantify the components of the plantation water balance on annual and seasonal time scales. The completed project will provide data sets of intensive observations of stand water use and environmental conditions for representative plantations, and modeling tools for applying these to predict the productivity and sustainability impacts of management alternatives.

The poster displays the results obtained from monitoring water use in two plantations of *Eucalyptus urophylla* during the dry season from September to March, with concurrent records of leaf area index, soil moisture, and potential evaporation. Water use of single trees was measured by the heat pulse technique, and scaled up to whole-stand estimates on the basis of sapwood area. Climate parameters including solar radiation, relative humidity, temperature and wind speed were recorded at 30-minute intervals by an automatic weather station at each site. Soil moisture was also automatically monitored at frequent intervals using buried dielectric sensors. Leaf area index was determined at monthly intervals from ceptometer measurements along transects through each plantation.

The daily and longer term variation in plantation water use observed at each site during the dry season is attributable to changing seasonal climate conditions and the depletion of soil moisture stored in the soil profile within the root zone. The data allow separation of the reduction in plantation water use due to leaf shedding from that due to decreased sap velocity.

The results will be combined with additional hydrological observations to estimate annual recharge beneath plantations for comparison with alternative land uses, and to derive a quantitative response to suggestions that groundwater depletion and erosion are aggravated by plantation establishment. The data will also be valuable as input and validation data sets for modeling of plantation growth and hydrology.

Mapping of evapotranspiration at forest areas by infrared radiation thermometer images

Nobuhiro Ebisu, Osamu Nakakita
Ehime University, College of Agriculture, 3-5-7, Tarumi, 790-8566 Matsuyama, Japan
Email: ebisu@ehimegw.dpc.ehime-u.ac.jp

Key words: evapotranspiration, remote sensing, infrared radiation

A knowledge of evapotranspiration from a forested watershed is important for solving water resources and forest management issues. Evapotranspiration is also an important component of the hydrologic cycle of forested watersheds

The purpose of this study is to map evapotranspiration from forested areas using the surface temperature (ST) method, and to estimate it using the image data of surface temperature by an infrared radiation thermometer and energy balance data. The image data of surface temperature were measured on the ground or by using balloon remote sensing at a height of 100-200 m.

Comparisons were made of estimates of evapotranspiration using the ST method with those from the Bowen ratio and eddy correlation methods. The results show that averaged differences of hourly sensible heat flux are from -35 W m^{-2} to 26 W m^{-2} between the ST and eddy correlation methods. Estimated values of hourly evapotranspiration by the ST method are roughly equal to those by the Bowen ratio and eddy correlation methods up to about 0.6mm hr-1 and are smaller than those over about 0.7mm hr-1. Mapping of transpiration using the ST method on the ground is ascertained by such results.

Other results are given by balloon remote sensing. A small balloon was equipped with an infrared radiation thermometer sensor, a control system, a battery and a micro wireless video camera. The measurement of surface temperature by this remote sensing system was carried out over 15 second intervals . The angle of the sensor was controlled by an operator who checks the pictures sent through this system. There were differences between the surface temperature of the stands measured from the balloon and from the ground. Evapotranspiration estimated from the balloon is smaller than that from the ground. It is concluded that surface temperature is more accurately assessed using balloon remote sensing than using the infrared radiation thermometer on the ground.

The study was conducted in 2 stands of Japanese cypress. These stands were different in aspect and slope angle. The difference in surface temperature at the two plots was 1.8^{o}C on average. Evapotranspiration estimated using the ST method at the plot where surface temperature was lower, was about 0.07mm hr-1 higher than the other plot. Evapotranspiration using the Bowen ratio method showed similar values. The ST method based on balloon remote sensing is good for estimating evapotranspiration from large forested areas with different aspects and slope angles.

Interception loss by stands of Douglas fir and radiata pine, South Island, New Zealand

Barry D. Fahey
Landcare Research, Post Box # 69, 8152 Lincoln, New Zealand
FAX: +64-3-3252418, Email: faheyb@landcare.cri.nz

Key words: Douglas fir, *Pinus radiata*, interception loss, throughfall

There are about 1.4 m ha of exotic forests in New Zealand, and current afforestation rates are over 50 000 ha per year, mostly on land originally in pasture. Large-scale conversions of this type may significantly alter water yields. When pasture is converted to forest, changes in runoff are largely controlled by changes in interception loss and transpiration. In areas where the canopy is wetted frequently or remains wet for long periods, interception loss exceeds transpiration . Thus water yield changes in medium-to-high rainfall regimes are likely to be dominated by changes in interception loss.

The bulk of New Zealand's plantation estate is in *Pinus radiata* and rainfall interception by stands of this species have been widely investigated. In recent years, Douglas fir (*Pseudotsuga menziesii*) has become a popular alternative species especially in drier and colder areas. To assess the impact of plantings of Douglas fir on water yield, it is crucial that we have some understanding of the expected interception losses likely to be associated with this species under the silvicultural regime practiced in New Zealand. However, little information is available on the water use characteristics of Douglas fir as a plantation species.

Throughfall and stemflow were measured at 3 sites 60 km west of Christchurch for a 9 month period (November 1998 to August 1999). One was in a 17-year old (654 stems/ha) stand of radiata pine, and the other two were under 18-year old (1360 stems/ha) and 54-year old (570 stems/ha) stands of Douglas fir. Rainfall during the period was 700mm. Total interception loss was 23% under radiata pine, and 33% and 34% for the 18-year old and 54-year old Douglas fir stands respectively. A single factor ANOVA showed no statistical difference in the event-based interception for the two Douglas fir stands.

Studies elsewhere have shown that interception loss under Douglas fir is dependent on age class, stand density, and climate, and that values tend to fall between 30 and 40%. The results of the present study lie within this range, but they suggest that differences in interception loss due to age and stocking density cannot be detected. They further suggest that losses under Douglas fir stands exceed those under mature radiata pine in the climatic regime characteristic of this area.

A long- term hydrological monitoring of a small mountainous catchment

Motohisa Fujieda
Forestry and Forest Products Research Institute,
Tsukuba Norin Kenkyu Danchi, Post Box # 16
Tsukuba Norin Kenkyu Danchi, 305 Ibaraki, Japan
FAX: +81-298-73-1542, Email:
Fujieda@ffpri.affrc.go.jp

Key words: hydrological monitoring, flood flows, low flows

The Takaragawa Forest Experimental Station was established by the Forestry and Forest Products Research Institute (FFPRI) in 1937 to clarify the influence of forest development on streamflow and floods in the headwaters of the Tone River in central Japan. Hydrological measurements at the 19.1 km^2 Honryu Catchment, a small mountainous catchment within the station have been taken over the past 60 years. Results of the hydrological studies and statistical summaries of hydrological data have been reported by the FFPRI. Long-term hydrological monitoring is important not only for forecasting water resources and floods in the region but also as an indicator of conservation and maintenance of soil and water resources for sustainable forest management (the Montreal Process, 1995). This paper describes a set of streamflow data from 1938 to 1997 which characterises the hydrological environment of the Honryu catchment.

The annual streamflow from the Honryu catchment varies from 2,296.6mm yr^{-1} to 4,120.3mm yr^{-1} with a mean of 3,127.9mm yr^{-1}. The estimated snowmelt runoff (total streamflow from April to May during the snowmelt season at the catchment) accounts for about 51% of annual runoff. The long-term trend of snowmelt runoff with a small variation is almost parallel to that of annual runoff. However, annual runoff over the past 15 years has been highly variable perhaps because of abnormal weather compared with other periods.

A flood and low flow probability analysis for the catchment was conducted using the Gumbel method to estimated the magnitude of floods and low flow which have occurred during the recent abnormal weather. The largest flood flow (160.2 m^3 s^{-1}) which occurred in July 1983, was equivalent to a return period of 130 years. The smallest low flow (0.21mm day^{-1}) which occurred in September 1951, was equivalent to a 80-year return period. Flood flows have tended to increase owing to the abnormal weather. However, the low flow of 1994, which created a critical water deficiency in the Tokyo Metropolitan area was a 1-in-7 year event. This indicates that the problem of low flow is more closely related to the water demand in the region than to the hydrological environment. Long-term monitoring with high accuracy at the station is recognized as a useful indicator to understand changes in the hydrological environment.

Soil water-retention characteristics of natural Scots pine and Norway spruce sites in Finnish Lapland

Juha Heiskanen, Mäkitalo, K.
Suonenjoki Research Station, Juntintie 40, FIN-77600
Suonenjoki, Finland
Tel: +358-17-513811, FAX: +358-17-513068, Email:
juha.heiskanen@metla.fi

Keywords: forest soil, particle size, spatial variability, site class, till soil, water content.

Scots pine (*Pinus sylvestris* L.) has been the most widely used tree species in forest regeneration in Finnish Lapland since the 1950s. However, severe failures have occurred in pine plantations during the last three decades, especially on sites formerly occupied by Norway spruce (*Picea abies* L. Karst.). Unfavourable physical soil conditions, mainly excess water and low temperatures, have been suggested to be one of the causes of these failures. However, there is a lack of information about the physical soil properties on different sites. The aim of this study was to survey the physical soil properties, especially water-retention characteristics, and their variability on mineral soil sites naturally dominated by Scots pine and Norway spruce in Finnish Lapland.

Data were collected from sites dominated by natural stands of Scots pine (n=10) or by Norway spruce (n=10) in central Lapland. The soil was till on 19 sites, and sorted sand and gravel on one. Soil characteristics were measured according to standard laboratory procedures. Air-filled porosity was estimated by subtracting the water content at a given matric potential from that at -0.3 kPa.

The desorption water-retention characteristics and other measured variables showed similar values to those reported earlier for till soils in Fennoscandia. These properties differed (ANOVA) significantly ($p<0.05$) between the sites (n=20). The most significant differences were in the water retention (vol.%) at -5 and -10 kPa matric potentials (around field capacity) and in the sum of the organic matter content and fine particle fraction <0.06mm (grav.%). In general, the variables showed spatial dependence within sites of <60 m (semivariogram analysis).

Almost all the variables differed (t-test) significantly between the pine (n=10) and spruce sites (n=10). Compared with the spruce sites, the pine sites had on average thinner genetic soil horizons, and lower organic matter and fine particle-fraction contents and water retention. The air-filled porosity and saturated hydraulic conductivity were higher on the pine sites. The proportion of pine (of basal area) in the tree stand showed a significant positive correlation with the air-filled porosity at -5 and -10 kPa matric potential. About 80% of the observations made on the pine sites occurred at points where the mean water content and air-filled porosity at -10 kPa matric potential were <30 and >20 vol.%, respectively. The respective values for spruce were >30 and <20.

Water retention at -1 to -10 kPa matric potentials correlated best with the sum of the fine particle fraction and organic matter content, while at lower potentials it correlated best with the organic matter content. Air-filled porosity at -10 kPa and saturated hydraulic conductivity correlated best with the fine particle fraction.

This study suggests that sites on which pine occurs naturally tend to have a lower soil-water content, especially around field capacity, than spruce sites either due to the lower water-retention capacity or to the lower water table in situ e.g. on hilltops. This conclusion is in line with recent surveys which show that Norway spruce occurs naturally on sites with a higher water-content range (10-50 vol.%) in the topmost 20 cm soil layer, while Scots pine tends to occur within a markedly lower and narrower moisture range (1-28 vol.%). Therefore, pine-plantation failures could be avoided by planting pine seedlings on sufficiently dry sites.

Effects of variation of rainfall on the chemistry of streamwater

Shinji Kaneko, Takafumi Miyama
Kansai Research Center, FFPRI, Nagai-kyutaro,Momoyama,Fushimi, 612-0855 Kyoto, Japan
Tel: 075-611-1201, FAX: 075-611-1207, Email: kanekos@fsm.affrc.go.jp

Key words: streamwater chemistry, forested catchments

Streamwater chemistry is the product of various environmental factors in forested catchments, but hydrology is one of the most important. We compared the chemistry of streamwater of forested catchments in two areas with contrasting annual precipitation. One is located on Mt. Tatsunokuchi in Okayama city, Okayama prefecture (E 133°58', N 34°42', altitude 45-250 m, and annual precipitation 1000 mm). The other is located at the foot of Mt. Hira in Shiga town, Shiga prefecture (E 135°55', N 35°13', altitude 320-450 m; annual precipitation, 2500mm). Hydrological observations at Okayama extend back to 1926. Those at Shiga began in 1995. Sampling in Okayama was done twice weekly from June 1994 to May 1995 and bi-weekly from June 1995 to May 1996. In Shiga sampling was done twice a month from October 1995 to March 1998. Measurements were made of pH, electrical conductivity, dissolved organic carbon, inorganic carbon, cations, anions and silica. Electrical conductivity and the concentrations of most of the other constituents at Okayama were apparently higher than other normal steams in Japan. During storms, the concentrations of HCO_3, Ca, Mg and Na decreased, and those of K, HNO_3 and dissolved organic matter (DOC) increased. At Shiga, the concentrations of most constituents were lower than those of Okayama. The anion and cation concentrations at Shiga were relatively constant and their CVs were less than 25%, except for NO_3.

The Okayama area is characterized by less precipitation and more insolation than Shiga. Baseflow is normally under 0.2mm per day which favours high concentrations of chemical constituents. Cl concentrations were also high in Okayama, but input and output of Cl were almost balanced in both catchments. At Shiga, discharge exceeded 1.7mm per day and was more stable than that at Okayama, which was reflected in the relatively constant concentrations of the streamwater constituents. These results suggest that hydrology has a strong influence on the chemistry of streamwater in forested catchments. If global warming decreases precipitation in the future, it will not only lead to a decrease in runoff from forested catchments, but will also alter water quality.

Soil impact from manual felling and cable yarder compared to feller-buncher and rubber wheeled skidder in tropical forest plantation.

Paul Liau, Anders Malmer
Sabah Forest Industries, Sdn Bhd, WDT 31, 89859 Sipitang, Sabah, Malaysia
FAX: +60 87 801 381, Email: Anders.Malmer@sek.slu.se

Key words: soil disturbance, forest harvesting

Areal extent of soil disturbance, soil dry bulk density (DBD), loss on ignition (LOI) and steady state infiltrability (SSI) have been investigated with different harvesting methods. The investigations were conducted within a paired catchment study on environmental effects and production when converting dipterocarp forest to *Acacia mangium* plantations in western Sabah, Malaysia.

The disturbance by cable yarders was 9% of the clear-felled area. These tracks and landings were made with crawler tractors. The impact on the soil from crawler tractors at this site has been thoroughly described earlier. After only a few passes, most top soil is removed, resulting in compact surface soil devoid of organic material and soil structure. SSI is reduced to practically nil, and natural rehabilitation may take as much as 15-25 years.

Areal distribution of soil disturbance from the feller-buncher and the rubber wheeled skidder was not investigated in the same way as for the cable yarder and for crawler tractors. However, the disturbance was estimated to be more than 25% of the clear-felled area, which is the normal figure for a crawler tractor operation in the area. Both the feller-buncher with crawler motion and the rubber wheeled skidder, reduced SSI as much as crawler tractors do. This was the case with a few passes even when running on top of logging residues, or not using a blade to push top soil aside. In the case of motion on top of residues, compaction in terms of DBD was less compared to tractor tracks, due to the higher content of organic material. Because running on top of residues incorporated some of the residues into the soil, organic content (LOI) of the disturbed soil was in many spots considerably higher than in the undisturbed control.

Soils in this region are normally moist at all times under the forest canopy and have a fragile top soil structure. Hence machinery, even running on top of residues, can drastically reduce soil permeability for water and roots. This underlines the preference for systems such as cable yarders that minimise the area affected. The cable yarder uses only main tracks and landings which are are easy to find and to use again. With second and third order tracks from tractors, feller-bunchers or different kinds of forwarders, it is not as likely that old tracks will be used again as these tracks are planted and not as easy to identify after a decade or more. Quicker natural rehabilitation may occur where organic matter is incorporated into the soil when running on top of residues.

Sustainable management of hydrological functions of main forest ecosystems in China

Shirong Liu, Yuanguang Wen
Chinese Academy of Forestry, Research Institute of Forest Ecology, Environment and Protection, 100091 Beijing, China
FAX: 86-010-62884972, Email: liusr@prot.forestry.ac.cn

Key words: forest ecosystems, interception, moisture holding capacity

Water and forests are closely related and mutually influenced through various physical, chemical and biological processes within an ecosystem. Their complicated interactions make a significant contribution to the water cycle by which mass circulation is driven and energy flow occurs. Forest hydrological functions refer to the effects of forests on the redistribution of rainfall, water conservation, water purification, protection of water and soil erosion, regulation of flooding and runoff, as well as drought mitigation and water logging. The sustainable management of forest hydrological functions is critical to the maintenance of human living and healthy environments.

Based on case studies in forest ecological research stations in different geographical zones in China, the characteristics of hydrological functions of the main forest ecosystems in China were quantitatively analyzed and compared among forests according to three spatial layers, i.e. canopy, litter and soil. Furthermore, the sustainable management strategies of forest hydrological functions were explored.

Canopy rainfall interception ranged from 134 to 626mm, and was ranked in the following order (lowest to highest): tropical mountain rain forest, subtropical western mountain evergreen conifer, tropical semi-deciduous monsoon forest, temperate mountain deciduous/evergreen conifer, cold-temperate/temperate mountain evergreen conifer, subtropical bamboo forest, subtropical/tropical eastern mountain evergreen conifer, cold-temperate/temperate mountain deciduous conifer, temperate/subtropical deciduous broadleaf forest, subtropical mountain evergreen broadleaf forest, subtropical/tropical south-west mountain evergreen conifer, south subtropical evergreen broadleaf forest, subtropical mountain evergreen/ broadleaf forest. Within the rainfall range of 500-600 mm, there was no statistical difference in interception among the majority of forests, but there was a difference between semi-deciduous monsoon forest and bamboo forest, evergreen broadleaf forest, China fir forest, evergreen/deciduous broadleaf forest, *Paulownia* plantation, Chinese pine forest, and between Scotch pine forest and oak forest, bamboo forest, evergreen/deciduous broadleaf forest, masson pine forest, Chinese Fir forest. Interception is largely dependent on stand structure and canopy coverage, rather than tree species.

The moisture holding capacity of litter can be two-to-four times as much as its dry weight, but varies with forest type. The tropical mountain rain forest has relative lower capacity compared to subtropical mountain evergreen/deciduous broadleaf forest. The soil non-capillary moisture capacity of forests ranged from 36-142 mm with an average of 89 mm. Evergreen broadleaf forests have a non-capillary capacity of more than 100 mm, while cold-temperate/temperate deciduous broadleaf forest and evergreen conifer forest have a non-capillary moisture capacity of less than 60 mm. The soil non-capillary moisture capacity accounted for more than 90% of the total as an ecosystem, followed by the moisture holding capacity of forest litter, which ranged from 3-10mm, but interception only occupied a small proportion (less than 2 mm).

Sediment generation following harvesting of *Pinus radiata* in New Zealand: a variable story

Chris Phillips
Landcare Research, PO Box 69, 8152 Lincoln, New Zealand
FAX: +64-3-3252418, Email: phillipsc@landcare.cri.nz

Keywords: sediment generation, *Pinus radiata*, harvesting

Understanding the variability in soil erosion measurements is critical if they are to be used in soil erosion models or for regulatory compliance purposes. It is generally accepted that variability in soil erosion measurements can be large, but this is not well documented. Often the number of replicates needed to satisfy low coefficients of variation are potentially large and are traded against cost and practicality of conducting the experiment. A study was initiated to determine sediment generation from a range of plots and small basins following clearfelling of a radiata pine plantation on the Coromandel Peninsula, in the North Island of New Zealand.

Bounded and unbounded 1 m^2 to 9 m^2 plots were installed on steep slopes(16^o-36^o, mean=27^o) a few weeks after clearfelling. Plots were located on deeply disturbed sites (exposed mineral soil) or lightly disturbed sites (litter and/or topsoil removed). In addition, nine small (0.25-2.3 ha) harvested ephemeral sub-catchments were monitored for sediment yield. Two unbounded plots (166 and 193 m^2) were located on the upper slope to the crest with maximum slope angles of 40-45°. The plots were cleared of all surface waste wood and branch material to expose erodible soil, and five 0.5 m-wide runoff collectors were installed across 6-7 m of slope width.

On a per m^2 area basis an order of magnitude variation existed between plots. For the first 3 months of measurement, the sediment generated on the 9 m^2 plots averaged 20 and 130 g/m^2 for light and deeply disturbed plots respectively. For 1 m^2 plots, it averaged 1 and 50 g/m^2 for light and deeply disturbed plots. Generated sediment values decreased from a high 2 months after harvesting. The average monthly unbounded plot yields from April to September 1999 were 10 g/m^2 (range 2.8-18.4 g/m^2) for the 166 m^2 plot and 0.2 g/m^2 (range 0.02-0.3 g/m^2) for the 193 m^2plot. Thus over a year, total sediment yield would average 20 -120 g/m^2. Despite similarities in treatment, size, and slope gradient between the plots, the larger plot differed in that there was more litter material mixed in the upper 10-20 cm of soil; this may have limited soil detachment and sediment delivery to the collectors.

Total sediment yields from the sub-catchments were in the range of 0.2-8.4 kg/ha/yr (0.02-0.82 g/m^2/yr) with a mean of 2.4 kg/ha/yr (0.24 g/m^2/yr) and a median of 1.6 kg/ha/yr (0.16 g/m^2/yr). The relationship between specific sediment yield (kg/ha) to the proportion of exposed soils is weak and accounts for about 38% of the variation.

Clearly sediment yields from plots are two-to-three orders of magnitude greater (in the first three months) than estimated annual yields from small basins. This difference is an artifact of the reporting convention for sediment yield. Care must be taken in extrapolating soil losses from plots to a larger scale. Soil losses from plots cannot be assumed to equate to losses at the basin

Effects of rainfall on nutrient dynamics and ligno-cellulose degradation of decomposing forest litter

Eric F. Salamanca
Don Mariano Marcos Memorial State University,
2515 la Union Bacnotan, Philippines
Tel: +63(72)41-5354, FAX: +63(72)242-5641

Key words: forest litter decomposition, nutrient dynamics

The dynamics of ecologically important chemical elements under various natural systems during the decomposition of forest litter is well documented. However, information on environmentally modified systems such as rainfall reduction is nil. In this study, the influence of rainfall on changes in concentrations and amounts of nutrient elements, lignin and cellulose in decomposing forest leaf litter were monitored for one year. A transparent plastic cover was installed to control the amount of rainfall reaching the forest floor. Leaf litter of *Quercus serrata, Quercus acutissima*, *Acer rufinerve* and *Pinus densiflora* was incubated in litterbags and sampled at 3, 6 and 12 months after set up. Residue litter was dried (60°C, 72 h), ground in a Wiley mill to pass a 0.5-mm screen. N and C of litter and soil samples were determined by dry combustion (N-C Analyzer-Sumigraph High Sensitive NC 90A). Other elemental analyses were prepared using a 1:1 mixture of HNO_3 and $HClO_3$ following the wet oxidation procedure (Jones and Case, 1990). The extracts were analyzed for their Ca, Mg, P, Mn, Fe, Al, Co and Zn using the inductively coupled plasma spectrometer (ICPS-2000, Shimadzu Co., Kyoto, Japan); and K by flame emission spectrometry (AA-6700F Shimadzu). Lignin and cellulose were determined by proximate analysis via acid detergent fiber (ADF) method, and total extractable polyphenols (TEP) by AOAC method using Folin-Denis reagents.

Results indicate that fully exposed and partially covered litters were comparable but differed when compared to fully covered ones. The nutrient dynamics pattern in covered litters deviated from the normal trend. The concentrations of both macro- and microelements had generally increased with time, irrespective of covering regime. Some exceptions were noted in *Q. acutissima* (P, Mn, Zn), A. rufinerve (K, Mg, Fe) and *P densiflora* (N, K, Ca, Mn, Cu), whose concentrations had either decreased or fluctuated during the course of the study. The amounts of these elements had followed three patterns: 1) element mass had initially increased then decreased, 2) the element mass had decreased all throughout, and 3) the element mass had fluctuated but tended to decrease towards the end of the study. In both the concentrations and amounts of various chemical elements, significant differences were noted even within species with comparable mass loss rates. Apparently, the litter incubated in covered plots was different from that in fully- and partially exposed ones. Generally, the C/N ratio of residue litter had declined through time, with the exception of covered *P. densiflora* and *Q. serrata*, where a rise in C/N ratio was apparent on the 12th month. The C/N ratio of covered litter was different from fully- and partially exposed litter across all species, except P. densiflora whose value had increased on the 12th month. The concentrations of lignin in exposed litter for *A. rufinerve* and *Q. acutissima* were higher after 3 and 6 months while those for *Q. serrata* were higher throughout the study than covered litter. On the other hand, *P. densiflora* was not affected by cover treatment. The concentrations of cellulose in covered litter seemed to remain constant after one year. After 12 months, the concentrations of cellulose in exposed *A. rufinerve Q. acutissima* and *Q. serrata* litter were significantly lower than the uncovered ones.

This study has demonstrated that rainfall affected the mobility of chemical elements. In some elements, the concentrations and mass were significantly different despite comparable litter mass loss rates. Likewise, zero-rainfall significantly reduced cellulose and lignin degradation. Finally, rainfall, through its buffeting effect, may alter the turn-over of ecologically important elements in the forest ecosystem.

Evaluating evapotranspiration and surface conductance of a tropical rainforest in Peninsular Malaysia

Makoto Tani, Abdul Rahim Nik, Zulkifli Yusop,
Yoshikazu Ohtani, Tsutomu Watanabe and Shoji Noguchi
Forestry and Forest Products Research Institute (FFPRI),
Post Box # 16, 305-8687 Tsukuba Norin, Ibaraki, Japan
Tel: +81-298-73-3211 (ext384), FAX: +81-298-73-1542,
Email: tani3@ffpri.affrc.go.jp

Key words: rain forest, evapotranspiration, surface conductance

Understanding the effects of the tropical rain forest on climate at both the local and global scale as well as on the regional water resource is one of the most important scientific concerns involving environmental issues. It requires intensive observational studies for estimating energy exchange including heat and vapor fluxes between the tropical forest and the atmosphere.

Observations on the energy exchange above a tropical rain forest have been conducted in the Pasoh Forest Reserve in Peninsular Malaysia. This study evaluates surface conductance, which represents stomatal response to environmental variables at the whole catchment scale. This evaluation assists in quantifying the effects of these variables on the energy exchange above the forest. It is necessary for estimating long-term evapotranspiration rates from a single source or "big leaf model" such as the Penman Monteith equation applied to estimating evapotranspiration from an Amazonian rain forest. The analyses were made using data collected with the aid of a 52 m tower in the forest reserve, where the canopy height was about 35 m, but with some emergent trees over 45 m. The Bowen ratio method was used for estimating sensible and latent heat fluxes from the forest canopy, and the profile method, taking into consideration the effects of atmospheric stability, was applied to estimate aerodynamic resistance. The surface conductance was calculated through the Penman Monteith equation from the fluxes and the resistance.

Results from the data set collected during the rainy season showed that surface conductance was mainly controlled by the specific humidity deficit and solar radiation, as expected from common stomatal responses. An empirical functional expression for these relationships obtained from other forests explained the characteristics of the surface conductance in our forests although the values tended to be large compared to those from other forests. The results will be applied to elucidate the characteristics of surface conductance in drier conditions.

Water and soil loss from a eucalyptus plantation in Kerala, India

Thomas P. Thomas, Sankar, S and Sujatha, M.P
Kerala Forest Research Institute, , Peechi-680 653
Kerala, India
FAX: 0487-782249, Email: libkfri@md2.vsnl.net.in

Key words: *Ecalyptus* plantation, soil loss

Eucalyptus is one of the important species grown by the Forest Department of Kerala State to meet industrial pulpwood requirements. Water and soil loss through accelerated erosion on sloping terrain starts as soon as the natural vegetation is removed, and eucalyptus plantations are no exception to this rule, although the actual loss has never been quantified. This study was established to generate data on loss of water and soil through surface runoff from a *Eucalyptus tereticornis* plantation in the Thrissur Forest Division of Kerala.

The study site at Palakathadom, Machad Range, Thrissur Division, is moderately steep with slopes of 15 to 20% and undulating terrain on all aspects. *E. tereticornis* was replanted in 1992 at a spacing of 2 x 2m. The study was carried out during 1994-95. The ground was bare except for some grasses and shrubs and some leaf litter. The soil is a fairly deep, well drained ferralsol derived from gneissic parent material. It is an acidic, reddish yellow sandy loam with a massive structure and is low in organic carbon and nutrients. The climate is humid tropical with 2000-3000 mm rain and temperatures ranging from $18^{-}38^{o}$C. Most of the rain is contributed by the southwest and northeast monsoons. The area receives around 120 rainy days annually and rainfall exceeds 10 mm on more than 60 days.

Soil and water loss from the eucalyptus plantation was quantified by establishing three 50 x 8m runoff plots along the slope and measuring runoff and sediment concentration. Stage level recorders of the Stevens F-type with stage graphs of 8 days duration were used to calculate runoff while sediment load was sampled daily from water collected in cisterns with a multi-shot divisor system arranged in series.

In 1994, the plots received on average 1183 m^3 of rainwater of which 227 m^3 (19%) was lost through surface runoff. The highest value recorded on a particular day was 33.8 m^3 of rain and 8.45 m3 of runoff. In 1995, 898.8 m^3 of rain fell on the plot of which 178.25 m^3 (20%) was lost as surface runoff. A peak day in 1995 received 78.6 m^3 rain and lost 42 m^3 (54%) through surface runoff.

When seasonal differences were considered 88% of the total runoff in 1994 occurred during the south west monsoon, while in 1995, 90% was lost during this season. During the north east monsoon the loss was 11.5% of the total runoff for 1994. The loss in 1995, during this season was negligible. Loss of water during the summer rains of 1994 was also meagre although in 1995, 7.5% of the total runoff occurred during the summer season.

The influence of plenitude and species of the forests on dynamic and erosion processes in Tajikistan.

Hukmatullo M. Ahmadov, Kokul H. Kasirov
Tajik Forest Institute, , 724055 Dushanbe, Tadjikistan
FAX: (3772) 213332, Email: farhod@kokul.td.silk.org

Keywords: mountain forests; dynamic and erosion processes; high zones

The mountain forests of Tajikistan play very important nature protective role. All of them are belong to the first category. By existing laws of the Republic the cutting down of forests is absolutely forbidden. However the intensive cutting had been take place since 1992 and restoring of forests happens slowly. The main types of the forest vegetation are broad-leaved forests, small-leaved forests, jungles, xerophitic sparse woodland, junipers, mixed forests, shrubbery and half-shrubbery vegetation. By depending on high natural-climatic zones the mountain forests are situated in such sequence: jungle-valley zone, small-leaved (sometimes broad-leaved) forests and kserophitic sparse woodland-low mountain zone, juniper, mixed and broad-leaved forests-middle and high mountain zones. The biggest part of forest areas are subjected to erosion and dynamic processes. This is because the forests which plenitude is bigger than 0,6 are occupy insignificant areas. The biggest index of the dynamic and erosion processes can be observed in the forest formation which plenitude is 0,1-0,3. The aforementioned processes are almost absent in the forests with 0,6 plenitude. The landslides sometimes can be observed here. In the forests which plenitude is bigger than 0,4 the temperature of soil and air is below than it is in open territories. The amount of precipitation until 20 mm stays on the leave surface. It is used for moistening of the leaves and for evaporation. The amount of precipitation above 20 mm reaches the soil surface but surface flow didn't formed. The amount of precipitation above 30 mm are forming the small amount of surface flow. The drop erosion is developing here. The soil indexes are better under the forest than in the open territory. By depending on natural factors the leaves can hold different amount of precipitation. The different types of trees are regulating dynamic and erosion processes. The detail characteristics of the forests and their influence on environment is given. The highest index of the soil washout can be observed in the *Amygdalus* and *Cercis* zone and it comes to 250 t/ha. The intensive development of the soil degradation observed in the *Pistacia* zone (4-113 t/ha) and depends on complex of natural factors and peculiarities of the growth of *Pistacia* especially with dynamic of the leaf surface. In these forest formations there are surface, gully, underground erosions, land sliding can be observed. The soil degradation in the nut forests with plenitude 0,1-0,3 comes to 24 t/ha. The soil washout and the flowing coefficient in the juniper forests with plenitude 0,1-0,3 comes 55 t/ha 0,14-0,52 respectively. The surface, gully and drop erosions, karst can etc. are wide spreading here. The influence of the different climatic, soil and erosion indexes on the forests is investigated. The investigations are carried by such scheme: precipitation-forests-surface flowing and infiltration-changes of environment.

The characteristics of shallow landslides occurring after clear-cutting beech stands and planting conifers on heavy-snow mountain slopes in central Japan

Hideharu Aiura, Akio Kato, and Mikio Hasegawa
Toyama Forest and Forest Products Research Center, Forest Experiment Station, Yoshimine, Tateyama-machi, 930-1362 Toyama, Japan
FAX: +81-764-83-1512, Email: aiura-h@fes.pref.toyama.jp

Keywords: shallow landslides, topographic factors, slippage of snow cover, stump roots, restraint function

The distribution and the transition of shallow landslides, those have occurred after clear-cutting beech (*Fagus crenata* Blume) stands and planting conifers (*Cryptomeria japonica* D.Don or *Larix leptolepis* Gord), on heavy-snow mountain slopes in central Japan were investigated using aerial photographs.

Relationships between the distribution and topographic factors were analyzed by using quantification method. In the analysis, azimuth, inclination, elevation, longitudinal-section form and cross-section form were employed as the factors. The analysis units were 25m, 50m and 100m meshes. The item to be related to the distribution of shallow landslides most closely was azimuth. The feature of the distribution of shallow landslides in the investigated area was different from that in the cause of heavy rain. The following categories promoted the instability of shallow landslides: azimuths of SE, inclinations larger than 30-35°, elevations between 1300 and 1400m, concave longitudinal-section and cross-section forms. On slopes of these conditions slippage of snow cover is more severe. According to the results, the distribution of shallow landslides was considered to be caused by the difference of slippage of snow cover.

The number, the area and the range of shallow landslides increased for more than 10 years. However, heavy rain or heavy snow initiating the landslides was not found during this period. Small shallow landslides, less than 100 m^2, held a greater part in number through the survey duration. The area of shallow landslides increased according to data collected in the years after afforestation.

However, the area of shallow landslides changed in very little in the area that afforestation was not carried out. As a result, the occurrence process of shallow landslides was concluded as follows: 1) the glide of snow cover was restrained by the stumps and the effect of the stump roots on slope stability emerged in the several years after the clear-cutting. 2) the glide of snow cover became obvious with the decrease of the stumps and the effect of the stump roots on slope stability deteriorated. 3) the glide of snow cover was restrained by ground clearance and the frictional resistance increased at the bottom of the snow cover be cause of weeding. 4) the brush wood decayed and the restraint function of the glide of snow cover was lost, while the growth of planted trees was not enough to restrain the glide of snow cover and affected slope stability for several years after planting. 5) the shallow landslides resulted in shear fracture by the annual snow displacement.

Characteristics of landslide distribution in the Toyama Prefecture, Japan- spatial analysis with GIS

Hiroyuki Kobayashi
Toyama Forest Research Center, Yoshimine, Tateyama-cho, 930-1362 Toyama-pref., Japan
FAX: +81-764-83-1512, Email: kobayasi@fes.pref.toyama.jp

Keywords: landslide GIS, geologic and geographic analysis, Tertiary formation, active faults

Toyama prefecture, which is frequently affected by landslide disasters, is located on the western coast of the central part of Japan. About 280 landslide areas in the prefecture are reserved for landslide-threatened areas by the Japanese Landslide Prevention Law. It is very important to recognize characteristics of landslide distribution to locate vulnerable landslide areas. Basic information related to landslides is usually on maps. Many maps, such as topographic maps, geological maps, landslide location maps and so on, are published by the national and local governments. It has not been easy to do some spatial analysis with those maps, because most of them have been paper maps and produced in different scales. However, we are able to obtain some digital maps and able to use relatively cheap PC based Geographic Information System (GIS) software recently. Purpose of this study is to make a data set of landslide related matters with digital and paper maps, and to do some spatial analysis with GIS.

Maps used in this study are: (1) Digital Map 25000 (Administrative Boundaries) by the Geographical Survey Institute (GSI); (2) Digital Map 50m Grid (Elevation) by the GSI; (3) FD Map (Railroads, Roads and Rivers) by the GSI; (4) Geological Map of Japan 1:1,000,000 by the Geological Survey of Japan (GSJ); and (5) Landslide Distribution Map by the Toyama Prefecture. The maps (1)-(4) were distributed in digital format so they were imported from a GIS software directly, but (5) was distributed as paper maps, so it was necessary to digitize all landslide area polygons by a digitizer. Municipality polygons from (1), which were divided by 1:25,000 map borders, were combined and the prefecture polygon was combined from the municipality polygons as vector data. Railroads, roads and rivers from (3) and faults from (4) were added into different layers as line type vector data. Geology polygons from (4) were added and extracted by the prefecture polygon as vector data. Elevation data from (2) was combined and added into a raster layer.

The results of some spatial analysis showed that, more than 90% landslide-threatened areas were located, at least partially, inside the Tertiary formation and more than 50% areas were located, at least partially, inside the 2 km buffer zones from faults. They suggest that the distribution of landslides is strongly related to geologic factors.

Spatial analysis of geologic and geographic factors with GIS will be effective for recognition and identification of landslides. Detection of vulnerable locations will be possible if combined with other investigations, such as aerial photographs and satellite data interpretation.

Potential soil erosion risk in the watershed basin of Struma River

Ulrik Martensson, Ivan Ts Marinov, Ilia Malinov
Lund University, Lund, Sweden
Email: marinbg@bas.bg

Keywords: soil erosion inventory; GIS; anthropogenic impact; suspended sediment; topography; vegetation

The Struma river basin occupies the southwestern part of Bulgaria, covering an area of about 9000 km^2 inside the country. The present project aims to make an inventory of the potential erosion in the Struma Watershed in western Bulgaria by modeling in a Geographical Information System (GIS) environment. Few studies on the difficulties rendering such an approach operational exist at present since most scientific studies tend to work in ideal environments with very good data availability. In the present study, only available data, of the kind that can be found in most countries has been used. Field plot measurements and suspended sediment measurements have been used for validation and comparisons between different measurement levels have been made. The use of digital GIS technique will permit easy up-date and enlarging of the current database.

In most of the Struma River watershed the natural features (relief, main rock type, precipitation, soil and vegetation) combine to favour the development of erosion processes. The mountain part of the watershed has a very rugged relief. Areas with slopes over 10% prevail. At some places the vegetation is insufficient to protect the soil from erosion. The cultivated areas on steep slopes are abundant. The anthropogenic impact on erosion intensity is also significant in the lower parts of the watershed. The eroding riverbanks, including those of the tributaries also make a considerable contribution to the generation of sediments in the river.

It was concluded that the results from the modeling and actual measurements of suspended sediment correlates well. It was also concluded that it is difficult to transfer information from one scale of measurement to another as well as adapting measured data to data acquired by modeling.

Concerning erosion in the Struma watershed it has been concluded that topography has a very strong influence on potential soil erosion. Soil erodibility is the second factor influencing erosion, mainly on Distric Cambisols (CMd), Eutric Cambisols (CMd) and Humic Cambisols (CMd) soil types. The inclusion of vegetation in the modeling that was done for the two pilot areas shows the extreme importance of this factor on erosion intensity. Large areas that was classified as high potential erosion areas was classed down to moderate or even low actual erosion at sites were the vegetation cover was important. The scale of mapping proved to be very important when comparing the results for the two areas using the scale of mapping for the whole watershed and when using the detailed 1:25000 input data for the pilot areas. Topography was much more accurately depicted in the pilot areas and results for the potential erosion modeling generally higher. This implies that the results from the general modeling should be used for general planning and prioritising soil conservation actions while the 1:25000 scale could be used for actual in site planning of conservation measures.

The major benefit of this project is that a methodology for soil conservation planning has been tested and found very appropriate when addressing this kind of problem. Interesting links between different scales has been examined and the need for more knowledge in this field has been underlined by the analysis.

Use of intensive soil working technique in afforestation of wastelands

Vijay Singh
Forest Development Corporation of Maharashtra Ltd., Rawel Plaza, Kadbi Chowk, 440004 Nagpur, India
Tel: 0091-0712-531957 / 533442, FAX: 0091-0712-551686, Email: vjsinh@hotmail.com

Keywords: soil erosion; water retention; 'V' shape furrows

The degraded forest wastelands are prone to heavy grazing in India and are consequently eroded and compact. Therefore, 90% of rainwater runs away leaving very little portion of it to percolate into subsoil. By traditional pit planting method only about 20.25 cubic metre rainwater can be harvested perha at a given time. This is highly inadequate. In order to harvest maximum precipitation by percolation there is need to carry out intensive soil working before planting operation. The method suggested in this paper deals with technique of water retention through ploughing and digging of 'V' shape furrows intercepted by small bunds at 2 metre intervals. By this technique, 1500 cubic metre of rainwater can harvested perha at a given time. The technique is very simple but effective and relevant in plain areas having low rainfall and high temperature, particularly the drought prone area. Accordingly this applied research study was carried out, on a moderate scale, in Jalgaon district of Maharashtra State in India. (Note-the study has earned Brandis award to the author for the year 1991 of Indian Forester, a monthly journal of forest and forestry research, Indian Council of Forestry Research, Dehradun, India. Summary of the paper was also published as voluntary paper by XIth. World Forestry held in Turkey in 1997).

Problems of development of adir slopes of the Hissar Valley in Tajikistan

Svetlana Vinnichenko, Akmal Akhmedov
Tajik Association of Woods and Wild Animals Protection, 734025 Dushanbe, Tadjikistan
FAX: (3772) 213332, Email: akmalk@td.silk.org

Keywords: landslides; erosion; mountainous seismoactive territories; aerial survey; engineering and geological exploration

The development of mountain seismoactive territories is traditionally confronted with a number of difficulties:

- Geomorphologic shortage of arable lands and lands good for construction;
- The development of nearly all types of dangerous geological processes on the slopes;
- High Seismisity;
- Shortage or abundance of water;
- Large areas of easily eroded volume changeable soils, etc.

Traditionally valley and mountain cavities are the first to be developed and then foothill territories. In Tajikistan one of the main zones for economic development is the Hissar valley situated on the junction of two largest tectonic regions-south Tyanshan and south Tajik regions. The cultivated zones are mainly situated on the medium-sized and high foothill adirs, surrounding the valley. The largest seismoactive tectonic breaks Hissaro-Kokshalsky in the north and Ilyaksho-Vahsh in the south, run across the adir foothills. From time to time seismic and tectonic activity of the breaks intensifies landslides and erosion just on the inhabited and cultivated territories. It causes damage and threatens people's lives. The typical example of such phenomena is the territory adjacent to the northeast outskirts of Dushanbe-capital of the Republic of Tajikistan. Agricultural development here is concentrated in the valley and in the watersheds of 4 erosive gullies-Gulbista, Kiblai, Kamchin, and Loiob. The upper reaches of these streams represent huge circuses of ancient seismogenic landslides aggravated by the seismic breaks. The decoding of aerial survey, engineering and geological exploration showed that during the last 30 years the activity of dangerous geological processes was registered 3 times in the anomalously rainy years (1969, 1987, 1998) that caused motion lasting 3-4 years, a rise in the ground water level and erosion. These dangerous geological processes every 10-12 years make it important to displace as soon as possible inhabitants from the villages, situated in the land sliding circuses. It should be also mentioned that the zones of landslides are the places that cause mud flows and threaten the northeast outskirts of Dushanbe. The size of active landslides in 1998-1999 is ranging from 5-7 thousand to 60 millions cubic meters (Loiob). Frequent landslides and erosion in the adir area of the Hissar valley bring to the forefront the task to resettle households from those dangerous territories and to make forest-park belts and gardens here. These actions will help to solve the problems of ecological improvement of the environment and to reduce the consequences of dangerous geological processes.

Ring shear tests on mixtures of fine sand and loess

Gonghui Wang, Kyoji Sassa
Kyoto University, Graduate School of Science
Tel: +81-774-38-4107, FAX: +81-774-38-4300, Email: Wanggh@landslide.dpri.kyoto-u.ac.jp

Keywords: sliding surface liquefaction, ring shear test, excess pore pressure, shear resistance, fine sand, loess

Liquefaction landslide is usually characterized by high sliding velocity and large run-out distance. It always causes great hazards. In the studies of earthquake-triggered-landslides based on ring shear tests, a concept of Sliding surface liquefaction was proposed by Sassa to interpret the high mobility. Sliding surface liquefaction takes place along sliding surface, it even can happen in medium or dense soil structure, because grain crushing along the sliding surface can result in volume shrinkage and then lead to pore pressure generation.

Two new sets of almighty intelligent ring shear apparatus were made and improved by Sassa to simulate the earthquake-triggered-landslides. The obvious advantage of ring shear apparatus is that there is no limitation in the shear displacement during shearing. For the sliding surface liquefaction, the most obvious characteristic is that with increasing of shear displacement, accompanying the grain crushing, pore water pressure built up gradually and then shear resistance decrease slowly, and finally reach constant value respectively, known as the steady state.

The relationship of grain crushing and sliding surface liquefaction had been mostly studied by using different samples under different loading conditions (static loading and dynamic loading). But the effects of grain size on sliding surface liquefaction behaviour had been poorly studied. It was pointed out that fine sand with some content of clay, are more prone to suffer from liquefaction failure, showing larger run-out distance, and many researches on this aspect had been carried out based on triaxial tests. However, the undrained behaviour of fine sand along the sliding surface is still poorly understood and requires further study. Therefore, in this research, a series of tests was conducted on fine silica sand in ring shear apparatus to study the undrained shear behaviour.

By mixing loess into silica sand with different loess content, the undrained shear behaviour of the mixtures had been studied, and then the pore pressure generation behaviour has been analyzed. It was found that with increasing loess content, the shear resistance at phase transformation and final steady state becomes smaller. In some tests on sample with greater loess content, the results show that even turned into drained condition after being sheared to steady state, the generated high pore pressure within the shear zone can be kept through a very long time due to the very low permeability of shear zone.

A Modified Geotechnical Simulation Model for the Quasi-Three-Dimensional Prediction of Landslide Motion

Fawu Wang and Kyoji Sassa
Disaster Prevention Research Institute, Kyoto University, Gokasho, Uji, Kyoto 611-0011, Japan
Tel : +81-774-38-4111, Fax: +81-774-384300, E-mail:wangfw@landslide.dpri.Kyoto-u.ac.jp

Keywords: Landslide; Prediction; Shear resistance, Thickness change, Pore pressure generation possibility

On the previous work (Table 1) of geotechnical simulation on the motion of landslides conducted by Sassa (1988), a modification is made on the shear resistance item and the geotechnical simulation model is improved.

Table 1 Geotechnical model on the motion of landslides by Sassa (1988).

Landslide has a two-layer structure, upper debris layer overlaying on the sliding zone (sheared layer). After sliding for a certain distance, the soil at sliding zone will reach its steady state, and the shear resistance will mobilize to the minimum value (Eq.(4)). In the sliding process, the thickness of upper debris layer always becomes thin, and results in decrease of the normal stress (Eq.(5)). Then, the apparent friction coefficient $\tan fa$ can be obtained by Eq.(6). Here *h* is the thickness of the sliding mass, and *Bss* is pore-pressure generation possibility. When the upper debris layer becomes thinner than a critical thickness, *hcr* (defined by Eq.(7)), suction will take action. In the actual case, because it is almost impossible to keep suction in the sliding zone, we assume that the apparent friction coefficient equals to

$$\frac{\partial M}{\partial t}+\frac{\partial}{\partial x}(u_0 M)+\frac{\partial}{\partial y}(v_0 M)=gh\frac{\tan a}{q+1}-kgh\frac{\partial h}{\partial x}-\frac{g}{(q+1)^{1/2}}\cdot\frac{u_0}{(u_0^2+v_0^2+w_0^2)^{1/2}}\{h_c(q+1)+h\tan f\} \quad (1)$$

$$\frac{\partial N}{\partial t}+\frac{\partial}{\partial x}(u_0 N)+\frac{\partial}{\partial y}(v_0 N)=gh\frac{\tan b}{q+1}-kgh\frac{\partial h}{\partial y}-\frac{g}{(q+1)^{1/2}}\cdot\frac{v_0}{(u_0^2+v_0^2+w_0^2)^{1/2}}\{h_c(q+1)+h\tan f\} \quad (2)$$

$$\frac{\partial h}{\partial t}+\frac{\partial M}{\partial x}+\frac{\partial N}{\partial y}=0 \quad (3)$$

h: depth of the sliding mass; *M*, *N*: Discharge in x and y direction per unit width, respectively ($M = u_0 h, N = v_0 h$); *k*: lateral pressure ratio; $\tan f$: apparent friction coefficient of the soil in the sliding zone; *hc*: cohesion head (defined as cohesion $c = rgh_c$, it is zero after sliding for a long distance. ρ: density); $\tan a$, $\tan b$: inclination of the intersection between the original slope surface and the x-z plane, y-z plane, respectively. $q = \tan^2 a + \tan^2 b$, $w_0 = -(u_0 \tan a + v_0 \tan b)$

$\tan f$ when *h* is smaller than *hcr*, as presented in Eq. (8).

The apparent friction coefficient will increases with the decrease of the thickness. It is also affected greatly by the *Bss* value. This model is added to Sassa's model, and the simulation program is modified.

$$t_{ss}(h, B_{ss}) = t_{ss} + (s(h)\tan f - t_{ss})(1 - B_{ss}) \quad (4)$$

$$s(h) = gh\cos^2 q \quad (5)$$

$$\tan f_a = \frac{t_{ss}(h, B_{ss})}{s(h)} \quad (6)$$

$$hcr = {}^{t_{ss}}\!/\!{}_{g\cos^2 q} \quad (7)$$

$$\tan f_a = \tan f\,,\ \text{when } h \le hcr \quad (8)$$

An application study is then carried out on the Sumikawa landslide, a rapid and long runout landslide occurred in Akita Prefecture in 1997. The simulation results of aerial prediction shows a good correspondence to the actual landslide.

8.05.00 Forest Fire. Land Use, climate variability anf forest fires in South-east Asia

Fire occurrence in relation to weather conditions

Ertugrul Bilgili, Saglam, Bulent
Karadeniz Teknik Universitesi, Department of Forest Entomology and Protection
Faculty of Forestry, TR-61080 Trabzon, Turkey
Tel: +90-462-325-3223 ext. 2845, FAX: +90-462-325-7499, Email: bilgili@osf03.ktu.edu.tr

This paper presents and evaluates the effects of fine fuel moisture content of forest floor fuels on fire occurrence in Mediterranean ecosystems of Turkey. Fine fuel moisture contents were measured in an even-aged, fully stocked red pine (*Pinus brutia*) stand near Izmir. Three fuel samples were taken daily in the early fire season in June and once or twice a week thereafter. Fuel samples were weighed and oven-dried at 100 ^{o}C for 12 hours or until no change in weight was attained. Moisture contents were determined based on the weight difference between before and after oven-drying. Weather measurements were taken daily at noon local standard time from a nearby weather station located at Menderes Interantional airport. Measurements included temperature, relative humidity, wind speed and direction, and precipitation. Fire occurrence data during the study period was obtained from the Regional Forest Directorate in Izmir. Analyses showed that a close relationship exists between weather conditions and fire occurrence. Indexes generated from this study should be invaluable for fire managers in the region and other places having similar conditions.

Further posters regarding the topic 'Forest and Fire' can be found in Part 3 / Task Forces A2 (this volume).

Capercaillie (*Tetrao urogallus* L.) as the indicator of conservation and changes in forest ecosystems in mountain landscape of Slovenia

Miran M. Cas
Slovenian Forestry Institute, Vecna pot 2, 1000 Ljubljana, Slovenia
Tel: +386 (0)61 123 13 43, FAX: +386 (0)61 273 589, Email: miran.cas@gozdis.si

Keywords: forest ecosystem; Capercaillie populations; human impact; habitat suitability; Slovenian Alps, forest history

The present analysis of indigenous European beech-silver fir forests in the eastern part of the Karavanke range in Carinthia and in the eastern part of the Kamnik-Savinja Alps, both in northern Slovenia, in the last two centuries - the transition period from rural-pasture landscape with a low proportion of forest to forested landscape - shows the influence of changes in which high-altitude pastures reverted to scrub and coniferous (Norway spruce and Alpine larch) woodland on the increase of Capercaillie (*Tetrao urogallus* L.) populations, after the year 1875 to their peak in 1933. After last prove optimum of population density in 1961 a sharp fall was observed until the minimum was reached in 1982. This is attributable to a decreasing fluctuation phase of Capercaillie populations and to an increasing adverse human impact on the mountainous forest area.

On the carbonate Peca (2126 m o. s. l.) and non-carbonate Smrekovec with Mozirje mountains (1684 m o. s. l.), on the two mountains under investigation in this study (309 km^2) with 80% of forest cover, the density of populations does not differ (0.9 birds/km^2), but it differs significantly at the height of over 1100 m, that is above inversion layers, in favour of Smrekovec with Mozirje mountains (2.8 birds/km^2) with lower pH (neutral and acid soil).

The results of the study show an positive influence of forest areas in the mountains preserved from period of the Josephine military maps from 1784-1787 (on Smrekovec with Mozirje mountains 34.2% and on Peca 10.9% of forest cover) on the distribution of Capercaillie habitats in the current forest coniferous landscape. The proportion of the number of

overgrown centres of habitats in forest areas from 200 years ago is up to three times higher than the then (today's) forest cover. Distribution of capercaillie leks and overlapping with forest areas from the period 1784-1787 in the present forest landscape is distinct in north eastern positions of slopes, as the preserved forest land on the unsuitable rural surfaces. The present proportion of forested land was attained by Smrekovec with Mozirje mountains as early as 1875, and by Peca only in 1962.

On these two mountains, an increase in the proportion of forest areas preserved from the period 1784-1787 in Capercaillie habitats of subpopulations in 500 m around the centres of leks is leading to a significant decrease in the distances among habitats ($p<0.001$), from about 1500 m at 0% of preserved forest area to 700 m at 80%.

Monitoring of Capercaillie in whole area of Slovenia showed that the condition of population density in 1998, is alarmed, specially in Dinaric Alps area. Only 48,8% of 592 known leks in Slovenia occur active sub-populations. In potential habitat on the 33,8% surface of Slovenia in area from 1600 to 600 m o. s. l. in 200 m altitude zones we found out significantly linear decrease of share of active leks, from 70,3% to 16,0%. Maximum of active leks is in layer betwen 1201 to 1400 m o. s. l. with 42,5% of all active leks, maximum of population density in 1998 is in layer between 1401 to 1600 m o.s.l., with 6,5 birds /10 km^2. In this area of both layers with 1.015 km^2 on the 4,7% surface of Slovenia, we establish suitability of habitats. Capercaillie, this endangered species of mountain forest fauna in Middle Europe, indicates the conservation of this forest ecosystems and habitats of other rare species of forest fauna (biodiversity) under the forest border at 1650 m.

Social changes in the Kani tribals and its impact on human-wildlife conflict: a case study from the tropical forests of southwest India

E. A. Jayson, G. Christopher
Kerala Forest Research Institute, Division of Wildlife Biology, Peechi 680 653 Kerala, India
FAX: 91-0487-782249, Email: libkfri@md2.vsnl.net.in

Keywords: Tropical forests; man-wildlife conflict; crop damage; Kani tribals

Man-wildlife conflicts and social changes of Kani tribals inhabiting the Peppara Wildlife Sanctuary in southwestern India was studied during the years 1993 to 1996. The study was carried out by observational methods and also from field plots. Structured questionnaire was used to collect data on the social aspects of the tribals. Major man-wildlife conflict was in the mode of crop damage and human slaughters. Out of the thirty species of larger mammals, five species were recorded as destructive to 17 crops of the tribals. Crop damage by wild boar (*Sus scrofa*) was severe, followed by elephant (*Elephas maximus*). Thirteen indigenous crop protection methoods were recorded from the area, which are effective up to certain extent.

Analysis of social changes of Kani tribals revealed that peripheral settlements of the sanctuary have more educated people compared to the settlements deep inside the sanctuary. Access to the educational institutions was comparatively easy from the peripheral settlements. Due to the high educational background, people in the perpheral settlements cultivated cash crops like coconut, cashew nut and casava in large scale and due to this crop damage was severe in the peripheral settlements. Where as in the interior settlements, tribals cultivated only traditional crops, with low input and the crop damage was of low intensity. Crop damage is found linked to the cropping pattern and location of the settlements in the sanctuary.

The effects of forest management on the biodiversity of insect communities

Stephen A. Woods, J. C. Jaros-Su
University of Maine, Department of Biological Sciences, Deering Hall, ME 04469 Orono, USA
Tel: (207) 581-2955, FAX: (207) 581-2969, Email: Woods@maine.maine.edu

Keywords: insect communities; forest management; harvest systems; biodiversity

As forests continue to be managed for commercial production, sensitive land stewardship requires principles for applying forest harvest techniques in a way that minimizes the impact on non-commercial species of plants and animals to retain biological diversity. To date, appropriate strategies in forested landscapes have been constrained to the management of a handful of vertebrate species.

The Penobscot Experimental Forest in Bradley, ME has provided an unusual opportunity to evaluate the effects of different harvest systems on biodiversity. We deployed insect traps from 1995 through 1998 in 10 ha stands that ranged from even-aged shelterwood and clearcut harvest systems through uneven-aged selection harvest systems that retained a significant portion of mature trees within the stand. Diversity was high in the selection stands, that had moderate levels of plant species diversity and high levels of plant structural complexity, and the clearcut stands, that harbor a relatively rich plant species community and low structural complexity. Communities in the clearcut stands were distinct from those in the selection stands and were relatively rich in herbivore and parasitoid species, while those of the selection stands were rich in fungivores and predators. Stands managed under a shelterwood system provided low plant species diversity and low structural complexity resulting in the dramatically lower levels of insect diversity. Plant species richness and structural complexity were not correlated in these studies. The results of these studies provide prescriptions for managing forests at the stand and landscape levels in order to foster the maintenance of biodiversity.

The community structure and species diversity of *Pinus massoniana* forest in the Three Gorges Reservoir Area, China

Ruimei Cheng, Xiao Wenfa
Chinese Academy of Forestry, Institute of Forest Ecology, Environment and Protection, 100091 Beijing, China
FAX: 0086-10-62889555, Email: Shizm@fee.forestry.ac.cn

Keywords: community structure; species diversity indices; sub-tropical pine forests; human disturbance

The Three Gorges Reservoir Area is located in the sub-tropical moist region of China. *Pinus massoniana* forest is one of the important vegetation types and the main commercial forests in this area. According to the data of 32 plots, the forest was divided into 21community types. The vertical structure of all community types is obvious, it can be divided into tree layer, shrub layer and herb layer. The trend of the species richness index, diversity index and evenness index of different layers in all community types is herb layer>shrub layer>tree layer. But maybe because of the strong disturbance of human activities in the area, the trend of these indices along the altitude gradient is not obvious.

Monitoring changes in tropical forest environments using moths

Jurie Intachat
FRIM, Kepong, 52109 Kuala Lumpur, Malaysia
Email: intachat@frim.gov.my

Keywords: tropical forests; moth diversity; monitoring; environmental assessment; disturbance impacts

Changes in tropical forest environments may occur naturally or be induced by man. Physical and climatic changes arising from man's activities can affect the ecological functions of tropical forest ecosystems. Examples of physical changes are conversion of land-use, or logging activities, whilst climatic change may be brought about through the greenhouse effect. In assessing the effects of these changes on forest ecosystems, monitoring organisms is far more informative than monitoring physical and chemical variables. Choosing the right organisms, however, is important if they are to be an appropriate tool for monitoring and interpreting change.

Moths from the superfamily Geometroidea or in short, geometroid moths, are a suitable group of insects for monitoring changes within the tropical forest environment because of their abundance, species richness, ubiquitous occurrence and importance in the functioning of the natural forest ecosystems. The response of geometroid moths to changes in the forest environment results from changes to the floristic components of the forest. As larvae, they exhibit a high degree of specificity in their herbivorous diets and feed on various parts of the plants such as flowers, leaves and fruits or seeds. As adults, some groups are nectar feeders, indirectly playing the role of pollinators.

Monitoring and detecting changes in the abundance, species richness and species composition of the geometroid moths gives a good indication of the state of a forest environment. These measurements can also be used in a predictive sense in relation to environmental assessments. An assessment of the state of the forest environment may include the levels of disturbance or recovery of the forest. The assessment carried out can be based on the presence or absence of, and/or the increase or reduction of geometroid moth species unique to a particular forest ecosystem. High numbers of geometroid moth species unique to the environment may in turn suggest a potential loss of these species following the destruction of this forest.

Some genera or species of geometroid moths are good indicators of a particular type of change in the tropical forest environment. High representation of species from the subfamily Sterrhinae for example, indicates that the forests are highly disturbed, a result that is usually associated with an open forest canopy such as in a logged forest. For more detailed conservation evaluation, however, the choice of a particular key geometroid moth species or genera within a group will depend on the precise objective. Geometroid moth species that are unique only to a particular forest site stand out and provide a strong argument for conserving the site. *Chloeres quantula* Swinhoe, for example, is such a species that has been found to be unique to mangrove. Species from the genera Ornithospila and Ectropidia on the other hand have strong associations with dipterocarp representation.

Biological indicators for monitoring the genetic and reproductive status of declining populations of red spruce, *Picea rubens*

Alexander Mosseler, O. P. Rajora and J. Major
Canadian Forest Service, Post Box # 4000, E3B 5P7
Fredericton, New Brunswick, Canada
Tel: (506) 452-2440, FAX: (506) 452-3525, Email: amossele@nrcan.gc.ca

Keywords: population viability analysis; conservation; forest genetic resources; genetic diversity; reproductive success

Red spruce, *Picea rubens* Sarg., has historically been an important and characteristic component of old growth , late successional, upland forests of eastern Canada. However, this species is in decline and has become increasingly rare across most of its range in eastern North America as a result of environmental changes related to various human impacts, including harmful forest harvesting practices. Various reproductive (e.g., cone, seed, and seedling growth) traits and biochemical genetic estimates of diversity were used as indicators of the status and viability of natural populations across the northern margins of the geographic range. These traits were quantified to provide benchmark information for population monitoring. In general, the reproductive and genetic status of small, isolated stands from disjunct populations at the margins of the geographic range in central Canada compared favourably with the fecundity and genetic diversity of much larger, more extensive populations of eastern Canada. While some of the smaller, remnant populations appeared to be quite resilient to the effects of small population size, increased levels of inbreeding and inbreeding depression were beginning to affect fecundity, growth performance, and genetic diversity. Traits such as filled seed production per cone, the ratio of seed weight to cone weight (a measure of reproductive efficiency), seed efficiency, and the ratio of filled seed to aborted seed provide useful indicators for assessing reproductive status in trees at risk due to small population size, low within population densities, and the restricted gene flow imposed by population isolation. The reproductive indicators described here have general validity for assessment and monitoring population viability in most conifers; they are relatively easily measured; and they provide useful indicators for monitoring biological processes important to maintaining population viability. Our results suggest that in the short-term, small remnant forest stands can maintain surprisingly high levels of reproductive fitness. However, in the longer term, such small remnants can be expected to lose genetic diversity through inbreeding and genetic drift. Furthermore, such populations are at increased risk of local extirpation through stochastic events. It is often difficult to separate the genetic from the environmental effects on reproductive fitness in small populations at the margins of their geographic range because such populations experience both the genetic effects of reproductive isolation as well as the effects of physical stress in environments to which they may not be well adapted

Ecological research on plant biodiversity and biomonitoring in tropical evergreen forests of peninsular India

N. Parthasarathy, N. Ayyappan, S. Muthuramkumar, J.Annaselvam and C.V.Chittibabu
Pondicherry University, Salim Ali School of Ecology and Environmental Sciences, 605 014 Pondicherry, India
Email: partha@pu.pon.nic.in

This paper consolidates the results of plant biodiversity inventories in the permanent plots established in various tropical evergreen forests of peninsular India and discusses the potential use of those data and goals of biomonitoring. Large-scale plant biodiversity inventory program on a 30-ha scale at Varagalaiar tropical wet evergreen forests of Anamalais, Indian Western Ghats, yielded a total of 432 vascular plant species, of which 153 were tree species (>30cm gbh) in a total sample of 13,418 stems, 75 species of lianas in a sample of 11,200 stems (>1cm dbh) and 155 species of understorey plants in a total density of 2,18,471 plants and 26 species of herbaceous vascular epiphytes in 3,392 individuals. The recruitment of trees (>30cm gbh) for the one-year period was greater (mean 4 trees per ha) than the mortality (mean 3 trees per ha). In the Kolli hills of Eastern Ghats, four 2-ha permanent (contiguous) plots were established with increasing human disturbance, to evaluate the difference between them in tree species composition, stand structure and dyanamics. A total of 3,825 stems >30cm gbh (266-632 per ha) and 78 species (26-54 species per ha) were enumerated. Reduction in species richness (by 52%), basal area (56%) and tree density (58%) is evident in disturbed sites. First recensus data are in analysis stage. In two tropical dry evergreen forests at Kuzhanthaikuppam and Thirumanikkuzhi near Cuddalore town on the Coromandel coast of India, woody species diversity and density were 38 and 42 species per ha and 1367 and 994 stems per ha respectively. First recensus is being recently completed. Permanent plots provide opportunities for multifaceted research activities(e.g.forest production, various component interactions, forest functioning etc.). Repeat census of permanent plots has the advantage of multi-taxa monitoring in a cost-effective manner than separate species studies and these data are useful in basic and applied research in forest ecology.The fronitiers in this research area will be discussed in the light our large-scale ecology research program

Spatial and temporal changes in plant biodiversity

Dieter R. Pelz, Paul Luebbers
Universität Freiburg, Abteilung Forstliche Biometrie, Werderring 6, D 79085 Freiburg, Germany
Tel: 49-(0)761-203-3750, FAX: 49-(0)761-203-3751, Email: pelz@forst.uni-freiburg.de

Keywords: plant diversity; spatial and temporal changes; hardwood forests; diversity indices

Biodiversity of a forest is not static but dynamic. In a given forest, the plant diversity changes spatially, biodiversity measures for different locations vary considerably, as indicated by measurements of fixed area plots. Depending on the time of the year, the diversity of plants in a given forest will vary also. The results of a study are presented for which diversity was assessed on sample plots in a hardwood forest in Southern Germany. Observation were taken since 1997 every 3-4 weeks during the growing periods, all plants on small sample plots were measured, counted, or their cover percent estimated. For these data diversity indices were calculated. It was found that the spatial and temporal changes in diversity was significant, the various indices studied showed different trends. The problems of measuring diversity of plants on sample plots are discussed.

Impact of disturbance and fragmentation on conservation of biodiversity and genetic resources a global synthesis of current knowledge and impacts

John Grynderup Poulsen, Abdou-Salam Ouédraogo
CIFOR, Post Box # 6596 JKPWB, 10065 Jakarta, Indonesia
FAX: +62 251 622 100, Email: J.Poulsen@cgiar.org

Keywords: disturbance impacts; fragmentation; tropical forest biodiversity; conservation of genetic resources; conservation policies and strategies

We review past and current research activities with respect to the impact of disturbance and fragmentation on the conservation of tropical forest biodiversity and genetic resources. Following the Rio conference in 1992, substantial financial and manpower resources have been invested in researching these issues, yet very little effort has been put into synthesizing and integrating the acquired knowledge. We attempt to consolidate the gains from past and ongoing projects to reach such a synthesis. The goal of the publication is to evaluate current knowledge regarding the impact of disturbance and fragmentation on conservation of biodiversity and genetic resources, as it relates to the implementation of the CBD. We do: a) by describing and comparing the impact pathways for conservation of biodiversity and genetic diversity, respectively, and with particular reference to policy implementation strategies; b) through a concise synopsis of what is known, key elements not known and topical research areas; c) through a critical review of projects that have been, and/or are being conducted, and discussion of issues for/from each project still to be resolved; d) through a critical review of methods that have been used and discussion of methodological issues still to be resolved (this will serve to examine the compatibility among results obtained by various projects. The global emphasis will be reached through comparison of the themes within eco-regions, followed by comparison of themes among eco-regions.

Extrapolation of multivariate diversity measures, with a case study from the tropical rain forests of Sumatra

Keith Rennolls
University of Greenwich, , United Kingdom
Email: k.rennolls@greenwich.ac.uk

Keywords: Multivariate diversity measures; Tropical rainforests; Sumatra; Tree species diameter models

Sample plots have a limited area. The species-area relationship is commonly used to estimate the number of species in a forest from data collected from such a finite-area sample plot. This paper first considers and compares a number of non-linear models that may be used in this extrapolation. The dependent variable is then extended to other measures of species diversity than species count.

Finally the work is generalised to area-based extrapolation of the Renyi Functional Alpha-diversity measure. A less commonly considered sampling constraint is that of the tree-diameter cut-off used. This can have a major effect on diversity measures. The use of species diameter models are therefore developed which allow an extrapolation to zero diameter. The generalisation to multivariate functional diversity measures will also be considered. Finally the development of joint area-diameter (cut-off) models is reported, and their use for extrapolation. These new methodological techniques are developed in the context of a case study on data collected on trees in a tropical rain forest in Jambi, Sumatra.

Introduction d'espèces pour la foresterie ou l'agroforesterie et risques d'invasions biologiques

Jacques Tassin
CIRAD-Forêt Programme Arbres et Plantations, 7, chemin de l'IRAT Ligne Paradis, 97410 , France
Email: tassin@cirad.fr

Keywords: agroforestry; alien species; potential invasiveness; threats to native biodiversity

Les invasions biologiques sont aujourd'hui considérées comme une menace majeure à l'égard de la conservation de la biodiversité. Or, l'introduction incontrôlée d'essences ligneuses utilisées dans des programmes agroforestiers ou forestiers peut donner lieu à de nouvelles invasions biologiques, tout particulièrement, mais non exclusivement, dans les milieux insulaires. Ce risque est d'autant plus important que les espèces forestières colonisatrices ont été largement privilégiées ces 40 dernières années et qu'il est aujourd'hui matériellement possible de faire parvenir des semences de toutes essences forestières dans toutes les parties du monde. Les invasions à partir d'espèces ligneuses potentiellement invasives dans le monde sont bien renseignées en Amérique du Nord et en Europe, mais assez peu sur les autres continents, à l'exception des îles du Pacifique, de la Nouvelle-Zélande, de l'Australie et des îles de l'océan Indien. Les Mimosacées, les Pinacées et les Papilionacées constituent les familles qui recouvrent le plus d'espèces forestières invasives. A elles seules, les Mimosacées regroupent plus d'un tiers des espèces ligneuses invasives utilisées en sylviculture ou en agroforesterie. Parmi celles-ci, certaines espèces potentiellement invasives ont bénéficié d'efforts de diffusion très importants, comme *Leucaena leucocephala* ou différentes espèces du genre *Prosopis*.

Certaines plantes ligneuses invasives ont un développement tel qu'elles supplantent des formations végétales entières, comme par exemple différents acacias d'origine australienne dans les *fynbos* d'Afrique du Sud. La composition des écosystèmes et de leur biodiversité est dans ce cas fortement perturbée. On peut également assister à une homogénéisation des habitats, un appauvrissement des communautés, et à des modifications de la biomasse. Mais le plus souvent, les modifications induites par les plantes invasives portent sur la structure et les fonctions des systèmes écologiques et de leur biodiversité. La physionomie de la végétation est modifiée, la structure des populations est perturbée, les caractéristiques des sols peuvent changer, ainsi que les caractéristiques hydriques. De même, les invasions de plantes ligneuses peuvent entraîner des modifications des régimes de perturbation (ex : feux), des cycles biogéochimiques, de l'érosion, des régimes hydriques ou de la productivité primaire.

Dans l'attente d'une meilleure connaissance des critères de caractérisation des plantes invasives, le principe de précaution doit s'appliquer en situation de doute ou en connaissance de cas d'invasion pour une espèce donnée, observés en d'autres pays. Des bases de données sont aujourd'hui consultables sur Internet et permettent maintenant de décider d'une introduction en connaissance de cause.

Une liste d'une centaine d'essences potentiellement invasives à usage forestier ou agroforestier est fournie. Environ 25% de ces espèces seulement ne sont invasives que dans les îles, ce qui atteste du fait que les espaces insulaires, bien que plus sensibles aux

invasions biologiques que les zones continentales, n'en ont pas pour autant le monopole.

Strategies for conserving biodiversity in the Kii Peninsula, Japan

Tsuyashi Yoshida
Kyoto Prefectural University, Faculty of Agriculture
Laboratory of Forest Management, 1-5 Nakaragi-Shimogamo, 606-8233 Kyoto, Japan
Tel: 81-703-5629, Email: F9830602@kpu.ac.jp

The Kii Peninsula is located at the central part of Japan's mainland, and it has rich natural resources including forest and wood products and unique wildlife habitats. In addition to its resources, the area has attracted various national and international attentions in recent years, because the Miyagawa Basin of the Kii Peninsula is a now candidate for third Japanese "Model Forest."

However, because of lacking adequate protection and distracting of natural habitats, the Peninsula's biodiversity is in dangerous status. Many mammalian species such as Japanese serow (*Capricornis crispus*) and Japanese black bear (*Selenarctos thibetanus japonicus*) are listed as endangered species in the Peninsula (Yoshida et al 1997). We believe that these species and other biodiversity should be maintained at large scale of ecosystem, not just for small land-uses, especially for a new "Model Forest " establishment.

The Gap Analysis is unique and well-known method for proactive approach for assessing the current status of biodiversity at large regional base and at the all level of ecosystem. By using computerized mapping software called GIS (geographic information system), we are able to identify "gaps" in biodiversity conservation. Gap analysis is basically a coarse-filter assessment of representation of actual vegetation types, satellite imagery, and wildlife-habitat relationship model (Noss and Scott 1997). If "gaps" between hot-spots of biodiversity and our conservation efforts are identified by this analysis, new appropriate conservation or management practices should be taken in order to protect biodiversity in the Kii Peninsula.

Our Gap Analysis includes three primary layers of GIS maps: land ownership and uses, distribution of vegetation cover, and distribution of terrestrial wildlife species as predicted from wildlife-habitat relationship model. By using the GIS function of map overlays, wildlife distribution and land ownership are compared to estimate the relative extent of protection afforded each vertebrates species (Edwards 1995).

The objective of this study is to apply Gap Analysis for assessing the conservation status of wildlife habitats in the Kii Peninsula. We will briefly explain the process used for this analysis and models used for mapping wildlife and vegetation cover distribution. To assess adequate conservation level, we will use several "key species" of the Peninsula to define "gaps". One of key species must be represented from each vertebrate classes. Key species for this analysis are listed in following Table 1. Our tactics to conserve biodiversity in the Kii Peninsula is to establish new preserves or alternating land-use practices based on the "Gap Analysis".

Table 1: Key species for the Kii Peninsula Classes Species common name Scientific name Mammal
Japanese black bear *Selenarctos thibetanus japonicus*
Japanese serow *Capricornis crispus*
Japanese dormouse *Glirulus japonicus*
Aves Japanese golden eagle *Aqulia chrysaetos japonica*
Japanese falcon *Falco peregrius japonesis*
Japanese harrier *Ciurus aeruginosus*
Reptiles Loggerhead (Marine turtle) *Caretta caretta*
Amphibians Asiatic salamanders *Hynobidae* spp
Japanese giant salamander *Megalobatrachus japonicus*

8.08.00 Forest and Climate

Research on effects of climatic factors on forest vegetation changes in the north part of eastern Anatolia Region

Mehmet Güven
Eastern Anatolia Forestry Research Institute, 25050 Erzurum, Turkey
FAX: 442 233 06 77, Email: eafri@orion.net.tr

Keywords: ecology; forest; vegetation; climate; geology; watershed

This is a fundamental research and the aim of this research is to determine nature vegetation changes and relationships with climate (temperature, rain, humidity etc.), which is one of the environmental factors in the North Part of Eastern Anatolia Region.

The research area, which is a watershed, is at passing zone between two different regions because of assorted plants and climate conditions. It will be very useful to determine relationships between climate and vegetation for future planting in the area. Scotch pine, juniperus, fir, oak have constituted the forest vegetation of the area.

Firstly general geology, general geomorphology, climate and vegetation of the area have been explained. Then effects of climatic factors on vegetation changes have been handled. Temperature, rain and humidity degrees belong to last 25 year degrees, supplied from General Directority of Meteorology, have been used as climatic factors.

This research has been carried out in three phases. In land working plant samples were picked up, spreadings of plant groups have been examined by paying attention to slope and aspect condition also a vegetation map has been drawn. In laboratory studying, plant samples picked up have been identified. In office studying, data supplied from land and identification of plants have been evaluated. Changes of vegetation, related to climatic factors, have been determined by drawing necessary maps and graphics. And also water balance values of the watershed have been calculated by Thornthwaite method and it has been drawn a water balance values graphic.

Especially, juniperus (*Juniperus* sp.) and oak (*Quercus* sp.) species have been grown where Mediterranian sea climate type was seen in the research area. In these places it is suitable to make oak breeding working. Fir (*Abies nordmanniana*), which is an element of East Blacksea plant society, has been grown together with scotch pine (*Pinus sylvestris*) in the northern part of watershed. It is important not to degrade this mixture for continuity of forestlands. So it is necessary to protect fir.

At the result of research, according to some priorities evaluated, it has been found that climate is one of the definite factors in the distribution and changes of vegetation, but it does not have priority. That is, there are another factors having been effective on vegetation changes. It can be easily said that edaphic factors and other ecological conditions can be affect. Because grazing pressure, smuggling have been observed in the research area. And also it has been seemed that there are quite clear differences between sides when the development of forest and species mixture have been examined.

Injuries of forest tree species by air pollution and their economic evaluation

Blanka Mankovska, Viera Petrásová
Forest Research Institute, Masarykova street 2195, 960 92 Zvolen, Slovakia
Tel: +421 855 5314169, FAX: +421 855 5321883, Email: Blanka.Mankovska@fris.sk; mankov@fris.sk

Keywords: air pollution, foliar analysis, economic evaluation

Air pollution in Slovakia is serious not only in the surroundings of all industrial centres but also in mountain regions. Regarding whole Europe worse forest conditions is only in the Czech Republic and Poland. With an increase of air pollutants loading also the loss of foliage increases what reflects also in diameter increment. Forests cover about 41% of the territory of the Slovak Republic what is about 20 thousand km^2. The proportion of commercial forests is 72%, of protective forest 14% and of special purpose forests 14%. The proportion of coniferous tree species is 42.7% (spruce 26.8%, pine 7.7%, fir 5%, larch 1.9%, dwarf pine 1.0% and others 0.1%) and the proportion of broadleves is 56% (namely beech 29.1%, oak 11.3%, others 16%). Health condition of the forests in Slovakia is deteriorated due to air pollutants impact. A region of the border of Slovakia, Poland and Czech Republic was declared the second black triangle in Europe. Main disturbances of forest ecosystems appear. They lead to their gradual degradation and decline. Due to long-lasting load by high concentrations of various air pollutants a mass dieback not only in the stands in the surroundings of the sources of air pollution also pollutants from remote transfer, particularly from Poland and Czech Republic are accumulated on our territory. Slovakia has compared with these countries very disadvatnageous location due to prevailing northern, northwestern and western air flows. Moreover, it should be taken into account that Slovakia is a country with broken relief and the altitude reaching 2632 m whereas the timber line with dwarf pine is extending to the altitude 1800 m. All these unfavourable circumstances together have caused that in the 90ies 85% of forests exhibited symptoms of damage. To characterize the condition of forest stands in Slovakia there were set 8 air pollutant deposition types (acidic with fly ash from coal combustion or combustion of heavy oils, with fluorine and chlorine, with organic substances and dense dust, alcaline -lime or magnezite and ammonia). These types determine main chemical components of air pollutants. In the year 1996 total emission from the sources of air pollution reached 224.2 thousand tons of sulphur dioxide, 139.5 thousand tons of nitrogen oxide, 373.3 thousand tons of carbon monoxide, 67 thousand tons of solid pollutants including heavy metals, 150.5 tons of fluorine, 2 256.3 tons of carbon sulfide, 937.3 tons of hydrogen sulfide, 86.7 tons of chlorine and 12.3 tons of mercury. Total emission of air pollutants in Slovakia has increased in the period 1970-1985 by about 25%. Since 1985 the level of emission has been stagnating.

With an increase of air pollutants loading also the defoliation increases what reflects also in diameter increment. Diameter increment has been gradually decreasing for spruce and fir with defoliation. For beech and oak increment is not decreasing up to 30% of defoliation. This increment is reduced by about 25% if the defoliation is for fir 20%, for spruce 40% and for beech and oak 60%.

The area of forest was 1, 987, 909 ha in 1996. Reduction of increment represents 327 mil. SKK. An annual amount of 1.5 thousand millions SKK (US=41 Sk) is needed for recovery measures. The poster demostrates the effect of air pollution on a model territory in Turcianska valley by means of foliar analyses and presents calculation of economic loss in forest stands due to air pollution.

Carbon exchange of forest at the ecosystem level: results over a three-year period from two contrasting ecosystems of the Italian Peninsula

Giorgio Matteucci, Giuseppe Scarascia Mugnozza, Riccardo Valentini
University of Tuscia, Department of Forest Environment and Resources (DISAFRI), Via San Camillo de Lellis, I-01100 Viterbo, Italy
Tel: +39-0761-357292, FAX: +39-0761-357389, Email: macchia@unitus.it

Keywords: carbon flux; energy exchange; carbon budget; Eddy covariance; Mediterranean forests; mountain forests

The question on global carbon cycle quantification and the role of carbon sequestration by vegetation has become increasingly important. Even if the uncertainties are decreasing, global estimates are, at the moment , unable to univocally assign the so called 'missing-sink' i.e. the uptake of a fraction of the CO_2 released in the atmosphere, to either the oceans or the biosphere. In the past the studies of exchange between vegetation and atmosphere have been carried out mainly by leaf, stem and soil level gas exchanges, within this decade, the developments in the eddy covariance theory and technique are starting to make routine the study of the interaction between vegetation and atmosphere at canopy and ecosystem level. The advantage of the technique is that it is possible to integrate the carbon fluxes at spatial scales of the order of ha to squared kilometers and at time scales of one or more seasons, allowing to determine the overall ecosystem fluxes and, finally the yearly carbon budget or Net Ecosystem Exchange (NEE), that is the amount of carbon stored in the ecosystem at the end of a year and can be considered as the terrestrial sink.

Within the framework of the project EUROFLUX, funded by the European Union, the carbon and energy exchanges by means of the eddy covariance technique have been monitored over 15 forest sites for the period 1996-1998. Two of those sites are located in Central Italy, where a Mediterranean evergreen oak forest (Castelporziano, 41º45’ N, 12º22’ E, 3 m a.s.l.) and a Apennine beech forest (Collelongo, 41º 45’ N 13º38 E, 1500 m a.s.I.) were studied.

At the first site, measurement started with the onset of the project (1996), while the beech forest is a long-term monitoring station, where our Department is performing ecological and silvicultural research since 1991. At this site, carbon fluxes are measured since 1993. Both sites are closed forest stands.

The result of the two sites will be presented and contrasted, with particular respect to the pronounced inter annual variability of carbon fluxes.

For the beech forest, profiting of different structural, micrometeorological and ecophysiological variables that have been concurrently measured with canopy fluxes, the ecosystem level measurements will be linked to leaf and canopy physiology and to microclimate, providing a frame of ecophysiological interpretation of canopy fluxes.

At both sites, the result of net ecosystem exchange obtained by canopy fluxes, will be compared to the productivity estimated with other techniques, like biomass growth (above and below ground), litter and soil organic matter decomposition.

Regional and yearly changes of flowering date in *Prunus yedoensis* studied for the observation by the Japan Meteorological Agency

Atsushi Nakashima, Shinobu Yabu, Shiro Nakao, Hiroyuki Yamada, Tatsuya Kushida and Hiroshi Nagata
Wakayama University, Department of Environmental Systems, 930 Sakaedani-Wkayama, 640-8510 Wakayama, Japan
Tel: +81-0734-57-8378, FAX: : +81-0734-57-8378, Email: nakat@sys.wakayama-u.ac.jp

Keywords: cherry trees; flowering date; phenology; environmental change*; Prunus*; air temperature

We investigated the yearly changes of the flowering dates in Japanese cherry trees of Someiyosino *(Prunus yedoensis*) from 1953 to 1996 in Japan, using for the data recorded by Japan Meteorological Agency. Monitoring sites were located between 30^{o}4'N and 43^{o}3'N regions. Since Someiyoshino is the grafted garden species, monitored plants have hereditary unity. They will tend to react similarly under the same set of environmental changes. The flowering dates changed year by year at every monitoring site. The flowering dates of the normal year at the sites from 31^{o}N. to 35^{o}N on the Pacific coast were not different from each other, especially at the sites below 33^{o}N. At northern regions from 35^{o}N to 42^{o}N, the flowering dates got late as gain for latitude. And the flowering dates in the very mild winter (e.g. in 1978-79) were earlier than that in the normal year, especially from 36^o-38^{o}N. At southern regions, the flowering dates in this year were greatly later than that in the normal year. Especially, in Tanegashima island (the most southern site of 30^{o}4' N), the flowering date was about 19 days later than that in the normal year. It was almost the same time as the flowering dates at about 40^{o}N sites, for example at Miyako. So, the earliest regions for flowering from 31^{o}N to 43^{o}N were around 36^{o}N sites, for example at Choshi. In this year, on the cost of Japan Sea from 32^{o}N to 42^{o}N, the flowering dates got late as gain for latitude. Inland sites had intermediate patterns between the two seacoasts. Another, we investigated the effects of the winter chilling on the release for dormancy of flower buds in *Prunus yedoensis*. The temperature at the time of flowering started came down as gain for latitude. And there was a negative relationship between the numbers of "the chilling days (daily mean temperature below 10^{o}C)" and the daily mean temperature at flowering started. Thus, the temperature conditions of flowering started came down for going as far as to meet chilling stimulation. It is considered that the decrease for winter chilling stimulation may cause to come up the flowering possible temperature. It is exhibited on the delay of flowering started at Tanegashima site in the mild winter. So the earth getting warmer may cause to the flowering periods to be later than today at southern regions. But at northern regions, it may not be short for chilling stimulation in the mild winter. So the earth getting warmer may cause to the flowering periods to be earlier than today at northern regions.

Estimation of obtaining a "zero" carbon balance for the forest of European Russia

Anatoly I. Pisarenko
Federal Forest Services of Russia, 59/19, Pyatnitskaya Str., 113184 Moscow, Russia
Tel: +7-095-230-8729, FAX: +7-095-233-0950, Email: leshoz@space.ru

Keywords: carbon budget; land-use change; afforestation; deforestation; forest cover

The forest area of the European Russia (ER) has decreased nearly by one third from 1695 to 1914, mainly because of transformation of privately owned forests into agricultural lands for cereal production. By end-17th century arable lands in the ER occupied nearly 8%, and forest - 50% of the total land area of the country. As human population grew, arable lands, hayfields and pastures extended, and forest lands decreased. According to historical chronicles and reports of the Ministry of Domain Properties (economic and statistical Atlas of ER development 1696-1914), the forest cover was 52.68% in 1696, 51.16% in 1725, 42.27% in 1861 and 35.16% in

1914. In 1998 forest were growing on 39.1% of the ER area.

During 300 years Northern regions of the ER practically kept their forest cover. By 1915 up to 91.8% of initial forests were conserved in (given present-day administrative units) Arkhangelsk and Vologda regions, and in the Republic of Komi; 80.6%-Perm R., 77.4%-in Novgorod, Pskov and St.-Peterburg R. In the beginning of 1998 the forest cover of the Arkhangelsk R. was 53.9%, Vologda R.

- 70.0%, Republic of Komi-72.1%, Perm R.-66.6%, Novgorod R.-64.1%, Pskov R.-38.1% and Leningrad R.-55.7%.

In Russia as a whole, relatively favourable climatic conditions for forest growth exist on 59% of land area, while in the ER 70% exists. Here, by end-20th century the spatial distribution of forests, agricultural lands and areas suitable for growing forests, but not agricultural crops, has been stabilised. Nevertheless, it needs to say that already since the first third of the 20th century ecological problems appeared in regions with low forest cover. In 1949 large-scale works begun on vast areas of the ER Southeast with the view of forest restoration and afforestation, in order to create artificial forests and forest belts able to maintain multiple natural functions: water protection, anti-erosion, sanitary, recreational, biological (preservation of wildlife habitats and biodiversity). This was called "State plan of nature transformation". Operations were done on working and reserved agricultural lands. By 1952 artificial forests were created in form of compact massifs and many kilometres long belts, their total area exceeded 1.2 million ha.

The results of this work are now especially important as we are searching for solution of the problem of establishing a "zero" balance for dynamics of atmospheric carbon accumulation in the system "emissions-sink". The forest planting should be considered as the most realistic possibility of a practical solution of this problem.

On the basis of methods worked out in All-Russian Research and Information Centre for Forest Resources (ARICFR) for determination of storage, average annual increment and carbon balance in Russian forest at the level of forest management units (leskhozes), a preliminary assessment of the carbon balance ws done for ER forests. The analyse shows that there is a large margin for forest restoration and growing in regions with "minus" carbon balance (Astrakhan, Volgograd, Veronezh, Lipetsk, Rostov Regions, Stavropol and Krasnodar Territories, republics of Ingushetia, Daguestan, Kalmykia-Khalm-Tangch). In order to achieve the "zero" carbon balance in these regions it needs to provide for an additional depositing of about 2 million tonnes of carbon per year. To do it, one must replant nearly 2.5 million ha. It is a difficult task, but its scale is comparable with work of 1950s. Moreover, it is necessary to reduce emissions into the atmosphere through improving forest protection (including measures of fire fighting, control of pests and diseases, of AAC, improving technologies of harvesting, processing and wise use of forest products, etc.), such as measures being well grounded by a preliminary evaluation of profit/expenses ratio for carbon sequestration deal.

A general equation of relationship between forest evapotranspiration and climatic factors

Deying Xu
Chinese Academy of Forestry, Forest Ecology and Environment Institute, Wan Shou Shan, 100091 Beijing, China
FAX: 86-10-62881937, Email: deyingxu@fee.forestry.ac.cn

Keywords: forests; actual evapotranspiration; model; climatic factors

Forest evapotranspiration (EPT) is one of the important components in the forest hydrological balance, taking 30-95% of precipitation. There has been a large amount of literature on this context. However, a general equation for calculating the actual EPT for forests under various natural conditions has not been available owing to multiple factors involved. Forests are such rough surfaces that the methods based on active surface characteristics, such as Penman-Monteith equation, are difficult to apply, because of the difficulties in obtaining aerodynamic parameters and other surface resistance parameters.

In this paper 65 samples of EPT data resulted from the differences between precipitation and runoff for the temperate forests, and 35 samples for the tropical forests have been collected and analyzed. The author found that when merely the EPT and precipitation are taken as the variables, no good relationships could be established. And there are no good relationships between the ratio of EPT over precipitation and the forest species, because that the ratio depends on the precipitation intensity.

However, when the evapotranspiration ratio (the ratio of EPT over precipitation) and precipitation were taken as the interdependent variables there was a relatively fine relationship. And further the dots for tropical forests and temperate forests were separately treated and two dots with extreme values are deleted, then much better relationships appeared. The two curves were separately fitted for the temperate forests and tropical forests as follows

Temperate forests: Y= 0.9734exp(-0.0004X) (R2=0.5187) Tropical forests: Y=1.4338exp(-0.0004X) (R2=0.741) in which Y is the ratio of actual EPT over rainfall, and X is rainfall in mm.

Good relationships existed between the rainfall and the ratio of EPT over rainfall. And the equation for the tropical forests is better than temperate forests. Further suggestions on improving this model have been proposed by the author. Finally the Turc equation were used to make comparisons with the calculated EPT in this model.

8.09.00 Human impacts on tropical rain forests with long term view

Comparison of canopy gap dynamics between unlogged and selective logged forests

Naoki Adachi, Toshinori Okuda, N. Manokaran
Forest Research Institute Malaysia (FRIM), Kepong, 52109 Kuala Lumpur, Malaysia
Tel: +60-3-630-2355, FAX: +60-3-636-7753, Email: naoki@pc.jaring.my

Keywords: Malaysia; gap dynamics; tropical rain forests; logged and unlogged forests; aerial pictures

A tropical rain forest is considered as a mosaic of patches of different developmental phases as seen in a temperate or boreal forest. When a tall canopy tree or an emergent tree falls down, a canopy gap is created. Seedlings or saplings of some species can grow only in such gaps, because they cannot even survive under closed understory where light intensity is extremely low. Therefore, gaps trigger the establishment and enable the regeneration of these species and analyzing the dynamics of canopy gaps is essential to understand the dynamics of the forest. Since the size distribution of standing trees is much different in logged forests and natural unlogged forest, it was expected that frequency, size distribution and other features of canopy gaps were also different between them.

In order to reveal such difference between unlogged and logged forests, we have analyzed the canopy gap dynamics in Pasoh Forest Reserve (State of Negeri Sembilan, Peninsular Malaysia) using aerial pictures taken above the forest. The analyzed unlogged forest is the eastern 38 ha of the core area (50 ha plot). For this area, aerial pictures were available both for May 1995 and February 1997.

Stereo-pair pictures were used to determine the canopy elevation. Then, canopy height was calculated by subtracting the ground elevation from the canopy elevation. Areas whose canopy height was below 15 m were regarded as canopy gaps and all the individual gaps larger than the minimum recognizable size (6.3 m^2 =1 cell) were followed. As a selective logged area, 6 ha plot south-west to the former area was analyzed. Aerial pictures were taken in 1998 for this area and the pictures were processed in the same manner.

In the unlogged forest, 509 gaps (= 13.4/ha) existed as of 1995 and the number of gaps decreased to 463 (= 12.2/ha) in 1997, which accounts for 7.9% and 6.9% of the whole area, respectively. Size distributions of gap were J-shaped with extreme aggregation in small size in both years. The mean gap size was 84.0 m^2 and 72.2 m^2 in 1995 and 1997, respectively, while the median size was 18.8 m^2 in both year. On the other hand, the logged forest found 28 gaps in 6 ha (= 4.7/ha), which was 5.5% of the whole area. Though the mean size was 119.4 m^2 because of one exceptionally large gap (1400 m^2), the median was 15.6 m^2, which is slightly smaller than that of the unlogged forest. If the largest gap was omitted, the mean and the median were 72.0 m^2 and 12.5 m^2, respectively.

Therefore, it is suggested that the logged forest has less number and area of canopy gaps than the unlogged natural forest. This may be ascribed to the difference in tree size compositions; logged forests have only immature and shorter trees than in unlogged forests. It is also predicted that the frequency of gap formation is much lower in logged forests. These difference of gap size, area, and frequency are expected to affect greatly the regeneration of whole tree species, not only light-requiring ones but also shade-tolerant ones, by altering the microenvironments in the forest.

Effects of tree falls on diversity of wood decay fungi

Tsutomu Hattori, S. S. Lee
Tokyo Noko University, Faculty of Agriculture, 3-5-8 Saiwai-cho, 183-8509 Fuchu, Tokyo, Japan
Tel: +81-42-367-5719, FAX: +81-42-334-5700, Email: hattori@cc.tuat.ac.jp

Key words: biodiversity; rainforest; tree fall; wood decay fungi

In the previous studies, we revealed that florae of wood decay fungi on substrata are affected by diameter, tree species, and decay process of the substrata. Therefore, it is suggested that presence of various types of substrata may increase the diversity of wood decay fungi. In the Logged Plot with intensive logging in the past established in Pasoh Forest Reserve, a lowland rainforest of

the West Malaysia, diversity of wood decay fungi is lower than the diversity in the Unlogged Plot established in the same site. Less newly fallen trees with large diameter and old fallen trees exist in the Logged Plot, and few species restricted on large substrata and well-decomposed substrata are seen in the plot.

Here, we made a comparative study of the diversity of wood decay fungi between the areas with and without recent tree falls within the Ecological Plot 1 (EP1), situated in an unlogged area of Pasoh Forest Reserve. EP1 was divided into 200 subplots (10 x 10m). These subplots were classified according to the presence of tree falls accompanying gap formation on and after 1992 as follows:

subplots with tree falls on July 1995 (93G, 5 subplots); those on 1993-1995 (3 subplots); those on June 1995 (95G, 29 subplots); those with few effects of intensive tree falls (NG, 159 subplots). Occurrence and frequency of each wood decay fungi was recorded in each subplot on August 1995, December 1995, December 1996 and December 1997. Taxa of wood decay fungi examined here were Erythromyces crocicreas and Stereum ostrea in addition to all species of lignicolous polypores.

Total frequency of wood decay fungi specific on small twigs (ramicolae) was almost same in 95G and NG each year, and few fluctuation was observed in both of the subplots. On the other hand, total frequency of non-ramicolous fungi distinctly increased between August 1995 and December 1996 then slowly decreased after December 1996 in 95G while almost no fluctuation was seen in NG. Species number of wood decay fungi was also increased from August 1995 to December 1996 in 95G. It is suggested that diversity of wood decay fungi be maintained by occurrence of tree falls.

This suggests that high species diversity in unlogged areas is attributed to the presence of several non-ramicolous fungi in the parts with recent tree falls, and high species diversity is expected for some years after the tree falls. Because of the frequent tree falls, thereby creating a larger variety of woody substrates, high diversity of wood decay fungi can be maintained in unlogged forests. However, in logged forests with intensive logging in the past, fewer tree falls are expected because of the limited number of emergent trees and this reduction in the variety of woody substrates could result in the loss of some rare fungus species from the forests. Intensive logging may therefore induce a reduction in the diversity of decay fungi in the future although flushes of some fungi may occur just after logging.

Ecology of wind dispersal of fruits of dipterocarp species in Pasoh Forest Reserve

Ichikawa, San'ei, Kachi, N., Tani, M., Sasaki, S., Niiyama, K., Yasuda, M., Tang,Y-H., Manokaran, N.
Japan Science and Technology Corporation, 229-3 JWRC Yushima, Bunkyoku, Japan
Tel: +81-3-3813-8897, FAX: +813-3813-8898, Email: ichikawa@haken.jst.go.jp

Keywords: *Dipterocarpus;* regeneration; seed shadow; tropical rain forest; wind dispersal

We examined the effects of wind dispersal on the regeneration process in some dipterocarp species. Fruit dispersal provides an opportunity for terrestrial plants to "move" their living sites. To examine the ecological significance of wind dispersal of fruits during an early stage of tree regeneration in tropical rain forests, we estimated the fruit shadow for individual trees at the event of mass fruiting in 1996 in Pasoh Forest Reserve in Peninsular Malaysia.

We monitored the development of fruits and the wind speed at horizontal directions on a tower at a height of 51 m during the period of fruit dispersal in 1996. We determined the descending speed of fruits, which were manually released, from the height of 13 m on the tower. Based on these data we estimated the fruit shadow for individual mother trees.

We directly determined the dispersal area of fruits around individual mother trees that sporadically fruited in December 1997 and in September 1998. We also measured spatial variations in the diffuse site factor around the mother trees to assess the light conditions of germinated seedlings. We observed seedling establishment around the mother trees in 1998, 2 years after the mass fruiting.

It was suggested that the descending speed of fruits under little or no wind at horizontal directions was faster than that under strong winds. The size of the fruit shadow of a 40-m tree was approximately three times larger than that of a 30-m tree. Under a condition of the horizontal wind speed of 5 m/s, fruits dispersed from a 40 m height were expected to reach beyond the shadow of the canopy of a mother tree, where the light conditions for seedling growth were more likely better compared with the sites under the canopy. The 2 year-old seedlings were not always established well at the distance of the highest fruit density on the ground and the establishment was partly influenced by the local light conditions. We will also demonstrate the mechanism of wind dispersal of fruits and discuss the role of fruit dispersal for seedling establishment of dipterocarps.

Leaf gas exchange characteristics of pioneer and late successional species

Keywords: photosynthesis; transpiration; stomatal conductance; water use efficiency

Seedlings raised under shaded and well-watered conditions in the nursery are susceptible to water stress when planted in the open because of their reduced ability to cope with drought. Thus, keeping transpiration low in order to avoid excessive water loss is important for survival of the transplants. However, closing stomata to reduce transpiration also may cause limiting photosynthesis, which is essential for growth. Therefore, information on stomatal gas exchange such as balance between the release of water vapour and uptake of CO_2 is important to assess adaptability of seedlings to drought. In this study, net photosynthetic rate (A) and stomatal conductance (G) were measured for 25 tropical tree species including both pioneer and late successional species. Diurnal changes of A, G, and transpiration rate (E) of leaves were also studied for seedlings of one dipterocarps, *Hopea odorata* and two pioneer species, *Acacia auriculiformis* and *Tectona grandis*, planted on sandy tin-tailings. Based on the results, gas exchange properties were compared among species in order to classify them according to the adaptability to drought. A was lower in the dipterocarps, generally known as late-successional species, than in the pioneer species, but water use efficiency (WUE, A/g) was not different between the dipterocarps and the pioneer species. Highest A was observed in A. mangium and *A. auriculiformis*, both well known as fast-growing pioneer species. Other fast-growing species like *Tectona grandis, Endospermum malaccensis, Cinnamomum iners*, and *Azadirachta excelsa* showed relatively high A. High A was also observed in the relatively fast-growing dipterocarps like *H. odorata* and *Shorea assamica*. High A in *S. assamica, T. grandis, A. mangium, E. malaccensis*, and *C. iners* was mainly due to high G, suggesting that these species may require large amount of water to maintain their rapid growth. When the seedlings planted on the sandy tin-tailings were exposed to direct sunlight during midday, both A and G decreased in all the species studied. Such midday depression of A and G was more remarkable in *Hopea odorata* than in *A. auriculiformis* and *T. grandis*. T. grandis maintained relatively high G even in the afternoon when vapour pressure deficit largely increased, resulting in extremely high Tr and visible wilting of the leaves. Such lack of drought avoidance of this species may cause frequent dieback of the seedlings planted on the sandy tin-tailings.

Edge effects on the nest predation and avian community in Pasoh Nature Reserve

H. Nagata, Zubaid Akbar and Azarae Hj Idris
National Institute for Environmental Studies, 16-2 Onogawa, Tukuba, 305-005 Ibaraki, Japan
Tel: +81-298-50-2493, FAX: +81-298-50-2493, Email: hnagata@nies.go.jp

Key words: bird community; edge effect; predation pressure; artificial nest

Tropical lowland rainforest have drastically decreased and fragmented in last few decades in Peninsula Malaysia. Habitat fragmentation will increase the amount of edge relative to the amount of interior habitat, and will enable omnivorous predators to increase in numbers, and to disperse into the interior of habitat. In order to detect edge effects on avian community in the Pasoh Forest Reserve, monthly netting have been started at the core area since 1992 and at the boundaries since 1996. The Pasoh Forest Reserve is small isolated forest surrounded by oil palm plantations, though virgin forest is still remaining in the core area. Totally, mist-net operations were carried out for 4,319 net days, and 1,168 birds belonging to 93 species were captured during the study period.

All captured birds were measured and banded with a uniquely numbered aluminum ring, and released beside net site captured. The abundance of understory birds among study plots was almost identical, and the species diversity was dropped at forest edge. Insectivorous ground forager like babblers, Timaliidae, were decreasing from the core to the boundary of rainforest, and nectarivore and frugivore like sunbirds, Nectariniidae, and bulbuls, Pycnonotidae, were oppositely increasing at the boundary. If edge effects occur, higher predation pressure is expected in the peripheral area than core area of rainforest. In order to evaluate predation pressure, 862 experimental nests with a few quail eggs were set in the understorey. A couple of nest was set near netting sites, and was monitored until depredated for 4 days. An automatic triggered camera set was placed near the nest to confirm predators, when quail eggs were depredated. Proportions of experimental nest depredated became higher according to approaching to forest edge. This result showed that predation pressure was severer near forest edge than the core area. Automatic triggered camera set revealed that pig-tailed Macaque, common treeshrew and short-tailed mongoose were predominant predators In summary, species diversity of understorey birds in Pasoh will be gradually decreasing from the core to the boundary, because predation pressure on birds building the nest on the ground is increasing near forest edge. It might be a reason why ground foragers like babblers are decreasing from the core to the boundary.

Comparisons of tree species diversity, composition, and population structures between primary and regenerating forest plots in a hill dipterocarp forest

Tel: +81-298-73-3211, ex.356, FAX: +91-298-73-1542, Email: niiya@ffpri.affrc.go.jp

Key words: hill dipterocarp forest; regenerating forest; species diversity

A large area of tropical rain forests in the southeastern Asia was already disturbed by logging, fires, and many other artificial activities. To manage and improve these disturbed forests was an important task for foresters. Logging is now continued in hill forests under the Selective Management System in Malaysia. However, regeneration success of timber trees was not confirmed and the impact of logging on the community and population levels was not fully investigated.

Species composition, diversity, and population structures of common tree species were compared between a 6-ha primary (natural forest) plot and a 4-ha regenerating (logged forest) plot in , Peninsular Malaysia. The primary plot was established in a hill dipterocarp forest in Semangkok Forest Reserve in 1993, and the regenerating plot was established in the selectively logged site neighbouring to the reserve in 1994. Logging was carried out in 1989. All young and mature trees larger than 5 cm d.b.h. (diameter at breast height) were tagged, identified and their g.b.h. (girth at breast height) were measured.

Total number of species was larger in the primary plot (464 species) than in the regenerating plot (421 species). In the primary plot, 170 of 464 species were specific to the plot, and 127 of 421 species were specific to the regenerating plot. Total numbers of families and genera were larger in the regenerating plot. In the primary plot, species richness (number of species) was as follows; gamma=464, alpha=26.7, and beta=0.12.

In the regenerating plot gamma=421, alpha=26.2, and beta=0.16 where gamma (total richness) = alpha (mean richness) x beta (turn over rate).

Species diversity H' was slightly larger in the primary plot (H'=5.28) than in the regenerating plot (H'=5.13). Species evenness J' was similar in the primary (0.86) and in the regenerating plots (0.85).

Although these species diversity indices were not largely different each other, the composition of common 30 tree species remarkably altered between the plots. *Shorea curtisii*, which is the most important timber tree in the hill forests, was dominated in the primary plot. *Macaranga triloba* was the only light demanding tree species among the 30 common species in the primary plot. On the other hand, pioneer or secondary tree species of families Euphorbiaceae, Verbenaceae, Melastomaceae, and Elaeocarpaceae occupied the half of 30 common tree species in the regenerating plot.

Size structures of emergent tree species (*Shorea curtisii*), canopy tree species (*Antidesma cuspidatum*) and typical light demanding tree species (*Macaranga triloba*) were compared between the two plots. Size structure of *Shorea curtisii* changed by selective cutting, but those of *Antidesma cuspidatum* and *Macaranga triloba* were not largely changed. Relative growth rate (RGR) of *Shorea curtisii* based on basal area at breast height in the regenerating plot was three times larger than that in the primary plot. On the other hand, RGR of Macaranga triloba was similar in both plots. These were results of short-term study during four years. We need a more long-term ecological study to predict the community dynamics of regenerating forest and to improve the management system in the hill forests.

Rainfall-runoff responses to storms at Bukit Tarek Experimental Watershed, Peninsular Malaysia.

Shoji Noguchi, Abdul Rahim Nik, Zulkifli Yusop, Baharuddin Kasran, M. Tani, Y. Tsuboyama and T. Sammori
Forestry and Forest Products Research Institute, P. O. Box 16, 305-8687 Ibaraki, Japan
Tel: +81-298-73-3211, FAX: +81-298-74-1543, Email: noguchi@ffpri.affrc.go.jp

Keywords: tropical rain forest; rainfall-runoff responses; stormflow; soil moisture

Hydrological observations were conducted at Bukit Tarek Experimental Watershed in Peninsular Malaysia to investigate the relationship between rainfall-runoff responses and variation in soil moisture in a tropical rain forest. There was a distinct diurnal cycle in precipitation at Bukit Tarek, where about 60% of the rainfall occurred between 13:00 and 19:00h. The sine wave, which was decomposed by Fourier transform consisting of 24-h, 12-h, and 8-h cycles and applied to the observed data, was useful (r=0.97) in order to re-evaluate the diurnal cycle of precipitation. The amount of rainfall in each rain event ranged from 1.0 to 96.0mm with mean of 14.3mm. The rainfall was characterized by short duration and high intensity: about 55% of rain events fell within 1-hour periods, testifying to the predominantly convectional storms. There was a high positive correlation (r=0.95) between amount of rainfall in each rain event and maximum hourly rainfall intensity during rain event. The saturated hydraulic conductivity (Ks) decreased with increasing soil depth. The macro- and meso-porosity of the soil also decreased with increasing soil depth. The Ks values were higher than those reported for other tropical soils. The geometric means of the Ks values ranged from 4.69 x 10-3 (80 cm) to 4.07x10-2 cm/s (10cm). This suggests saturation overland flow may not be dominant but that subsurface flow must play an important role in stormflow generation. Stormflow depended strongly on the antecedent wetness as represented by the initial runoff rate.

Though heavy rains fell in almost every month, the soil moisture decreased when fair weather was sustained. The soil moisture depleted and became dry at 160 cm depth during occasional dry spells. During dry conditions, streamflow responded quickly to rain events but declined rapidly after the rain stopped, and the soil moisture of surface soil (<20 cm) increased but remained dry at lower depths (>80 cm). This suggests that the rainwater was mostly retained in the soil and only small proportions appeared as stormflow. As soil moisture conditions became wetter, the recession limb of the storm hydrograph was more gradual. Stormflow volume increased with increasing soil moisture. During wet conditions, the soil profile was moist at all parts of the slope. The hydraulic gradient was around 1.0 and there was downward soil water flux, which followed the pressure gradient. This suggests that subsurface flow from the upper part of the slope might also be important for streamflow production. The behavior of the subsurface flow might be an important determinant of stormflow.

Leaf dynamics of dipterocarp seedlings in a primary and secondary forest in relation to the effects of leaf herbivores and light conditions

Shinya Numata, N. Katchi, T. Okuda, N. Manokaran
National Institute for Environmental Studies (NIES), Onogawa 16-2, Tsukuba, 305-0053 Ibaraki, JAPAN
FAX: +81-298-50-2483, Email: numata.shinya@nies.go.jp

Keywords: dipterocarps; forest regeneration; leaf dynamics; light environment; Peninsular Malaysia

Logging is one of the major human disturbances to natural forests. Selective logging, in which only the large-sized trees are felled, is a typical logging treatment to obtain timber products. Selective logging causes significant changes in forest structure such as size distribution and species composition. For example, variances in tree size distribution tend to be decreased by the removal of large-sized trees. These changes in the forest structure affect physical and biological environments at the forest floor, where successful regeneration of tree species is to be expected.

During the process of regeneration of tree species in a forest, seedling establishment is a critical stage, because seedlings suffer high mortality risk in their life. Seedling survival and growth are affected by several abiotic and biotic factors. Improvement of light environment caused by canopy gaps has been particularly emphasized for regeneration of canopy tree species, because light intensity is a major limiting resource at a forest understorey. On the other hand, herbivory and disease frequently exert a major impact on seedling establishments. Leaf damage by herbivores and pathogen diseases reduce growth and survival of plants. To examine seedling regeneration, information on the leaf dynamics is essential, because their growth process is basically determined by the photosynthetic production of individual leaves. In this study, we examined leaf dynamics and damages of seedlings of six dipterocarp species growing in the understorey of selectively logged and primary forests to estimate the effects of selective logging on the regeneration processes of dipterocarp species.

Our study was conducted in a lowland rain forest at Pasoh in Negeri Sembilan, Peninsular Malaysia. Two ecological plots (2-ha each) established in a primary forest and a secondary forest which was logged in 1950's were used for the study. One hundred subplots (1 x 1 m) were set regularly in each 2-ha plot. In every subplot we marked individual leaves of seedlings of six dipterocarp species to estimate plant growth and leaf dynamics. We also determined light conditions at the 1.0 and 0.5 m height on the all plots by taking hemispherical photographs.

Firstly, we analysed the effects of logging on leaf dynamics (leaf production rates, leaf loss rates, and net leaf gain rates) and damages (percent of heavily damaged leaves for individual seedlings). While there were significant differences in leaf production and loss rates among the six species, net leaf gain rates were not significantly different among species. Effects of logging on leaf production and loss rates, and percentages of heavily damaged leaves were still detectable even more than 40 years after logging practice, while the trends of the effects of logging were significantly different among the six species.

Secondly, we compared understorey light environments between the logged and the primary forests. Estimated canopy openness and photosynthetically photon flux density indices of the logged forest were higher than those of the primary forest. Two slower-growing species showed significant relationships between leaf demographic parameters and light environments. This result may suggest that changes in light environments caused by logging would favor for the regeneration of slow-growing species, whereas fast-growing species would require large gaps which are produced more frequently in a primary forest than in a logged forest.

Effects of disturbance by selective logging on occurrence of termite species

Kenzi Takamura, Laurence G. Kirton
NIES, 16-2 Onogawa, Tsukuba, 305-0053 Ibaraki, Japan
Tel: +81-298-50-2470, FAX: +81-298-50-2493, Email: takaken@nies.go.jp

Key words: dead wood; termite; *Hospitalitermes; Macrotermes*; Selective logging

In order to know how the disturbance by selective logging affects occurrence of termites in tropical lowland rain forest, soldier individuals as well as worker ones of termites were collected from the dead wood both in the undisturbed and disturbed sites of the Pasoh Forest Reserve, Pahang, Malaysia. Free-ranging termites of the genus *Hospitalitermes* which walked in lines on the ground and foraged on living tree trunks in the morning were also censused and collected.

The total number of dead wood pieces searched was 73 and 43 in the undisturbed and the disturbed site, respectively. Termites were found from 34 and 25 wood pieces in the undisturbed and the disturbed site, respectively. In most of the other pieces from which no termites were collected, soil-fills constructed by termites were found. These results indicate that most of dead wood on the forest floor was utilized by termites. Termites collected from dead wood counted up to more than seven and six species in the undisturbed and the disturbed site, respectively. The fungus-growing termite *Macrotermes malaccensis* occurred predominantly both in the undisturbed and disturbed sites, but it was more predominant in the latter, thus lowering the diversity of termite fauna in dead wood at that site.

A total of 20 colonies of *Hospitalitermes* were found in the undisturbed site, while 12 colonies were found in the disturbed site. The number of colonies with observed foraging activity at one morning was generally higher in the undisturbed site than in the disturbed one. These census results show that the activity of *Hospitalitermes* termites was lower in the disturbed forest than in the undisturbed one. In the undisturbed site, the frequency distribution of tree diameters at breast height was compared between all trees and the trees where foraging of Hospitalitermes termites was observed. The frequency of foraging-site trees was the highest in the diameter range of <30 cm and the second highest in the ranges of 50-70 cm. The second-highest frequency was disproportionately higher compared with that of all trees. This indicates that Hospitalitermes prefers large trees that are rare in the forest as a feeding site. This preference may be one of the major reasons why the activity of

Hospitalitermes was lower in the disturbed forest where large trees had been logged.

Micrometeorology of a tropical rain forest at Pasoh, Peninsular Malaysia

Makoto Tani, Abdul Rahim Nik, Y. Ohtani and Zulkifli Yusop

Tel: +81-298-73-3211 (ext384), FAX: +81-298-73-1542, Email: tani3@ffpri.affrc.go.jp

Keywords: tropical rain forest; micrometeorology; albedo; ENSO

Data sets on meteorology in a tropical rain forest are important not only as a background of ecological studies conducted there but also for understanding its influences on the environment at local and global scales. Micrometeorology was continuously monitored at a lowland mixed dipterocarp forest in the Pasoh Forest Reserve , which is located near Simpang Pertang in Negeri Sembilan about 140 km south east of Kuala Lumpur in Peninsular Malaysia. A 52 m observation tower was used for this monitoring. The continuous canopy height was about 35 m, although some emergent trees exceeded 45 m. The leaf area index (LAI) was 6.52. The climatic variables such as downward and upward solar radiation, net radiation, air temperature, humidity, wind velocity and direction, and rainfall have been measured at the top of the tower continuously since March 1995. Vertical distributions of air temperature, and humidity were also measured in a short period in 1995.

Vertical distributions of air temperature show that temperature differences within canopy were small and recorded a low near the forest floor in the daytime. This could be attributed to the complex and wide canopy structure. Vapor pressure decreased with elevation and this suggests that the latent heat seemed to be carried upward throughout a day.

Seasonal variations of climatic variables were monotonous under the climate of tropical rain forest. The albedo was about 0.12 and the seasonal variation was not clear. Wind velocity was weak except at the time just before a short and intense storm in the afternoon. Two rainfall seasons reflecting the southwest and northeast monsoons were found from March to May and from October to December, respectively. However, rainfall was remarkably large in the latter monsoon season whereas that in the former monsoon season was not prominent. This tendency caused a large solar radiation with high air temperature and dry humidity in the earlier half of each year and a small solar radiation with low air temperature and wet humidity at the end of each year. During the observation periods, the amount of rainfall was large only in the year of 1995, and it was small in each year of 1996, 1997 and 1998 compared to that in a common year. This result depended strongly on an ENSO episode which caused a huge forest fire in Indonesia. One of the effects of the fire on this site was recorded as decreasing of solar radiation caused by the haze in September 1997. The driest condition with large values of vapor pressure deficit was shown later in April 1998. The monitoring results suggest that this natural forest is maintained by a comparatively small amount of rainfall considering a climate of tropical rain forest with constant large radiation energy.

Logging effect for genetic diversity of Shorea ciurtisii forest in the hill dipterocarps forest of Peninsular Malaysia

Y. Tsumura, T. Kawahara, T. Ujino, T. Nagamitsu, H. Yoshimaru, Norwati Muhammad, Chai-Ting Lee and Lee Soon Leong

Tel: +81-298-73-3211, FAX: +81-298-73-3795, Email: ytsumu@ffpri.affrc.go.jp

Keywords: dipterocarps; inbreeding; macrosatellite; mating system; regeneration

Tropical rain forests have been becoming fragmented into small patches or simplified in structure and composition by exploitation for timber. The resulted fragmentation may reduce the genetic diversity of future generation in each species. While plant have evolved the flower and inflorescence characters to attract particular animal pollinators which then convey pollen from flower to flower. If the pollinators can move between the small patches without hesitation due to the attractive flowers, the genetic diversity of the species may maintain for the future. The majority of tropical trees examined are insect pollinated and predominantly outcrossed. However, the mechanism for maintenance of relatively high genetic diversity in tropical tree species is not still clear.

Mating systems of some tropical tree species have been investigated using allozyme. These results indicated that the average outcrossing rate of tropical species are more than 80%. Murawski and Hamrick (1991) reported that positive correlation between outcrossing rate and flowering tree density for tropical tree species. They suggested that the synchronized mass-flowering which promoted the effective movement and development of pollinator population even in the secondary forest kept the same level of outcrossing event. These results suggested that the relationship between the density of flowering tree and pollinator behavior is much important for success of mating, however, there is no clear explanation for them. *Shorea curtisii* Dyer ex King is an emergent and canopy tree in the hill dipterpcarp forest of Peninsula Malaysia. In tropical region, selective logging has been conducting for the sustainable forestry, and this species also one of the targets in Malaysia for consumption as a construction timber. This kind of logging is making the fragmentation for this species. For low-density population such like selectively logged forest, therefore, key questions are how much genetic diversity still have kept in the forest and whether healthy regeneration of this species is expected. Recently, microsatellite DNA markers have applied to study the gene flow within forest because these markers can be determine the parental individual with a high probability. In this paper, we discuss for the outcrossing rate and disturbance effect for genetic diversity of *Shorea curtisii* in hill dipterocarpas forests from the results using microsatellite analysis. We also compared the genetic diversity, outcrossing rate and pollen flow between undisturbed and disturbed forests. Genetic diversity and outcrossing rate of *Shorea curtisii* (Dipterocarpaceae) were investigated in undisturbed and disturbed forests using the microsatellite analysis. The heterozygosity, the number of alleles per locus and the proportion of polymorphic loci were not different significantly between two forests. To estimate the outcrossing rate, seeds from 11 and five individuals were analyzed in undisturbed and disturbed plots, respectively. The average outcrossing rate of undisturbed forest was 87.7%, which was similar as the former reports of dipterocarps species with isozyme analysis. However, the disturbed forest was 40.9%, which was remarkably lower than that of undisturbed forest. This decline of outcrossing rate in disturbed plot was considered to be strongly affected by the density of flowering tree with four-fold difference and the behavior of main pollinator of this species.

Keywords: Russian forest fires; light forest; dark forest; succession

The area of the forest stock in Russia, including forests transferred to the permanent use, according to the calculation made in January 1, 1993 is 1180,9 million ha. Burned-out forests, cuttings, swamps and hayfields are also included into this territory. Forests proper take the area of 705,8 million ha; 507,7 million ha are covered by coniferous species: larch (52%), pine (22,5%), spruce and fir (17,8%), and cedar (7,7%). Acerous leaves (needles) and timber of these species contain essential oils and colophony, that is why they are too flammable (susceptible to fire). Russian forests have a multiple-aged structure: undergrowth-22%, middle-aged-33%, maturing-11%, mature and overmature-34%. Formation of such forest structure was influenced by industrial cuttings; but the main factor of taiga forests formation is forest fires. According to the official statistics their number varies from 13,4 thousand (1987) to 31,3 thousand (1997); the area of forests, subjected to fires -from 569 (1987) to 2450 (1998) thousand ha. Pine and larch forests of the North, Siberia and Far East, growing on the drained, rising grounds are mostly subjected to fires. The average temporal interval, during which these forests may undergo low fires is 30 years. In the course of this period the critical amount of combustibles, able to catch fire in hot dry weather and keep burning, is accumulated under the forest canopy. Spruce young growth, which is a constant competitor to pine and larch, burns out in low forest fires. Dark-colored spruce-fir forests grow on the low areas with damp (moist) soils close to subsoil waters. That is why fires can hardly occur in these forests even in the short-term periods of drought. In case of fierce droughts, occurring every 70-90 years, when caught by fire spruce-fir forests burn out completely, without any young growth left. Due to this reason their further reforestation goes, as a rule, through the change of species, that is, at first, the process of regeneration of cutover stands by broad-leaved species (birch and aspen) takes place, and only then young spruce and fir sprouts start growing. In the light-colored coniferous 30 year-old forests low fires, which do not cause damage to them, prevail. These fires play the role of thinnings, by means of taking away weakened trees and those falling behind in growth, providing the rest of trees with optimum light condition and space for roots development. In the permafrost region of light-colored coniferous forests low fires destroy the mossy cover, warming overburden layers. After fires the level of permafrost goes down, but the power of root layer increases, providing conditions for significant increment of trees. It is found out that successful reforestation of pine and larch can be possible only as a result of low fires, destroying thick mossy cover and debris layer. With the average interval between fires of 30 years and the mean age of mature and over-mature forest crops in the boreal forests of 150-200 years, every crop is subjected to low fire as many as 4-7 times during the period of its growth before it is completely replaced by young growth. Only top fires may happen on the areas covered by coniferous young growth, but they lead to the complete damage of the latter. By the way, pine undergrowth is mostly subjected to fires. Dead larch undergrowth cover burns out only in the periods of drought, accompanied by strong wind. Artificially planted even-aged coniferous crops seldom happen to grow till their natural decomposition. On the contrary, wild multiple-aged forests, formed by fire during millions of years, not only survive in the temporal fire weedings, but even improve, becoming more fire-resistible. We have a powerful overland and aviation forest service, which protects forest stock territory on the area of more than 700 million ha. With the help of aviation, tele-and infrared equipment, and data obtained from artificial Earth satellites, forest service detects and eliminates considerable number of forest fires in proper time. But we should admit, that these activities do not exert great influence upon the general amount of forest fires. On the contrary, eliminating forest fires we favor the accumulation of combustibles under the forest canopy, which may cause destruction of the crop in case of fire. Every year in two or three regions of the country fire passes through the area of 1-2 million ha. Coordinates of these regions, time of fires origin, their number and extent of the burned out territory are programmed by nature itself, but it is still beyond our capacity to make a prediction in advance. Specialists in the field of fire fighting assure, that fire behavior in the forest is unpredictable. It is necessary to carry out a thorough and detailed research of this natural phenomenon, to reconsider our hostile attitude to the fire and to start using it as an ally.

An analysis of forest fire behaviour based on estimation of wind direction and wind velocity at the time of the fire

Shoji Inoue
Ehime University, Tarumi 3-5-7, 790-8566 Matsuyama, Japan
Tel: +81-89-946-9875, FAX: +81-89-946-9875, Email: inoue416@dpc.ehime-u.ac.jp

Keywords: forest fire; fire behavior; wind direction; wind velocity; stem-bark char

Wind direction and wind velocity data are necessary to analyze the behavior of forest fire and its propagation. It is possible to obtain prevailing wind data from weather stations but not the characteristics of fire whirlwind at the site of the forest fire unless we measure it at the time of the fire.

This paper presents a procedure of estimation of wind direction and wind velocity from the stem-bark char remained at the forest fire damaged area. In this investigation, in order to clarify the relation among the factors affecting fire-scar of stem, wind tunnel experiments were carried out. And in order to establish how to predict the forest fire behavior, field experiments were carried out using opportunities of prescribed fire.

In the wind tunnel experiments, it was observed that the height of stem-bark char registered at the windward face of a stem is smaller than that of the opposite face of a stem under all the experimental conditions. Therefore, an estimate of wind direction from the remaining stems in a burned field can easily be done.

Further it was found that, the height of stem-bark char of windward face of a stem decreased as the wind velocity increased. The height of stem-bark char of a stem opposite the windward direction increased as the diameter of the stem increased. It was derived from these results that the magnitude of the difference in height of stem-bark char of windward face and opposite face of a stem was an important factor for estimation of wind velocity. From a viewpoint of field application, stem-bark char ratio of both faces of a stem tends to be significant as well as the difference in height of stem-bark char of both faces, because of the dissimilarity of scale in wind tunnel experiment and actual phenomena in the field. Dimensional analysis was carried out for the factors affecting the stem-bark char using the observations mentioned above. Based on the results of the study, the equations for estimation of wind velocity were proposed when the stem partially burned.

In the field experiments, first, the wind velocity calculated by experimental equations was compared with wind velocity observed in two prescribed fire sites. It was observed that the wind velocity could be expressed with a high accuracy by the above-proposed equations.

When the fire behavior was an upslope fire, the fire whirlwind directions estimated from the stem-bark char showed a fixed direction. Fire whirlwind direction agreed approximately with slope azimuth, in spite of a prevailing opposite wind direction. Further relationship between fire whirlwind velocity estimated by experimental equations and maximum slope gradient was investigated.

Forest plantation fire: the SAFODA experience (Sabah Forestry Development Authority)

Harma Haji Liwangsa, Nissanto Hajimasri, Zaina Saridi
Sabah Forestry Development Authority, Locked Bag 122, 88999 Kota Kinabalu, Malaysia
Tel: 088-751267, 752384, Email: safoda@po.jaring.my

Keywords: SAFODA; reforestation; afforestation; plantation fires

The Sabah Forestry Development Authority (SAFODA) was enacted in December 1976, its objectives are to convert wasteland and marginal agricultural land to a highly productive forest plantation and to uplift the living standard of inhabitants through employment in reforestation and afforestation work related to forest plantation establishment. SAFODA has allotted 118,756 ha. of land throughout the state of Sabah for that purpose. By the end of July 1998, SAFODA has planted about 31,417 ha. of trees mainly *Acacia mangium* and 8,356 ha. of rattan. Other than pest and disease problems, fire is still the most dangerous phenomenon due to its extensive negative impact toward certain ecosystems and has long been the major threat in forest plantation project. In 1983, it is recorded that about 5,565 ha. of the SAFODA forest plantation throughout the state of Sabah had been burnt and the latest occurrence was during El Nino 1998 period, which 3,818 ha. of plantation were totally burnt. The objectives of this paper are to highlight and share the experience of forest fire occurred in the Bengkoka Forest Plantation Project in Sabah, its also discuss the problems encountered, annual budget, fire fighting technique, material and equipment used as well as the future direction of research needs. Since 1983-1998 there were 124 fire cases in Bengkoka Forest Plantation Project caused by mainly farm burning, smokers, campfires and incendiary. Most of the fire occurred in March to October each year. It is also noted that one to five years old forest plantation is very severe to fire. Therefore, an effective forest fire management system is really needed to lessen these problems.

Effect of fire on soil properties in pine and natural forest in Sri Lanka

Ranjith B. Mapa
University of Peradeniya, Department of Soil Science
Faculty of Agriculture, 94-8-388041 , Sri Lanka
Email: mapa@agri.pdn.ac.lk

Keywords: Sri Lanka fires; fire severity; soil properties

Forest fires have become regular events in Sri Lanka due to intentional burning by livestock owners and hunters and practice of slash and burn agriculture (shifting cultivation). The foresters as a tool to eliminate undesirable weeds or dominant species in forests also use burning. In Sri Lanka other than the natural forest, part of the hill country is reforested using exotic species as *Pinus* and *Eucalyptus*. Much information is available on the regeneration of forests and regarding the change of the composition of vegetation after forest fires, its effect on soil properties have not been studied in detail. Studying the effect of forest fires on soil properties will help in understanding forest regeneration patterns and help in efficient management of natural and plantation forests. Therefore the objective of this study was to study the effects of fires on soil physical and chemical properties in a natural and pinus forest in Sri Lanka. These were studied at three stages, namely before the occurrence of fire, one day after fire, one and three months after fire.

This study was conducted in adjoining pinus and natural forest in the mid country of Sri Lanka. The soil profiles of the two sites were described using the FAO guidelines and the major soil horizons were identified. Soil properties as soil texture, acidity, total nitrogen, available phosphorus, organic matter and aggregate stability were measured. The area were burnt as usually done at the end of the dry season before the rains and similar measurements were conducted for soil samples obtained one day and three months burning.

More emphasis in this study was given to the determining of dry and wet soil aggregate stability, as soil erosion is one of the major problems in these sloppy lands. The dry aggregate stability was determined using dry sieving with a nest of sieves. The mean weight diameter and log standard deviation was obtained as aggregate indexes reflecting resistant to erosion by wind. Wet aggregate stability was determined by wet sieving using a single sieve technique. The percentage of the initial sample remaining after 18 minutes of sieving was used as the index showing the resistance to erosion by water.

The results showed that the soil pH increased just after burning and again decreased to the original value after about three months. The increase was higher in the pinus plantation than in the natural forest. The increase was from 4.6 to 5.1 and is mainly due the basic nature of ash remaining after burning. Afterwards these bases are easily leached due to rainfall and the soil becomes strongly acidic as before. The soil organic matter content nitrogen decreased with burning which the most damaging effect related to the loss of biomass to the atmosphere. The available phosphorus increased significantly in the surface layers of natural forest due to burning. The available P increase from 40 to 62 ppm in just after burning and decreased to 50 ppm after three months. The change in available P in pinus plantation was not significant.

The dry aggregate stability and wet aggregate stability decreased in the pinus forest with burning. In the natural forest the decrease in soil aggregate stability? were not significant. These aggregates developed to the original size after three months of burning. This shows the vulnerability to soil erosion by wind and water in the pinus plantations during the first three months of burning. This study shows how the soil property change after burning in natural and pinus forests in the mid country of Sri Lanka. In both forest types the chemical properties changed significantly after burning. In natural forest the properties attain the pre-burning values in three months after burning while in pinus forest it took longer times. In the pinus forest the susceptibility to soil erosion increased during the first three months after burning when compared with the natural forest.

Impact of fire on forest insect species diversity - a study in the Silent Valley National Park, India

George Mathew, P.Rugmini and C.F.Binoy
Kerala Forest Research Institute, Division of Entomology, Peechi-680 653 Kerala, India
FAX: 0487-782249, Email: libkfri@md2.vsnl.net.in

Keywords: Western Ghats; India; biodiversity; fire impacts; succession

The Western Ghats of India, which is the most imposing, but extremely threatened topographical, floristic and faunistic feature of the Indian subcontinent is one of the 18 biodiversity 'hotspots' of the world. Spread over an area of 175,000 sq.km. in six States, this mountain range extends more or less parallel to the west coast of Indian Peninsula from Kerala to Gujarat traversing a length of 1600 km.

The Silent Valley National Park is situated in the Palghat District of Kerala State, between latitudes 1103' and 11015'N and longitudes 76023' and 76030'E. As per the world classification of Udvardy, the area falls under the Malabar Rainforest Realm.

The total area of this forest is 90 sq.km. and accessibility to this area is restricted due to the steep slopes on all sides. The region is characterised by heavy summer rains and the mean annual rainfall is 4400mm. The major forest disturbance is fire which ferequently occurs during the summer season in the grasslands and spreads to the adjacent natural forests. As a result, several patches of natural forests get degraded leading to disappearance of many evergreen species. The 'gaps' thus formed in the forest due to burning are subsequently colonised by various secondary species that are found in the adjacent moist deciduous forests and grasslands.

The impact of fire on insect species diversity was studied in representative plots. Altogether. eight plots were taken along a transect in such a way that four plots were in the fire affected zone and the remaining in the unaffected forest patch. Plot size was fixed as 625 m^2 and the distance between plots was 25 m. Data on vegetation and insects were collected from all the plots and from this, the species composition as well as the indices of diversity, dominance, evennes, species richness etc., were computed separately for plots in the fire affected and unaffected zones.

There were 3951 plants belonging to 130 species in the study area, of which 1608 plants belonging to 81 species were found in the undisturbed area and 2343 plants belonging to 109 species in the disturbed area. The diversity index for the undisturbed area was 3.66 and the value for the disturbed area was 3.55.

The floral composition in the disturbed and undisturbed areas was also interesting. While the undisturbed areas had good representation of primary species like *Palquium ellipticum, Aglaia* sp., *Myristica dactyloides, Mesua ferrea, Cullenia exarillata, Holigarna arnottiana, Casearia bourdiloni* and *Persea macrantha*, the disturbed areas had only poor represention of these species. More over, there was an invasion of various secondary species like *Olea dioica, Scolopia crenata, Macaranga peltata, Zizyphus rugosa, Walsura trifolia, Celtis sp., Albizia chinensis* and weeds like *Clerodendron viscosum, Mikania micrantha* and *Lantana* sp.

Altogether. 10451 insects belonging to 578 species under 13 Orders and 67 families were collected from the study area. Of these, 5781 insects belonging to 449 species were from the undisturbed area and 4670 species belonging to 417 species from the disturbed area. Thirteen Orders and 61 families were represented in the undisturbed area and 12 Orders and 60 families in the disturbed area. The species diversity index was 4.76 in the former and 4.65 in the latter.

Consequent to the changes in plant composition following forest disturbance, there was a higher representation of arboreal feeding insect families (Geometridae, Saturnidae, Cossidae etc.) in the undisturbed area where as herbaceous feeding families like Pyralidae, Noctuidae, Chrysomelidae etc., were very abundantly found in the disturbed area. The Orders Diptera, Lepidoptera, Coleoptera and Hymenoptera were the most dominant groups in both the areas.

Natural regeneration of *Tectona grandis* and *Gmelina arborea* after fire in Ikrogon Forest Reserve, Cross River State, Nigeria

Daniel Otu
Nigeria
Email: drill@infoweb.abs.net

Keywords: Nigeria; plantation fires; regeneration; fire severity and timing

Ikrigon Forest Reserve is a dry lowland rainforest, surrounded by a Derived Savannah and located between latitude 6.17 degrees north and longitude 8.36 degrees east. The total forest reserve area is about 600 ha.

The soil is loam to loamy sand with rock composition of mainly granite, quartzo-feldspathic biotite and hornblends-bearing gneisses, schists and magmites (Wright et al 1985).

Since the forest reserve is within a derived savannah, there is yearly fire occurrence which affects the natural and artificial forest in the area. At the plantation forest edge, bordering the savannah where *principally Gemlina arborea* (Gmelina) and *Tectona grandis* (Teak) are the planted reserve boundary species, there is annual seed dropping on the forest floor and the adjoining savannah area. This annual seed dropping has led to the natural establishment of seedlings of these plantation species on the frontiers of the adjoinging savannah woodland. Over the years, the seedlings have grown under the strong competition induced by annual fire, spatial distribution of seedlings, nutrients, soil, water and sunlight.

The result of this situation is natural selection in which some seedlings have grown to poles and trees while others remain stunted as perpetual understorey species due to lack of adequate sunlight and persistent annual fire. The litter drop of *T. grandis* is heavier than that of *G. arborea* and the leaves of the former wider in area than the latter. The leaves of *G. arborea* decay faster than those of *T. grandis*. The result is that there are *more G. arborea* seedlings on the forest floor than those of *T. grandis*. The perpetual persistent litter of Teak does not support profuse seedling production in Teak.

Data collected in mini-quadrats of 10 m by 10 m show an average spread of about 8,900 seedlings perha in Teak and 8,547 in Gmelina. There are also 494 trees established in one ha of Teak and 567 in Gmelina. This means that the trees naturally establish themselves at an average espacement of 4.5 m by 4.5 m for Teak and 4.2 m by 4.2 m for Gmelina. It is also deduced that in Teak area, over 8,406 seedlings lose the competition battle due to annual fire, heavy leaf litter, root competition, and canopy closure of dominant trees. The maturity survival percentage of the species under natural and untended conditions is 5.6%. Similarly, in the Gmelina area 7,980 seedlings lose the attainment of mechartable size due to fire, competition for nutrients, sunlight, and weeds.

The maturity survival percentage of Gmelina in the area is 6.6%. The heavy litter and canopy in the Teak area neither permits weed growth nor speedy development of seedlings. In the Gmelina area however, canopy is almost open thereby allowing for more Gmelina seedlings and weed growth. This is proved by the tree survival in the two plots assessed. The Teak plot does not therefore allow for encroachment of many indigenous species while the Gmelina plot does - especially weeds (*Cromolena odorata*)

Recruitment and survival is therefore based on the annual severity and time of occurrence of fires, competition for nutrients, sunlight, weeds, and canopy effects. Natural espacements for Teak and Gmelina seedlings on the forest floor are 1.06 m by 1.06 m and 1.2 m by 1.2 m, respectively. Also natural espacement for mature teak and Gmelina are 4.5 m by 4.5 m and 4.2 m by 4.2 m, respectively. The espacements exhibited by these tree species can scientifically influence espacement decision in plantation silviculture.

Seedling survival, mortality and regeneration after fire in a tropical high forest in Ghana

K. Owusu-Afriyie, Joshua Ayarkwa
Forestry Research Institute of Ghana, UPO Box 63, Kumasi, Ghana
Tel: +233 51 60123, FAX: +233 51 60121, Email: forig@africaonline.com.gh

Keywords: Ghana tropical forest; regeneration; early/late burning

Tropical high forests were previously thought to be immune to fire. However, studies and empirical evidence have suggested that fire might have played an important role in their evolution. Following the extensive bush fires throughout the tropics in 1982-3, fire has become a major issue impacting on the management of dry semi deciduous forest types of the tropical high forest of Ghana. Several ha of intact forest have been degraded due to the combined effects of recurrent fires and logging.

Studies including prescribed burning have been conducted elsewhere with the aim of reducing the detrimental effects of fire on the forest, whilst promoting re-growth of woody vegetation. However, most of these studies have focused more on the savanna woodlands and transition zones and least on the tropical high forest itself. At present, data is not available for a systematic study of the influence of fire on seedling survival, regeneration and tree mortality following fire in the tropical high forest.

This study attempts to quantify the effects of early and late burning on the survival and mortality of seedlings and trees and regeneration after fire in a tropical high forest in Ghana. It has been observed that tree seedling survival and mortality and regeneration thereafter are greatly influenced by the time of burning. Early or late burning is rather subjective and is determined by the prevailing weather conditions at the time of burning.

The implications for forest management in the dry zone of the tropical high forests are discussed.

Growth and development of a maritime pine stand after fire

Ángelo M. Carvalho Oliveira, Jaime Sales Luis
Instituto Superior de Agronomia, Departamento de Engenharia Florestal, Tapada da Ajuda, 1399 Lisboa, Portugal
FAX: +351.1.364500, Email: angoliveira@isa.utl.pt

Keywords: Portugal fires; regeneration; growth rates

Three permanent plots, each with 1000 m^2 were laid out in 1989 in a State managed pine forest in the northwest of Portugal. The plots, installed in 1989, are located on a natural regenerated pure evenaged stand of maritime Pine (*Pinus pinaster* Ait.), after a forest fire in 1975. To decide about the most appropriate degree of thinning for this kind of stands two degrees of intermediate thinning were performed in 1992. In August 1993 a forest fire attained the three plots but it was decided to keep it to evaluate the impact of the fire on tree vigour, tree mortality, tree growth and yield and the occurrence of natural regeneration of maritime pine and other forest tree species.

At the first measurement, in 1989, each plot contained six tree rows, approximately four meters apart. Diameter measurements, at 1,3 meters above ground level, were collected for all trees within each plot, by taking the average of two calliper measurements. Tree height measurements were performed for sample trees only, ca. 40 in each plot, using an extending measuring pole. At the second measurement in 1992 tree height and breast height diameter were measured in the same manner. The height of the beginning of the crown was measured for all sample trees using a pole. The crown was considered to begin at the point on the tree stem where the first two green branches were detected. Furthermore, for all trees within the central four rows of each plot, four crown radii measurements, considering the greatest extension of tree crown, were made at approximately 90 degrees to each other. The overall plot dimensions and the spatial arrangement of the trees within each plot were measured using a extending tape. The corrected distance measurements, for the slope, together with crown radii measurements were utilised to construct crown maps of each plot. In 1994, 1996 and 1998 tree height, breast height diameter and the height of the beginning of the crown were measured in the same manner, all the trees were examined in relation with the occurrence of pests or diseases and classified according their vigour. In 1998 new crown maps were realised and the natural regeneration was identified and counted in ten square plots randomly located , each with 1 m^2, in each plot.

The effect of fire on all the above-described parameters and their evolution in the last five years are reported in the poster.

Sustainable Management of Natural Resources: fire and forests

I. D. Pande, Sammer Pande
Kumaon University, Glenthorn, Mallital, 263002 Nainital, India
FAX: 91594236218

Keywords: Indian forest fires; economic impact; sustainability; fire research

Forests are not merely an economic resource but constitute an essential life support system, especially for the people living in mountainous or rural areas, Recurring forests fires cause considerable damage and degradation to forests and environment every year and more so in a cycle of four to five years. Ministry of Environment and Forest, Govt. of India, appointed a committee to assess the damage from forest fires in Uttar Pradesh (U.P.) and Himanchal Pradesh (H.P.) in 1995. This committee assessed direct economic losses to the tune of 139.3 million rupees, in U.P. alone during the Fire season of 1995. It also recommended that studies to make a scientific and comprehensive assessment of damage resulting from forest fires should immediately be undertaken by the Indian Council of Forestry Research & Education (ICFRE) and then the result of those studies applied in all states in evaluating the loss from the fire damage. These recommendations clearly reveal that research on forest fires has seriously been neglected.

It is paradoxical that fire protection was one of the first tools of scientific forest management in India, yet research in forest fires has been a neglected field in this country. Although research on two other injurious agencies off forest viz. diseases and insect pests started a long time ago, limited studies have been made on forest fires so far.

To estimate the true extent of fire losses, quantitative value has to be assigned to various impacts of forest fires. Forest fires are known to bring down considerably the various values e.g. productive, wild life, aesthetic-recreational grazing, socio-economic & others. It is also essential to have a reliable data base to generate the desired type of information. Expenditure on fire control can be justified only up to an amount representing the savings or loss reduction, which results from that expenditure. The more valuable the forest, the greater is the amount that it is worth spending to control fires. Research has to encompass all aspects of forest fire from pre suppression, prevention, detection, control, reporting, quantification and monitoring of losses. In the Himalayan region specific research is required towards cost effective & environment friendly hazard reduction methods e.g. some economically viable use for chir pine needles or some process to hasten its rate off decomposition. A modest beginning towards forest fire research has been made during the past two decades by adopting fire danger rating system for different type of forests, evaluating direct fire losses, designing statistical format for fire reporting for subsequent use in fire damage analysis. In view of the importance of the forests in Himalayan eco-system forest fire problems of this area need prioritisation in the Forestry research agenda.

About necessity of new approach to pyrological estimation of forests

A.P. Sapozhnikov
71, Volochaevskaya Street, 680030 Khabarovsk, Russia
FAX: (4212) 216798, Email: sergey@niilkh.khabarovsk.su

Keywords: Russian far east; 1998 fires; biodiversity; protection strategies

Principles of forest protection from fires, the evaluation of their consequences and their elimination, as has been shown by the catastrophic fires 1998 in Khabarovsk Territory, Russia, are no longer the matter of any separate country or any of its regions alone. Catastrophic forest fires periodically appear in this or that region and not only in Russia. No atrocious forest exploitation can be compared with the pyrogenic consequences, because only due to fires in a very short period are possible irreversible disturbances and destructions of formed many centuries ecological connections and trophic chains on the vast territories. Besides, as a result of fires, the indirect consequences are possible which it is impossible to take into account immediately. For example, soils destruction on mountain slopes in the result of burned stand decomposition which could happen after 10 or more years after the fire.

Experience shows that no country having large forest volumes located in insufficiently accesible areas (due to weakly developed road networks) is indemnified from the development of fires up to catastrophic sizes with all ensuing global ecological consequences. The world community is not so much worried by the loss of raw potential of the forest lands as by those ecological consequences which follow mass deforestation of the territories. Among the most meaningful ecological consequences are soil erosion, low river water, the loss for a long period carbon sequestration functions and, as a consequence, contravention of climatic situation on the planet. Evidently, it is necessary to improve all facilities of forest protection from fires - from their forecast and inventory to elimination of their consequences.

One of the important aspects is the determination of fire cause needed both for current and retrospective analysis of succession dynamics. If earlier it had a specifically administrative meaning, then today the role of cause in determination of priorities in pyrologic territory organization, prophylactic work with the population, improvement of legislative and regulatory bases becomes more actual.

It is evident, that both physically and economically there are no possibilities to fight all forest fires. In other words, it must be discriminatory relating territory and relating the value of forests. Such experience has been accumulated, particularly, by Canada. For Russian conditions, with its mammoth and hardly accessible territories, it is necessary to zone areas on a new basis - first of all according to forests ecological value, not only formally stated in the regulatory documents, but also actual, for example, according to carbon sequestration ability. The last could be estimated on green mass production and not only by the stand, but forest cenosis on the whole. According to these signs, the territory must be differentiated by zones according to prioritization of fire control active methods use under mass ignitions, similar to fires 1998, and according to the necessary expenditures for prophylactic measures.

Fire occurrence in relation to weather conditions

Bulent Saglam, Ertugul Bilgili
Kafkas Universitesi, Department of Forest Entomology and Protection, Artvin, Turkey

This paper presents and evaluates the effects of fine fuel moisture content of forest floor fuels on fire occurrence in mediterranean ecosystems of Turkey. Fine fuel moisture contents were measured in an even-aged, fully stocked red pine (*Pinus brutia*) stand near Izmir. Three fuel samples were taken daily in the early fire season in june and once or twice a week thereafter. Fuel samples were weighed and oven-dried at 100°C for 12 hours or until no change in weight was attained. Moisture contents were determined based on the weight difference between before and after oven-drying.

Weather measurements were taken daily at noon local standard time from a nearby weather station located at Menderes Interantional airport. Measurements included temperature, relative humidity, wind speed and direction, and precipitation. Fire occurrence data during the study period was obtained from the Regional Forest Directorate in Izmir. Analyses showed that a close relationship exists between weather conditions and fire occurrence. Indexes generated from this study should be invaluable for fire managers in the region and other places having similar conditions.

Wildfire occurrence in a forest district and other Brazilian protected areas

Ronaldo Viana Soares, Otávio Bezerra Sampaio
Federal University of Paraná, Curitiba, Brazil
FAX: +55-41-253-2332, Email: rvsoares@cce.ufpr.br

Keywords: fire danger rating; fire occurrence prediction; Brazil fires

Wildfire is a permanent threat to native and planted forests in most part of the Brazilian territory. Periodical dry seasons and abnormal weather conditions have induced to large and destructive fires from time to time. In 1998, for instance, an extremely large fire burned about 13,000 km^2 of tropical forest and savanna vegetation in the State of Roraima, located in the amazonian region.

Despite the preoccupation with the tropical forests, data on fire occurrence in that ecosystem are not sufficient to make a good description of fire occurrence in Brazil. This paper presents the history of fire occurrence in the Agudos region, State of Sao Paulo, southeastern Brazil, from 1984 to 1995 and other protected areas throughout the country. The center of the forest district area is located approximately at 22^{o}28'S 48^{o}59'W and 526 m above sea level. The fire season in the region goes from June to November. There was statistical difference among the months of the year for both, number of fires and burned area. August, with 21.60%, presented the higher number of occurrences, and 76.36% of the fires occurred from June to November. September presented the largest burned area (28.49%), and 80.41% of the total area affected by wildfires burned from August to November. There was no statistical difference in the number of fires or burned areas among the days of the months and the weekdays, although sunday, with 17.36% of the occurrences and monday, with 24.86% of the total burned areas had presented the highest numerical values. However, significant difference was observed both, in the number of fires and burned areas, among the hour of the day. About 85.17% of the fires and 91.97% of the burned areas were recorded between 10:00 AM and 06:00 PM. The hour that presented the highest occurrence was 02:00 PM, with 17.20% of the recorded fires. Precipitation was the weather variable that presented the best correlation with fire occurrence. About 42.1% of the annual precipitation and 82.41% of the recorded fires occurred between April and October. August was the month with lower precipitation and higher number of fires. Data collected from protected areas in the Brazilian territory in 1994 and 1995 presents similar results showing that the history of forest fire occurrence is similar all over the country.

September, with almost 30% of the recorded fires, was the leading month in fire occurrence, and 84.61% of the fires and 97.85% of the burned area were observed between July and October. Arson (41.40% of the fires and 11.81% of the burned area), Debris burning (32.26% of the fires and 79.55% of the burned areas), and Smoking (10.21% of the fires and 1.13% of the burned area) were the leading causes of forest fires.

Performance of the Monte Alegre formula on fire danger evaluation in different regions of Brazil

Ronaldo Viana Soares, Otávio Bezerra Sampaio
Federal University of Paraná, Curitiba, Brazil
FAX: +55-41-253-2332, Email: rvsoares@cce.ufpr.br

Keywords: fire occurrence; fire causes; Brazilian tropical forest/savannas

The occurrence of forest fires is highly influenced by weather conditions. For that reason, fire danger rating indices based on meteorological variables are important tools to aid in planning and supervising fire control activities in fire protection units. Besides presenting a good performance, an index must be adapted to the local conditions, mainly to the available data for its calculation. That is why sophisticated indices that require data that is not easy to obtain cannot be used in developing countries, where meteorological and other necessary information are seldom available. The "Monte Alegre" formula (MAF) was developed in 1972 using meteorological and fire occurrence data of the central part of the State of Paraná, and has since been used by most forest institutions and companies in Brazil and other South American countries to predict fire danger. It uses only three variables: relative humidity (directly), number of days without rain and amount of precipitation (both indirectly), and can be easily calculated every day through the following equation:

MAF = 100 SUM FROM { n=1 } TO { n } 1 OVER H

where n is the number of days without rain and H is the relative humidity measured at 1:00 PM. The performance of the MAF was evaluated in three deferent forest districts in the southeastern and southern regions of Brazil. Firstly, using a data set from the region where the index was developed (Cfa climate, according to Koppen's classification), its performance was checked. Results showed that 52.5% of the fires registered in that period occurred when the index indicated a very high danger; 31.7% when the danger was high; 13.8% when the danger was medium; 2.0% when the danger was low; and no fire was recorded when the index indicated no danger. Secondly, using data from a forest district in the southern State of Santa Catarina (Cfb climate), the MAF was compared to the locally used index, developed by the South Carolina State Department of Forestry, USA, (SCI) in the 1960s. By the MAF, 13.0% and 87.0% of the recorded fires occurred when the index indicated high and very high danger, respectively. When the SCI was used, 43.5% of the fires occurred when the danger was low, 26.1% when the danger was medium, and 30.4% when the danger was high; and no fire was recorded when the index was very high. Thirdly, using data from a forest district in the central region of the southeastern State of Sao Paulo (Cwa climate) the performance of the MAF was compared to three other indices: Nesterov, Tellysin, and the Canadian Fire Weather Index (FWI). Three methodologies were used to test the efficiency of the indices: Mahalanobis distance, Friedman's test, and distribution of the occurrences through the danger scale of the indices. According to the Mahalanobis distance and Friedman's test, the FWI was more efficient but when the distribution of the occurrences through the danger scales was used, the MAF was more efficient in estimating the fire danger of the region.

Monitoring and assessing forest fires using NOAA-AVHRR data with special emphasis on Borneo

Aswati Surep
Forest Research Institute Malaysia (FRIM), Regional Centre for Forest Management, Kepong, 52109 Kuala Lumpur, Malaysia
Tel: 603-6377633, FAX: 603-6377233, Email: aswati@psph.frim.gov.my

Keywords: Indonesian fires; remote sensing; smoke/haze; fire management

Forests are managed not only for the production of wood, but also as a safeguard for environment. One of the main factors effecting forest degradation is forest fires and uncontrolled burning. Asean countries especially Malaysia and Indonesia were most affected by forest fires during July-November, 1997. The worst haze occurred in Sarawak, Malaysia when the Air Pollution Index (API) reached 800, exceeded the 500 danger level. Consequently the state was declared emergency by the government. This paper will highlight the capabilities of satellite image (NOAA-AVHRR and SPOT image) in monitoring forest fires. Observation and studies showed that the haze was caused by fires and burning. This paper also assessed the burned forest areas and the relationship between the number of hot spots and the severity of haze occurrence i.e. affected areas. The causes of forest fires were highlighted and management plan of forest fire control was proposed.

Influence of bush fires on the dynamics of dry forest: case of degraded forests in North-Benin

André M. Tandjiékpon
Unité de Recherches Forestières, 06 BP 70 Cotonou, Benin
Email: inrabdg4@bow.intnet.bj

Keywords: Benin; bushfires; early fires; late fires; regeneration; dry forests; natural forests; forest management.

The North-Benin is in the dry part of the country where dry season covers 6 to 7 months of the year with a rainy season of 5 to 6 months. The average temperature is about 27°C with the rainfall oscillating between 900 and 1200mm annually. The vegetation is savannah type with low density of large trees. The main activities are agriculture, breeding and hunting. In this part of the country, bush fires are widely used by farmers, breeders and hunters for their activities. So, every year, many ha of forests are burnt with consequence of gradual degradation of forestland. This attitude of populations has a sociological foundation, which is not easy to overcome. In order to appreciate the real impact of fires on natural regeneration of forest, an experiment was initiated in 1990 with objective to determinate the appropriate periods for fires use as a tool for forest management. For this purpose, five treatments have been applied on six different sites as following: a) use of "Early fires" (EF) on 11 November and 11 December; b) use of "Late fires" (LF) on 11 January and 11 February; c) no fire use (NF) as control. After some years of observation, the tests have been evaluated in 1996 and 1997 in order to appreciate the evolution of plots. The results appear that the LF is very damaging for young regeneration with about 95% seedling burnt causing in fact progressive genetic erosion and the destabilization of soil. On the other hand, the EF of 11 November stimulated more the natural regeneration with appearance of new species in the experimental plots. With this treatment, it has been observed a natural pruning of trees with best development of trunk. Concerning the protected plots, grass has grown with high concurrence to young regeneration and natural sowing and seedling. On these plots, it also appeared that the renewal of grass is low comparing to EF, the trees have developed large crown with big branches and the high accumulation of dead vegetation. The conclusion is that, fire is a real tool for forest management in dry regions when its use is well analyzed. For now, fire appears as the best tool to fight against the risks of uncontrolled bush fires in dry regions in regard to the context of socio-economic conditions of the populations concerned. The EF applied just at the beginning of dry season has a positive influence on natural regeneration and the reconstitution of dry forests for wood and fodder production as well for biodiversity conservation.

Prognosis of emergency situations under wildland fires

A. V. Volokitina, Nozhenkova L.Ph., Sofronov M.A., Nazimova D.I.
V.N.Sukachev Institute of Forest, Akademgorodok, 660036 Krasnoyarsk, Russia
FAX: (3912) 43-36-86, Email: volokit@cc.krascience.rssi.ru

Keywords: Russian fires; climate change; vegetation mapping; fire behavior

It is proved that climate changes occur with extreme declination of seasonal weather variations and may cause large scale fire emergency situations (Stocks, 1993; Wein, Groot, 1996; Fosberg, Stocks, Linham, 1996). In the last years climate changes are vividly seen in the South of Siberia and the Far East and they are the cause of intensified spring and summer droughts. Due to these droughts such emergency situations often occur when forest and steppe fires become dangerous for inhabited localities and even inflict casualties. This work analyses the peculiarities of dangerous wildland fire development, the forecasting and possibilities of prevention emergency situations on the basis of vegetation fuel maps. Emergency situations take place when a strong fire threatens an inhabited locality or some valuable object.

The dangerous fire intensity depends on the mass of vegetation fuel burning down in flame regime in time unit per long meter (but not per square meter!) of fire edge. This mass depends on two factors: a) the stock of such vegetation fuel per unit of area and b) the speed of fire edge spread. If the speed of spread is large, the intensity of fire can be very high even under small stock of vegetation fuel. The presence of considerable stock of vegetation fuel burning down in the regime of smoldering (litter, peat, duff) decreases the intensity of flame burning. Fires become of high intensity and, therefore, of danger if they reach the so called ‘phase of self development’. Firstly, it happens at the expense of their speed increase under ‘potted’ spread with throwing about burning particles in front of the fire front. It is especially characteristic of ‘explosive’ fires.

Ignitions in inhabited localities and industrial objects occur because of burning particles which are thrown about in front of a strong forest or steppe fire front. This usually happens in dry windy weather, therefore, ignition of separate dwelling houses and industrial buildings can spread over other buildings and objects. Burning particles can spread up to 500 meters distance and more. Due to this, strong vegetation fires can get over the rivers, unburned bogs and other obstacles.

The main way of protection objects against an approaching strong fire is preliminary backfiring. The history of very large forest fires (for example, fires in the Northern China in 1987) shows that such fires are able to spread freely over the area for a long time destroying inhabited localities and crossing the rives and roads which could be the best initial line for preliminary backfiring. The list of problems on prevention of loss under the emergency situations, connected with wildland fires close to inhabited localities and others valuable objects, includes the following tasks: 1) showing up of inhabited localities which can be damaged under wildland fire (forest, steppe and so on); 2) elaboration of prophylactic measures on protection of such objects from wildland fires; 3) prognosis of possibility of wildland fire dangerous development, active near the inhabited locality or near the industrial object; 4) prompt, safe and reliable stoppage of dangerous fires with the least expense of strength and means.

The solution of enumerated tasks is possible on the basis of vegetation fuel maps usage and method on vegetation fires behavior prediction. Technology of vegetation fuel maps creation on the basis of forest inventory data and air-space information and method of fire behavior prediction are elaborated (Volokitina, Klimushin, Sofronov, 1995).

Assessment of forest fire impacts in East Kalimantan using satellite remotely sensed data

Keywords: Indonesia; Landsat TM; JERS-1 OPS; NDVI; GIS

It is difficult to assess and get general view of large scale forest fire with ground survey alone. Satellite remote sensing technique, which enable monitoring over a large area multi-temporally, were employed to map the extent and degree of the large scale forest fire occurred in East Kalimantan Province, Indonesia, between mid 1997 and early 1998. According to the report of Indonesian government, this fire damaged more than 520,000ha of forest in this Province. Southern part of Samarinda, the capital city of East Kalimantan Province, was selected as a study site. The study site covers 24,1000ha, including Bukit Soeharto Education Forest (BSEF) and Sungai Wain Protection Forest (SWPF). Although BSEF and SWPF are both protection forests, they have different degree of protection level and different types of vegetation management.

Two change detection analysis methods, Normalized Difference Vegetation Index (NDVI) analysis method and Change Vector Analysis (CVA) method, were introduced to map vegetation cover changes caused by the forest fire, using 5 scenes of Landsat TM data (acquired on 1997/4/13, 1997/8/3, 1998/1/26, 1998/2/11, and 1998/3/31) and 3 scenes of JERS-1 OPS VNIR data (acquired on 1996/9/27, 1997/8/1, and 1998/6/5). Maps of detected change derived from NDVI analysis represented suitable results compared to CVA when using limited ground information, and were adopted as the maps of vegetation cover change in this study. From this satellite remote sensing data analyses, 26.8% of land area in the study area showed vegetation decrease from February to March 1998, which probably caused by the forest fire, and 11.8% showed vegetation increase from March to June 1998 by regeneration of vegetation after the forest fire.

A GIS database of this study area was newly constructed to find out the relationship between human activities and forest loss due to the fire. The database comprises spatial data such as 1) slope model, 2) basin/ridge model, 3) buffer zones representing human activity area, 4) boundary of the BSEF and SWPF, and 5) land cover map of the study area before the forest fire obtained from RS data classification. By overlaying vegetation cover change layers with other GIS layers, it was possible to assess the scale and degree of the forest fire in relation to human impact and vegetation management condition.

From February to March 1998, 54.8% of forest area in BSEF, where protection of vegetation by university had been not carried out sufficiently, showed vegetation decrease caused by the forest fire. While in SWPF, where sufficient vegetation protection by Indonesian Government had been carried out, 31.5% of forest area showed vegetation decrease in the same period. Furthermore, SWPF showed 6.1 times large vegetation regeneration area compared with BSEF after forest fire, from March to June 1998. By using 1 kilometer buffer zone of human activity area, where human impact to vegetation environment thought to be large, 65.1% in BSEF and 50.2% in SWPF showed vegetation decrease from February to March 1998. They suggest that the vegetation change of the study site caused by forest fire have strong relation to the conditions of vegetation management.

A3 Sustainable Management of Natural Resources. Management and Conservation of Forest Gene Resources

Conservation of Endangered Genetic Resources in Forests of Cuba

Angela Orlidia Hechavarría Kindelán,
Forestry Research Institute, Calle 174 # 1723 e/ 17 B y 17 C, Rpto Siboney. Playa, Cuba
FAX: 33 46 04 c/o José Moreno Castillo, Email: josebec@mixmail.com

Key words: conservation, genetic, endangered species.

There are 820 plant species (626 native and 173 foreign) associated with forests in Cuba. A significant number of species (109) are at risk of extinction as a result of human presence and evoluties factors. The Forestry Research Institute has been working on conservation, management and rescue of endangered species in different forestry ecosystems in Cuba through a combination of *in situ* and *ex situ* studies. Studies were conducted on forestry species in the natural conditions to characterize phenotypic and anatomical variation and on seedling/clonal regeneration. To restore or augment endangered populations, seedlings were planted in natural area for *in situ* conservation and at other suitable locations for *ex situ* conservation.

Recommendations for post-planting management were developed. *In situ* and *ex situ* conservation planting is important techniques to ensure recovery of certain species in forest ecosystems.

Contemporary Approaches to the Ex situ Conservation of Malaysia Rain Forest Tree Seed Germplasm

Erica E. Benson, M. Marzalina, Keith Harding, Nashatul ZN Azman,
Harry Staines, and Baskaran Krishnapillay
University of Abertay, Plant Conservation Biotechnology Group, Bell Street, DD1 1HG Dundee, United Kingdom

This presentation explores the contribution that contemporary research methods (i.e. biotehnology, in vitro conservation, molecular biology, cryopreservation and bioinformatics) can make in the conservation of Malaysian Rain Forest tree seed genetic resources. Research has included: preliminary assessments of phenological studies , which may be used to assist seed germplasm collection; pre-storage seed evaluation and the control of phytosanitary and moisture content status; seed storage characterization; zygotic embryo rescue and in vitro culture; rapid screaming of cryopreservation protocols; cryogenic storage; molecular stability characterization , and the application of statistics for the improvement of conservation experiment design.

The significance of these contemporary, multidisciplinary approaches for the improvement of conservation strategies for Malaysian Rain Forest tree seed germplasm will be presented, a key factor to their success will be their integration with sustainable management programmes and their complementary use in conjunction with other ex situ and in situ conservation regimes.

Reproductive Biology and Genetic Diversity of Selected Rain Forest Species of Sri Lanka: Implications for Management

I. A. U. N. Gunatilleke, C.V.S. Gunatilleke, S. Dayanandan, B. Dayanandan, D. Murawski, K.S. Bawa and P.S.Ashton
University of Peradeniya, Department of Botany, 20400 Peradeniya, Sri Lanka
Tel: 94-8-389026, FAX: 94-8-388018, Email: savnim@slt.lk

Reproductive phenology, floral biology, mating systems and genetic diversity of selected rain forest plant species of traditional economic importance were examined in Sinharaja World heritage site and the surrounding forests of South-western Sri Lanka. Dipterocarps belonging to the local group Beraliya whose seeds are edible, flower supra-annually often coinciding with maior El-Nino events while the Thiniya-Yakahalu-Dun group flowers annually. They are pollinated by *Apis* species and the fruits are dispersed by gravity and wind. The dioecious medicinal vine, *Coscinium fenestratum* (Menispermaceae) is an annually flowering species. Its likely pollinator is a dipteran and the fruits are dispersed by the Ceylon Fruit Bat (*Rousettus* sp.) and the arboreal palm civet (*Paradoxurus* sp.). The herbaceous wild cardamom Elettaria cardamomum var. major is an out-breeding species pollinated by an Amegilla species.

Mating system studies on dipterocarps have revealed a predominantly out-breeding system for *S. congestiflora* (tm = 0.87) and a mixed mating system for both S. trapezifolia (tm = 52 - 62%) and *S. megistophylla* (tm = 0.74). The average single-locus out-crossing rate for *S. megistophylla* was significantly lower than the multi-locus rate in the selectively logged forest but not in the adjacent unlogged forest indicating a greater level of biparental inbreeding (kin mating) in thinned populations. The fixation index for adult individuals of all three species was lower than that of the progeny suggesting a considerable selection against selfed progeny in them while reaching adulthood.

Genetic variation parameters were calculated for 10 populations of S. trapezifolia separated by 8-45 km from each other. The proportion of polymorphic loci, effective number of alleles per locus and the observed and expected heterozygosity were lowest in a small relict forest, a likely result of forest fragmentation, degradation and consequent genetic isolation. The highest genetic variation was observed for populations outside the Sinharaja protected area which had 18% of the total alleles sampled exclusive to them. 89% of the genetic variation was found within populations indicating a relatively low genetic differentiation among populations sampled. UPGMA cluster analysis and a correlation analysis however, failed to recognize any geographical pattern of population differentiation..

This serves as a bench-mark study in population genetics of Sri Lankan dipterocarps particularly for monitoring long-term effects of forest fragmentation and degradation on population genetic structures of incumbent species. It strongly recommends setting aside of larger areas of contiguous forests or clusters of forests linked through 'gene-bridges' such as riverine forests, ridge top forests etc. for conservation of genetic diversity of out-breeding species. Furthermore, it also advocates that the distribution of genetic diversity of at least some key species should be taken into consideration in protected area design and management.

Biodiversity and exploitation of cedars (*Cedrus* spp.) in Mediterranean region

Joël Allainguillaume, Alastair Culham, Sawsan Khuri, Andrew Wetten, Mike Wilkinson and Peter Caligari
University of Reading, School of Plant Sciences, Department of Agricultural Botany, PO Box 221, RG6 6AS Reading, United Kingdom
Tel: +44 118 931 6684, FAX: +44 118 931 6684, Email: Caligari [p.d.s.caligari@reading.ac.uk]

We have started to develop the necessary genetic and population data and methodologies to allow the identification of cedar genotypes and their distributions within populations, between populations and across countries. These approaches are being used to define the underlying structures of the remnant forests in Lebanon along with the more extensive and exploitable ones in Turkey and Morocco.

The genus *Cedrus* includes four species which have geographically distinct origins. These are: *C. libani* A. Rich in Lebanon, Syria and Turkey; *C. atlantica* Manetti in Algeria and Morocco; *C. brevifolia* Henry in Cyprus; and *C. deodara* Loudon in Afghanistan and India. Some of these species, however, are difficult to distinguish phenotypically which led some authorities to regard them as a single species.

Cedar forests are among the oldest forests in the Mediterranean basin and have a significant economic role in many countries of the Mediterranean basin, both as a source of highly valued timber but also as ornamental trees. Currently most cedar forests are facing serious problems of degradation and mismanagement partly as result of the lack of an efficient regeneration system. The remaining natural sites have been under intensive human pressure due to demographic increases, the absence of other resources of timber with similar or better quality than cedar and simple “mismanagement”, arising from a lack of reliable information. In Lebanon, for example, there are several forest stands of Cedars extending from Kammoua in the North to the Shouf in the South. But, as a result of previous reforestation efforts, some of the Lebanese stands now include, in addition to native C. libani, C. atlantica, C. brevifolia, and/or C. deodara.

It was, therefore, perceived to be imperative that the genetic diversity of the natural stands was determined in order to assess the available genetic base and hence to determine necessary procedures for further reforestation. This is allowing not only the specification of protocols to preserve the genetic diversity but also the identification and encouragement of sustainable exploitation. Alongside the increase in the basic information on diversity it was essential that an effective and efficient propagation system was developed which would facilitate planned plantings and sensitive development to proceed.

Results will be presented from our current programme which has been combining modern biotechnological approaches, made available by the rapid development of molecular marker technology, with conventional methods, but undeveloped for cedar, for propagation and screening.

This research project is funded by the European Union within the INCO-DC work programme (ERB IC18-CT97-0177).

Strategies for Genetic-Resource Conservation of Commercial Tropical Timber Species in Asia Pacific Region

Nasaruddin bin Abd RahmanMARA Institute, Dept. Landscape Architecture, , 40450 Selangor, Malaysia
Tel: 603 556 3629, Email: niara@tm.net.my

The tropical rainforests in Asia-Pacific region are considered among the most complex eco-system in the world. These forest provide multiple benefits to its host countries, both in socio-economic development and environmental services. In the 80’s, the rate of deforestation for the region was one of the highest in the world. Deforestation, however, is still a major problem in some countries in the region due to unsustainable practices of logging operations and continued land-use conversation. The region is a major source of supply for the tropical timber products, contributing about seventy five percent of all tropical timber products traded in the international market. As timber are produced mostly from the region’s natural forests, the conservation of genetic timber resources becomes very critical. This paper highlights the outcomes of an ITTO funded study carried out in five countries in Southeast Asia on in-situ and ex-situ conservation. The paper review the current status of in-situ and ex-situ genetic conservation of timber species in those countries and proposes measures to be undertaken to further strengthen it’s the conservation. New sets of guidelines for in-situ and ex-situ conservation to be adopted for Asia-Pacific region are also discussed.

Mating System Parameters of *Dryobalanops aromatica* Gaertn. f. (Dipterocarpaceae) in an undisturbed natural population, a logged over natural population and two planted populations

S. L. Lee
Forest Research Institute Malaysia, Kepong, 52109 Kuala Lumpur, Malaysia
Tel: 03-6302173, FAX: 03-6302105, Email: leesl@frim.gov.my

The mating system of Kapur (*Dryobalanops aromatica* Gaertn. f.) from Peninsular Malaysia was quantified by allozyme analysis of progeny arrays using a mixed-mating model. Four populations were compared: an undisturbed natural population, a logged over natural population, a multi-species planted population and a mono-species planted population. The undisturbed natural population had the highest multilocus outcrossing rate (tm = 0.92), followed by logged over natural population (tm = 0.77) and multi-species planted population (tm = 0.67) with mono-species planted

population showing the lowest (tm = 0.55). This finding may indicate that reduction in population density of *Dryobalanops aromatica* following logging activities and changing in population structure under plantation condition can significantly levitate the proportion of seeds produced through inbreeding. It could also be attributed to differences among populations in genetic compositions and environmental conditions. Only the progenies from mono-species planted population showed evidence of biparental inbreeding (tm – ts = 0.12), suggesting that the population was established using related seed sources.

Management and Conservation of Forest Genetic Resources in Uruguay: Role of the National Reseach Institutions.

Zohra Bennadji
Instituto Nacional de Investigación Agropecuaria, Estación Experimental del Norte, Ruta 5 - Km.386, C.C.78086-C.P.45000 Tacuarembo, Uruguay
Tel: (063)22407, FAX: (063) 23969, Email: Zobenn@tb.inia.org.uy

Keywords: Forest genetic resources; Management; Conservation; Research institutions; Uruguay.

The present work aims to an analysis of the role of the Uruguayan national research institutions in the management and conservation of forest genetic resources field through:

a presentation of the forest genetic resources current state in the country,

an analysis of the actions of the national research institutions,

and a proposal for an effective implementation of a national research strategy.

The study of the forest genetic resources present state will be developed in the conceptual framework of biological diversity, highlighting the tree forest genetic resources component and considering the regional and global trends in their scientific and political dimensions. The peculiar features of Uruguayan natural environment and their relationship with the management and conservation of forest genetic resources will be presented.

The actions of the national research institutions will be analysed at the scientific, technical and institutional levels, emphasising the contribution of the National Agriculture Research Institute (INIA) and his National Forestry Program.

The proposal of an effective implementation of a national research strategy in management and conservation of forest genetic resources will describe both home and abroad Uruguay's policies and long - term actions required for strengthening this area.

The delimitation of the role of the national research institutions is of a strategic importance in the present stage of forestry development in Uruguay. In fact, during the 1987-1999 period, an overwhelming plantation program of fast growing species has taken place in four main suitable soil zones of the country, favoured by a highly structured state policy with an exceptional package of incentives. At the same time, this forestry state policy has been based on regulations protecting the natural native forests. The public opinion has also a great sensibility to environmental topics, including the biodiversity one. Uruguay has at present 3.6 million hectares of soils suitable for forestry. There exist 670 thousand hectares of natural forests and 450 thousand hectares of plantations, almost all them installed during the 1992-1999 period, with an annual plantation rate of 40.000 ha/year.

A5 Sustainable Management of Natural Resources. Sustainable Forest Management and Productivity

Under-Canopy and Preliminary Forest Cultures as a System of Forest Growing in Conditions of Smooth Natural Generation Change in the Boreal Forests of Russia

A. F. Chmyr, Maslakov E.L.
Saint-Petersburg Forestry Research Institute, Institutsky pr., 21, 194021 Saint-Petersburg, Russia
FAX: (812) 552-80-42, Email: spb330@spb.sitek.net

Natural spruce forests of the boreal taiga are usually presented by multiple-aged forest stands. Spruce reforestation under the canopy of such crops is a natural process, corresponding to the natural peculiarities of the zonal (area) forests. However, in the considerable area of the exploitable crops of the European part of Russian boreal forests it is quite difficult to run a forestry, orientated to the conservation and further utilization of the young growth during the cutting of the mature forest stand.

During the last 35 years in the north-western and central parts of Russia there were probated new methods of planting and conditions of artificial growing of spruce and other shade-requiring species under the canopy. Depending on their purpose these cultures are subdivided into preliminary and under-canopy.

Common to both types is the fact they are planted under already existing (growing) canopy; while the difference is that preliminary cultures are planted under the canopy of maturing and mature crops (approximately 10-12 years before cutting), but under-canopy cultures- under the canopy of open undergrowth(I-II age class).

The technological system of preliminary cultures provides for preventing unfavorable succession of spruce species and gradual(progressive) replacement of old generations by young, ecologically stable forests. Planting and growing of preliminary cultures, unlike the clear cutting forestry management and further reforestation, has a number of technological, ecologically-silvicultural and economic advantages. The purpose of under-canopy cultures is slightly different and consists in planting structurally and compositionally complex forest crops on the basis of open unsuccessful or damaged forest stands.

Young spruce growth in the open cutting usually suffers greatly because of the late frosts and sun burns. Besides, its growth is greatly restrained by grassy vegetation and broad-leaved sprouting. Microclimatic conditions are much softer and more favorable for survival and growth of young plants under the parent canopy. In particular, there is no competitive pressure on the crops from grassy vegetation and broad-leaved sprouting, the fact that greatly decreases care costs.

Moreover, under the canopy of forest crops the processes of bogging are weakened as here, in contrast to clear cuttings, water regime(condition) is regulated by growing forest crops.

We can’t help mentioning a most important ecological effect of the under-canopy reforestation system, that is reduction of the amount of open forests peculiar to clear cutting forestry.

Nowadays, when forests suffer immensely from air emissions and other technogenic (industrial) pollutions, under-canopy “covered” system of forest growing considerably reduces the probability and degree of salvage.

The under-canopy system of forest growing essentially reduces and prevents CO2 release into atmosphere owing to unproductive temporal interval (10-15 years), until the territory of cutting is planted by new crops.

The long-tem researches of the stationary plots showed that during the processes of planting and growing of preliminary cultures. The latter accelerate their growth abruptly when the upper canopy is cut or thinned. Their biometric parameters and productivity become similar to those of the cultures planted earlier in the open areas.

In all its technological and forestry components the under-canopy system of reforestation and forest growing will favor ecologolization of the forestry management system in the boreal forests.

Tropical forests management based on tree populations dynamics: the example of moabi in the Dja forest (Cameroon)

L. Debroux, Philippe Lejeune
World bank, Cameroon
Email: ldebroux@worldbank.org

Though Central African rain forests contain a wide diversity of tree species, present logging practices are extensive and mining, and focus on a relatively restricted range of valuable timber species Considering the complexity of management practices aimed at controlling global stand dynamics, we propose an approach based on ecological characteristics and demography of particular timber species and we assume that forest management mainly consists in the management of timber tree populations living in their natural environment. This approach is illustrated with the example of moabi (*Baillonella toxisperma* Pierre, *Sapotaceae*), a timber species from Cameroon.

For two and a half years (1994-1997), we measured survival, growth, fecundity and spatial distribution of every class of seedlings and trees of this species in permanent plots covering 347 ha, located in the Réserve de Faune du Dja and in the adjoining logging concession (South-East Cameroon).

After a description of the Dja’s floristic diversity (chapter 1), we present the phenology and germination of moabi (chapter 2), seed dispersal and predation by mammals as well as impact of hunting on its natural regeneration (chapter 3), and then seedling growth in the understorey related to light availability (chapter 4) and finally the demographic parameters of its adult population: diametrical structure, growth, mortality and spatial distribution (chapter 5). Moabi start fruiting from 70 cm DBH, some individuals reach 280 cm DBH as maximum size and trees are cut over the legal limit diameter which is 100 cm. The density of adult trees is 0.1 stem/hectare. The specific growth curve is calculated by mean of three different methods: measurement of 273 living individuals for a period of 2,5 years analysed with both Gompertz’s model and a polynomial model; annual growth rings counting for 10 trees; and carbon dating for 4 trees.

On the basis of these observed values of fecundity, survival and growth, we build a matrix model (Lefkovitch 1965, Usher 1966, Favrichon 1995) which reproduces the evolution of class sizes of moabi over a period of time (chapter 6). This demographic model is a management tool which can be used for predictive simulations.

On the one hand (chapter 7), we quantify the impact of the present logging practices on moabi population dynamics. Thirty years after first logging, moabi population will recover 27% of the initial number of adult stems and this reconstitution level will be 83% after 300 years.

On the other hand (chapter 8), the matrix model enables to assess the impact of forest management scenarios designed by changing management parameters. We successively simulate (1) the elevation of limit diameter from 100 to 130 and 160 cm, (2) the lenghtening of rotation period from 30 to 60 years; (3) the reduction of impact of logging from 10 to 5% of the ground area and (4) the increase of growth speed due to the implementation of selective thinning. These simulations enables to compare the cumulative timber production yielded over a period of 480 years by the present logging practice *vs* an extremely conservative management scenario (limit diameter = 160 cm; rotation time = 60 years; reduced impact logging; selective thinning).

This approach based on tree population dynamics with regard to their natural regeneration logically fits into the classical scheme of natural forest management plans in Central Africa baesd on selection system. It enables quantitative recommandations for long term timber production from these forests to be formulated and, consequently, contributes to their sustainability.

Modelling Norway spruce young stand development based on IUFRO international stem number experiment

Ivo Kupka, Marian Slodicák
Czech University of Agriculture, Forestry Faculty, Prague, Czech Republic
FAX: +420 2 20923132, Email: kupka@lf.czu.cz

There is an expectation of new plantation and regeneration on abandoned agricultural land in Europe. These new plantations should be ecologically stable and sound. The models for regeneration and young stand development are sought as one of the tool to reach the above given goals.

The presented model is based on the IUFRO international stem number experiment for Norway spruce where radical reduction of the number of trees per hectare in the juvenile stage has been done. The experiment was established in 1971 in eight years old spruce thicket originated from planting in regular spacing with density 2500 trees per hectare. The series consists of five obligatory treatments with two replications. The stand is situated on previously cultivated agricultural land in 5th (spruce-beech) vegetation degree on elevation of 600 m above sea level. The pattern of experiment includes control plot 1 without thinning. All other programmes are based on first heavy thinning (top height 10 m). Thinning regime 2 represents heavy treatment in young age (top height 12.5 and 15 m). The regimes 3 and 4 (fully mechanised selection) are similar treatments planned later when the stands achieve top height 20 and 22.5 m. Thinning along with treatment 5 (commercial thinning) is to be done only when 80 m3 of stem wood can be removed on trees with DBH over 12 cm excluded 400 crop trees.

The data set gives detailed information on every tree growth including the stem and crown shape and the position of the tree within the stand. The data are recorded since 1971 and represent high quality long time period for juvenile growth stand. The higher volume of stem wood (474.7 m^3 per hectare) is accumulated (last survey in 1998) in the control stands 1, but total production (together with volume removed by thinning) is the highest on plot 2 (541,1 m^3) as well as the volume of selected trees - 217.5 m^3. Various thinning programmes affected stability of experimental stands in favour of tended stands.

The model could help with the formulation of the growth process of young Spruce stands under very new silviculture regimes which should create the stable stems with low value of stem sliminess coefficient and long and vital crowns. It is expected that these silvicultural regimes could increase the vitality of the stands suffering in Central Europe by the air pollution and other climate stress.

Nutrient Management Guidance for Enhancing Sustainable Forest Productivity

Robert J. Luxmoore, P.S.J. Verburg, M.J. Ducey, R. Harrison, A.R. Sidell, D.W. Johnson, W.W. Hargrove, M.L. Tharp and F.M. Hoffman
Oak Ridge National Laboratory, , P.O. Box 2008, 37831-6038 Tennessee Oak Ridge, USA
FAX: +1-423-576-8646, Email: rjl@ornl.gov

Guidance on the nutrient management requirements to support enhanced productivity goals for new plantations of loblolly pine (*Pinus taeda*) in the southeastern United States or of Douglas-fir (*Pseudotsuga menziesii*) in the northwestern United States is developed. Sustainable forest management with enhanced productivity is needed on commercial forestland as opportunities for timber harvests from public forests declines in the United States. A suite of Excel spreadsheet "models", derived by simplification of simulation models, is provided at two Internet websites for use by the Forest Industry in their stand management planning. A three-step procedure is designed for use with personal computer systems.

First, the productivity goal for a new plantation is estimated for the specific soil and climate conditions of a field site to be planted with selected planting stock and managed with practices that enhance productivity (e.g., planting density, vegetation control, fertilization, thinning). The target biomass projection for each year of the new plantation is determined from growth and yield models available to the forest company or from the 3PG spreadsheet model calibrated for plantation growth. The 3PG model was developed by Landsberg and Waring (1997, Forest Ecol. and Manage. 95:209-228).

The nutrients required to support the target growth are next estimated with the REMSS spreadsheet model. This code determines nutrient requirements from empirical relationships established from the nutrient content of stems, branches, foliage and roots of the two tree species. These calculations determine the time course of nutrient requirements for the target plantation growth.

In the third step, the soil supply of nutrients for the specific soil and climate characteristics of a selected site is determined with the NuCSS spreadsheet model. Soil data from forest company measurements or from estimates provided from soil databases are used to determine the annual nutrient supply from the soil to the vegetation. The difference between the REMSS vegetation nutrient demand and the NuCSS soil nutrient supply provides guidance on the fertilizer requirements to meet the target productivity.

Repeated simulations with the spreadsheet models provide insight on the nutrient management requirements for sustaining enhanced forest productivity through several rotations. The procedures also estimate changes in soil carbon sequestration due to nutrient management.

Supplemental features are included at the Internet websites. The nutrient status at a field site may be evaluated prior to planting by foliar vector analysis with the DIAGNOSIS spreadsheet model. This analysis can be made if foliar mass and nutrient data are available from the previous forest stand. Further, the Crystal Ball software may be used with all Excel spreadsheet models for conducting sensitivity and uncertainty analyses. Sensitivity analysis shows the important variables that contribute significantly to the outputs at each step. Sensitive variables need to be accurately determined. However, variability (uncertainty) of soil, climate and vegetation attributes is often large at field sites. If this variability is known, uncertainty analysis may be undertaken with Crystal Ball to estimate plantation nutrient requirements with statistical confidence intervals.

Research sponsored by the Office of Industrial Technologies and in part by the Office of Biological and Environmental Research, U.S. Department of Energy. Oak Ridge National Laboratory is managed by the University of Tennessee-Battelle, LLC, under contract DE-AC05-00OR22752 with the U.S. Department of Energy.

Détermination de la productivité des jachères dans cinq régions du Mali

Yves Nouvellet, Mallick Sylla, Amadou Kassambara
CIRAD-Forêt, BP 1813, Bamako, Mali
FAX: 223 21 48 29, Email: nouvellet@cirad.fr;nouvellet@afribone.net.ml

La filière bois-énergie au Mali permet de couvrir 91 % des besoins énergétiques natinaux. Le bois est issu des formations naturelles et des formations "hors forêt" ou diffuses des espaces agro-sylvo-pastoraux. Pour mettre en place une gestion durable et raisonnée de la ressource ligneuse, le Mali s'est doté d'une politique énergétique : la Stratégie Energie Domestique.

La production de la biomasse ligneuse des formations forestières est connue, alors que celles des jachères (formations forestières diffuses) sont tout à fait empiriques.

Pour mieux appréhender sa production, la Cellule Combustibles Ligneux (volet offre de la Stratégie Energie Domestique) en liaison avec l'Institut Polytechnique Rural de Katibougou, a installé des sites d'étude dans cinq régions du Mali d'Ouest en Est : Négala, Ouéllésebougou, Fana, Cinzana et Koutiala. Les sites choisis doivent permettre une meilleure connaissance des formations "hors forêt" du pays.

L'inventaire des arbres (de jachères et de parc), de la régénération, le cubage par classes (0- 5 ans, 6-10 ans, 11-15 ans, 16-20 ans et plus de vingt ans) ont été réalisés dans ces sites. La répartition par classes d'âge a été obtenue par enquêtes auprès des paysans exploitants de ces jachères.

La productivité annuelle de ces formations est fortement liée à l'anthropisation, elle varie de 0,06 m3/ha/an à Koutiala (fortes occupations des terres pour la production du coton) à plus de 0,25 m3/ha/an dans les régions de Fana et Négala. Ces résultats n'incluent pas les arbres dits de "parc" tel que Vitellaria paradoxa, Parkia biglosa, et Lannea spp..

Les essences caractéristiques de ces formations "hors forêt" sont pour l'étage dominant les arbres de parcs cités au pargraphe précédent, pour l'étage dominé: *Combretum nigricans, Acacia macrostachya, Combretum glutinosum* ; la régénération est caractérisée par des espèces pionnières : *Piliostigma reticulatum, Acacia macrostachya, Guiera senegalensis*.

Ces données partielles seront utilisées pour la réactualisation des Schémas Directeurs d'Approvisionnement des principales villes du Mali (Bamako, Ségou, Mopti et Koutiala).

Growth Models Control Sustainability of Forests in Transition

Hubert Sterba, Thomas Ledermann
University of Agricultural Sciences in Vienna, Institute of Forest Growth and Yield, Peter Jordanstraße 82, A-1190 Vienna, Austria

Keywords: *Dauerwald* management, Individual tree growth models, permanent forest inventory

In Central Europe there is an increasing trend to convert even-aged to uneven-aged forests, aiming at a *Dauerwald* (permanent forest) forest management system. Under this situation the former age class methods, derived from the “normal forest model”, or from the dbh-class models based on de Liocourt’s negative exponential dbh-class distribution, are appropriate to both, determine and control sustainable annual cut with respect to age classes or dbh-classes and the way how to best approach the *Dauerwald*-structure of the forests.

Two developments in European forest science help this situation: (i) individual tree growth models have been developed, aiming at the substitution of classical yield tables, and (ii) forest inventory designs have shifted to permanent sampling methods in order to more accurately identify changes in forest structures and damage.

This presentation will demonstrate that combining both, permanent inventories based on angle count sampling and the distance independent individual tree growth model PROGNAUS, will enable foresters to choose harvesting strategies, appropriate to achieve both high value sustainable yield and uneven-aged forest structures.

The example presented is a forest management area of 1270 ha, where more than 40 years ago the clear cut system was abandoned and replaced by target diameter harvest. In 1988 permanent plots were established. Sample trees were selected using Bitterlich’s angle count method with a basal area factor of 4 m²/ha. The first re-measurement in 1998 served to calibrate the growth model PROGNAUS. With the calibrated model, different harvesting scenarios are calculated for a 40-year period. Stocking volume, dbh- and stem quality distributions are compared.

Using forest inventory, remote sensing, GIS and growth models to monitor some sustainability indicators at management level

Margarida Tomé, Paula Soares, José Carlos Paúl and João Moreira
Instituto Superior de Agronomia, Dept. Forestry, Tapada da Ajuda, 1399 Lisboa, Portugal
FAX: +351 1 3645000, Email: magatome@isa.utl.pt

Criteria and indicators for the sustainable management of forests have emerged as a central element of international and domestic forest policy discussions. The Third Ministerial Conference on the Protection of Forests in Europe, that took place in Lisbon, Portugal, in June 1998, adopted the six Pan-European criteria for sustainable forest management. The European countries involved in this conference committed themselves to promote the development and implementation of national criteria and indicators, taking into account specific country conditions, as well as to improve the quality and promote the necessary adaptations of national data collection systems, to fulfill the needs of information to assess sustainable forest management. In Portugal, the definition and implementation of adequate indicators to be used at a practical level in the assessment and monitoring of forest management sustainability at management area level have attracted particular interest since then. The implementation, in practice, of the proposed indicators strongly rely on the availability of forest inventory and mapping of forest resources over time, seldom available in Portugal at the management area level. In this context, a management area is a forest area, subdivided into management units (stands) that is subject to the same management plan. The objective of this poster is to analyse alternative methodologies of up dating forest resources information, including spatially specified information. Data from the continuous forest inventory of the National Forest of Leiria are the basis for this study. The National Forest of Leiria is a state property with an area of 11,000 ha located in the coastal dunes of Marinha Grande in central Portugal. Most of the area (8,700 ha) is made up of pure maritime pine stands managed for high quality timber production. A relative small percentage along the coast is protection forest with the maritime pine as dominant species (2,000 ha) and a little more than 300 ha are devoted to other land uses. The forest is subdivided into 342 management units approximately rectangular that are sometimes subdivided into 2 or more stands. For management purposes, a continuous forest inventory systematically covers the forest since 1979 with an intensity of one 500-1,000 m2 plot per ha (two plots per ha till 1988) and a periodicity of 5 years. Alternative methodologies of up-dating forest information were simulated on the basis of these data, including the use of traditional forest inventories of different intensity, combined or not with the use of growth models, as well as the use of remotely sensed information and other ancillary data available in a GIS system that is available for the area.

The application of growth and yield models for yield regulation and to assess indicators of sustainable forest management for mixed tropical forests.

P. R. van Gardingen, P.D. Phillips, G. Lawson, R.I. Smith, J. McP Dick
The University of Edinburgh, Institute of Ecology and Resource Management, West Mains Road, EH9 3JG Edinburgh, Scotland
FAX: +44 131 667 2601, Email: p.vangardingen@ed.ac.uk

Yield regulation has been identified as a key constraint to sustainable management of natural tropical forests. Growth and yield simulation models are being developed as tools for growth prediction and yield regulation using data from permanent sample plots and forest inventory. This paper illustrates the application of an individual-based (single-tree spatial) model for simulation of the growth and yield of moist tropical forest systems. SYMFOR is a modelling framework that has been principally designed to study and predict the effects of different silvicultural treatments for sustainable yield management of natural Dipterocarp forests in Indonesia.

The current version of SYMFOR has been applied to illustrate the utility of both empirical and process-based growth and yield models for three applications: (1) growth and yield prediction, (2) evaluation of alternative silvicultural systems and (3) evaluation of indicators of sustainable forest management. Predictions of growth and yield are presented for an area of lowland dipterocarp forest in East Kalimantan (Indonesian Borneo). These predictions are used to describe and predict the recovery of the forest following logging compared to its pre-logging condition. This analysis is then extended for the same dataset to determine the effect of altering the silvicultural system applied to the forest through alterations in either diameter cutting limits or length of cutting cycle. These results are then further analysed to illustrate simple indicators of sustainable forest management. The analysis of these simulation runs demonstrated the importance of appropriate statistical analysis of model simulations

The paper concludes that growth and yield models will become an increasingly important tool for the management for sustained yield of tropical forests and can be further applied to develop and implement effective criteria and indicators for sustainable forest management. These applications will require the development of appropriate analytical procedures to utilise output from simulation models and to make their results readily available for application by forest managers.

The Determinants of Silvicultural Investment in British Columbia: An Economic and Policy Perspective

Sen Wang
Canadian Forest Service, Industry, Trade & Economics Program, Pacific Forestry Centre
Natural Resources Canada, 506 West Burnside Road, V8Z 1M5 Victoria, BC, Canada
Tel: 250 363-0726, FAX: 250 363-0775, Email: senwang@PFC.Forestry.CA

Being a key link in the chain of sustainable forest management practices, silviculture occupies an important place in British Columbia's forest policy considerations. This poster aims at providing an economic and policy analysis of the silvicultural investment in BC's public forestlands. First, a brief historical overview of the Province's silviculture programs is presented to outline the institutional context in which the silviculture sector has evolved. Next, silvicultural activities and expenditures are reviewed statistically. Then, a regression analysis is undertaken in an attempt to reveal the effects of several explanatory variables such as harvest areas, timber prices, non-timber values and government stumpage revenues on the levels of silvicultural investment. Finally, the policy implications of the research findings are discussed from the perspective of sustainable forestry. The paper ends with a comment on the emerging trends of BC's forest policy regarding silvicultural operations in the Province.

B4 Forest and Society Needs. Evaluation of Technologies for Society Needs

Fulfilling Societal Needs through Participatory Silviculture - An Evaluation

Prodyut Bhattacharya, Joshi, B.; Ojha, H.R.
Indian Institute of Forest Management, P.O. Box # 357, 462003 Nehru Nagar, Bhopal, India
Tel: 091-755-775716, FAX: 091-755-772878, Email: prodyut@iifm.org

A revolutionary development in forest management took place in India in the late 1980s, when participation of local, forest-dependent communities was sought for the management and protection of State forests under the umbrella of the Joint Forest Management (JFM) program. This new approach has now been adopted by 21 of the 25 Indian States. Approximately 3.5 million ha of forestland have been regenerated by more than 35,000 forest protection groups in different parts of the country. This has been accomplished through indigenous and innovative methods and approaches. The Latest Report on the State of Indian Forests (in 1997) shows that, although the amount of new forest cover is small in regions where JFM has been implemented, there have been marked increases in biodiversity, biomass productivity, tree basal area, and other ecological parameters in these areas.

As the phenomenon of JFM has strongly taken root, managers have realized that classical silvicultural systems and operations are not adequately equipped to address the newly emerging needs and demands of the society. The JFM program considers the dependence of local, forest-dwelling communities as well as those living on the forest fringes. Thus, intermittent yields of locally valuable, multiple forest products become critical to the sustainability of this co-management concept. This also conforms to the emerging global consensus regarding the vital role of forests in facilitating the anti-poverty crusade, which is high on national agendas around the world.

Forest management is now recognized as being more than just protection. The local community should be involved in the manipulation of trees and other forest vegetation if total and effective co-management is to be achieved. Thus has evolved the practice of Participatory Silviculture, which is the new thrust area in the JFM-practicing States of India. The techniques and operations implemented under Participatory Silviculture incorporate local knowledge and use perceptions, temporal and spatial dimensions of local needs, and institutional setup. Additional factors include aspects of a wider socio-economic environment apart from forest types, the history of forest management, and other vegetation-related characters. Beginning with species selection and through to silvicultural operations, local needs and aspirations are considered supreme. These silvicultural methods, though simpler, are evolved jointly and continuously by the technically skilled foresters and the forest-dependent community. Local communities now conduct their own operations, such as lopping for fodder and fuelwood, rotational blocking for NTFP collection, multiple shoot (MS) cutting, stump dressing, pruning, etc.

This poster attempts to answer the following questions regarding the potential role of Participatory Silviculture in the sustainable management of community forests:

Are community forests being managed effectively to respond to the needs of the user groups?

What kind of silvicultural manipulations are being carried out by the forest user groups, and how do both scientific and local knowledge come into play in determining such practices?

Is there any need and/or scope for further strengthening and improvement of these silvicultural interventions to address both social and environmental needs?

The poster highlights and analyzes the results obtained from field studies in Central India (Harda Forest Division), Bihar (Singhbhum Forest Division), West Bengal (Bankura Forest Division), and Nepal (Kavre Forest District). Ecological factors have been re-examined that limit natural forest recovery on degraded areas under co-management. The studies also evaluated various management options and the socio-economic and policy issues that influence silvicultural decisions for restoring and rehabilitating degraded natural forests.

Transfer of Timber Harvesting Technology to Societies in Economic Transition – The Taiga Model Forest Project in Northwestern Russia

Nuutti Kiljunen, Pertti Harstela and Lauri Sikanen
University of Joensuu, Faculty of Forestry, Post Box # 111, FIN-80101 Joensuu, Finland
FAX: +358 13 251 3590, Email: nuutti.kiljunen@forest.joensuu.

A dramatic economic transition in Russia has caused difficulties for Russian forest industries. Annual cuts have been drastically decreased, and numerous sawmills and pulp mills are experiencing hardships because of a shortage of raw material. At the same time, exports of roundwood make up the core of forestry income. Reliance on earlier timber-harvesting systems has been very difficult, because Russia's own machine production is also struggling in the transition. Therefore, redesigning the harvesting systems is proposed as a solution. Western machine manufacturers consider Russia a potentially strong market, but the lack of capital hinders transactions. In addition, unemployment is a serious problem among forest workers.

A Taiga Model Forest (TMF) project was launched to establish a model forest area for demonstration and experimental purposes. One objective of this project was to find profitable and cost-effective technological applications for forest operations in northwestern Russia. Technology transfer within the project itself was mainly an exchange of scientific knowledge among scientists. Nevertheless, one purpose of the project was to demonstrate Scandinavian timber harvesting and to compare it with local Russian methods in a large thinning experiment. Shortcomings of this approach included the Russian counterparts' lack of knowledge in the actual planning of forest operations, as well as the unstable situation in Russian society. Both of these situations have caused serious problems with the realization of the TMF project's goals. In this paper, the TMF project was analyzed in a Samli's framework of technology transfer. One aim was to examine international transfer of forest technology by observing an on-going case. The Samli's model used in this study was improved upon by attaching outside motives to the framework. These outside motives (from non-governmental environmental organizations) had been one of the driving forces when the TMF project was established.

Comparative studies based on unit-cost calculations indicate that, economically, an intermediate technology would be the most profitable method in this case. This is because of a low level of salary in relation to the price of advanced technology. An intermediate timber-harvesting technology would also be more profitable for the economics of northwestern Russia because of its positive influence on employment and its smaller demand for foreign currency when procuring harvesting equipment.

The best results from the TMF were obtained in the training and advising of forest workers, who quickly adopted the principles of the new methods. In the TMF, Scandinavian forest road-construction methods also were demonstrated in cooperation with Russian road-construction companies. The local machinery labor was suitable for forest-road construction when the Scandinavian methods were used.

Intermediate technology practices in timber harvesting seem to be the most promising way to help northwestern Russian forestry in this difficult situation. However, because the current need for forest worker education is so great, the transition to more cost-effective Scandinavian systems may be slow.

Using the Delphi Method to Forecast Priorities in Forest-Engineering Technology

Toshiaki Owari, Hiroshi Kobayashi and Toshio Nitami
Hokkaido University, Graduate School of Agriculture, Division of Environmental Resources, Research Group of Forest Management and Conservation, Kita 9, Nishi 9, Sapporo 060-8589 Kita-ku, Japan
Tel: +81 11 706 2522, FAX: +81-11-706-3343, Email: owari@for.agr.hokudai.ac.jp

Key words: effective measures for realization; forest-engineering technology forecast; forecasted realization

Forest engineering technology must be promoted as a pivotal component in sound management of Japan's forests. Using the Delphi method, we conducted a technology-forecast survey to gain a long-term perspective on the future of forest engineering. Survey results were consolidated through two questionnaires. We selected respondents who were experts with extensive knowledge of forest engineering: 20% from the forestry sector, 19% in machine manufacturing, 26% university-related, 29% in public research institutes, and 6% in other areas. For the first part of the survey, we sent questionnaires to 79 respondents, of whom 50 were then sent the second questionnaire. We excluded those who withdrew from the survey after the first questionnaire. The rate of response was 63% for the first part and 90% for the second.

The preliminary questionnaire was used to determine the forecast topics. We divided forest-engineering technology into four categories: machinery, operations, ergonomics, and roads. Within each category, the respondents were asked to state topics of concern that could be addressed, or ”realized”, in Japan by 2030. Predictions for the technological stage of fulfillment for each topic were made with one of three phrases: ‘in development’, ‘in practical use’, or ‘in widespread use’. The respondents proposed more than 100 topics. After all topics were prioritized according to importance and generality, 37 were selected for special consideration (14 in machinery, 13 in operations, 5 in ergonomics, and 5 in roads).

The respondents forecast the time for realization of half the topics by 2010, 90% by 2015. The earliest two topics forecasted (in 2007) were ”Widespread use of the instruction manual of forest operations for voluntary workers” and ”Widespread use of non-clear cutting operations using mobile tower yarders”. The topic ”Development of unmanned harvesting machines” was forecasted for realization after 2020.

Based on results from the second survey, an importance index was calculated for each topic; the overall average was 59.7. The topics with the three highest indexes (all >80) were related to environmentally aware technology: ”Widespread use of the evaluation and management methods of environmental conservation in forestry”, ”Widespread use of near-natural road construction methods”, and ”Widespread use of the accurate predicting methods of environmental impact through forest operations”. We also asked for ‘Effective measures the government should adopt for realization’ of each topic. Among the choices, ”Increase in government funding for research” was most frequent (average 50.5%). ”Personal exchange between the industrial, academic and government sectors” was chosen in 39.9% of the replies.

The forecasted realization time for each topic will be referred to during development of technology strategies in the forestry sector. Environmental concerns should be emphasized more in the future as R&D is promoted in the field of forest engineering technology. In particular, financial support for R&D and collaboration between industry, university, and government are expected to be considered when forest technology policies are proposed.

Impacts of Forest Harvesting Operations on Soil Properties

Molong Sun
Northeast Forestry University, Centre for Forest Operations & Environment, Post Box # 245, 150040 Harbin, China
FAX: +86-451-2110146, Email: wanglihai@usfs.auburn.edu

Key words: forest operations; impacts on soil properties; regeneration quality.

Forest operations in northeastern China include planning for harvest systems, logging, transport, road-network design and construction, slash disposal, and planting after harvesting. These activities are significantly correlated with soil disturbance, which can be measured in terms of the degree of break and compaction as well as the loss of soil nutrients. Four sub-projects were conducted to study the effects of forest operations on physical and chemical soil properties at the operation sites. The study variables included such factors as cutting system, skidding traffic, layout and construction of forest-road networks, and slash disposal. In general, the degree to which soil physical properties were affected was closely related to the level of energy input, i.e., how much timber was removed from the forest, during operations at the harvest site.

Three cutting systems were employed: selective cutting, thinning, and small-area clear-cutting. Of these, selective cutting has been the most commonly used system over the past 10 years, and will probably be the best harvesting method in the near future. However, soil physical properties were affected most significantly by this method, as measured by the degree of disturbance associated with the volume of timber removed per ha. This is because more movements and greater energy inputs were required for executing the operations on each tree. Clear-cutting and thinning were ranked second and third, respectively. In terms of disturbance per unit area, however, the clear-cutting system had the most significant impact on both physical and chemical properties of soil, accounting for approximately 15% of the variation. This was because of the more-concentrated operations involved with this system.

Timber was moved from the site by tracked crawler, wheeled skidder, cable-yarding, or animal skidding. During the winter, ground-skidding traffic did not significantly influence soil physical properties, even after six to eight passes by the machinery. However, the opposite was true when the ground was not frozen. The wheeled skidder then had a greater impact than did any other means of log transport. Field investigations showed good natural regeneration in the areas disturbed by crawlers, but not at the landings or in the main skidding-track ruts. Animal skidding was an environmentally sound technique, with moderate operating costs. Because no soil damage is inflicted during winter operations and only slight amounts during the other seasons, the use of animals has increased to about 90% of all the skidding done in the last 5 years.

Three slash-disposal methods -- burning, piling, and spreading -- have been employed during the last 10 years of harvesting. Although the burning method has impacted the soil more because of nutrient losses, it has been beneficial in improving soil acidification. The other two slash methods have had moderate influences.

A well-planned forest-road network can reduce soil erosion. To lessen the impact of forest-road construction on soil properties, we are presenting a new mathematical model for optimal layout of forest roads. Both economical and ecological benefits are considered in this plan.

A Practical Approach to Prioritizing Forestry Research Projects

Sanniyasi Shanmugasundaran
1/41, Thanam Nagar Nagar, Mugalivakkam, Chennai, India
Tel: + 091–044–2312942, Email: s_shanmugasundar@hotmail.com

Key words: forestry; prioritization; research programs; step-by-step procedures.

Various approaches have been proposed for prioritizing forestry research programs. Evaluating the merits and demerits of each approach may provide a means for ranking individual programs. Unfortunately, all of the current methods are rooted in agricultural environments, with the primary focus only on prioritizing particular species in annual crops. In contrast, the man-made models that are designed for studying natural systems in forestry consider species to be but one of many components in the system. Therefore, a practical approach is needed, which is applicable to the unique requirements of forestry. Our proposed method comprises two phases: Phase I -- prioritization of forestry projects; and Phase II -- prioritization of research programs. This approach reduces subjectivity by introducing objective questions whenever judgments must be made.

The process of Phase I begins by identifying the relevant issues in forest management, viz., Geographical Cover of forests; Conservation of Bio-diversity; Protection of forest resources from all kinds of destabilizing factors; Restoration of the degraded forests; Production of material goods; and Extension of forestry for practice by the public. These are the primary objectives in tropical forest management. Forests are categorized, based on both biotic and abiotic characteristics, by the amount of ground they cover. At this stage, judgments are made according to the relevance or importance of each objective in various forest categories. Grades are assigned as Absent, Poor, Low, High, and Highest.

The subjectivity inherent with making judgments can be reduced by using objective questions. The graded judgments carry scalar values of 0, 1, 3, 6, or 10. Direct or inverse weights are introduced that account for the extent to which a forest is impacted by each objective. The total scores earned by the various combinations of forests and objectives are ranked in descending order. Rankings are improved by introducing the level of impact that each objective has on Economic, Environmental, Political, and Sociological aspects. The final ranking, which includes the improved, combined scores, provides the priority for forestry projects.

Phase II commences with identifying the chief components involved in technological activities. These components are ranked according to their contributions toward fulfilling forestry objectives. The technological activities are assigned to one of five levels: 0, 1, 2, 3, or 4, with 'Level 0' referring to rudimentary or absent, meaningful technology; and 'Level 4' indicating the highest level of technology that is feasible for a particular component. Technological Levels are scored as 0, 10, 30, 60, or 100%, respectively.

The goal of all research programs is to progress from some lower level to higher technological levels. Each upgrade is a gain toward fulfillment of the objectives. The gains from technological upgrade are estimated for all the components of Prioritized Forestry Programs. This is followed by an estimate of the final score, which is the product of both the expected gains from the technological upgrade and the score of the Prioritized Forestry Programs that was estimated under Phase I. Using this method results in the identification of Prioritized Forestry Research Programs, with final scores listed in descending order.

The Historical Development of Forest Operations in China and a Look Ahead 10 Years

Lihai Wang, Wang Yueshan
Northeast Forestry University, Centre for Forest Operations & Environment, Post Box # 245, 150040 Harbin, China

Key words: forest operations in China; historical development; 21st century; 10-year look ahead.

The history of forest operations in China since ancient times (more than 2000 years ago) has included developments in operation technology, equipment, organization, and professional education. We used the Entropy Growing Analysis method for studying the dynamics of these developments, particularly with regard to the interaction between human society and forest ecosystems in a given region. In China, the deforestation rate is highly correlated with an increasing population rate i.e., each era of great population explosion has resulted in large-scale deforestation.

Forestry activities have changed greatly in the last century because of the fast development of science and new technology, unbelievable population growth, and rapidly changing social structures and market systems. In the first half of the 20th century, large forests were destroyed during continuous wars, mad land-grabbing by invaders, and unanticipated establishment of farms by immigrants. The main goal of forest operations during that period was to extract as much timber and farmland from the forest as possible. Machinery, such as a forest railway transportation system powered by steam engines, significantly improved operational efficiency. Unfortunately, this new trend toward mechanization increased the capacity for human interference in the forest. However, the rest of the work was done manually, and contracted teams were a popular means for organizing forest operations.

Since 1949, and particularly in the past 20 years, forest operations in China have been greatly modified. Not only have the science and technology of forest operations been developed significantly; the environmental aspects, profitability, and economic efficiency have also been emphasized. Forests are now recognized as important suppliers of non-wood forest products such as water and soil protection, climate adjustment, and an assortment of flora and wildlife. These factors are considered when decisions are made about harvesting, timber extraction, and civil engineering in forests. In integrated forestry, planning is done from the viewpoint of sustainability for both timber and non-timber forest products. All activities, e.g., forest resource surveying and harvesting planning, road planning and construction, harvesting, post-harvest site disposal, and planting and protection must now serve these key purposes. As well, forest-operations technology and techniques have been converted from manual- to machine-driven, and are now part of an environmentally sound complex. Planning and organization has been changed from that of small, manual working groups to large-machinery operations. The working system now involves many contracted groups at different levels.

"The Natural Forest Conservation Project", begun in 1998, identified the challenges and opportunities in Chinese forest operations. The market for small- and mid-sized machines, with multi-functions, will be the most dominant in the near future, depending on the forest resources available in China. Environmentally sound, low-cost, and highly efficient forestry technology and techniques will be in the spotlight of both research and practice in the next 10 years. Forest operations will also play quite an important role in the management of sustainable forestry

C3 Changes in Environment and Society. Interaction between Environment and Society

Forest and Land-use Structure in the Urban Landscape in Tokorozawa, Japan

Masamichi Takahashi
Forestry and Forest Products Research Institute, Tsukuba Norin Kenkyu Danchi-nai, P.O.Box 16, 305-8687 Ibaraki, Japan
Tel: +81-298-733211, FAX: +81-298-731542, Email: masamiti@ffpri.affrc.go.jp.

Key words**:** urban forests, agricultural land, land-use change, spatial analysis, Japan.

Forests in urbanized and suburban areas have a wide range of functions, ranging from contributing to human daily life to providing habitats for wildlife. On the other hand, forests are source of real estates for urban development. Thus, it is important to examine the actual and historical situation of forests and land-use when developing a forest management plan in urban and suburban areas. This study aims to show the historical change and actual situation of the forest and land structure in the urban landscape of Tokorozawa, Japan.

Tokorozawa is a city about 30 km north from the Tokyo metropolitan area, located in the middle of the Kanto planes. Its area is about 7,200 ha and topologically gentle, except for the southwestern part. The population dramatically increased from 57,000 in 1960 to 303,000 in 1990.

Base data used were the actual vegetation map of Tokorozawa city in 1956 (26 categories) and in 1985 (54 categories). These were converted for digital data and re-categorized for land-use maps. Analysis was done using ARC/INFO and Arcview 3.

According to the overlay analysis of land-use maps, Tokorozawa had 1,940 ha (26.7%) of forests and 4,038 ha (55.7%) of agricultural fields in 1956. But in 1985, these had rapidly decreased to 1,150 ha (15.9%) of forest and 2,343 ha (32.3%) of agricultural field. In contrast, the urban area had increased from 367 ha (5.1%) to 2,046 ha (28.2%). According to the overlay analysis of actual vegetation between 1956 and 1985, over 80% of total area had changed, and mainly from forest and agricultural vegetation to urban areas.

In addition, structural changes occurred in forest and agricultural vegetation. Most of agricultural vegetation in 1956 consisted of a field weed community, and some of these were changed to a tea garden in 1985. At the same time, part of the forests' structure also changed. Coniferous communities (*Pinus densiflora* community, *Cryptomeria japonica*, *Chamaecyparis ovtusa* plantation) were succeeded by a deciduous substitutional community (*Quercus serrata* forest).

The structure of Tokorozawa's landuse dramatically changed from a forest and agricultural town to a satellite city of Tokyo. Accordingly, the forest and agricultural vegetation also changed.

Eco-Design In Nature-Based Parks: A Precondition Of Accomodation Facilities

Mohd Ariff Jamaludin, Abdullah Mohd, Dennis Chumg Soon MIN, & Phoon Wan Siong
Universiti Putra Malaysia, 43400 UPM Serdang Selangor, Malaysia
Tel: 60-3-9486101 Ext. 2442, FAX: 60-3-9432514, Email: arif@forr.up.edu.my

Malaysia is blessed with naturalness features in combination with varieties of flora and fauna. It is of the country's advantage to use these resources to the benefit of the country's population and economy. The opportunity for people to enjoy the nature-based activities should be expanded with minimum impact upon the natural environment. Sustainable development and eco-design development concept should be considered which include the contributions from nature resources.

All of the factors or variables associated with a built structure should be interrelated with one another and co-existed within a symbiotic environment. In general, the development of eco-design structures involved the analysis of the site, infrastructure, and related activities. These include evaluation on visitors, flora, fauna, environment, government aspiration, local population needs and their culture and relationship with the surrounding facilities. This paper discusses on the concept of eco-design with respect to studies carried out in Taman Negara, Kuala Tahan, Pahang and Pantai Kerachut, Penang. Basically, this paper focuses on accommodation facilities within the selected sites which are nature-based recreational areas.

The eco-design concept of building structures in Taman Negara Resort, Kuala Tahan, Pahang was carried out to evaluate the ecological consciousness of specific features of the buildings, especially the accommodation facilities. The study was divided into two aspects; namely, the assessment of human responses toward lighting comfort, thermal comfort and outdoor vegetation, and the investigation of building design. The features that have being investigated include the aspect of building design, the orientation, shape and form, materials of building, energy efficiency and waste disposal. Analysis of variance on the thermal comfort during daytime between respondents staying in shaded and non-shaded accommodation facilities showed that there is a significant differences ($p < 0.0001$) between the two variables. Analysis of variance of lighting comfort between respondents staying in shaded and non-shaded accommodation facilities showed significant differences ($p < 0.0001$) in glare sensation during daytime. Most of the accommodation facilities were oriented with the long axis in north-south plain and elongated in shape, which was unfavourable in reducing solar radiation. The materials of chalets and chalet suites were of lightweight and suitable in tropics. In the aspect of energy efficiency, costs and benefits analysis of replacement of incandescent lamp to fluorescent lamp has shown that the savings on electricity were able to cover the additional cost within a year of payback period. The sewage treatment and waste disposal practised in the resort were of conventional method whereby recycling of waste was minimally practised. Replanting of shade trees was practised but provided little shading to the accommodation facilities. The evaluation of ecologically conscious building features in Taman Negara Resort revealed that the resort design was minimally manipulated to blend with the natural features. Over dependence on mechanical systems to alter the interior climate has signified inappropriate design, disassociation from the environment, and non-sustainable use of resources.

The demand for eco-tourism or nature based tourism has increased drastically during these few years. This has caused the rush for development of more accommodation facilities in natural areas to cater for the demand. These developments usually do not give enough considerations to the impacts that it will impose on the natural environment. The study in Pantai Keracut was to develop a design of ecologically conscious accommodation structure based on the local and natural settings of the area. This study also consisted of two major phases. In the first phase, data gathering and analysis were carried out and plans indicating features within the study site was produced to determine the nature features and settings of the study site. It was used in the selection of the best area for siting the accommodation structure. The second phase of the study involved conceptualization of the ecologically conscious design for the accommodation structure. The ecologically conscious accommodation structure design consisted of three major features namely passive design feature, energy conservation feature (photovoltaic) and waste treatment feature. The incorporation of various naturally operated systems into an accommodation structure has demonstrated the potential of natural features to be utilized and could replaced the conventional power oriented system in many tourism areas. The low scale built environment proposed in Pantai Keracut Recreational Forest emphasized ecologically conscious features such as natural daylighting, natural ventilation and photovoltaic systems as an alternative towards a „clean and green“ tourism in the future, especially in the context of local environment.

D1 Cultural Diversity in Forest Management. Agroforestry

Performance of ginger as an understorey crop in *Ailanthus triphysa* stands grown at different densities and fertiliser regimes in Kerala, India

B. Mohan Kumar, Joseph Thomas and Richard F. Fisher
Kerala Agricultural University, College of Forestry, 680 654 Vellanikkara, Thrissur, India
Tel: 0487-370050, FAX: +91-487-370019, Email: kumar1@md3.vsnl.net.in

Keywords: Understorey production, PAR, Soil fertility

Ginger (*Zingiber officinale*) is an important spice crop of the humid Indian tropics. Being a shade-loving plant, ginger is grown in association with an array of tree species. *Ailanthus triphysa*, a fast growing multipurpose tree, is common in the ginger-based agroforestry systems of Kerala. Owing to its compact crown, moderate root spread and deep rooting tendency, *Ailanthus* is thought to be less competitive with associated field crops.

A split plot experiment with *Ailanthus triphysa* was initiated at Vellanikkara, Kerala, India in June 1991. Objectives included assessing the productivity and quality of understorey crops in agrisilviculture systems involving different *Ailanthus* densities and fertiliser regimes, besides analysing the growth and productivity of *Ailanthus* trees and the partitioning of solar radiation among the different components of the system. Main plot treatments consisted of four densities of *Ailanthus* (3333, 2500, 1600 and 1111 trees ha^{-1}) with three replications. Four fertiliser levels (0:0:0, 50:25:25, 100:50:50 and 150:75:75 kg ha^{-1} N, P_2O_5 and K_2O) formed the sub plot treatments. Ginger was planted as an understorey crop in this experiment in May 1994. There were six beds in all plots. Three monospecific ginger plots were established in the contiguous area. They, however, did not form part of the replicated experiment, and the mean was compared with other treatments using the ‘paired t test’.

Until four years after establishment of the experiment (when the current observations were made), there was no significant difference in *Ailanthus* growth and/or foliar chemical composition owing to tree density or fertiliser regime. Ginger grown in the interspaces of *Ailanthus* exhibited better growth as compared to the sole crop. In general 2500 trees ha^{-1} registered better growth of ginger. Fresh and dry rhizome yield of ginger was highest at this density.

Availability of photosynthetically active radiation (PAR) was inversely proportional to stand density. Available PAR ranged from 35-72% and 40-75% of that in the open, at 50 and 150 cm above ground level respectively in four-year-old stands. A strong relationship, however, was not established either between PAR and foliar nitrogen content of the tree or between PAR and rhizome yield of ginger.

Foliar N, P and K contents of ginger increased as growth progressed, but declined after reaching a maximum value at around two months after planting. Although monospecific plots recorded higher initial nitrogen levels, intercropping, particularly in the denser treatments recorded higher nitrogen levels subsequently. P and K followed a similar trend. Higher foliar nutrient concentrations observed in the high density treatments may be due to elevated physiological activity of the leaves, as they remained greener for a longer period. Ginger LAI/LAD was higher in the denser treatments. This in turn re-confirms the fact that optimal levels of shade may promote growth of the understorey ginger crop. Fertilisers applied to the tree component of the system did not influence the growth and yield of ginger. Essential oil and oleoresin contents of ginger also were unaffected by tree density and fertiliser regime, although the sole crop of ginger recorded the highest values for essential oil (0.98%) and oleoresin (3.98%) contents.

Three years of *Ailanthus* growth resulted in a noticeable reduction in site nutrient capital. Soil nutrient availability declined with increasing tree density. Control plots recorded higher values for mineral elements and organic C. Reduction in soil nutrient levels at higher densities can be explained by rapid nutrient removal by trees. *Ailanthus* being a fast growing tree may absorb nutrients rapidly, especially during the initial years, although this may be compensated by nutrient cycling later. Reduction in soil pH can be rationalised by litter decomposition and the consequent release of organic acids. Fertiliser application to *Ailanthus* altered soil mineral nutrient status, except N. Residual soil fertility (organic C, N and K levels) after the ginger crop was higher than before, presumably because of green manure and/or nutrient addition to the ginger crop.

The potential of *Albizia saman* (Jacq.) F.Muell (SAMAN) in silvopastoral Systems in Venezuela

Eduardo E. Escalante
Universidad de los Andes. Mérida, Facultad de Ciencias Forestales y Ambientales, Instituto para el Desarrollo Forestal (INDEFOR), ApartadoPostal 197, 3102-A Estado Trujillo, Venezuela
Tel: 58-71- 313952, FAX: 58-74-401580, Email: escalan@ forest.ula.ve

Keywords: *Albizia saman*, Agroforestry, Silvopastoral, Llanos, Venezuela

Saman *(Albízia saman)* is a multipurpose leguminous tree widely used in Venezuelan agroforestry systems as permanent shade in coffee and cocoa plantations, in small banana lots, homegardens and as live fences. Its main and most important use is as shade, shelter, and fodder in silvopastoral systems in Venezuelan savannas (llanos) and in the south and western areas around Lake Maracaibo. The high protein content of the fruits (15-18%), and significant pod production during the dry season in the savannas, makes this tree a key component of silvopastoral systems in the llanos of Venezuela.

Formerly known as *Samanea saman* (Jacq. Merr.) or *Pithecellobium saman* (Jacq. Benth), the species is found mainly in tropical dry forest, from 0 to 700 m above sea level, and also in tropical moist forest with 2200 mm annual rainfall, and can tolerate dry periods of up to 5–6 months. The tree has a wide crown, up to 30 m wide, providing good shade and shelter to animals in grazing lots, fodder (pods and leaves), wood for crafts, timber for construction and it also fixes nitrogen, so improving soil properties. Average total wood volume per tree has been estimated between 1.2 and 3 m^3 for individuals more than 50 years old and more than 100 cm in diameter, and total wood volume values (including the main and secondary branches) are up to 9 m^3 per tree.

A study conducted in Portuguesa State (Venezuela) showed the beneficial effect of saman canopy on soil properties and on pasture growing under the tree. Nitrogen, phosphorus and organic matter were found to decrease with distance from the tree stem (under the canopy) toward the open grassland.

Research done in llanos in Apure State, where trees were selected at random in grazing lots, allowed quantification of fruit production per tree during the dry season from February to May. Production ranged between 53 and 806 kg $tree^{-1}$, and average production was estimated at 219 kg $tree^{-1}$ during 110 days of fruit production. In the same study fruit protein content was determined at between 15.6 and 16.5%, during the dry season, with an average of 16% protein content during the four months of production.

Grazing lots with the highest percentage of saman shade (55-64%) had an average of 5 trees ha^{-1} which means that average fruit production can be estimated around 1095 kg ha^{-1} with 175 kg ha^{-1} of protein. The carrying capacity of Venezuelan llanos is very low, 3 to 5 ha Animal $Unit^{-1}$ depending on the season. Livestock farms with silvopastoral systems based on saman trees have the potential to supply 3000 kg of fruit AU^{-1}. Venezuela has 20 million ha of savannas, Colombia has also millions of ha in the southeastern llanos of the country, and more generally in seasonally dry pastures in Latin America, saman has a great potential to be the key component in silvopastoral systems of the livestock raising areas.

Participative Construction of Forest Farmers`Concepts and Expectations in the Philippines

Ernesto C. Bumatay, Jesus I. Giron and Eduardo O. Mangaoang
Visyas State College Of Agriculture, Department of Forestry, , 6521-A Baybay, Leyte, Philippines
Tel: 521 - 2027, 588 – 692, FAX: (632) 525 - 6849, Email: vicarp@mozcom.com

Keywords: Participative construction, Forest farmers, Concepts, Expectations, Philippines

This study was conducted in a village setting in the Philippines to: (1) picture the concept that forest farmers have of their collective and individual farms, trees and other forest resources and the extent of depletion and replenishment of forest resources; (2) determine forest farmers' expectations of their farm, what they will do and what they expect from outside intervention; and (3) explore forest farmers' concepts of environmental issues in relation to farm sustainability, the laws governing forests and community concerns over their farming systems.

The department of forestry of the Visayas State College of Agriculture (ViSCA) had a record of about 98 households farming in the ViSCA Forest Reserve. During interviews, 78 village households were identified as forest farmers occupying the Forest Reserve. Preliminary visits to respondents were done for a week. This enabled the researchers to introduce themselves, present the objectives of the study to the farmers and familiarize themselves with the forest farmers' domain and lifestyle, especially the forest farming cycle. Final data gathering was made through a series of personal and group interviews. During the interviews, no written questionnaire was used to allow respondents to freely express their ideas. There was unlimited time for interactions, and the seeking of information was conducted either individually or participatively in groups anywhere in the household, neighbourhood or in the farming area. When conducted in the residence, household members shared their thoughts and ideas. After interviews, farmers' responses were immediately reconstructed and recorded. Anecdotal recording was done after each visit to each respondent. Presentation of data is descriptive. Conclusive statements about respondents' concepts were based on consensus. Respondents were encouraged to reinforce their ideas with diagrams on paper or with stones, leaves and sticks on the ground.

Forest farmers have encountered various problems in their farming system within the Forest Reserve due to its terrain (steep slopes), the distance between their farms and their homes and prohibition of forest occupancy. They have told many times not to cut trees, to stop making 'swidden cultivation', and have eventually been asked to leave their farms by law enforcers. Most of the respondents said that they would continue to cultivate the farm they presently have because it was inherited from their ancestors. Other respondents said they would continue cultivating their farm because this was their primary source of livelihood.

Respondents said that having trees in the farm is good because they provide protection from strong winds and minimize surface runoff. Trees also serve as shade when they relax after work. However, the numbers of trees in the farm are already depleted and farmers perceive that it is necessary to replenish the area by planting fruit trees. The respondents preferred fruit trees because according to them this would serve two purposes: protecting their area from natural damage and providing income from their fruits.

The farms have become the main source of livelihood of the respondents. Despite the laws prohibiting the cultivation of forest areas for farming, respondents stand firm in their decision to continue planting in their farms. Respondents would like assistance from individuals, groups or agencies, either government or non-government, provided that this is not conditional on them being evicted from the farm they presently cultivate.

The respondents freely shared their knowledge, ideas, concepts and expectations related to their farming system. Results of the study should help development workers understand better the forest farmers' way of life and seek ways to alleviate marginal living among forest farmers.

Agroforestry Models in Karnataka: A Field Level Analysis

G. N. Dhanapal
University of Agricultural Sciences, 560 024 Hebbal, India
FAX: 00 91 80 3334804, Email: dhanapal@uasblr.kar.nic.in

Keywords: Agroforestry, Block plantation, Random planting, Species diversity, Social forestry range

Agroforestry is an integrated approach to develop land for growing food, fodder and fuelwood on the farm. Rainfed areas with large areas currently under wastelands could be brought under vegetation cover by adopting agroforestry techniques. This paper, based on a study conducted in different parts of Karnataka State, India, deals with the tree species on the farm under different agroforestry models, farmers' tendency to take up either block plantations or agroforestry and the various models of tree planting followed under different situations.

The study was conducted by selecting two social forestry ranges from each of the 20 districts in Karnataka State; thus a total of 1407 farmers were selected for the study. Out of this 39% had taken up block plantations, 54% random planting (planting of trees without any regular spacing or pattern, wherever there is space on the farm) and 7% both.

The important models under agroforestry are block plantations, bund planting, hedge planting, row/inter cropping and stream/river bank planting. Under block plantation, species diversity is limited as *Eucalyptus* hybrids and *Casaurina equisetifolia* are the dominant species but under random planting models, in addition to these two species, other species like silver oak (*Grevillea robusta*), subabul (*Leucaena leucocephala*), and *Acacia auriculiformis* are also planted.

Yakihata-zorin (Taungya) reforestation method as practiced in northern Japan: a perspective of this method in the Sampoku region

Hiroyuki Watanabe
Kyoto University, Graduate School of Agriculture, Sakyo-ku, 606-8502 Kyoto, Japan
FAX: 81-75-753-6372, Email: watanahi@kais.kyoto-u.ac.jp

Keywords: Taungya, Yakihata-zorin, Red turnip, Reforestation, *Cryptomeria japonica*

The taungya method is usually defined as a reforestation method in which tree seedlings and agricultural crops are simultaneously planted at the initial stage of reforestation until the amount of crop harvest decreases due to crown closure. After that only the trees are left, with the final aim to establish man-made forests. The reforestation method 'yakihata-zorin' or 'yakihata-ringyo' in Japan is virtually the same as the taungya method and dates back to the early 1700s. Many of the present well established forestry areas, where mainly the timbers of sugi (*Cryptomeria japonica*) have been produced, have their origin in yakihata-zorin. This method, however, is not currently being practised except in Sampoku, located (38° 30'N, 139° 30' E) in Niigata Prefecture facing the Japan Sea, and most reforestation elsewhere now involves tree planting without crop cultivation. The present conditions of areas using the yakihata-zorin method in the Sampoku region are examined here.

The main reason why this method is still used in this area is that crop cultivation after burning in newly logged area has been specialized for red turnip (*Brassica campestris* var. *glabra*), which is then processed into pickles with the brand name of 'Atumi-kabu' which is highly regarded as a delicious and natural food. Due to the popularity of natural foods, the demand for turnip cultivated in the burnt areas of yakihata-zorin is great and the market price has been increasing. The yield of red turnip is about 10 tons ha^{-1}. Red turnip can sell at a price of 160 Yen kg^{-1} and this profit goes to the cultivator. Repeated cultivation (continuous cropping) of red turnip in the same area, however, is not usually practised because of replant failure and in the second year azuki bean (*Vigna angularis*) is cultivated: after this no further crops are grown. At present, seedlings of sugi are provided by landowners and wages for planting are paid. According to estimates, about 840,000 Yen (approximately U.S. $8,000) are needed, including insurance, annuities, etc., both for land preparation and planting seedlings in the first year. Planting density is 2,500 trees ha^{-1} and cost of seedlings (2 years nursery grown) is 99 Yen. When landowners permit cultivation of turnip they can save at least 400,000 Yen (approximately U.S. $3,600) in expenses for land preparation. The expenses for weeding (approximately 120,000 Yen) in the second year are also saved due to azuki been cultivation. These economies in expenditure are the landowner's profits. The reduced cost of land preparation and tending with a shortening of the weeding period is the main factor contributing to the continuation of this method. In addition, activity in the marketing of turnip by the Forest Cooperative in this village is also highly regarded. The yakihata-zorin method has potential for improvement of taungya in tropical countries, mainly in southeast Asia.

The suitability of the Shamba system to forest plantation establishment in Kiambu district, Kenya: an evaluation of socio-economic issues

Joram K. Kagombe
Kenya Forestry Research Institute, Post Box # 20412, Nairobi, Kenya
Tel: 254-154-32891-3 or 32541, FAX: 254-154-32844, Email: kefri@arcc.or.ke

Keywords: Forest plantations, Shamba system, Socio-economics, Community participation

A socio-economic evaluation of the suitability of the shamba system in plantation establishment and improving the wellbeing of participating farmers was conducted in Kiambu district, Kenya. The study evaluated the development of the shamba system in Kenya through literature review and conducted evaluations of the current system through interviews with farmers using a questionnaire and interview with forest department (FD) officers using a prepared checklist.

The Kenya forest sector is characterised by the problem that the rate of forest estate clear fell does not match the rate of replanting, giving rise to backlogs in plantation establishment. Timely replanting of harvested plantation areas is a prerequisite to a sustainable plantation programme. Forest plantations are also facing increasing competition from other land-uses, mainly agriculture and settlements.

The FD has been establishing forest plantations using the shamba system since 1910. In its basic application, the shamba (shamba is a Kiswahili word for a small plot for cultivating crops) system can be considered as a temporal contact between a prospective farmer and the FD. The FD, as the owner of the land, is interested in the establishment of plantations at a low cost. It invites the farmer to assist in this process in exchange for allowing him/her to cultivate crops in the forest. The farmer clears the allocated forest area and cultivates subsistence crops for 18 months, after which the FD plants trees in the plot. The farmer takes care of the planted trees while cultivating crops for the next three years or until the tree canopy closes.

There have been changes in the management of the shamba system from its inception, including a period between 1987 and 1994 when the system was banned. These changes have had direct impacts in terms of delay in plantation establishment, as well as in the success and failure of these plantations.

The shamba system is critical to plantation establishment as shown by the consequences of backlogs in plantation establishment that followed its ban in 1987. It ensures low costs in plantation establishment and high survival of planted seedlings. The shamba system gives participating farmers high returns, in the range of US $1700 per hectare per year. It creates employment for farmers and ensures food security. Farmers valued shambas highly, stating that an empty shamba was worth US $61 and a shamba with crops US $1560. This means that farmers have economic motivation to own a shamba. However, it was also found that the methods used in shamba allocation are unfair and this can affect the commitment of farmers to forestry. Problems faced by farmers include: game damage, short periods of cultivation before trees are planted, lack of finances, poor roads and unstable market prices. The FD face the problem of damage of seedlings by farmers and management problems. The regulations in the shamba system are difficult to enforce without the farmer's participation.

The way forward for the shamba system is to consider it a form of Joint Forest Management (JFM), where the communities will get shamba and in return participate in forest protection. JFM allows establishment of joint management agreements that allow FD staff to redefine their relationship with the community and eventually to regain the trust and confidence of the villagers. The establishment of forest village committees in areas with shambas can act as a forum where the FD and farmers can discuss and solve various problems faced in the system before they get out of control. This will ensure a sustainable system of shamba, which will benefit the farmer and the FD.

The shamba system has a great potential to be developed as one form of JFM involving communities in forest management. Participation will ensure sustainability of forest plantations.

Agroforestry Systems and Their Bioeconomic productivity In North-Western Himalayan Region of India

K. S. Verma, S.R. Kachru and K. Upadhaya
College of Forestry, Dept . of Silviculture and Agroforestry, UHF P.O.Nauni, 173230 Solan, India
Tel: +91 1792 52422®,52270 (o), FAX: 91-1792-52242, Email: verma_ks@ yspuhf.hp.nic.in

Keywords: Biological yield, Co-efficient of variation, Lowlands, Operational land holdings, System type, Uplands

Productivity appraisal studies were carried out on existing agroforestry systems (AFS) in two agroclimatic zones, namely subtropical sub montane low hills (up to 914 m a.s.l.) (zone 1) and subtemperate subhumid mid hills (915-1523 m a.s.l.) (zone 2) in the North Western Himalayan region of India. The purpose of the study was to identify the existing AFS and to determine their bio-economic productivity.

A three-stage random sampling technique was used to select the sample area in both zones. Based on the size of their operational land holdings, farmers were divided into four social groups: marginal (<1 ha land), small (1-2 ha), medium (2-5 ha) and large (>5 ha). In zone 1 the sample area was sub-divided into uplands and lowlands based on topography. AFS were classified based on their structure and function. However, stratified classification of agroforestry practices was used to indicate the system types and the system units. Biological yield was calculated based on the harvested biomass from each system type whereas net returns were estimated on the cost of cultivation. Co-efficient of variation (C.V.) values which could explain the stability or the extent of system sustainability were also calculated.

In zone 1, a total of five AFS types, namely agri-silviculture, agri-silvi-horticulture, pastoral-silviculture, pastoral-horti-silviculture and pastoral-silvi-horticulture were found in uplands. In the marginal group agri-silvi-horticulture was practised by about 90% of the households. Its mean biological yield per farm and net returns were 7.8 t and US $97, respectively. The C.V. values for biological yield and net returns were 86.7% and 143.8% respectively (n=21). In the small farmers group also, agri-silvi-horticulture gave the highest mean biological yield and net returns. There were only two AFS in the medium group: agri-silvi-horticulture and pastoral-silviculture, each having only one system unit. None of the households fell into the large category.

Lowlands had the same five AFS as present in uplands. Marginal group farmers practised all five, small group farmers four and medium group farmers only three system types. Agri-silvi-horticulture gave the maximum mean biological yield (15.3 t) and net returns (US $371) per farm in the marginal group. The C.V. values were 53 and 152% (n=11), respectively. This AFS dominated the yield and net returns in the small and medium groups too. Uplands and lowlands had three AFS types, agri-silviculture, agri-silvi-horticulture and pastoral-silviculture, in common among the different social groups of farmers. Co-efficients of variation for biological yield and net returns for these systems were more or less of equal magnitude although in lowlands the variation in net returns was higher.

In zone 2, seven AFS types were found: agri-silviculture, agri-horti-silviculture, agri-silvi-horticulture, pastoral-silviculture pastoral-silvi-horticulture, pastoral-horti-silviculture and agri-horticulture. Farmers in the marginal group practised all seven, and in the small group all except agri-horticulture. Farmers in the medium and large groups each practised only two, agri-horti-silviculture and pastoral-silviculture by the medium group and agri-silvi-horticulture and pastoral-silvi-horticulture by the large group. In the marginal group agri-silvi-horticulture gave the maximum mean biological yield (11.6 t) and net returns (US $535) per farm with C.V. values of 76 and 124% (n=19), respectively. In the small group also agri-horti-silviculture gave the maximum mean biological yield (19.5 t) and net returns (US $ 961) with C.V. values of 40 % (n=3) in each case. Other system types behaved similar to those above for their yield, net returns and variability in both of these parameters.

Agri-silvi-horticulture in zone 1 and agri-horti-silviculture in zone 2 were found to be the most productive system types although biological yield and net returns accrued from these presently were found to be little more unstable.

Effect of tree prunings as a source of nitrogen on a rice-wheat cropping sequence

M. I. Ali, M. A. Haque
Bangladesh Institute of Nuclear Agriculture, Post Box # 4, Mymensingh, Bangladesh
FAX: 880-91-54091, Email: bina@bdmail.net

Keywords: Agroforestry, N uptake, Sustainable practices, Rice yield, Wheat yield

High fertilizer costs, decreasing soil organic matter, and an increased awareness that more sustainable production practices are needed have renewed interest in providing N for crops through agroforestry practices. This study was undertaken to quantify yield responses and the amount of N taken up by rice (*Oryza sativa* L.) and subsequent wheat (*Triticum aestivum* L.) crops from prunings of two perennial legume tree species (*Dalbergia sissoo* and *Albizia saman*). Rice and wheat crops were grown between hedgerows of trees in an alley cropping system on a medium high silt loam soil in Bangladesh. There were three treatments for upland rice, two of which had tree prunings from either *D. sissoo* or *A. saman* equivalent to 80 kg N ha^{-1} along with 20 kg N ha^{-1} from ^{15}N-labelled ammonium sulphate (10% a.e.) and the remaining treatment having no tree prunings but supplied with 100kg N ha^{-1} through ^{15}N-labelled ammonium sulphate (1% a.e.). Straw and grain yields and yield components were measured for the rice crop and the fraction of ^{15}N accumulated by the crop was determined. Wheat was then grown in the same plots during the rabi season to determine the residual effects of the ^{15}N fertilizer and tree prunings. In this case, the treatments which received tree prunings during the rice crop were fertilized with non-labelled N fertilizer at 75 kg N ha^{-1} while the treatment without tree prunings received 100 kg N ha^{-1}. The effect of any residual N contribution from tree prunings on wheat was estimated by comparing the values in treatments with and without tree prunings in the previous rice crop.

Yield of both grain (max. 4.39 t ha^{-1}) and straw (max. 6.72 t ha^{-1}) were significantly improved by the application of tree prunings, with the effect on both grain and straw being more pronounced for *A. saman* (42% higher for grain and 23% for straw) than *D. sissoo* (35% higher for grain and 17% for straw). Application of leaf litter substantially increased N uptake (61-92 kg ha^{-1}) of the rice crop by 42-50%. Fertilizer N recovery in rice was low, being 17 to 19% while the N contribution from leaf litter to rice yield was 49-55%. Residual effects on the wheat crop were not significant, although yields were increased where prunings had been applied to the previous rice crop even though less fertilizer N (75 kg ha^{-1}) was applied compared to plots receiving the full dose of N (100 kg ha^{-1}). Both the content and uptake (89-110 kg ha^{-1}) of N in wheat were also substantially higher in leaf litter treated plots. Residual ^{15}N in wheat was low (2.1-2.5% in pruning treated plots and 5.2% in untreated plots) but followed the trend of that in rice. The residual N contribution of tree prunings to wheat yield ranged from 19 to 24%. Incorporation of legume tree clippings increased total N and organic C content in soil determined at harvest of both crops.

It was concluded that N and organic matter applied through the tree prunings improved soil conditions and resulted in higher production of both rice and wheat. Therefore, applying tree prunings from *A. saman* and *D. sissoo* are recommended for soil enrichment and sustained productivity.

Biomass studies on Populus deltoides Marsh under different land use systems

P. S. Chauhan, A.N. Dey

FAX: +91-1792-52242, Email:
chauhanps@mailcity.com, tgri@yspuhf.hp.nic.in

Keywords: *Populus deltoides*, Biomass, Land use

The present investigations were carried out in the two experimental areas of the Department of Silviculture and Agroforestry of Solan district of Himachal Pradesh (India), which lies between 30°50′ N latitude and 70°11′E longitude. The objective was to evaluate and compare the growth and biomass production of *Populus deltoides* Marsh under different land use systems. The experimental areas, located at an elevation of 1200 m above mean sea level, embody moist sub-temperate climate and are characterised by undulating topography with similar climatic and edaphic conditions. The study was undertaken in agri-silvicultural and silvopastoral systems consisting of 15-year-old pure even-aged plantations of *Populus deltoides* at a spacing of 4 m x 5 m with three replications.

The biomass production of *Populus deltoides* Marsh was greater in the agri-silvicultural system (75.2 t ha^{-1}) than in the silvopastoral system (47.4 t ha^{-1}) under a similar set of environmental conditions. Diameter at breast height under the agri-silvicultural and silvopastoral systems varied from 22 to 28 cm and 12 to 19 cm respectively.

Height ranged from 20.4 to 23.9 m in the agri-silvicultural system compared with 13.8 to 15.1 m in the silvopastoral system.

Specific gravity, which greatly influences the yield and quality of wood products, although strongly controlled by genotype, varied considerably within in the two systems. Also it varied from trees of lower diameter class to higher diameter class and with the location of wood within the tree, i.e. from the base to the top. On average, specific gravity varied from 0.420 to 0.436 in the agri-silvicultural system and 0.404 to 0.410 in the silvopastoral system.

Such differences in growth parameters are the manifestations of the type of land use and thereby the management practices traditionally followed in them. In the agri-silvicultural system, wheat (*Triticum aestivum*) and tuberous crops (*Zingiber officinale* - ginger, *Curcuma longa* - turmeric and *Colocasia esculenta*) were raised and thus standard tillage practices along with application of irrigation and fertilizer were followed, whereas in the silvopastoral system, natural grasses viz. *Chrysopogon montanus*, *C. gryllus*, *Heteropogon contortus* and *Themeda anathera* grew between the trees and were not given inputs in the form of fertilizer and irrigation. The grasses were harvested every year during October - November. Thus, the trees showed better performance with agri-silvicultural land use compared to silvopastoral land use.

Data on nutrient content of leaf tissue of *P. deltoides* indicated that N, P and K contents were higher in larger diameter classes of tree in the agri-silvicultural system, while in the silvopastoral system the reverse pattern occurred (except for K), but there was no consistent variation in concentration with an increase in diameter. Considering the biomass production potential it is concluded that for poplar grown in similar edapho-climatic conditions, the agri-silvicultural system is a more viable proposition than the silvopastoral land use system.

Canopy management impact on root characteristics, water use efficiency, photosynthesis and biomass production potential in agroforestry tree species

P. S. Thakur, S. Sehgal
University of Horticulture and Forestry, Department of Silviculture and Agroforestry, 173 230 Solan (HP), India
FAX: 91-01792-52242, Email: saf@yspuhf.ren.nic.in

Keywords: Coppicing, Foliage and branchwood biomass, Pollarding, Resource capture, Yield advantage

In agroforestry systems, trees are grown in close proximity to crops and pastures. Trees and crops compete with each other for critical resources. The reasons why certain trees and crops are compatible while others are not need to be understood clearly. Substantial and reliable information is required before biomass production/yield advantage can be improved. Canopy architecture is an important character which influences resource capturing and sharing. The objective of the present investigation was to underline the impacts of canopy management practices like coppicing and pollarding on root characteristics, water use efficiency (WUE), photosynthetic rates and foliage and branchwood production in important agroforestry trees of the temperate region.

Coppicing (to 0.5 m height) and pollarding (to 1.0, 1.5 and 2.0 m) treatments were imposed on four-year-old plants of *Grewia optiva*, *Celtis australis*, *Bauhinia variegata* and *Morus alba* M-5 (2666 stumps ha^{-1}) planted at spacing of 1.5 m (plant to plant) x 2.5 m (row to row). Stump height was maintained at the same level by removing new shoots every year. Observations were made three years after imposing treatments.

During the present investigation, coppicing and pollarding significantly affected the number of lateral roots. Pollarded plants of *M. alba*, *G. optiva* and *C. australis* produced a significantly higher number of roots than *B. variegata*. Diameter growth of proximal and lateral roots was higher in pollarded than coppiced plants. In *M. alba* and *G. optiva*, 66-84% of the total roots were found distributed in the 90° quadrant between east and north.

Irrespective of cutting height, higher WUE was observed in *M.. alba* and *G. optiva* as compared to *C. australis* and *B. variegata* under similar growing conditions. WUE was comparatively higher from May to August in all four species. A close relationship between WUE and total biomass production indicated that even if WUE *per se* was less for all the trees, the available water was used economically for growth processes associated with the production of biomass.

The biomass production potential of tree species, indeed, depends on the ability to maintain higher photosynthetic rates. The data indicated that higher photosynthetic rates from May to August in *M. alba*, *G. optiva* and *B. variegata* resulted in higher total biomass production (t ha $^{-1}$) in these tree species.

Coppicing and pollarding significantly affected foliage as well as branchwood biomass production in all four species, with a maximum total biomass (12 t ha $^{-1}$) in *M. alba* followed by *G. optiva* (8 t ha $^{-1}$) pollarded at 2.0 m. Pollarding at 2.0 m cutting height is recommended as the best canopy management practice for producing higher total biomass in *M. alba* and *G. optiva* under rainfed conditions. The lower total biomass in *C. australis* is probably the result of inability of this tree species to withstand coppicing and pollarding over successive years.

Evaluating N-fixing Living Stakes for Organic Tomato (Lycopersicon esculentum) Production in Costa Rica

Patrick E. Chesney, A.M. Schloenvoigt, D.C.L. Kass, D. Murach and P.L.G. Vlek
CATIE, Area for Agroforestry, 7170 Turrialba, Costa Rica
Tel: +506 558 23 64, FAX: +506 556 15 76, Email: pchesney@catie.ac.cr

Keywords: Biomass, Diseases, *Erythrina poeppigiana*, *Gliricidia sepium*, Nutrient concentration, Yield

Conventional tomato production on hillside farms in Costa Rica is costly to farmers and to human and ecosystem health. This cost could be reduced with the incorporation of soil improving leguminous shrubs into tomato farms and the concomitant reduction in use of agrochemicals, the main cost factor. Additionally, the output of tomato with an organic label is likely to appeal to health conscious consumers. A study was initiated in 1998 to evaluate two common N-fixing tree species as living stakes for tomato produced without applications of mineral fertilisers and insecticides, in an alley-crop arrangement of shrub and crop components. *Erythrina poeppigiana* seemed to influence a more favourable environment for higher foliar biomass and fruit yield in tomato than *Gliricidia sepium*. Tomato diseases which attacked in tandem were differentially favoured by the leguminous species. Growing tomato plants in *Gliricidia* plots had higher mortality from infection with *Pseudomonas solanacaerum* than in *Erythrina* plots. Fruiting tomato plants suffered higher fruit loss and plant mortality rates from infection with *Phytophthora infestans* in *Erythrina* plots than in *Gliricidia* plots. Support age and by implication the shading effect influenced the severity of *Phytophthora* infection. Tomato staked to eight-year-old *Erythrina*, compared to two-year-old stakes, were more affected by this disease. The mitigation of the favourable microclimatic conditions for *Phytophthora* and the reduction of competition for light is considered to be the most efficient approach, in order to optimise the crop production in an organic management system. Thus, a study was initiated in 1999 to evaluate the shoot pruning management of the leguminous living stakes with the specific aim to re-evaluate the variables mentioned above and to quantify the concomitant below-ground effects of shoot pruning of the two woody species. This study is currently supported by the International Foundation for Science. The biophysical interaction of two common leguminous species for organic tomato production in an agroforestry arrangement in the humid tropics is discussed.

Intercropping Trials in Bamboo Plantations

Piramanayag Shanmughavel, K. Francis
Bharathiar University, Dept. Botany, 641 046 Coimbatore, India
FAX: 091 422 422387, Email: shanvel_99yahoo.com or botany@bharathi.ernet.in

Keywords: Bamboo plantations, *Bambusa bambos*, Intercropping, Pigeon pea, Growth, Yield, Land equivalent ratio (LER), Economics, Litter production, Nutrient return

Agroforestry is the practice of agriculture and forestry on the same piece of land. Bamboo (*Bambusa bambos*) is a household species and is the best friend of the farmers. The present crisis in sustained availability of bamboo can be resolved only by raising elaborate bamboo plantations. In India normally bamboo plantations are grown at a spacing of 6 x 6 m to meet the increasing demand for bamboo products. Research has increased rapidly in recent years to cultivate agricultural crops in the interspaces of bamboo plantations. This paper presents the results of intercropping trials with pigeon pea (*Cajanus cajan)* in bamboo plantations. The sampling area (4 ha) was a five-year-old plantation of pure bamboo. Throughout this area, bamboo culms in their fourth and fifth years were harvested. Pruning was done of the remaining culms. One ha of this plantation was kept as a control. In the other three ha, bamboo was intercropped with pigeon pea (ICPL-88034) with 1:1 rows. In another trial sole pigeon pea was cultivated. The density of pigeon pea was 278 plants ha^{-1} and the grain yield obtained was 600 kg ha^{-1} (intercropped stand) and 700 kg ha^{-1} (pure stand). For bamboo, an average of 11 culms were produced in the intercropped stand compared with 19 culms in pure stands. The profitability of pure bamboo stands would be in the order of Rs. 24,900 (US $600), whereas the profitability of the intercropped bamboo stand would be in the order of Rs. 21,800 (US $510), which is slightly lower due to underground competition for nutrients and water in the intercropped stand. The profit obtained from the intercropped agricultural crop is Rs. 7,900 (US $190), whereas the net income from the pure pigeon pea crop is Rs. 13,000 (US $300).

The land equivalent ratio (LER) of bamboo producing culms (dry weight) with a pigeon pea intercrop showed:

Sole pigeon pea	Sole bamboo	Intercropping
0.7 t ha^{-1}	2.2 t ha^{-1}	0.6 t ha^{-1} grain + 0.9 t ha^{-1} culms

The land equivalent ratio of the system =

$$\frac{0.6}{0.7} + \frac{0.9}{2.2} = 1.2$$

This means that the productivity of 1 ha under intercropping is equivalent to that of 1.2 ha under the sole system. The bamboo plantations intercropped with pigeon pea produced a higher quantity of litter than pure bamboo stands. Litter fall followed a bimodal pattern with a principal peak in the winter and another in the late summer. Of the total annual litter production, leaf litter accounted for 58% and twig litter 42%. The annual litter production was 13.5 t ha^{-1} in the pure bamboo stand and 15.7 t ha^{-1} in the intercropped stand. With regard to nutrients, the highest concentration of N, P, Ca and Mg was in leaf litter. In twig litter, the maximum concentration of K was observed. On an annual basis 89, 6, 78, 42 and 49 kg ha^{-1} (pure bamboo stand) and 113, 9, 106, 52 and 60 kg ha^{-1} (intercropped stand) of N, P, K, Ca and Mg respectively was returned through leaf litter. The results from these studies can be used as a guideline for improvement of productivity in agroforestry models.

Economic Evaluation of Tea Based Agroforestry

Rajesh K. Rana, SC Tewari, and YS Negi
Regional Centre NAEB, Ministry of Environment and Forests, 173 230 Nauni, Solan (H.P.), India
Tel: +91-1792 52487 (0), FAX: +91-1792 52242, Email: ssc@yspuhf.hp.nic.in

Keywords: Economic evaluation; Tea-based agroforestry; Linear programming; Returns-over-variable-cost; Employment generation

The present paper analyses the economics of tea-based agroforestry systems in the tea-growing pockets of Kangra and Mandi districts of Himachal Pradesh (India). Himachal tea, commercially famous as *Kangra Tea*, is known for its strong flavour and is often in demand for blending with Assam tea. The study was based on survey information obtained from 34 randomly selected agroforesters, spread over 12 villages in the Palampur tea-growing region of the state.

Tea productivity of the area is substantially lower than that of other tea-growing areas in the country. The reasons for this are the geographically distant and infrastructurally underdeveloped area, distant markets, lack of trained labour and legal restrictions on changing the land use pattern of the tea gardens. Forest tree harvesting rules also contribute towards this, as at times harmful shade trees like *Pinus roxburghii* cannot be easily removed from the gardens. The surveyed farmers, on average, had a large number of trees (226) in tea gardens, pasture lands (189) and on the bunds of agricultural holdings (30).

The linear programming technique was used for formal analysis of the data. The existing agroforestry system on the sample farms was compared with two variants, one involving the re-allocation of existing resources under existing technology (Plan-I), and the second incorporating the use of technology recommended by the local agricultural extension institutions (Plan-II). The systems were analysed in terms of their different components (real activities) like forest trees, tea gardens, pasture lands, livestock and agricultural crops. The model thus consisted of 39 real activities and 34 constraints. The economic advantage of a system was measured in terms of the net returns-over-variable-cost.

Under the existing management pattern, the average sample farm generated US$ 4232.02 per annum, of which the contribution of tea was nearly 86%. Tea was followed by forest trees, which had a contribution of about 5%. Under Plan-I, there was a significant change in the suggested physical levels of various real activities. The Plan-I activity levels, however, did not change in Plan-II. However, use of recommended technology under Plan-II improved returns over variable cost considerably. Plan-I suggested significant change in the composition of forest trees, with *Grewia optiva* (an excellent fodder tree) on field bunds and 238 trees of *Albizia chinensis* (a good shade tree) in tea gardens. Returns-over-variable-cost increased by 48.54% in Plan-II as compared to the returns-over-variable-cost under the existing management plan and 40.64% as compared to Plan-I. Similarly, employment generation potential under Plan-II increased by 36.91% over Plan-I and 46.14% over the existing farm management pattern. All this was linked to the additional capital requirement of US$ 95.04 per farm under Plan-I and US$ 594.31 for the shift from Plan-I to Plan-II.

The study revealed that the use of improved technology can improve the profitability and employment generation capacity of existing tea-based agroforestry systems. Thus efforts to build farmers' confidence through various incentives can go a long way in improving the health of tea-based farming systems in the region.

Product Quality Affected by Associated Plants in Agroforestry: Case Studies with Coffee and Timber from Costa Rica

Reinhold G. Muschler
CATIE/GTZ, Proyecto Agroforestal, Apdo 126, 7170 Turrialba, Costa Rica
FAX: +506 5561533, Email: muschler@catie.ac.cr

Keywords: Agroforestry, Aroma, Bean size, Coffee, *Cordia alliodora*, Costa Rica, *Erythrina*, Tasting, Timber

The evaluation of agroforestry associations has traditionally focussed primarily on the quantities of the crops and trees produced. Quality attributes, of increasing importance for emerging specialty markets such as gourmet coffee, have generally been neglected. In this paper, the possible effects of agroforestry associations on the quality of products are reviewed and illustrated with studies on the quality of coffee and timber from plants grown in agroforestry associations or in pure plantations.

In low-elevation, sub-optimal environments for coffee in Costa Rica, increasing shade intensity from 0% to more than 80% under unpruned shade trees (*Erythrina poeppigiana)* increased bean size of *Coffea arabica* significantly. While the large beans (diameter > 17/64ths of an inch (6.75 mm)) accounted for 49 and 43% of the coffee from sun-grown Caturra and Catimor, respectively, these proportions increased to 69 and 72% under dense permanent shade. Blind tasting experiments showed consistent shade-induced improvements in appearance of green and roasted coffee as well as in acidity and body of the brew. The higher quality under shade demonstrated the power of tree facilitation under sub-optimal low-elevation conditions.

Preliminary results on timber quality of 12-year-old *Cordia alliodora*, a high-value timber species from Costa Rica, showed increased cracking of centerpiece boards and significantly reduced branchless bole lengths from the trees that grew fastest. These were the trees grown in agroforestry associations where they benefitted from weeding and fertilization of the associated crops. Pure plantation timber had less defects. Detailed information on structural and stability attributes of the timber will be available by the end of 1999. The study of quality aspects and determinant environmental controls deserves increasing attention in the future.

Root and Water Dynamics in a Water-limited Agroforestry System

Sara Namirembe, R.M. Brook and C.K. Ong
Makerere University, Faculty of Forestry and Nature Conservation, Uganda
Tel: 256 41 543647, FAX: +256 41 533574, Email: agrofor.foresmuk@infocom.co.ug

Keywords: *Senna spectabilis*, Maize, Bean, Roots, Soil moisture

Investigations were conducted on a water-limited sandy-loam soil in Machakos, Kenya with *Senna spectabilis* (DC.) Irwin & Barneby (senna) grown as a standard tree or a hedge (pruned to 0.5 m) and planted as single rows in combination with *Zea mays* L. (maize) in April to July 1997 and *Phaseolus vulgaris* L. (beans) from October 1997 to January 1998. The effects of shoot pruning of senna on root turnover and soil moisture distribution were investigated. Soil moisture between 35 and 175 cm depth was monitored weekly using a Wallingford neutron probe. Soil moisture characteristics were determined using the filter paper method. Root sampling in the top 50 cm soil horizon was done at three time scales: every 14 days using minirhizotron tubes in conjunction with photography, every 30 days using coring and every 150 days using trenching.

Trenching was the most destructive method, but it yielded the most continuous spatial information for senna root distribution, whereas coring and minirhizotrons were prone to discontinuity and random differences due to sampling from discrete locations. Senna root presence over time in the two dimensional plane from minirhizotrons was poorly related to that in three-dimensional soil volumes from coring, possibly because measurements were started too soon after installation of the minirhizotrons. Nevertheless, the ability of minirhizotrons to detect root turnover over a short time scale is strongly supported by the self-explanatory nature of data they generated. This could not be observed from coring alone.

If minirhizotrons are to be used on their own, they are best suited for qualitative studies such as diagnosis of pathogenic activity or abnormal growth in roots, but not for quantitative root demography. Coring provided the best compromise, yielding reasonably quantitative information on spatial root distribution at a reasonable sampling frequency.

Maize and bean root length density were greatest in regions with low senna root length density and were higher in the hedge system than in the standard tree treatment. The synchrony of tree standard and hedge root dynamics observed from minirhizotrons implied that root death and growth were driven more by below-ground conditions than by the stage of development of the crown structures. Contrary to what others have observed, root turnover was lower in the pruned system. Root quantities estimated from trenching were similar in both senna treatments in February and September, 1997, showing that by the end of the dry season, pruning effects had been overtaken by the effects of limitation in water availability. Total root length density was poorly correlated with soil moisture, especially when soil water potentials were higher than -100 kPa because the drying effect of roots was quickly neutralised by equilibration of water within the soil matrix.

Architectural Variation in Tree Roots of Populus Deltoides Planted Under an Agrisilviculture System

Sunil Puri
Indira Gandhi Agricultural University, Department of Forestry, , 492 012 (M.P.) Raipur (M.P.), India
Tel: +91 771 420828, FAX: 91-771-424532

Keywords: Biomass, Root distribution, Fine roots, Coarse roots, *Populus deltoides*, Agroforestry system

Agroforestry involves matching trees and crops so that they complement one another and share the available resources effectively in order to attain maximum productivity. A knowledge of biomass production and the distribution of root systems therefore has considerable practical value. Above-ground and below-ground biomass production and the distribution of coarse and fine roots were studied in 9-year-old *Populus deltoides*. The roots were excavated by the skeleton method (dry excavation), digging along the course followed by the roots in the soil mass. An area of about 4 m radius around each tree was excavated up to 1.3 m depth. The roots were classified into fine (<2 mm) and coarse (>2 mm) roots. Tree densities were 2250, 531 and 208 per hectare in stands of 2 m x 2 m, 4 m x 4 m and 6 m x 6 m spacing, respectively. The total biomass (both above- and below- ground) varied from 71.50 tons ha^{-1} to 251.50 tons ha^{-1}, depending on tree density. Among the different tree components, stemwood contributed the maximum biomass (66.3-71.3 %), the biomass was in the order of stem > root > branches > leaves.

Patterns of root distribution showed that most of the coarse roots were distributed in the top 30 cm of soil, whereas fine roots were concentrated in the top 15 cm. Coarse root biomass decreased with an increase in spacing from 29.8 tons ha^{-1} in the stand of 2 m x 2 m to 5.6 tons ha^{-1} in the stand of 6 x 6 m. In contrast fine root biomass increased significantly (P>0.05) from 13.8 to 23.0 tons ha^{-1} in the stands of 2 m x 2 m and 6 m x 6 m, respectively. No significant difference was observed in the horizontal distribution of fine roots at different distances from the tree rows at a particular depth in any of the stands. Total below-ground biomass was equal in the stands of 4 m x 4 m and 6 m x 6 m, although the former had twice as much above-ground biomass as the latter. The shoot:root ratio decreased with an increase in spacing. The study indicates that the bulk of the roots of poplar are found near the surface, and hence there may be root competition with agricultural crops. The architectural variation data reveals that the general notion that under agroforestry system tree roots go deep and do not compete with crops is refuted at least in the case of *P. deltoides*-based agrisilviculture systems.

Evaluation and species selection for efficient agroforestry systems in central dry zone of Karnataka, India

T. B. Basavaraj, C.P.Gracy and B.L.Chidananda
University of Agricultural Sciences, Department of Agricultural Economics, Bangalore, India
FAX: +91-080-3431988, Email: gracy@uasblr.kar.nic.in

Keywords: Agroforestry systems, Light interception, Dryland, Central dry zone, Finger millet, Spacing trials

A study in tree species selection for efficient agroforestry systems was conducted in the sixth year of an ongoing agroforestry trial at the Zonal Research Station, Tiptur, in Karnataka State of India under rainfed conditions with a mean annual rainfall of 585 mm. The trial included nine treatment combinations of three fruit tree species (jack (*Artocarpus heterophyllus*), mango (*Mangifera indica*) and tamarind (*Tamarindus indica*)) at three spacings (8 x 8 m, 12 x 8 m and 16 x 8 m) with finger millet (*Elusine coracana L.* Gaertn.) grown between the trees during the rainy season. There was also a control treatment with finger millet grown without trees. The plot size for each treatment including the control was 48 x 24 m. The experiment was laid out in a randomized block design with two replications. The soil was red sandy loam in texture, slightly acidic in reaction (pH 6.5) and medium in available nitrogen (329 kg ha^{-1}), phosphorus (32.5 kg ha^{-1}) and potassium (425 kg ha^{-1}). Observations were made of tree growth, light intercepted by trees and crop and yield of finger millet at different distances from the trees. Data were analysed using analysis of variance.

Jack trees had significantly larger height (5.73 m), collar diameter (18.19 cm) and crown width (4.74 m) than mango (2.36 m, 11.7 cm and 3.04 m respectively) and tamarind (4.4 m, 11.64 cm and 3.59 m respectively). Diameter at breast height was significantly higher in jack (15.52 cm) than tamarind (11.08 cm), while that of mango could not be recorded as it had branches from the base of the tree. Jack intercepted more light (38.3%) compared with mango (23.4%) and tamarind (22%). Jack intercepted light up to 4 m from the tree compared with only 2 m in the case of mango and tamarind. Closer spacing of 8 x 8 m greatly reduced the availability of light to finger millet compared to wider spacing due to more canopy area of trees, as the number of trees were more in 8 x 8m spacing (156 trees ha^{-1}) compared to 12 x 8 m (104 trees ha^{-1}) and 16 x 8 m spacing (78 trees ha^{-1}). The grain and straw yield of finger millet were reduced in agroforestry compared to control. The reduction was more in plots grown with jack and at closer spacing. Significant reduction in yield was observed up to 2 m from trees in all the species (over 40% in jack, 28% in mango and 18% in tamarind). However, at distances of 4-6 m and 6-8 m there were higher grain yields than in the control in both mango- and tamarind-based agroforestry systems. Considering the total economics of the system as a whole, mango and tamarind species are better suited to agroforestry involving finger millet.

Insect pests and their impacts on forest Agroforest trees in the Western Himalayas

Tara Dutt Verma
Univ of Horticulture and Forestry, Dept. Entomology and Apiculuture, 173 230 Nauni, Solan (H.P.), India
FAX: +91 1792 52242, Email: asc@yspuhf.hp.nic.in

Keywords: *Diorhabda lusca*, *Ectropis deodarae*, *Dioryctria abietella*, *Curculio sikkimensis*, *Hypsipyla robusta*, *Apriona cinerea*

The incidence, extent of damage and impact of insect pests was studied in the last few years on some economically important forest and agroforest trees in the Western Himalayan region of India. Among the coleopterans, *Diorhabda lusca* Maulik was recorded as a serious pest of *Celtis australis*, a common summer fodder tree that grows naturally in the traditional agro-ecosystems of the middle and lower Himalayan region. Impact evaluation studies on the pest carried out during 1990-91 revealed that three larval instars and adult beetles caused 15.9, 37.5, 67.0 and 71.6% defoliation of the trees, respectively. The overall average foliage damage during May, June, July and August was recorded to be 34.9, 46.6, 50.7 and 53.6%, respectively. Similar damage symptoms were inflicted by other chrysomelid beetles like *Chrysomela populi* Linn. and *Plagiodera versicolora* Laich. on Populus and Salix foliage.

The bioecology of *Curculio sikkimensis* Heller, a pest of oak (*Quercus leucotrichophora*) acorns, was studied during 1996-97. The maximum infestation (81.6%) was observed at Kandaghat as compared to two other sites, one each at lower and higher elevation. The infested acorns did not germinate as the pest ate away the endosperm. Thus, natural regeneration was adversely affected as a result of pest attack. Shrinking of oak forests in the western Himalayan region in recent years can be attributed to pest attack besides over-exploitation of the species by the increasing population. The poplar stem borer, *Apriona cinerea*

Chever., is a serious pest of poplar (*Populus deltoides*) trees in the region. It is a well established pest in the Kashmir valley and also attacked poplar trees in Himachal Pradesh and the Tarai area of Uttar Pradesh where poplars are grown in social forestry and agroforestry plantations. Young trees (2-5 years old) are more prone to attack and 25% mortality of such trees occurs due to stem borers in establishing plantations.

Lepidopteran pests were the other important group infesting various tree species. In the deodar (*Cedrus deodara*) forests in Himachal Pradesh, *Ectropis deodarae* Prout appeared in epidemic form in the beginning of the 1990s. It caused complete defoliation of the trees in several localities, as a result of which the affected forest looked brown towards the end of June. The affected trees in such forests were found to show die-back symptoms. *Dioryctria abietella* Denis and Schiff. is another serious pest of all the conifers in this region. In addition to acting as a shoot borer, it is a serious pest of cones and seeds. Variable damage to cones of different conifers was recorded in 1992 and 1993 during June and August with respect to different crown levels of trees and locational aspects. The lower crown and southern aspect had higher levels of cone infestation as compared to the top and middle crown and northern aspect. However, in the case of chilgoza pine, *Pinus gerardiana*, cone infestation was higher in the middle crown as compared to the bottom and top levels. Seed infestation averaged 69.6, 26.3, 3.2, 62.3 and 16.9% in chilgoza pine, blue pine (*P. wallichiana*), chir pine (*P. roxburghii*), *Cedrus deodara* and spruce *(Picea smithiana*), respectively. *Hypsipyla robusta* Moore is a serious pest of Toona ciliata which caused very high shoot (62.5%) and sapling (93.3%) damage during 1994-95 in 2-3 m tall trees. The pest also caused as much as 44.4% fruit infestation and adversely affected seed germination by up to 20%. Infestation also resulted in deformation of apical growth and development of stag-headed, forked and crooked, branched boles unsuitable for timber, besides affecting natural regeneration by affecting seed germination. The poplar shoot borer, *Eucosma glaciata* Meyrick also caused similar type of damage on *poplar (Populus ciliata*) seedlings and saplings.

Reactions of changed water and nutrient supply on a forest ecosystem

Achim Dohrenbusch, Michael Bredemeier, Nobert Lamersdorf
University of Göttingen, Institute of Silviculture and Forest Ecology, Buesgenweg 1, D-37077 Goettingen, Germany
FAX: +49-551-393270, Email: adohren@gwdg.de

The effects of environmental parameters on individual reactions in forest ecosystems can be best investigated under laboratory conditions. Here it is possible to modify single factors while other variables are kept constant. However, the transfer of the results thus obtained to the ecosystem, is problematic. The roof project in Solling, FRG is a long-term experiment, where the impact of manipulated enviromental conditons can be observed for all compartments of a forest ecosystem. With this interdisciplinary experiment the important question should be answered, wether a strongly reduced acid and nitrogen input can improve the health of forest ecosystems.

The experimental site is a 60-year-old Norway spruce stand in the Solling mountains (51°46',09"N;9°34' 52" E), about 500 m above sea level, characterized by a cool humid climate and a high input of SO_2-pollution during winter months. The large scale experiment concentrates on two basic environmental changes, which were simulated by quantitative and qualitative manipulation of element inputs. The effects of an improved immission quality which can be expected as a result of implementation of air protection measures, were investigated in a de-acidification experiment („clean rain experiment“). The effects of long periods of drought phases were tested in a drying out experiment. Three transparent roofs of 300 m^2 each were constructed under the canopy of the 25 m high Norway spruce stand. In order to carry out the measurements in the crown area, a crane 30 m high was installed in the center of the roofed area. With this method regular physiological measurements of the carbon budget (photosynthesis, respiration) and the water budget (transpiration, xylem water potential, osmotic potential) as well as the shoot elongation were carried out. In addition each year needle samples were taken for element analyses and also an assessment of the condition by visual observation of the needle losses and needle chlorosis. The radial growth of the trees was determined at monthly resolutions by permanently fixed circumference measuring bands around the trees. The numerous, different results after 8 years show, that there are clear reactions of the trees in terms of vitality, nutrient supply, growth and physiological processes that underline the necessity of a persistent enviroment policy.

Ecological imperatives and remote sensing of rural tree decline in Australia

Rohan Ekanayake
Australian National University, Canberra, Australia
Email: ahimsa@coombs.anu.edu.au

'*Eucalypt* dieback' is the term used to describe the progressive dying of tree canopies. Possible causal agents include insects, pathogens, drought and changes in the properties of soil or groundwater. Rural dieback is a dramatic manifestation of tree decline, and is characterised by a widespread, relatively recent upsurge of premature dieback and death of trees on farm.

The main contributor to the dieback problem may have been the impact of human settlement and resulting numerous changes in the ecosystem. *Eucalypt*s affected by dieback are indigenous to the area and dieback seems to be more widespread where livestock grazing is a major activity. The nutrient enrichment caused by the redistribution of nutrients by livestock may be a key factor contributing to the abundance of defoliating insects, and hence rural dieback, in remnants of woodland used by livestock.

Eucalypt dieback is not restricted to native woodland alone in Australia. It now represents a serious threat to the conservation of important commercial *eucalypt* forests of eastern and western Australia. The control of the problem provides benefits through environment conservation and ecological restoration.

The problem of *eucalypt* dieback has been a major concern of botanists and other scientists in various parts of Australia although there has been very little research done since 1990. Ecological research no doubt has an important role in the long term for the enhancement of healthy vegetation in rural Australia to reverse the problem of land clearance. Meanwhile, *eucalypt* dieback and the resultant decline of native woodland in rural areas create more atmospheric carbon (CO2), and the spread of dieback has caused some greenhouse concern.

Land uses change and forestry contributes roughly 23 percent of the greenhouse emissions in Australia. Forests absorb carbon dioxide while dead trees slowly give off vast amounts of carbon dioxide as they decay, so fewer forest means more greenhouse gases. Australia's future efforts in reducing greenhouse emission levels largely depend on the health of its forest cover. Conversely, the spread of dieback may speed up the rate of land clearance.

If Australia's emission reduction and sink enhancement programs were to reach an internationally credible standard, data on Australia's carbon pools will have to be verified by satellite monitoring and audited by on-ground sampling procedures. This form of carbon accounting, which has been adopted by Intergovernmental Panel on Climate Change (IPCC), will enable Australia to benefit from full 'carbon value' of its sink development initiatives.

In the above atmosphere, a research was undertaken with the aims of: (a) identifying without-leaf cover biomass affected by dieback in Australian forests and woodland using satellite sensors; (b) verifying data on dieback on the net carbon pools by satellite monitoring; (c) estimating decay rates and the effect of dieback on the net carbon change for greenhouse modelling and (d) suggesting conservation and ecological restoration of remnants affected by dieback.

The research includes a scoping study and an expert analysis and estimates of regional dieback, a survey of the affected regions according to agro ecological zones, and case studies of affected woodland and forest areas quantified according to the area of occurrence.

Dieback is an important component in the decay and dead wood component in the greenhouse model. As the effect of dieback on the emission level is measured, the results indicate whether the CO2 is increasing due to dieback (decay), or decreasing as a result of regeneration (recovery). The research highlights the declining condition of fragmented vegetation in rural areas and forest environments, and the increasing emission levels of atmospheric carbon from premature death of trees and associated clearing.

Indicators of nitrogen status nitrate leaching and effects of deposition in European forests

Per Gundersen
Danish Forest and Landscape Research Institute,
Hoersholm Kongevej 11, DK-2970 Hoersholm, Denmark
FAX: +4545 763233, Email: pgu@fsl.dk

The paper will synthesize the analysis of several regional and European wide data sets on N cycling in forests. In a database on nitrogen (N) input, cycling and leaching compiled from more than 75 temperate forest ecosystems in Europe, N concentration in vegetation and forest floor compartments increased with increasing input. At c. 60% of the included sites nitrate leaching was above 5 kg N/ha/yr. There were, however, a considerable spread in the N retention. Sites at relative low deposition leached all inputs whereas some sites at high deposition still retained a considerable fraction of the input. It appeared that for conifers N concentration in needles, N flux in throughfall + litterfall and forest floor C/N ratio were good indicators of N status and were correlated with nitrate leaching. Especially C/N ratio of the forest floor was strongly related to nitrate leaching. At C/N ratios below 25 all sites leached considerable amounts of nitrate and at C/N ratios above 30 no sites leached.

In the paper these findings will be explored and validated in other independent regional datasets as well as in the extensive database from the European Level II (ICP-Forest) monitoring program covering more than 200 sites.

Dendroclimatic Analysis of Tree-Ring Width, Tracheid Dimension and Wood Density Variations in Conifers Along the Regional Temperature Gradient (the Enisey Meridian

V. Kirdyanov
Institute of Forest, 660036 Academgorodok,
Krasnoyarsk, Russia
Tel: (3912) 433686, FAX: (3912) 433686, Email:
dndr@ifor.krasnoyarsk.su

Keywords: conifers; tree-ring cell structure; wood density; climatic changes

The analysis of climatic factors influence on tree ring width, radial tracheids sizes and wood density variability of different conifers (*Larix gmelinii (Rupr.) Rupr.*, *Larix sibirica Ledeb*, *Picea obovata Ledeb*, *Pinus sylvestrys L.*) from the forest-tundra zone, from the northern and the middle taiga was made. It is shown what kind of information about environmental conditions is contained in variations of different tree ring parameters and how response of tree rings on environmental changes depends on local conditions of tree growth.

Temperature regime of a growing season (especially, of it's beginning) is the main factor that defines tree ring structure. Different characteristics of tree rings are connected with temperature of different intervals of a growing season. For example, cell sizes correlate with temperature of 2-3 pentads of the beginning of a season and maximum latewood density correlates significantly with temperature of almost the whole season. In the northern taiga tree ring width is influenced by June temperature (the beginning of growing season) and May precipitation (negative correlation).

Dendroclimatic analysis of chronologies obtained for the middle taiga show that different species accumulate in variations of tree ring parameters information about different climatic changes (temperature regime of the beginning of a growing season is important for larch and spruce growth and winter precipitation - for pine tree ring growth).

Different tree ring characteristics of one species accumulate information about conditions of different intervals of a year (for example, June temperature is very important for tree ring width of spruce, June-July temperature - for minimum density and May-June temperature and August precipitation - for maximum density).

Trees of one species from different sites (different local conditions) have different response on climatic changes. For example, the cambium of larch trees from the sites on south exposition slope initiates earlier (up to 10 days) than those of trees from the sites on north exposition slope.

The same parameter of tree ring of different species from the same site in the middle taiga records temperature variations of different intervals of a growing season. Temperature from May, 30 till June, 18 is important for larch, from June, 9 till July, 3 - for spruce, and from June, 24 till July, 3 (the latest interval) - for pine tree ring growth.

The results obtained clearly show that along the gradient of temperature the role of temperature regime become less important for tree growth but the influence of precipitation increases. In the middle taiga (the region where the role of the main limiting factor general for the whole region is not so important as for the forest-tundra zone) variations of tree ring characteristics depends on local environmental factors to a great extent.

Desertification Disaster Assessment and Combating Strategies in China

Lu Qi
China National Research & Development Centre on Combating Desertification, , CAF Campus, 100091 Beijing, China
Tel: +8610-6288 8791, FAX: 8610-6287 2015, Email: Luqi@caf.forestry.ac.cn

In light of the definition and criteria of the UN Convention to Combat Desertification, the scope of arid, semi-arid and dry sub-humid areas (i.e. dryland) in China is approximately 3.32 million sq.km, occupying 34.6% of the total land territory of China, which is widely distributed in 471 counties of 18 provinces, municipalities and autonomous regions of whole China. Of which, the total area of the dry sub-humid area is 0.75 million sq. km. occupying 7.8% of the total land territory of China; the total area of semi-arid area is 1.14 million sq. km. covering 11.9% of total China's land territory; and the area of arid area is 1.43 million sq. km. consisting of 14.9% of China's total land territory. At present, desertification affected areas are mainly distributed in arid, semi- arid and dry sub-humid areas in the west part of the Northeast China, the northern part of the North China and the most regions of the Northwest China. The area affected by desertification in China is approximately 2.622 million sq.km, occupying 79.0% of the arid, sub-arid and humid sub-arid area or 27.3% of total territory of China, in which the 1.607 million sq.km of desertification land is caused by wind erosion is, the 0.205 million sq.km by water erosion, the 0.363 million sq.km by frozen and melting processes at cold plateau, the 0.233 million sq.km by salinization alkalization and the 0.214 million sq.km by other factors. The estimated direct lost caused by desertification every year is 54 billion RMB Yuan. The Combating Strategies were summarized into 4 items including 8 measures.

Assessing the environmental changes and forests of Bangladesh

Laskar Muqsudur Rahman
Bangladesh Ban Bhaban, Forest Department, Gulshan Road, Mohakhali, Dhaka-1212 Bana Bhaban, Bangladesh
Tel: +88 02 872011, FAX: +88 02 870704, Email: laskarmr@Bangla.Net

Bangladesh is a small low-lying deltaic country surrounded mostly by India and the Bay of Bengal. Three major types of forests are hill forests, coastal mangrove forests and inland forests. The forests of Bangladesh is at stake mainly due to excessive population, poverty, natural disasters, scarcity of fuel, urbanization, industrialization and lack of awareness about importance of forests.

The impact of human activity on the forests is clearly felt from the reduction of forest area, which has been cleared for agriculture and human settlements over the past centuries. Besides more direct deforestation of the forest areas, the increasing need for food, fuel and shelter for the growing population in the immediate vicinity of the forests has had dire effects on the remaining forest areas.

Urbanization and industrialization resulted in the destruction of millions of trees for housing construction of roads, towns, and cities. Besides construction of giant projects such as dams, bridges, roads, hydroelectric works, townships etc. involve extensive removal of vegetative green cover.

Oil spills and indiscriminate discharge of bilge and bunker waters from the ships and other vessels occur in Mongla port located immediately upstream to the Sundarbans, the largest single mangrove forests of the world and in the Bay of Bengal. It is found to cause mortality of seedlings, fishes, shrimps and other aquatic animals from the Sundarbans and other coastal forests.

Flood is a common and frequent natural disaster in the country. There is connection between flood disasters after persistent heavy rain and forest density in the precipitation area. In case of treeless forestland or degraded forestland, the forest cannot fulfill its retention function and the soil's absorption capacity diminishes. The denuded areas expand steadily uphill due to continuing erosion, and land slides increases accordingly.

Soil erosion is a severe problem in the country. Due to high rainfall, low organic matter content, poor soil structure, surface soils are being continuously washed away, even there are severe land slides in many places mostly in hill and coastal areas. Part of the sediments carried to the rivers are deposited on the river beds, thus decreasing the carrying capacity of the rivers and increasing the flood hazard. Salinization, waterlogging, sedimentation and many other environmental problems tend either to diminish or destroy the biological potential of land known as desertification process. This process has been detected in the northern part of the country, hill areas, coastal areas and polder areas and in many patches of lands in the country due to unwise landuse practices deteriorating the forests.

Tropical cyclones are most frequent in the country that causes colossal mechanical damage to trees, particularly in the hill and coastal region.

Strong cyclones develop enormous wind forces, which are often accompanied by heavy precipitation and invariably by tidal surges and on occasion thunderstorms of a destructive character. Cyclones cause lasting damage to forests. The surmised global climatic changes resulting from the "green house effect" aggravate temperature extremes and lead to pronounce instability of the weather phenomena, with a tendency to extremes.

Forest fire is not very common in the country. But new pests and diseases are now coming up and are mainly associated with the man-made forest, use of exotics species, monoculture and large plantations of uniform size. This has a considerable role in degrading the quality of the forests.

By the year 2030, global temperature will rise by 1.9-4.5°C that may cause rise in the sea level rise 20cm-165cm. With 1 m sea level rise, the entire 401,600 ha of natural mangrove forests (Sundarbans) as well as 42,000 ha of man-made mangrove forests along the coast will gradually destroyed. As a habitat for wildlife Sundarbans is unique. The forest and the numerous waterways by which it is dissected together support wide range of mammals, including famous Bengal tigers, birds, amphibians, fish reptiles and crustacean. With such sea level rise most of these animals will lose their habitat and will become extinct.

The country would be more vulnerable due to environmental changes in the years to come, if some mitigation measures cannot be adopted right now. This paper attempts to assess the environmental changes and its impacts on forests of Bangladesh. It also suggests some mitigation measures to combat the situation.

People's Participation and Development of Forest Management Strategies in Western Himalayan Region of India.

B. S. Burfal
Uttar Pradesh Forest Department, 17- Ranapratap Marg, 226001 Lucknow, India
FAX: 91- 0522-283322, Email: upfdres@lw1.vsnl.net.in

The Himalayas constitute a complex ecosystem with a varied climate, ranging from dry cold desertic, moist temperate and wet temperate to subtropical and tropical. The mountains exert profound influence on the climate of the Indian subcontinent and rivers originating in these mountain ranges nourish agriculture and industries in the vast Indo-Gangetic plains. The mountains are considered to be rich store houses of land, forest, water, hydro-electric power, aesthetic and recreational resources. In the Himalayas, forests are intimately involved in the everyday life of the villagers. People need *Timber* and poles for construction, agricultural implements and packing cases, fuel for heating and cooking, fodder & grazing land for cattle and sheep. People's dependence on forests is also associated with protection, conservation and development of these forests.

This article describes the way the management and administration of forests in the Western Himalayan region of India with particular reference to Kumaun and Garhwal hills were influenced by the awareness and active participation of the local people. Prior to 1823 when first settlement of the forests was started, villagers used to protect the forests (mainly from fire) and use the produce according to their needs without any restrictions. The settlement started in 1823 demarcated the village boundaries and the forest area of the villages to meet their requirement. Until 1865 there was no system of forest conservancy, when an Act to regulate forest management and fellings were promulgated. Forest settlement operations were done on an extensive scale and a bulk of the forest area was constituted as protected forests and reserved forests; mainly during the period 1893 to 1917.

The reservation of extensive areas and enforcement of strict control provoked serious resentment from the local people, which compelled the Government to set up a committee in 1921. This committee looked into grievances and made detailed recommendations about the various demands put forward resulting classification of the forest in three main categories for management purpose- Reserved Forests, Civil Forests and Panchayat Forests. Later on three more classes of Forests viz. Soyam Forest, Khat Forest and other Forests also emerged.

The Panchayat Forests, i.e. the Forests managed by a society of the villagers, which came in existence since 1925, is one of the oldest legalized Institution of forest management involving local people for sharing responsibilities and benefits which at present is popularly known as Participatory Forest Management or Joint Forest management. Panchayat Forests are very popular in the mountain area and presently there are about 4802 Panchayat Forests Consisting of about 354270 hectares which is 10.35 % of the total forest area of the concerning civil districts.

In this paper an attempt has been made to describe how awareness and involvement of the local people caused evolution of various classes of forests for management purposes and development of the Institution of Forest Panchayat in the Himalaya. The procedure for constitution of Forest panchayat and Panchayati Forest, their responsibilities and duties and benefit sharing of the produce are also been described which would be helpful to frame rules and regulations for various participatory or Joint Forest Management programmes currently undergoing in the developing countries mainly in tropics.

Sustainable Management of Himalayan Eco-System through Societal Approach

B. Gupta, R.M. Singhal and Vinay Kumar
Dr. Y. S. Parmar University of Horticulture and Forestry
Post Box # New Forest, H. P. -173 230 , Nauni, Solan, India
Tel: 91 - 0135 - 759382, FAX: 91+1972+52242, Email: Guptab@yspuhf.hp.nic.in

Himalayan system is fragile and sensitive even to small disturbances caused by human activities. The pressure exerted by the rapidly growing population of human and cattle coupled with unsustainable management policies have resulted in severe ecological degradation which has rendered almost one third of the land area (i.e., 17,000 sq. km) totally unproductive. Expansion of indiscriminate agriculture on unsuitable slopes, uncontrolled grazing, intensive logging for fuel wood, lopping for fodder, inappropriate farming, wrong animal husbandry practices, clear felling and burning for shifting cultivation have degraded these lands to the extent of near non recovery. Disposal of material in the vicinity of the mine to slide into natural drainage channels have caused disturbance to water bodies. The hill topography has changed and the slopes become unstable and prone to erosion. In the deforested areas, the resultant debris, contributed by mining and road construction has spread as finer sediments on the flood plains and resulted in diminished productivity of the agricultural land.

Rapid destruction of the natural base resource has impoverished the poor and powerless and pushed them down the poverty line. The ecological degradation in this earth's most sensitive eco-systems and the fountain head of a multitude of natural resources, upon which depend over half a billion disadvantaged people has reached an alarming dimension.

The well-being of the poor and powerless can only be improved by rehabilitation of eco- system through economically viable and ecologically sound methods and through a "Do it yourself" approach. It has been postulated that application of technologies based on isolated biological, physical and social science researches cannot resolve this issue and that a proper understanding of the socio-economic compulsions of the population is essential. In the model developed under this approach, the village organisation assumes responsibility to meet the needs of the community. In addition to policies of consolidating the land use, tenure and related issues are also addressed so as to ensure sustainability of the technology packages with people's participation. The use of conventional method of policy and management practices which results in alienation of local population from forest and, consequent forest degradation are given up in this approach.

An example of research on sustainable management of mountain forests aimed at protection against erosion: the afforestations of Austrian Black Pine on marly land (southern Alps, France)

Keywords: mountain forest; sustainable management; protection against erosion; marls; Austrian Black Pine; forest restoration; minimal management; priority forest intervention zones; ARC/INFO; sylviculture

The sustainable management of mountain forests aimed at protection against erosion is a major preoccupation of forest managers in the French southern Alps. Current problems of erosion management with forest vegetation particularly concern old afforestations of Austrian Black Pine (*Pinus nigra ssp. nigra*), undertaken by the services of Mountain ground restoration (Restauration des terrains en montagne : RTM) during the last century on marly lands. These artificial, monospecific and even-aged forests provide protection against erosion and torrential floods; but as they are now overmature, it is critical to consider their renewal. We thus propose here principles to support the sustainable management of these mountain forests, to provide permanent protection against erosion. Present financial restrictions require the establishment of minimal management, i.e., management recommending minimum forest intervention for maximum effectiveness against erosion.

First, we present a method for the identification and cartography of Priority forest intervention zones (Zones d'interventions forestières prioritaires: ZIFP) for permanent protection against erosion, using the ARC/INFO Geographical information system. This method is based on the principles of a "multirisk " method of ZIFP determination developed in the French northern Alps; an adaptation to the context of erosion in the French southern Alps is then realised. It consists of the analysis of two elements: the lithology, which allows the characterisation of erosion and hazards (torrential floods); and the forest stability, which can be obtained by overlaying two datasets: forest physical stability and forest regeneration capacity. Three classes of ZIFP are thus defined: classes with low priority corresponding to no-intervention zones; and one class of zones of eventual rehabilitation (Zones de réhabilitation éventuelle: ZRE), corresponding to forests without natural regeneration. For these last zones, rehabilitation interventions with biological engineering must be considered when the forest cover is not renewed after cutting. An application of the method is proposed for two forests of the Alpes-de-Haute-Provence.

Second, the necessary silvicultural rules are defined, in order to guarantee permanent protection against erosion by minimal management. To do this, we seek on the one hand to maintain a permanent, stable and perennial plant cover; on the other hand to support ecological diversity for a return to the climax forest. Establishment of these rules is largely based on an ecological study of the dynamics of forest restoration, studied on an experimental site of the southern Alps 130 years after the first afforestations, and focusing particularly on potential and limiting factors of regeneration. These rules are the first general principles for minimal management of Austrian Black Pine. The choice of management type is then realised according to land constraints: presence or absence of regeneration, forest density, infestation bym. Concerning regeneration cuts for old forests, two types of cut are recommended: regeneration cut step-by-step if there are few natural seedlings under pines or if they are abundant but little diversified; regeneration cut by gaps if natural seedlings under pines are abundant and diversified.

Forest density and infestation by mistletoe then determine the number of cut passages to apply. Concerning the management of the regeneration and the future forest, the diversification of species and structures must be considered through thinning and precocious clearing, and the adoption of irregular grove silviculture.

A Societal Approach to Sustainable Agroforestry in the Garhwal Himalaya

R.M. Singhal, Vinay Kumar and Pramod Kumar
Indian Council of Forestry Research and Education, Dehra Dun, India
FAX: 91-135 754776, Email: singhalrm@icfre.up.nic.in

Himalayan system is fragile and sensitive even to small disturbances caused by human activities. The pressure exerted by the rapidly growing population of human and cattle coupled with unsustainable management policies have resulted in severe ecological degradation which has rendered almost one third of the land area (i.e., 17,000 sq. km) totally unproductive. Expansion of indiscriminate agriculture on unsuitable slopes, uncontrolled grazing, intensive logging for fuel wood, lopping for fodder, inappropriate farming, wrong animal husbandry practices, clear felling and burning for shifting cultivation have degraded these lands to the extent of near non recovery. Disposal of material in the vicinity of the mine to slide into natural drainage channels have caused disturbance to water bodies. The hill topography has changed and the slopes become unstable and prone to erosion. In the deforested areas, the resultant debris, contributed by mining and road construction has spread as finer sediments on the flood plains and resulted in diminished productivity of the agricultural land. Rapid destruction of the natural base resource has impoverished the poor and powerless and pushed them down the poverty line. The ecological degradation in this earth's most sensitive eco-systems and the fountain head of a multitude of natural resources, upon which depend over half a billion disadvantaged people has reached an alarming dimension.

The well-being of the poor and powerless can only be improved by rehabilitation of ecosystems through economically viable and ecologically sound methods and a "Do it yourself" approach. It has been postulated that application of technologies based on isolated biological, physical and social science research cannot resolve this issue and that a proper understanding of the socio-economic compulsions of the population is essential. In the model developed under this approach, village organizations assume responsibility to meet the needs of the community. In addition to policies of consolidating land use, tenure and related issues are also addressed so as to ensure sustainability of the technology packages with people's participation. Conventional policy and management practices, which result in the alienation of local population from the forests, and consequent forest degradation, are given up in this approach.

On Criteria and Indicators for Sustainable Forest Management of Forest Farm, An Experiment Site in Semi-arid Western China

Jiang Youxu
Chinese Academy of Forestry, The Institute of Forest Ecology and Environment Science, , 100091 Beijing, China
FAX: 86 10 62889555, Email: jiangyx@fee.forestry.ac.cn

Experimental site of Zhangye region is located at 38°N and 100°E with the cold and semi-arid climate in Qilian Mountain of Gansu Province, Northwest China. Water supply for cities and villages in the Xeshi Corridor (including Zhangye region) is coming from 2859 glacier that contains about 81100 million m^3 of ice. Natural *Picea crassifolia* forest in Qilian Mountain stores and regulates the runoff to irrigate the Xeshi Corrido plain in the semi-desert. The Forestry Is Consisted Of 3 Forest Types: Water Resources Conservation Forest (WRCF), Shelter Belt For Farmland (SB) and Economic Plantation (orchard) (EP). Such forestry structure is suitable to whole semi-arid region with the mountain forests in northwest China, so that the C & I for Zhangye could be used for that region at all. The C & I on SFM of Zhangye Region, of Forest Farm for WRCF and that for SB and EP are provided.

Integrated Planning for Sustainable Forest Management

David B. Field
University of Maine, 5755 Nutting Hall, ME 04469-5755
Orono, USA
FAX: 207/581-2875, Email: field@umenfa.maine.edu

Integration of forest operations with regional planning is of increasing importance as landowners, *Timber* producers, states, regions, and nations compete in international markets for forest products. Sustainable forest management and productivity is now a matter not only of individual landowner goals but also of regional and national planning and policy.

Competitiveness in national and international forest products markets will become more and more a function of an assured sustainable wood supply.

This poster describes a system for integrating forest operations planning with policy analysis. A geographic information system (GIS) database, supplemented by a forest growth and yield model, provides input for a strategic/tactical forest operations planning model. Alternative forest policies affect planning choices. Alternative plans that result from policy constrained management choices are linked to a regional economic analysis model that indicates the full impact on jobs, wages, and production values resulting from those policies and management choices.

An application in the state of Maine, U.S.A. is described.

Site classification - a basic requirement for tropical forest management planning An example from Sabah / Malaysia

Reinhold Glauner
Institute for World Forestry, Federal Research Centre for Forestry and Forest Products
Leuschnerstr. 91, D-21031 Hamburg, Germany
Tel: +49-40-739 62 102, FAX: +49-40-739 62 480,
Email: glauner@aixh0001.holz.uni-hamburg.de

Keywords: forest soils; management planning; forest functions; site classification

The objective of this project is to develop a planning concept for integrating site classification into medium-term forest management planning. The three-tiered approach, State - Forest Management Unit (FMU) - Compartment, facilitates a systematic methodology and hierarchic vertical integration.

At state level, Sabah is ecologically stratified into 17 growth regions and 94 -districts. Differentiating parameters are altitude, geology, and climate. At FMU level, Deramakot Forest Reserve (DFR) is chosen for determining the forest formations, soil and site conditions, and management restrictions. Vegetation and site data are collected in a 1 x 1 km systematic inventory. The forest formations and associations are identified by cluster analyses and show to be predominantly correlated with landform and texture of the topsoil. Landform is the major determining factor at association level.

Site-related management restrictions are identified as: soil erosion, soil compaction and soil nutrient status. For soil erosion hazard assessment, the Universal Soil Loss Equation (USLE) is used and facilitates a zonation of the total area by additionally defining preliminary thresholds of tolerable soil loss. For inherent soil compactibility assessment, soil texture is stratified into compaction susceptibility classes. Soil moisture is not incorporated yet and more work is needed on this subject. For soil nutrient status assessment, 437 profile descriptions of DFR (1 x 1 km grid) and 374 profile descriptions including soil samples of a sub-area (0.2 x 0.2 km grid), are used. Soils have a moderately poor to medium content of exchangeable basic cations, are very acid, and aluminium saturation is high. The variation of nutrient contents within a soil type on different landforms in DFR is larger than between different soil types on the same landform. A classification by soil type alone is, therefore, not sufficient. The assumption that repeated *Timber* harvesting will cause soil degradation by loss of nutrients is warranted for fast-growing industrial plantations, but yet unsupported for Selection Systems in tropical rainforest. Nutrient input-output analyses indicate that a *Timber* harvest may cause a reduction up to 25% of the plant-available soil nutrient stocks by erosion and *Timber* removal in one cutting cycle.

Consideration of the management restrictions is incorporated in a 3-D decision matrix. The combinations of nutrient quality, erodibility and soil compactibility lead to one out of four possible management intensity classes (MIC). These MIC options are stratified by their environmental effects ranging from no adverse environmental effect = protection forest (TPA) through Reduced Impact Logging (RIL) techniques to severe environmental effects = industrial tree plantations with quick-growing species. Policy and management decisions can thereby be based on ecologically and environmentally relevant, verifiable and sound information on the area suitable for production forestry and areas, which are only suitable for TPA.

People's Participation in Sustainable Forest Management

Karagada M. Jayaramaiah, S. Venu Gopal

Email: wildlife@cal.vsnl.net.in

In many developing countries, including India, the Government has managed environmentally significant forests. Protection was through policing. Management was according to prescriptive working plans. Over the years, emphasis of the Government as well as that of the people about the forests have shifted from *Timber* and firewood production to Forest Conservation for eco-balance, environment and livelihood support.

Realizing that Sustainable Forest Management (SFM) is possible only with the willing and active participation of local people, Government of India launched the concept of "Joint Forest Management (JFM)" in alignment with the revised National Forest Policy 1988. In Karnataka, Joint Forest Planning and Management (JFPM) was introduced systematically through a project approach in the Western Ghats Forests Region, the project being supported by the DFID (UK).

The Project has focused on Participation of Stakeholders, Reorientation and Organization development of Karnataka Forest Department, Institutional development at the village level, through formation of Village Forest Committees (VFCs), Self Help Groups, Site-specific Planning System, Micro-planning at the village level, Zonation of forest areas by objectives, Management Information System, Demand-led research, training and development of shared vision. The new process was facilitated by policy support in the form of special Government Order, which provided the framework for participatory role of local people and a provision for sharing of forest produces between People, VFC, and Government.

VFCs provide a forum for participation of all people in planning, negotiating and managing the natural resources at their disposal. Special efforts were made to ensure participation of all stakeholders in planning, especially the poor, and women through series of meetings and participatory Rural Appraisal (PRA) exercises.

People have taken interest in protection of the forests in the neighborhood of their villages from smugglers and fire; afforestation, introducing fuel saving devices and alternate energy resources, choice of species in plantations, management of NTFP on a sustainable basis, skills enhancement for better earning through value addition to raw materials, marketing arrangements, and other community development activities. Although not everything is seen everywhere, different attempts have been pursued across a range of about 400 VFCs spread in three districts.

A number of independent Impact Assessment Studies and case studies in specific villages have been undertaken to assess the impacts and the trend so far. They all indicate to a greater interest and participation of local people, enhanced protection of forests, adoption of fuel saving devices, better relationships between people and the Forest Department officials, greater rapport with the Non-Governmental Organizations, attitudinal change in the front line staff of the forest department.

Some of the areas where the Project is yet to make significant progress so as to achieve the desired objective of Sustainable Forest Management include: greater participation of disadvantaged poor people, women, expansion of project to all villages, extension of sharing of benefits in nondegraded forest areas with special emphasis on NTFP, organization development of Forest Department, higher degree of devolved decision making, networking of VFCs, and information dissemination.

Le Partenariat entre Service Forestier et Exploitants-industriels : une Solution pour l’Aménagement Durable des Forêts Denses Tropicales : Cas de la Sodefor (Côte d’Ivoire)

Armani Konan
Centre National de Recherche Agronomique, 08 BP 33, Abidjan 08, Côte d’Ivoire
Tel: +225-44 28 58, FAX: +225-44 21 08, Email: louppe@africaonline.co.ci

Le modèle retenu par les pays tropicaux producteurs de bois, en matière de gestion forestière, n’a pas beaucoup favorisé l’aménagement durable des forêts. En effet trop souvent, l’action forestière vis - à - vis des populations a été vécue en terme d’interdiction, de répression, de limitation de liberté et même d’abus de pouvoir. Ainsi, ces populations se préoccupaient très peu du devenir de la forêt.

Aux exploitants, traditionnellement impliqués dans cette gestion forestière, il n’a été réservé que le droit de récolter le bois. Ils n’avaient pas de droit véritable sur les concessions qui leurs étaient octroyées et l’avenir de ces concessions ne les intéressait guère.

De plus en plus conscients des limites de ce modèle qui a conduit à la raréfaction de la ressource ligneuse voire à la disparition d'importantes surfaces boisées, ces pays ont compris la nécessité d'élaborer des systèmes appropriés pour l'aménagement de leurs massifs forestiers. Il s'agit désormais d'impliquer tous les acteurs vivant directement ou indirectement de la forêt dans sa gestion :

- l'Etat, propriétaire, représenté par son Administration forestière ;
- les populations locales qui dépendent directement de la forêt et de ses produits ;
- les exploitants et les industriels

Dans le cadre de la gestion participative impliquant les exploitants - industriels, différentes formes de partenariat, fonction de la politique forestière de chaque pays, ont été retenues. C'est dans cet objectif que s'inscrivent les conventions provisoires d'aménagement - exploitation initiées par la SODEFOR (Côte d'Ivoire) dans le but d'associer les industriels dans les travaux de prise en main des forêts classées. L'entrepreneur - exploitant met ainsi sa logistique au service des travaux de génie forestier (délimitation de pistes), d'inventaire ou de sylviculture. Pour appliquer l'aménagement il faut réaliser les coupes, et elles sont inconcevables sans les spécialistes que sont les exploitants.

Ce système de partenariat avec les exploitants - industriels pour une gestion rationnelle et durable des massifs forestiers du domaine permanent de l'Etat n'a cependant pas donné les résultats escomptés. Certains industriels ayant souscrit aux conventions, ont souhaité l'arrêt des conventions sous la forme telle qu'elles étaient conçues.

La SODEFOR n'a pourtant pas arrêté d'entretenir les relations commerciales avec ces exploitants industriels. Notamment la SIFCI, la CIB et THANRY qui exploitent respectivement dans les forêts classées du Haut - Sassandra, du SCIO, de GOIN - DEBE. Elle vend aujourd'hui son bois par des contrats de courte durée (2 à 3 ans) par appel d'offres ou de gré à gré.

Les industriels qui veulent garantir leur approvisionnement afin d'entreprendre des investissements souhaitent l'établissement de contrats de longue durée ou conventions pluriannuelles d'approvisionnement..

En ce qui concerne la SIFCI, qui considère la première expérience comme une réussite, des données techniques nécessaires sont réunies pour la mise en place de la convention pluriannuelle d'approvisionnement, il ne reste plus qu'une concertation entre les parties pour affiner les clauses de cette convention.

Mots-clés : forêt tropicale, aménagement durable, gestion forestière, partenariat, Côte d'Ivoire

Traditional skill: a way to sustainable management of tropical forests

Tapan Kumar Mishra, S.K. Banerjee and S.B.Roy
Raja Narendra Lal Khan Women's College, 721102
Midnapore, West Bengal, India
Email: subirsengupta@mailcity.com

Management of forest can not have any generalised prescription for all sorts of forests. even within a country like India there can not be a common strategy of management as because the ecological parameters vary from forests to forests. Management strategy is very much dependent upon ecosystem of an area. Some studies have been done on management strategies in South West Bengal of India where tropical deciduous sal (*Shorea robusta*) forests with 10 years coppice rotation exists. A major portion of these forests in the region is under Joint Forest Management (JFM). So it has been easy for us to carry out an indepth study. The studies show that the present tactices followed by some of the Forest Protection Committee (FPC) are progressive and so may be included within the process of management. These strategies concern non-*Timber* forest products (NTFPs) in particular. The survey has been conducted for stratifying FPCs according to their management within twenty FPCs of the region.

1. The FPCs having a good management network at least at the institutional level, feel that a canopy cover below 40% is always desirable to have a good NTFP return particularly *Diospyros melanoxylon* from the forests.

2. Perfect protection of a forest ecosystem is not an answer to diversity and better productivity of NTFPs. In turn, exploitation within a particular limit (may be called sustainable limit) also increase productivity of certain NTFPs. This has been proved in some species like *Combretum roxburghi* (basket producing woody shrub species) and *Hollarhaena antidysentrica* (a medicinal shrubs, species)ÿ in South West Bengal. It is found out that exploitation of NTFPs within a limit increases productivity than a perfectly protected forest area.

3. Sweeping of leaves form under the trees, is a general practice in these forests. These leave are generally used a fuel. In this area leaf fall occurs during middle of November till the end of April. December and January being the rice processing months, sweeping of leaves from the forests floors

disturb nutrient cycling of the forest. Thus, it will be pertinent to prescribe that there should be no sweeping of leaves from under the trees after February. Leaves have to leave for decomposition during the next rainy season.

4. Some FPCs have earmarked some species to be used as fuel-wood. These are exotic to the region and have a prolific growth.

The gregariousness of these species decrease the species diversity of the region as these species can compete well eliminating the indigenous herbs and even *shrubs Eupatorium odoratum* and *Lantana camara* are tow such species which has been specified by some FPCs for extraction.

These management decisions taken by FPCs have not been docated by the Forest Department and the traditional in nature. These decisions are useful to keep the health of the forest in good condition.

Implementing sustainability in Ukraine's forestry

Maria Nijnik, Cornelis van Kooten
Wageningen Agricultural University, De Boelelaan 1115, 1081 HV Amsterdam, Netherlands
FAX: 31 20 4449553, Email: maria.nizhnik@alg.aae.wau.nl

Previous economic development of the country and shortcomings in its past forestry policy and management practices negatively affected the forests, having resulted in their depletion and degradation. Ukraine's forests suffered from overcutting until the 1970s, especially in the western region. Besides, popular during the period of Soviet industrialization practice of spruce plantations has not proved to be wise in the Carpathian mountains causing disastrous windfalls. Wide spread hydroamelioration also failed and led to a considerable loss of biodiversity in the Polissja region. As a result, the Ukraine despite its originally favourable natural conditions, high productivity of forests, MAI of 3.96 m3/ha, and their richness in biological diversity is a scarcely wooded state. Only its western region has a high share of forests. An average share of artificial plantings, consequently, has reached 50%. Forests distribution has become uneven. Age composition of forests is not optimal (52.6% - young stands). These factors influence future *Timber* production and endanger sustainability in Ukraine's forestry.

Besides, the environmental situation in the Ukraine impacted forest ecosystems causing their damage. Radioactive pollution after Chernobyl accident is observed on 2.3 mil ha of forests. The highest level of forests' damage from nuclear contamination is in the central part, from chemical pollution in south-eastern and southern parts of the country. Consequently, the Ukraine satisfies its demands in *Timber* only on 30% by its own production. The conditions of the Ukraine's forests do not allow them to fulfil in a proper way their regulatory, protective and shelter functions. Thus, in-depth changes should be urgently brought into the Ukraine's forestry.

The paper presents key forestry policy and management measures to approach sustainability. From one hand, substantiated on the basis of sustainability concept *Timber* rotation should be put into practice. From another hand, an expansion of wooded area should be achieved at the account of waste, eroded and marginal agricultural lands. The program of afforestation, as a key building block of sustainable forestry policy will shorten *Timber* deficit inside the country, will enhance output possibilities of forest products and services and enables the Ukraine to fulfil its targets regarding the Kyoto Protocol on Climate Change.

Cambios en la diversidad del bosque húmedo tropical después de la intervención

Ruperto Quesada Monge
Escuela de Ingeniería Forestal, Instituto Tecnológico de Costa Rica, Cartago, Costa Rica
Tel: 00 506 552 53 33, FAX: 00 506 5914182, Email: plinia@sol.racsa.co.cr

De las tres áreas geográficas donde se ubica el bosque húmedo tropical en el mundo, el trópico asiático es el que presenta mayor cantidad de especies entre 12.000 y 15.000, le sigue el trópico americano con 5.000 a 7.000 especies y por último el trópico africano con 2.000 á 3.000 especies de plantas con diámetro mayor a 10 cm.

América Central constituye una unión intercontinental, lo que le permite desempeñar desde el punto de vista de dispersión florística un rol de puente biológico entre las regiones Neártica y Neotropical.

Entre los múltiples factores que influyen en la distribución de la flora en América Central, sobresale el carácter de puente y de filtro biológico que constituye el istmo. Este, además de ser un extrecho puente entre dos continentes ricos en especies posee una historia independiente, como archipiélago con un grado variable de aislamiento, lo cual trajo como resultado una expectación, parte de la cual persiste hoy día entre la flora endémica del país.

En Costa Rica la gran variabilidad de factores tales: lluvia abundante, temperatura variada y el vulcanismo reciente han producido suelos ricos en minerales, lo que ha dado un sistema dinámico, con gran heterogeneidad local.

La investigación se desarrolló en la Región Huetar Norte de Costa Rica, específicamente en la localidad de Boca Tapada de Pital. La misma se caracteriza por presentar una estación lluviosa muy marcada de 8 a 10 meses, con una precipitación media anual de 3 163 mm. La temperatura varia entre 25 °C y 27 °C. La zona de vida es de bosque muy húmedo tropical según Holdridge.

Las evaluaciones se realizarón en parcelas permanentes de medición de 1 ha, en las cuales se midieron todos los indiviuduos con un d igual o mayor a 10 cm. Se evaluaron tres áreas de bosques intervenidos (rodales) bajos tres intensidades de aprovechamiento forestal: de bajo impacto (I), media (II) e intensivo (III). Para el bosque no intervenido de la Región, se reporta un promedio de 91 especies arbóreas por hectárea.

Para los rodales evaluados, se obtuvo en total 106 especies en el rodal intervenido bajo el aprovechamiento de bajo impacto, 117 especies en el intermedio y 91 especies en el severo. Para los rodales I y II se contabilizaron más de 82 géneros, en el rodal III se presentaron 68 géneros, el número de familias botánicas varió entre 46 y 36. En promedio el rodal III tuvo 67 especies/ha, los rodales II y III alcanzarón 83,5 especies/ha. Se puede indicar que la composición florística de los boques es compleja.

Las especies comúnes y más frecuentes en los tres rodales fueron*: Ferdinandusa panamensis, Henriettea odorata, Welfia georgii, Pouteria sp*. y *Couma macrocarpa*. En cuanto a las familias más dominantes aparecen *Sapotaceae, Mimosaceae, Rubiaceae, Euphorbiaceae* y *Papilionaceae* son las que dominan con una mayor cantidad de géneros. De acuerdo con la curva especie/área, se determinó que en el rodal I presentó más especies que el bosque no intervenido. Aunque en general la composición florística del bosque intervenido no cambia sustancialmente, lo que se ve modificado es la dominancia de algunas familias y géneros.

A través de los índices de Shannon y Simpson se establecen mejor las diferencias entre el bosque no intervenido y el intervenido. Donde el Rodal I presenta la diversidad mayor, y por su parte para con el índice de Simpson fue el Rodal III, en ambos caso no fue el bosque intervenido.

A study on regional sustainable forestry

Meng Xian Yu
Beijing Forest University, College of Forest Resources and Environment, Qing Hua Dong Road, 100083 Beijing, China

Sustainable development is the common objective and the course of development in all over the world. The practice and study of regional sustainable development is the basis for our country and even the world. It's also the final state of the department and sector's sustainable development. The sustainable forestry plays an important role in the development on the globe, nation, and region.

The idea of sustainable development makes a change for our reconsidering the forestry. In this dissertation, based on understanding the content of the forestry and analysing the circumstance of sustainable forestry. The author demonstrates the status and circumstance of Chinese forestry in the light of Chinese situation and forestry's condition. The two conclusions have been made in this paper: (1) Chinese forestry should be brought into the framework of regional sustainable development, (2) Forestry is the dominant sector for environment reproduction, therefor, it should be protected.

Based on the study of the change regularity of the Haihe River Volley, we proposed the regional mode of sustainable development in the TaiHang Muontain. Meanwhile, Fuping Country is taken as studding object, and the systematic analysis and quantitative assessment method assess the country's ability of sustainable development. By using the methods of AHP (Analytic Hierarchy Process), PCA (Principle Component Analysis) and Fuzzy Clustering, etc., the development advantages and potentiality has been found in Fuping County's sustainable development. Also, a development strategy with the sustainable development principle was put forward. Final, the object systems of Fuping County's sustainable forestry and the sub-regions of forestry type is given according to the forestry's role in the Fuping Country and even the whole Haihe River Volley.

Forest Genetic Resources on the Balkans As a Factor for Creation of Sustainable Forest Ecosystems in Europe

A. Alexandrov
Forest Institute - Sofia, , 132 Kliment Ohridski blvd, 1756 Sofia, Bulgaria
FAX: +359 2 622965

During the Pleistocene in Europe took place the process of formation of the contemporary autochthonous forest tree and shrub vegetation. The Balkan Peninsula as a whole was not affected by permanent glaciatin and became an enormous refugium. Here several hundred trees shrub species have been preserved forming huge forest complexes as in the mountain massifs so in the plains. This phytogeographic area in the crossing point of the European Deciduous Forest Region, the Eurasian Steppe- and Forest-Steppe Region and the Mediterranean Sclerophilic Forest Region. Here are spread termophytes, mesoterms and microterms from the mediterranean south-continental, north-continental, mountain and north-boreal phytogeographic centers.

Now the Balkan Penninsula is a center of forests with total area of 24 millions ha, with an average forest cover of approximately 30% containing significant biological and genetic diversity. Having in mid the new European forest policy laying down, these valuable in genetic potential species may be used as a source for stabilization and enrichment of the biological diversity; for increasing of the productivity and the resistance of the forest ecosystems in Europe. This especially concerns some Central and Northern European countries in which during the Pleistocene occurred strong reduction in the composition of their vegetation. The industrialization during the XIX and XX centuries caused the extermination of a significant part of the autochthonous forest and the improverishment of their biological and genetic diversity.

A great number of deciduous families as *Fagaceae, Betulaceae, Tiliaceae, Acaraceae, Rosaceae, Oleaceae, Salicaceae, Juglandceae, Ulmmaceae, Corylaceae*, etc. determine the basic composition of the contemporary forest on the Balkan Peninsula. The diversity of the conifetous species is deteermines by some main species from the Pinaceae family, the most important role of which have the genus *Pinus, Abies* and *Picea*.

Biotechnology: Key to Sustainability of Biodiversity

M. N. Salleh, K.I. Kandasamy & Annie George
Technology Park, TropBio Research Sdn Bhd, Level 2; Enterprise 2, 57000 Bukit, Malaysia
FAX: 603-9682888, Email: tropbio@tropbio.po.my

The conservation of both biodiversity and environment is gaining importance lately with the increasing numbers of species becoming extinct. Malaysia has the highest number of critically endangered tree species at 197. It is estimated that 95% of 270,000 species of plants in the world are found in the tropics. Moreover, an equivalent area in the tropics is expected to support four to ten times the number of species found at the temperate latitudes for any given taxonomic group. However, human activity, particularly mining and land conversion is contributing to its destruction. Drought and the clearing of land further exacerbate this, by fire. As it is a well-established fact that biodiversity supports human survival through health (the forest being a medicinal chest), food and industry (*Timber*), its conservation is of prime importance. Therefore, through the capture of germplasm using biotechnology tools such as micropropagation, we can not only make these into products with great commercial potential (for instance the commercialisation of the endemic pitcher plant, *Nepenthes spp*. and wild *orchids*) but also reintroduce and repopulate the natural habitat. *Timber* trees such as *teak*, *meranti* and *jelutong* that have high commercial value are produced via tissue culture techniques and can be used in enrichment planting in logged over forest areas. The problem of slow germination of seeds on the other hand is overcome through somatic embryogenesis techniques, a biotechnology tool in producing artificial seeds. Artificial seeds would then produce consistent and large amounts of viable seeds ensuring the sustainability of our biodiversity. The production of artificial seeds also allows easy broadcasting especially from the air. The use of molecular biology tools offers the possibility to identify and isolate valuable genes from our rich biodiversity as well as to identify where then is a most urgent need for conservation.

Markers developed using techniques such as Amplified Fragment Length Polymorphism (AFLP) are being applied to the improvement of our native plants towards higher productivity levels for viable commercial propagation and to prevent depletion from the wild due to poaching and biopiracy. The use of biotechnology in conserving biodiversity thus would be the next most natural thing to do in this time and era when money is in short supply, especially in developing countries where coincidentally the forest seems to be in abundance too.

Integration of tree breeding and gene conservation: strategies for sustainable use of forest genetic resources

Yongqi Zheng, Huoran Wang
Chinese Academy of Forestry, Institute of Forestry, 100091 Beijing, China
Tel: (86) 10 6288 9645, FAX: (00) 86 10 62872015, Email: zhengyq@rif.forestry.ac.cn

The objective for sustainable utilization of forest genetic resources is to find an optimal balance between the genetic improvement and the conservation of genetic diversity. Two strategies integrating breeding and conservation are proposed. These strategies can be characterized as 1. Breeding population subdividing, and 2. Selection optimization. The underlying implication of the population subdividing strategy is that the breeding population must be managed in separate or hierarchical sub-populations (groups or sub-lines). While intensive breeding can be applied to the various sub-populations, the genetic diversity is conserved through population subdividing.

Population subdividing also allows exchange of materials among the subdivided or hierarchical sub-populations to maintain genetic diversity within the sub-populations. Each of the strategies has its advantages and disadvantages, The choice of the different approaches depends on several factors such as breeding goals, conservation needs, finance and technologies. Several variants of the population subdividing strategy were demonstrated.

The selection optimization strategy seeks optimal compromise between genetic progress and conservation of genetic diversity in the selection decision regardless of how the breeding population is structured. With the optimization strategy, genetic diversity is first quantified with use of coancestry and then integrated with genetic gain by applying a weighting coefficient to the coancestry.

The weighting coefficient can be generally regarded as the importance of diversity relative to gain. This integration provides a single measurable scale to compare different outcomes from different selection alternatives regarding both genetic gain and diversity. Optimization was conducted by assigning a series of penalties to the coancestry in the selection process. Application of this strategy to a real breeding program demonstrated that in almost all cases the genetic gain and diversity were much better balanced in comparison with the traditional method.

In certain cases, combining the optimization strategy with the subdividing strategy may be a better choice to integrate breeding and conservation. In terms of long-term sustainable utilization of forest genetic resources, there are actually no fundamental differences between tree breeding and gene conservation programs. Integration of tree breeding and gene conservation in a single program substantially reduces the managerial and financial inputs required by running separate programs of tree breeding and gene conservation. This provides a new way towards gene management for sustainable uses of forest genetic resources.

Le santal dans le Pacifique sud insulaire, état de la diversité et stratégies de conservation.

Yves Ehrhart
CIRAD-Forêt Programme Arbres et Plantations BP 10001 Nouméa Nouvelle-Calédonie
Email: yves.ehrhart@cirad.fr

Le santal, arbre hémi-parasite dont l'huile essentielle extraite par distillation du duramen est très recherchée en parfumerie, appartient à la famille des *Santalaceae* exclusivement composée de plantes parasites. Le genre *Santalum* qui comptait 15 espèces dont une actuellement éteinte, se concentre autour du Pacifique à l'exception de deux espèces de l'Australie occidentale et des localisations indiennes de *S.album*. Les espèces du Pacifique sud insulaire sont *S. austrocaledonicum*, *S. yasi* et *S. insulare*. Ces trois espèces présentent des diversités botaniques variables, que l'on peut aisément rattacher aux caractéristiques géographiques de leurs aires plus ou moins morcelées et isolées. Mais ces dernières sont aussi à l'origine d'un facteur de risque humain qui pèse fortement sur la survie de certaines variétés à moyen terme.

La faculté de cette espèce à rejeter et à drageonner lui a plus ou moins permis de survivre aux campagnes d'exploitations et une partie non négligeable de l'information génétique a été ainsi conservée. Par contre, l'évaluation de sa diversité est difficile par des moyens simples en raison de la forme multicaule et tordue que prend le santal issu de drageons et, dans de nombreux sites, aucune régénération de franc-pied ne peut être trouvée. La composition de l'huile, caractère principal de la valeur économique de l'arbre, nécessite le prélèvement de duramen et son analyse chimique, opérations lourdes et coûteuses et qui demandent un arbre suffisamment vieux. Pour cela, la connaissance plus précise de la variabilité génétique est difficile en de nombreux sites et n'a pu encore être menée à bien.

L'état des peuplements est très variable. *S. insulare* présente une aire très dispersée et morcelée en très petites unités qui portent souvent chacune leur variété. La pression humaine directe, la modification de l'environnement végétal et animal à laquelle le santal est soumis, la faible taille des populations mettent souvent ces variétés en danger d'extinction. *S. yasi*, qui s'étend de Fidji à Tonga présente une unicité botanique et les populations sont plus importantes. Mais, excepté celle d'Eua à Tonga, les effectifs sont relativement réduits. Leur survie peut être mise en cause. Néanmoins, une action rapide de sauvegarde des ressources génétiques permettrait le maintien d'un pool génétique suffisant pour assurer une conservation efficace. *S. austrocaledonicum*, est l'espèce qui recouvre les plus grandes surfaces terrestres. Elle est encore constitué de peuplements relativement importants sur les îles coralliennes de Nouvelle-Calédonie et certaines île de Vanuatu. La diversité génétique y est encore importante bien que l'évolution sur les autres îles nécessite des actions urgentes. Une variabilité importante sur la composition de l'huile a été mise en évidence et la compréhension de ce phénomène est une étape forcée avant de se lancer dans une stratégie de conservation / replantation.

Cet état des peuplements conduit à proposer plusieurs stratégies de conservation selon la situation des peuplements. Si la conservation à but uniquement patrimonial se défend, elle se heurte à des notions de coûts et donc d'efficacité de la protection. Une vision plus économique doit y être associée pour valoriser au mieux et ainsi le justifier, l'effort de conservation. Elle nécessite une bonne connaissance du matériel végétal et du marché aval très limité et exigeant. L'utilisation d'outils génétiques se justifie et permettra des gains importants sur l'amélioration, en particulier sur celle concernant la composition de l'huile essentielle.

Keywords: GFIS, forests, Global Forest Information Service, Information, Internet, meta-data

Rapid, reliable and universal access to quality information on forests is essential for informed decision-making, and improvement of information systems is generally recognized as a global priority. To address this priority the International Union of Forestry Research Organizations (IUFRO) has convened a consortium of international, regional and national organizations, functioning as a IUFRO Task Force, for the purpose of developing a strategy for, and implementing, an Internet-based meta-data service to provide coordinated world-wide access to forest information. The envisioned Global Forest Information Service (GFIS) will provide substantial benefits: easier access to diverse sets of forest information (e.g., bibliographic, research capacity, forest resources, maps); better comparability of data sets through adherence to common standards; improved user feedback to information providers; identification of information gaps and areas of duplication; generation of value-added products (e.g., reports, newsgroups, workshops); and facilitation of information dissemination and improved technology transfer.

The GFIS is based upon the notion of a distributed network of meta-databases, which catalogue the forest information resources of participating GFIS partners (nodes). It is proposed that GFIS will foster interoperability by providing a standardized core of meta-data (catalogue) fields, a standardized set of search criteria and a standardized interface between web sites and databases. Each GFIS node will host a locator, which serves as a meta-database to catalogue and organize nodal information resources and provides information-seekers with a means of rapidly searching for relevant information on the web. A central GFIS Information Server will coordinate the housekeeping functions of the GFIS network.

The GFIS is an open-ended system to which information providers (e.g., national and international organisations, universities and libraries) who wish to follow GFIS principles may contribute resources. These principles will be expressed in a collection policy, which will define subject coverage, target audience, types of resources to be included, submission procedure, quality assessment, meta-data standards and maintenance arrangements. Anyone with access to the Internet can seek information via the GFIS by: connection to the information locator at any GFIS node, selection of search criteria (e.g., topics), submission of search, examination of meta-data output and accessing or acquiring specific data.

MIRA - an information management system to support research and technology transfer on forest plantations

Luis Arias Ugalde
1CATIE, 7170 Turrialba, Costa Rica
Tel: 506 556-0026, FAX: 506 556-2427, Email: lugalde@computo.catie.ac.cr

During the decade of the 80's the Centro Agronomico de Investigacion Tropical (CATIE) together with the government institutions in charge of forest research in Central America developed a standardized method for the establishment and repetitive measurement of multiple use tree plots. Based on this methodology, more than 15,000 research plots were established in the Central American region. The system 'Management of Information about Forest Resources' (MIRA) was developed to manage and analyze this enormous quantity of information. - By means of MIRA, the network of growth plots and established scientific trials has generated valuable information for silviculture of the species and technology transfer. The system MIRA manages information about study sites, climate, soils, forest ------, seed sources, tree data, and the ----- of various forest products. It has generated data for many scientific publications, including growth and yield models for multiple use species. - Recently by means of an agreement between CATIE and CIFOR, MIRA has been converted into a bilingual system (Spanish and English) in the Windows 9 environment and at the same time the network of MIRA users has grown to include organizations outside of Central America and private companies. Besides being a tool for the management and analysis of information within an organization, the system MIRA has served as a means for the interchange of information and experiences between organizations. One unexpected result is the fact that any private businesses are disposed to combine their data at the level of plot summaries. This has allowed analysis involving a variety of growth conditions and management practices that would have been impossible with smaller data sets.

The XXI IUFRO World Congress in Summary

Preface

The XXI IUFRO World Congress was successfully organized and held at the Putra World Trade Centre (PWTC), Kuala Lumpur, Malaysia, from 7-12 August 2000. A total of 1,906 delegates and 209 accompanying persons from 96 countries participated in the largest forestry meeting ever held in Malaysia. IUFRO's Scientist Assistance Programme supported 169 scientists from 44 developing countries. A full list of delegates and their addresses is included in this Congress Report.

The Minister of Primary Industries, Malaysia, on behalf of the Rt. Honourable Prime Minister, Malaysia, officially opened the Congress. The Prime Minister emphasized the importance of sustainable forest management in order to meet the social, economic, ecological, cultural, human and spiritual needs of present and future generations. In addition, five series of Congress commemorative stamps were launched in the opening ceremony of this remarkable Congress.

During the six-day Congress many interesting scientific programmes were organized ranging from Plenary Sessions, Sub-plenary Sessions, Group Sessions to poster exhibitions and satellite meetings. A three-day Forestry Exhibition was also held at PWTC. Five Keynote Addresses by renowned speakers were delivered during the Congress. These speakers highlighted new visions for forestry and forest research as we enter the new millennium, and stressed the close linkages between forests and society as exemplified by the theme of the Congress: "Forests and Society: the Role of Research". More than 500 papers were presented in 125 Group Sessions and 99 papers in the Sub-plenary Sessions. Approximately 510 approved posters were also displayed during the Congress. Discussions during various sessions were generally of an exceptionally high standard and augured well for the future of IUFRO and the future of forest research.

Full papers of all the Keynote Addresses presented in the Plenary Sessions are included in this Report, in addition to speeches delivered during the Opening and Closing Sessions. Papers presented in Sub-plenary Sessions and abstracts of Group Sessions and posters had been published before the Congress in three volumes of Proceedings, which were also included in a CD-ROM. The Congress Resolutions as approved at the Congress are also included in this Report in all four official languages. These Resolutions are intended to inform governments in countries where IUFRO is represented as well as policy-makers all over the world.

In order to break the monotony of the meeting, an in-Congress tour was organized on the fourth day of the Congress. More than 1,200 delegates participated in the one-day tour and had a choice of nine routes. Twelve post–Congress excursions were also conducted to allow delegates to experience the beauty of Malaysia and the

neighbouring countries Thailand, Indonesia and Brunei. All these tours were specially designed with the focus on forestry, forest industries and attractive sites. The Accompanying Persons' Programme was also well organized. Out of the 10 tour packages, the 'fireflies' tour was the most popular and sensational one.

Special events such as the Tree Planting Ceremony with members of the International Council, as well as the welcome and farewell dinners were organized to enhance the social networking of all delegates over the world. In addition, multi-colour cultural shows of Malaysia were presented; Australia, the next Congress host country, brought in a wonderful didgeridoo player during the closing ceremony.

In letters of thanks written by delegates the Congress was regarded as one of the best Congresses ever held and it had left a memorable impression on the delegates and their accompanying persons. This was very much in line with the slogan adopted by the COC: "committed to ensuring a successful and memorable Congress".

From the very first day of their arrival in Kuala Lumpur, the delegates were impressed by the overall organization of the Congress. The smooth registration process, logistics arrangements in meeting rooms and services rendered at the Computer Centre and Information Counter left good impressions on the delegates. More importantly, assistance and arrangements provided by the Speakers' Service Centre and Congress Information System (CIS) constituted a fine contribution to the Congress. The CIS continues to provide crucial data of the entire Congress, and its generic framework will be beneficial to IUFRO and future Congress organizers in particular. The Congress daily bulletin "Belantara" religiously kept delegates up-to-date with the latest news and activities of the Congress and snapshot photos of events.

The material for this Congress Report was compiled and prepared by the Secretariat of the Congress Organizing Committee with kind contributions from the chairmen of various sub-committees who were responsible for their respective sections. The excellent translation work was done by the IUFRO Secretariat, for which I am grateful. Finally, I must thank everyone who has assisted wholeheartedly in the preparation of the Congress and this Report for their strong commitment and fine contributions.

Abdul Rahim Nik
Chairman of the XXI IUFRO World Congress Organizing Committee
Kuala Lumpur

Opening and Closing Ceremonies

Opening Ceremony
7th August 2000

The Opening Ceremony took place in the Merdeka Hall of Putra World Trade Centre (PWTC) and was attended by an audience of about 3,000. The ceremony was divided into two parts. The first part comprised the official events. During his welcome speech, Dato' Dr. Abdul Razak Mohd. Ali, the Chairman of the Congress Steering Committee, expressed Malaysia's pride in being the first developing country to host this prestigious international Congress.

Professor Jeffery Burley, the IUFRO President, said that the theme 'Forests and Society: the Role of Research' was timely in view of the increasing demands on forests and their products and the need for researchers and policy-makers to enter into closer dialogue.

In his opening speech, Dato' Seri Dr. Lim Keng Yaik of the Ministry of Primary Industries, Malaysia, delivered the Prime Minister's address and offered a warm welcome to all participants. The Prime Minister expressed concern about the glaring vacuum in the global agenda on forestry relating to legal instruments on forests. He urged the developed countries to furnish the financial and technological assistance to the developing countries in order to achieve sustainable management of their forests.

Minister of the Primary Industries, Dato' Seri
Dr. Lim Keng Yaik, declared the IUFRO Congress opened.

Besides speeches, there was the presentation of Honorary Membership to two distinguished members of IUFRO, namely Professor Dr. Franz Schmithüsen from Switzerland and Dato' Dr. Salleh Mohd Nor from Malaysia. There was also a special ceremony for launching the commemorative Congress stamps and the First Day cover.

The second part consisted of the award presentation ceremony for Scientific Achievement Awards and Outstanding Doctoral Research Awards. This was followed by a speech by Dr. Hosny M. El-Lakany, the Assistant Director General of FAO, who emphasized that close cooperation between IUFRO and FAO has enabled the smooth flow of information and knowledge in a multi-channel network. The Keynote Address entitled "Sustainable Management of Natural Resources" was delivered by Tan Sri Razali Ismail of Malaysia. He stressed the great extent and seriousness of the earth's destruction through human activities and outlined the various aspects of sustainable management as the solution to these inter-related problems.

Launching of the Congress Commemorative Stamps

Presentation of IUFRO Honorary Award to Professor Dr. Franz Schmithüsen

Winners of the Outstanding Doctoral Research Awards

Winners of the Scientific Achievement Awards

Closing Ceremony

12th August 2000

The closing ceremony was held on the last day of the Congress in the Merdeka Hall of PWTC. It was attended by almost 2,000 persons comprising the participants, Secretariat members and Congress assistants. In his speech, Professor Jeffery Burley thanked all participants and members of the Organizing Committee for a job well done. Dr. Abdul Rahim Nik in his capacity as Chairman of the Organizing Committee thanked the IUFRO Board for entrusting the job to him and the hundreds of volunteers and Congress assistants for supporting him.

The ceremony proceeded with the presentation of the Best Poster Awards. Dr. John Youngquist read the citations and Dr. Eric Teissier du Cros presented the awards to the ten winners. Mr. Jean Menetrier of Forestry Canada was announced as the winner of the IUFRO logo competition.

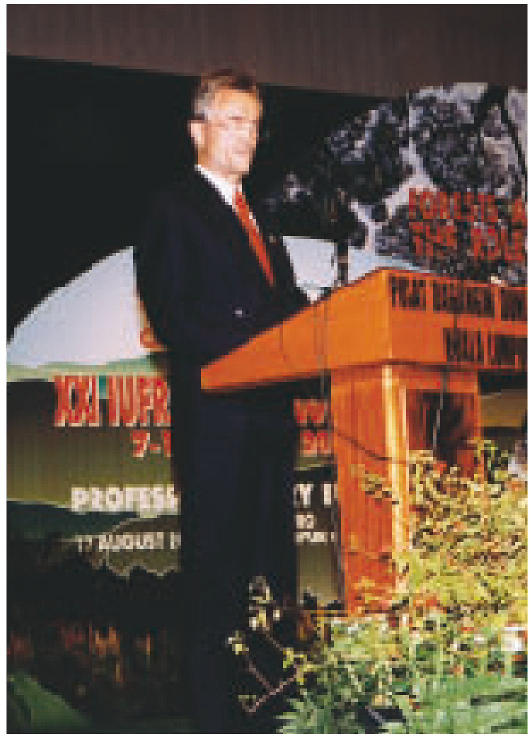
In recognition of their outstanding contribution, two awardees, namely Dr. Abdul Rahim Nik from Malaysia and Dr. Fujio Kobayashi from Japan, received the Distinguished Service Award from the Secretary of IUFRO.

In a short statement, Dr. Mohammed Ellatifi from Morocco thanked the organizers on behalf of the SAP recipients for having made their participation possible through funding.

The Congress Resolutions were presented by IUFRO President Professor Jeffery Burley. The President announced the new line-up of the Executive Board for the period 2001-2005 and introduced them on stage. The President-elect,

IUFRO Presidents and the President-elect R. Seppälä from left to right:
Risto Seppälä (Finland), Jeffery Burley (UK), M.N. Salleh (Malaysia), Robert Buckman (USA), Dusan Mlinsek (Slovenia), Walter Liese (Germany)

Dr. Risto Seppälä, presented his speech and revealed his vision for IUFRO in the next five years.



The President then announced Australia as the next host country for the IUFRO World Congress 2005. A spectacular performance on the Didgeridoo was given by an aborigine of Australia who welcomed all delegates to Australia in 2005 in his aboriginal language, which was translated into English. A video show of Australia and a speech by Professor Russell Haines, Chairman of the COC of the XXII IUFRO Congress 2005, followed.

The IUFRO flag was lowered and folded by four foresters from the Forest Research Institute Malaysia. Dr. Abdul Rahim Nik as Chairman of the Organizing Committee handed the flag to Professor Jeffery Burley who then handed it to Professor Russell Haines of Australia.

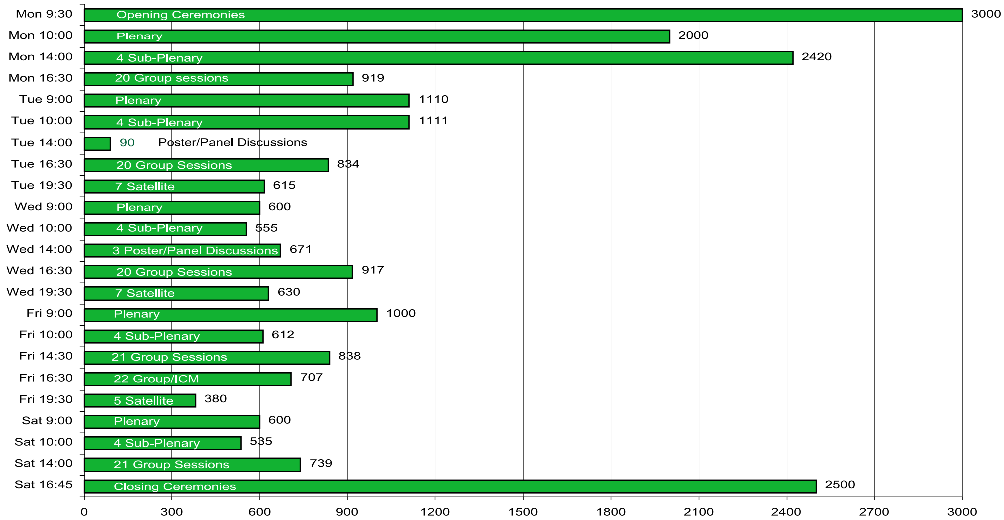
The organizing members from both the IUFRO Secretariat in Vienna and Malaysia were given a round of applause from the participants for successfully organizing the Congress. The Congress was officially closed by Professor Jeffery Burley who expressed thanks to all who had contributed to the IUFRO activities during his tenure and congratulated the new Board members and the new President on their appointment.

The new line-up of the IUFRO Board (2001-2005)

Scientific Programme

The scientific programme comprised five Plenary Sessions, 20 Sub-plenary Sessions and nine Task Force Sessions, which were cross-divisional. A total of 619 papers were presented as oral presentations in 146 sessions over the week, including 21 additional papers and another 527 papers presented during two poster exhibition sessions. This time posters were given strong emphasis in order to provide more opportunity for scientists to present their research findings. The fifth day of the Congress (Friday, 11th August) was the busiest day when 42 concurrent sessions were held. The level of participation in various sessions and the popular sessions are portrayed in Tables 1 and 3.

Table 1. Number of delegates participating in various scientific programmes



Plenary and Sub-Plenary Sessions

During the Plenary and Sub-Plenary sessions, no other sessions took place. On average more than 1,000 delegates attended the Plenary Sessions, and 300-350 participants were present in each of the Sub-plenary sessions. Altogether, five papers were presented in the Plenary Sessions and 99 in the Sub-Plenary Sessions.

All the Keynote Papers, except one, are published in this Congress Report. All the Sub-plenary papers have already been published in Volume I of the Congress Proceedings. In addition, the abstracts of the papers presented during the Group Sessions were published in Volume II of the Congress Proceedings.

Volume III of the Congress Proceedings contains the Abstracts of all Posters scheduled to be presented at the Congress. A CD of the three volumes of the proceedings had been produced and was distributed to participants during the Congress.

Group Sessions

The Congress Group Sessions were jointly organized by the IUFRO Divisions or Research Groups and Working Parties while Task Force Sessions were organized by their respective Coordinators. There were altogether 121 technical sessions with 521 papers presented, including nine Task Force Sessions. The number of Congress Group Sessions and papers by Divisions are given in Table 2, while the five most popular sessions in each Division are indicated in Table 3. The session on "Future of breeding and plantations in a sustainability-oriented world" of Division 2 attracted the largest number of participants in the Congress. Lists of additional papers were presented in various sessions with the details given in the Table 4. In addition, SPDC organized two sessions/workshops in cooperation with the BIO-REFOR project.

Table 2. Number of Congress Group Sessions and papers presented by Division.

Total	121	58	179	521

Table 3. The five most popular session themes by Divisions

Division	Theme	Number of participants
Division 1	- Tropical forest restoration (I) (poster/panel sessions)	136
	- International markets for carbon sequestration from tropical forests	90
	- Tropical forest restoration. Poster/panel discussion (II)	75
	- Tropical silviculture	70
	- Short rotation forestry for biomass production (I)	40
Division 2	- Future of breeding and plantations in sustainability-oriented world (II)	150
	- Genetic improvement	75
	- Vegetative propagation	52
	- Seed physiology and technology	47
	- Physiology of tropical and temperate trees	45
Division 3	- Forest operations in the tropics	75
	- Harvesting, wood delivery and utilisation (I)	68
	- Forest operations under mountainous conditions	45
	- Forest operations and environmental protection	38
	- Small-scale forestry	38
Division 4	- Effects of environmental changes on forest growth	95
	- Sustainable forest management under conditions of growing global pressures	77
	- Using models for forest growth and stand dynamics to evaluate sustainability (II)	75
	- Forest resources assessment 2000	65
	- Integration of GIS and remote sensing for assessment of forests and landscapes (II)	63
Division 5	- Production and utilization of bamboo and related species. Challenges for the new millennium	75
	- Non-wood forest products (I)	60
	- Wood quality (I)	60
	- Composite and reconstituted products	53
	- Forest products marketing	52
Division 6	- Sustainable land use as precondition for sustainable forestry	68
	- Bridging the gap between monetary and non-monetary valuation of environmental amenities	61
	- Modelling forest managers environmental decisions	55
	- Tropical forest history	50
	- Research driven by scientists' wish or society's demand?	50
	- Poverty and management of forest resources	50
Division 7	- Biological invasions as agents of global change (II), Management	62
	- Insect pest problems in replanted forests (II)	52
	- Insect pest problems in replanted forests (I)	46
	- Mechanism of tree resistance to phytophagous insects	45
	- Biological invasions as agents of global change (I), Ecology	38
Division 8	- Biodiversity	92
	- Forest fire (III). Temperate and boreal forests. General discussions. (poster/panel sessions)	50
	- Forest environment in general (II)	46
	- Human impacts on tropical rain forests with long term view	35
	- Site (I)	34

Table 4. Listing of Additional Papers Presented in Group Sessions

Session	Author(s) /Papers
4.01.03/4.11.00	a) Valerie LeMay and Christina Kovacs – Relationship of stand structural diversity to common stand measures.
8.08.00	a) Guiseppe Scarascia Mugnozza – Effect of atmospheric carbon dioxide enrichment on cultivated ecosystems - A phase on short rotation intensive Poplar plantations.
5.11.00	a) Karki M. - Biopartnership as a sustainable strategy for management of medicinal plants.
8.00.00	a) Alain Franc – Ecology and Forestry. b) Johann Goldammer – Global Fire. c) Folke Anderson - European Network for research into forest ecosystems. d) Boyle J. – Site definition in relation to forest ecosystems.
T5	a) Fred Watson , Lawrence E. Band and Lars L. Pierce – Hydro-ecological modelling of the impact of environmental change on forest ecosystems at the watershed scale. b) Michele Akeroyd – The use of stable isotope of water and carbon for investigating pant water use strategies.
6.15.00	a) Helene Lundkvist – Quality assurance in forestry education – The Swedish case. b) André Breytenbach - The role of student organisation in improving education.
Sub-plenary E3	a) Carol Colfer – Cultural diversity in forest management (Paper presented by Maffa).
3.07.00	a) Richard Parber – Centre for occupational human factors and ergonomics – New Zealand. b) Seca Gandaseca & Tetsuhiko Yoshimuna – A study on productivity and work loads of natural forest harvesting in central Kalimantan.
4.01.04	a) George Garther & Pablo Parysow – Accounting for interactions in hypothesis testing of simulated forest growth process model.
4.40.00	a) Colin Price – Exact values of vague products? Contingent valuation of passive use value.
5.11.00	a) Wanida Subansenee – Promotion of tropical NWFP in Thailand. b) Marion Karmann – Miombo woodland utilization by smallholders – Tanzania.

Business Meetings and Satellite Meetings

The Congress Business Meetings were organized jointly or individually by the IUFRO Divisions, Research Groups, Project Groups, Task Forces and Working Parties. There were altogether 58 Business meetings. Three evenings during the Congress week were allotted for 19 Satellite meetings organized by various forestry-related agencies, including IUFRO's Task Forces (Table 5).

Table 5. Satellite Meetings and Organizers

Title of meeting	Organization	Participants
- African Forestry Research Network: A joint partnership to promote scientific excellence & to bridge the research gap in sustainable forestry management in Africa	African Forestry Research Network (AFORNET)	50
- General Assembly	Asia-Pacific Association of Forestry Research Institutes (APAFRI)	60
- Forestry Compendium: Launch of Global Module	CABI/FRIM	100
- Challenges and Opportunities for International Forestry Research	Centre for International Forestry Research (CIFOR)	150
- Queens Award for Forestry 2000	Commonwealth Forestry Association (CFA)	120
- CO2FIX User-platform / EU - CASFOR project meeting	EU-CASFOR Project	30
- Oil Palm Utilisation Committee Malaysia	FRIM / UPM / FORIM	50
- Social & Association meeting	International Association of Wood Anatomists (IAWA)	60
- International Foundation for Science - Building Scientific Capacity in Developing Countries	International Foundation for Science (IFS)	100
- Consultation on International Rattan Research and Development Needs	International Network of Bamboo and Rattan (INBAR)	50
- Shaping an Information Service on the Forest Genetic Resources	International Plant Genetic Resources Institute (IPGRI)	30
- ITTO and the Promotion of Sustainable Forests	International Tropical Timber Organization (ITTO)	125
- How can gender research contribute to a more sustainable forest management?	Pilot Group: Gender Research in Forestry (Women & Forestry)	100
- Side meeting on Secondary Forests in Tropical Asia	Secondary Forests Management Group - CIFOR	50
- Consolidation of IUFRO Chapter for Indian Scientists	The Indian Society of Tree Scientists	100
- CITES and Agarwood Use and Trade	Trade Records Analysis of Flora and Fauna In Commerce (Traffic)	60
- Logistics	Wood Logistics Club	40
- How can global research by WFSE sustain forest development	World Forests, Society and Environments (WFSE)	120

Poster Presentations

Scientific posters were given emphasis in this Congress as they play an important role in facilitating scientific exchange besides oral presentations. To highlight this effort, the "IUFRO Best Poster Award" was offered to one poster per IUFRO Division and one for the pooled posters from Task Forces. Abstracts of accepted posters were published in the third volume of the proceedings that were distributed to participants during registration.

About 55% of the originally anticipated participation of 953 posters were eventually displayed (527 posters in total). The breakdown of acceptance and withdrawal per Division, Task Force, Poster/Panel is shown in Table 6. There were also 14 new posters presented as listed in Table 7 (walk-in registration). The IUFRO delegates showed considerable interest in the Poster Exhibition and filled the hall on both days to catch a view of the multitude of topics presented as posters.

In addition, this Congress saw the introduction of two interactive poster/panel sessions held in meeting rooms, one for a Group Session and the other one for sub-plenary discussion. These were therefore treated as relatively lengthy oral presentations of individual posters (rather than papers), or a version of oral presentations.

Table 6. Posters by Divisions

Poster category	# posters presented	# withdrawn
Div. 1	40	28
Div. 2	44	39
Div. 3	35	9
Div. 4	43	57
Div. 5	136	100
Div. 6	75	38
Div. 7	60	47
Div. 8	46	64
Task Forces	8	17
Interactive poster/sessions	26	27
New (walk-in) posters	14	na
TOTAL	**527**	**426**

Table 7. A List of additional poster titles

1.	Investigation on poplar short rotation systems in Iran by A. R. Modir-Rahmati, A. Hemmati and R. Ghasemi.
2.	Investigation on influence of overstory on pasture dry matter yield by Hossein Arzani.
3.	The manufacturing of particleboard from poplar wood produced under short-rotation forestry in Iran by Hosseinzadeh A., Nourbakhsh A., Golbabaei F. and Hosseinkhani H.
4.	Integrated pest management of wild pistachio in Iran by H. Askary, E. Sadeghi and R. Omid.
5.	Large-scale rainforest rehabilitation for CO_2 sequestration in Sabah, Malaysia: a case study on INFAPRO since 1992 by Yap Sau Wai, Pedro H.Moura-Costa and Igino M. Emmer.
6.	Growth Performance of Schizostachyum lumampao (Blanco) Merr. Planted by seeds after 24 years, by Aida Baja-Lapis.
7.	Efficient modelling of stem curves by Jouko Laasasenaho, Heikki Karttunen and Mark-Leo Waite.
8.	Survey of fungal biodiversity on wood packaging imported into New Zealand by Robin Janson, Arvina Ram, Shona Duncan, and Roberta Farrell.
9.	Succession and biodiversity of macrofungi and vegetation on Scots pine stand after forest fire in eastern Finland by Kauko Salo.
10.	The conceptual frames of the close-to-nature forestry in Slovenian forest wilderness by Milan Hocevar, David Hladnik and Marko Kovac.
11.	Hyrcanian forests (North of Iran), the unique ecosystem in the Near East Region by Khosro Sagheb-Talebi.
12.	Dormancy-breaking and storage strategies of Prunus campanulata maxm. seeds by Ching-Te Chien.
13.	Response of Casuarina seedlings to Frankia inoculation and nitrogen fertilization in sandy and calcareous soils by Kamel Dawh, A.E., Abd. El-Dayem, A., Awad, A.E. and Kamal, H.M.
14.	Determining an integrated information base on forest stands as a basis for the strategy of sustainable forest management by Karoslav Simon and Karel Drapela.

Speakers' Service Centre (SSC)

The Speakers' Service Centre (SSC) was the focal point for the speakers at the Congress. Its main functions were to assist the speakers to finalize and to preview their presentations. Several LCD projectors and slide projectors were available for the speakers for this purpose. For those presenting with slide projectors, slide trays were made available. Digital presentations were copied on CDs according to sessions.

The speakers were requested to report a day before their presentation in order to avoid last-minute haste.

Generally speaking, the SSC was well accepted by the participants and the system developed was effective and beneficial as there were no delays due to technical or logistics problems associated with the use of the AV equipment.

Summaries of the Keynote Addresses

The theme of the Congress, 'Forests and Society: The Role of Research', was eloquently elaborated in five selected topics of keynote addresses: Sustainable Management of Natural Resources; Forests and Society Needs; Changes in Environment and Society; People Issues in Forest Management; and the Global Vision of Forests and Society. The five renowned speakers highlighted new visions for forestry and forestry research as we enter the new millennium. They further stressed the close linkages between forests and society as exemplified by the above theme of the Congress.

Mr. Razali Ismail, currently a special adviser to the Prime Minister of Malaysia, offered his thoughts on the sustainable management of natural resources, while Dr. Christine Dean, currently forest geneticist at the Weyerhaeuser Company in the USA, traced on how best to match research to present and future society needs. Prof. Antonio Andaluz-Westreicher, currently teaching and researching on environmental law in Bolivia, discussed changes in the environment and the role of society in the sustainable management of the environment. Dr. Robert Lewis, who is the Deputy Chief for Research of the USDA Forest Service focused his presentation on cultural diversity in forest management. Finally, Prof. M. S. Swaminathan, who has been described by the UNDP as 'the father of economic ecology' forcefully presented a global vision of forests and society.

Mr. Razali Ismail

Sustainable Management of Natural Resources

Mr. Razali opened his speech by addressing the depth and seriousness of the earth's destruction through wanton human activity. He highlighted the close relationship and domino consequence of forest depletion, plant and animal extinction, water and air pollution and the direct impact all these impose on human survival.

He emphatically stressed that forests do not only support life systems, but actually generate and support life. The discoveries that originate from forest plants and animals have a direct implication and beneficial consequence on a variety of applications that continue to grow. World-wide forest loss is rapid and alarming and natural resources can no longer sustain this rate of destruction and degradation. This is a world-wide problem and forests everywhere are under grave threat. He mentioned that the opening of forest for agricultural expansion, and commercial logging are factors that contributed towards deforestation, although these are not the leading causes; it is rather the method of logging, the mismanagement and deforestation that are the primary causes of the problem.

Mr. Razali then outlined in his speech the various aspects of sustainable management as the solution. These are the allocation of land, establishment of a comprehensive system and maintenance of an adequate permanent forest estate as well as involving the communities that live in or near forests in decisions affecting forest conservation and development. He also addressed the perspective of economic pursuits being given precedence over sustainability of the land as an area of acute concern. It is the common people at large that suffer from the consequences, while a select few are made rich. He touched on the constant tussle between the opportunity cost of industrialization and the preservation of natural forests.

It is this, he said, which requires attention. People should be educated in order to learn about the value of forests and what they represent and then find ways to pay for their conservation and preservation. Mr. Razali said that as part of life on this earth, everybody has a role to play in sustaining the natural resources on the earth and not take more than nature can replenish. This may mean adopting life styles that are sustainable and developing an ethic of care for nature at the global, national and individual levels.

Finally, he pointed out the fact that no nation is self-sufficient and all nations stand to gain from world-wide sustainability. Unless we learn to protect the globally shared resources, all will be threatened. Mr. Razali left the audience with the poignant remark of a famous philosopher "To pluck a flower is to kill a star" and urged them to change it into "To plant a tree is to rekindle the universe".

Christine A. Dean, Peter Farnum & Mark Plummer

Science in Service to Society Matching Research to Society's Needs

This was a lively session addressing the role of science in forestry and the responsibility of the scientist to develop better ways for society to achieve its goals. The interesting and insightful views were presented in line with the argument of the " cognizant and transparent scientist" and how employing these two characteristics allow the scientist to discharge his/her social responsibilities while remaining true to the tenets of science. Also discussed were the perils of science in the real world and how scientific research has to function to contribute to social progress on a dual prong basis of offering better methods or products and helping us identify and quantify the consequences of our actions.

An eye opening slide presentation displayed very pertinent figures about demand on the forests. In 1996, the world consumed 1.5 billion cubic meters of industrial wood products, a figure that is expected to grow to 1.9 billion over the next century. Meeting the demand through harvests of natural forests would require up to 1.5 billion hectares of forestland, equivalent to 40% of the world's forests! However, growing and harvesting wood from managed forests could decrease the amount tenfold, switching to high-yield plantations would decrease it even further and reduce the forestland devoted to industrial production to two percent. The net result is "getting more from less". To this end, scientific research has allowed us to meet a growing demand from a smaller land base, creating the potential for more land remaining in its "natural" state.

An explanation was then presented on the role of forest genetics in the quest of managing to get more from less. Research associated with genetics ensures that the genetics populations are well managed and genetic potential is fully expressed and captured in the plantation. However, in today's complex society, this is rarely a simple task.

The next area that was addressed was the effect of forestry on fish habitat as there is a direct connection between these two. Diagrams were offered to portray the sets of stream characteristics measured on the ground to predict the presence or absence of fish.
"Precautionary Science" is when a precautionary principle is incorporated into a scientific practice, and encapsulating this principle is the rule: "When an activity raises threats of harm to human health or the environment, precautionary measures should be taken even if some cause and effect relationships are not fully established scientifically".

In merging social values with science, acknowledging the importance of values, interests and passions, as well as the wisdom of proceeding cautiously, does not overthrow the existing tenets of science. Indeed, it points to a stronger role for science, as it is for the society, not the scientist that must determine what "ought" to be.

Professor Antonio Andaluz –Westreicher

Changes in Environment and Society

Professor Antonio Andaluz-Westreicher enlightened the audience about the potential for conservation of our resources with passionate references to his personal experiences in his homeland Bolivia. In an introspective and invoking address, the Professor offered an interesting walk-through of the changes in forests and how they influenced society and what deforestation implied for society. Human tragedy, said the

Professor is that when speaking of the need of keeping and using the forest in a sustainable way, many who decide every day about the future of these forests are the ones who have probably never even been in a forest.

To have “the forest experience “ alone, is one factor that opens eyes and ears to cries of need that no amount of words and explanations alone could ever aptly portray. Forests are worth by their spiritual meaning for the human soul, they “calm you, lead you to serenity and repose; they make you sit down and take possession of yourself”. This is something that does not have a price in the market, and is not merchandise for trade, therefore making it a priceless creation, deserving of protection.

Professor Andaluz outlined the existential categories of man as a distinguished being, if not from the universe, certainly from the planet, in that he is a living being, an intelligent being, a historic being, a cultural being, a being with needs, a social being and finally, an ecosystemical being. Therefore there is nothing worse than for a human being to deny himself and not recognize himself in the existential categories to which he belongs. However, this is the first unfortunate change in human society when forests change into deserts. Divorced from nature, the human soul is isolated and the divorce of man is now with man, but even more tragically, with himself.

Having lost our sense of belonging to the ecosystem, it is not strange that we give only what we have as a sense of sociability – comparing with the goods and services that are exchanged among trees in order to build the forest that makes each of them into a complete individual reality. The destiny of the forest is decided in cities, where the divorce with nature is so apparent. Towns people have forgotten how their lives depend on natural resources and have no conscious idea about the way food is produced, or how the fibres of their clothes are made, or how they enjoy electricity at the flick of a switch and water from the turn of a faucet. They, therefore, have no idea that resources will be exhausted, let alone why they should be preserved.

Attention was also called to the issue of forest burning. As the cheapest tool farmers can use, the worst environmental damage is not produced as a result of lands farmers want to burn but the areas burned that were not supposed to be burned.

In ending his concepts, an explanation was offered elaborating on trees being cut to satisfy hunger, and instead, give rise to hunger because too much has been cut. We all know that the supply of water and its different goods and services depends on harvesting, storage and regular provision of the forest. There are already too many countries all over the world which suffer from the consequences of the destruction of protective basins and water catchment areas. It is even thought that many future wars will be caused by the scarcity of water.

In closing, a brief insight was provided about the new forestry legislation in Bolivia which created the Farm Land Plan as a mandatory tool which defines the ecological easements monitored by the Forest Service. This is one of the tools that are part of the National Forestry Regime, which works to ultimately build the culture of the tree in the human soul.

Robert Lewis, Jr.

People Issues in Forest Management

Robert Louis, Jr. aimed straight at the core issues, which are shrinking forest resources, increasing world population (much of whom is poor) and the loss of forest cover due to a host of reasons. Shrinking resources have seen increasing public attention being given to a variety of global issues including climate change, ozone depletion and loss of biological diversity. “Too many people, too little land” is a common lament and in the coming decades, distribution and population growth rates will only increase pressure on global forests for both industrial products and environmental services. A major contributing factor is poverty as more than half of the world’s population and two thirds of the population in developing countries still live in rural conditions. More than 80% of the world’s population is relatively poor and relies on forest for basic sustenance – primarily fuel and land for growing crops. These factors explain the rapid loss of tropical forests (170 million hectares of tropical forest between 1980 and 1990). He also highlighted use change as another element that contributes to this issue.

The research community, he said, plays an important role in the sustainability of the world's forests. In the United States, several issues are rather unique and deserving of attention from all government, academic and private sector research perspectives, namely: tribal relations, underserved communities, environmental justice, and subsistence/dependence on natural resources. Developing world issues that require addressing include upland development, loss of indigenous knowledge, involvement of local people to solve environmental problems, fair and equitable distribution of resources, agro-forestry and managing eco-tourism.

The speaker informed the audience that the Forest Service International Programs staff have a strategy of several focus countries where several programs are managed. Amongst these programs are fire management, forest monitoring/remote sensing, forest health/invasive species, migratory species/habitat management, watershed management, protected areas/eco-tourism, sustainable forest practices, policy analysis and development and disaster assistance. Forest Service programs are conducted in countries such as Brazil, Mexico, Venezuela, Indonesia, India, China, Vietnam, Russia and others.

Forest Service (FS) scientists have been involved in international work and several FS representatives at this IUFRO Congress are leaders in their fields of expertise. The role that FS R&D plays is to provide technical assistance with many areas of expertise such as fire management, insects and disease, silviculture, wildlife management, forest products technology, inventory, monitoring and more. A certain lack of capacity prevents more areas of engagement", Robert Lewis explained.

As part of his presentation, Robert Lewis then provided a list of suggestions on a few research areas for the science community. These were Preservation and Restoration of Indigenous Knowledge in a bid to capture the knowledge base of the environment and how to sustain it, and Community Forestry to engage the people's participation through research and an understanding of what people want and their ideas for co-management of the land.

From an economic development point of view, more research is needed in the areas of forestry and special forest products that provide options to local people, regardless of country or region of the world. In closing, he said that there is no doubt that research and development will play a larger role in sustaining the world's forests and the contributions go beyond technological and ecological fields.

Prof. M.S. Swaminathan

A Global Vision of Forestry and Society

Dr. Swaminathan began his address by highlighting the significance of 'trees" and in a collective term the 'forest' as a whole and its importance to mankind. The importance of tree has long been ingrained in the ancient civilizations of the world where inscription of trees are seen in ancient places of worship and also in literatures. As a point in case he focussed on the mangrove forests and how important such forests are in not only mitigating floods but also conferring multiple benefits to coastal communities. He pointed that in the past there has been indiscriminate cutting of such forests and now the awareness of its importance has led to the rehabilitation of such forest types.

He next went on to touch on issues relating to the new frontiers of science, with specific reference to climate, forest and crops. The ability to accurately predict cyclone movement with satellite imageries was highlighted in his talk using the images of the movement of the super-cyclone over Orissa coast in October 1999. He further touched on the great strides that have been taken in the field of biotechnology and the opportunities this new emerging field has to offer for the betterment of mankind. He spoke of the potential of the movement of genes across species and genera levels. Of interest, he highlighted the movement of salinity tolerance genes from mangrove trees to the mustard plants. He elaborated on the present strides in molecular breeding with special reference to marker technologies, genetic linkage maps and genetic fingerprinting technologies that are currently making available very vital information of specific gene traits that can be used to manipulate plants in favor of mankind. In this regard, he proposed an urgent need for the establishment of Gene Resource Centers where candidate genes and genotypes of useful value can be identified from different species, which can be isolated, enhanced and utilized in novel genetic combinations in specific problem solving breeding programs.

His next sequence of thoughts touched on the recent global initiatives such as the Agenda 21, Framework Convention on Climate Change and the Convention on Biological Diversity. Along these initiatives, he emphasized on the significance of carbon sequestration, human population in bio-diversity hotspots and biosphere reserves. He proposed that there is a need to integrate in situ, ex-situ and community gene conservation and management activities, to provide a holistic approach towards conservation of gene resources.

His next pertinent thought touched on bio-ethics and the need to give recognition to the contributions made by the indigenous people towards conservation. He eluded to the fact that there should be a shift from bio-piracy to bio-partnerships when useful gene resources were taken into commercialized products. On the issue of patents and the need for a fair mechanism to the sharing of profits, he strongly concurred on the needs to establish it urgently.

His thoughts next moved into the present much talked about phrase – ‘sustainable forest management’. He brought out the concept of ‘Forest Capital Index’ which he elaborated is a tool to provide a uniform numerical indicator of each nation’s current forest capital. The components of which could include items like surface area, stand biomass, net primary productivity, species richness and diversity, age class of trees, leaf area index, soil fertility including soil organic matter and health of forest stands. Following this he eluded to the concept of Agro-forestry, which he believed would be the harmonizing element of today and tomorrow agriculture and forestry. Participatory forest management, sharing of non-wood forest produce and gender considerations would be critical issues in the years to come.

In concluding he touched on the green revolution as a saviour to hunger and feeding of the mass which was an economic challenge form 1980 to the year 2000. Today the views are that of an ecological approach. There is a need for a paradigm shift where the Green Revolution of the eighties which was commodity centered will have to give way to an ever-green revolution that is integrated natural resource management centered. The evergreen revolutionary approach incorporating participatory gender sensitive management aspects, he envisions will be the global trend of forestry and agriculture of the future.

Scientist Assistance Programme

As in previous IUFRO Congresses, the organizers of the XXI Congress attached great importance to a strong representation of scientists and researchers from all parts of the world. Many promising scientists from developing and disadvantaged countries however, find it difficult to participate in such major meetings due to funding limitations. The Scientist Assistance Programme (SAP) was set up with the purpose of assisting potential participants from these countries with evident need. The programme provided funding assistance towards meeting the costs of travel, registration, board and lodging. In addition, some grantees were also sponsored to participate in one of the four Pre-Congress Workshops/Training Courses.

Funding

The SAP received funds totalling RM 935,854.00 (approximately US$ 0.25 million) from the following donor agencies :-

- Department for International Development, United Kingdom (DFID)
- Department of International Development Cooperation of the Ministry for Foreign Affairs, Finland (DIDC)
- IUFRO Special Programme for Developing Countries (SPDC)
- Malaysian government
- United States Department of Agriculture, Forest Service
- Swedish International Development Cooperation Agency and Swedish Agency for Research Cooperation with Developing Countries (Sida SAREC)

The largest contribution, 42% of the total, was received from the Malaysian government. Another major sponsor was the Special Programme for Developing Countries (SPDC).

The International Foundation for Science (IFS) separately supported the participation of 16 IFS grantees to the Congress and one of the Pre-Congress Workshops.

Pre-Congress Workshops/Training Courses

Four Pre-Congress workshops/training courses were organized with a view to attracting additional funds for SAP. A number of SAP grantees participated in three of these Pre-Congress Workshops/Training Courses:

1. Training Course on Forestry Research Strategy Formulation, Planning and Management, 1-5 August 2000.
   Organizer : Faculty of Forestry, Universiti Putra Malaysia.
2. Sustainable Forest Management and Criteria & Indicators, 1-4 August 2000.
   Organizer : Forest Research Institute Malaysia.

3. INFAPRO Workshop - Rehabilitation of Logged-over Rainforest in Sabah, Malaysia, 31 July - 4 August 2000.
   Organizer : Innoprise-Face Foundation Rainforest Rehabilitation Project.
4. Short Course on The Application of Biotechnology in Forestry, 1-5 August 2000.
   Organizer : Asia Pacific Association on Forestry Research Institutions (APAFRI).

Selection Process

All applications received by the extended deadline of 15 November 1999 were subjected to a review and ranking process, in which preference was given to candidates participating actively in the Congress through presentation of papers or posters or in some other specific capacity. In contrast to the previous Congress, scientists who did not play a role in the Congress programme were automatically excluded.

The selection criteria were drafted by the SC in consultation with IUFRO/SPDC and established by the COC for the approval of the IUFRO Executive Board. A modified scoring system modelled after the one developed for the previous IUFRO Congress in Tampere was used for guidance.

Results

The SAP supported a total of 169 grantees from 44 countries. About 92% of the grantees received full sponsorship, i.e. return air ticket, return airport-hotel transfer, costs of hotel accommodation, meal allowances, Congress registration fee, and costs for the In-Congress tour. In addition 36 grantees participated in three Pre-Congress Workshops/Training Courses.

Sixty-one of the grantees presented oral papers, 55 presented posters and another 11 had both oral and poster presentations. At least 4 of the grantees who made presentations were also coordinators of sessions.

The importance of SAP support to forestry researchers in developing countries and countries with emerging economies can be seen in the following statistics:

- representation of 6 countries depended entirely on SAP support
- participation of at least 50% of scientists from another 12 countries would not have been possible without SAP support.

Tours and Excursions

In-Congress Tours

The In-Congress Tours and Post-Congress Excursions were planned in early April 1997 after a meeting of the Sub-Committee then known as the Tours Sub-Committee. The Sub-Committee comprised five members representing the Forestry Department Peninsular Malaysia (FDPM), Faculty of Forestry, University Putra Malaysia (UPM) and the Forest Research Institute Malaysia (FRIM).

During the initial stage of the planning, Peninsular Malaysia was divided into three sectors and for each sector a coordinator was appointed. The responsibility of the coordinator was to gather and consolidate information regarding the sites of the visit. By the end of April 1997, the Sub-Committee decided that the duration of the excursions should be from three to four days, involving 14 different routes. The various routes selected were three routes for Peninsular Malaysia, two routes for Sabah, three routes for Sarawak, two routes for Southern Thailand, three routes for Indonesia and one route for Brunei.

In July 1997, representatives from the Sarawak Forestry Department and Sabah Forestry Department were invited to sit in the Tours Sub-Committee. It was also decided that the sub-committee be split into two, In-Congress Tours and the Post-Congress Excursions, respectively.

The Tours

The In-Congress Tours were held on Thursday, 10 August 2000. There were no concurrent events organized during the one day IUFRO In-Congress technical tours. There were a total of nine routes selected for the tours, which provided delegates and accompanying persons with an overview of Malaysia's forestry, forest industry and places of tourist attractions. The technical tours started at 0730 hrs and all buses departed from PWTC. Altogether 1,067 delegates and their accompanying persons from 96 countries participated in this one-day event. The number of registered participants was 1,123 (Table 8). Due to the large number of participants expected to register for this one-day tour, a professional Tour Organizer had been appointed to assist in transportation, training tour guides and officers, and making other arrangements related to the In-Congress Tours. The only problem encountered on the actual day was the delay of coach departures for some destinations at PWTC.

Short Description of the Tours

Route 1: Rubberwood Industry in Historical Malacca

This tour took the participants to two rubberwood-processing mills in Malacca. Participants were shown the processes involved and the types of products. Everything went well and a lunch at the Harbour Club followed. Participants were satisfied with the overall program and some expressed their desire to return on their own.

Route 2: Landscape, Recreation and Forestry

The tour brought the participants to two sites where major landscaping work has been done over the past few years: Paya Indah Wetland Sanctuary and Putrajaya (the new administration centre of the Malaysian Government). Participants were briefed on the Paya Indah Wetland Sanctuary as a "living experimental site" where modern research methods in environmental science and natural resource management can be applied and developed. At Paya Indah the participants were taken on a short tour of the sanctuary with stops at the biological sewage treatment plant, the boardwalk where several species of migratory birds stop during several periods of the year, the palm arboretum and also areas of natural vegetation of the peat swamp forests.

Table 8. Registration and Participation for In-Congress Tours. The breakdown during the actual event is shown below:-

Route	Theme	Registered Participants	Attended
1	- Rubberwood industry in historical Malacca.	238	233
2	- Landscape, recreation and urban forestry.	79	79
3	- The tropical lowland rainforest - research and recreation in the state of Negeri Sembilan .	99	95
4	- Sustainable forest management and wildlife conservation	156	144
5	- Plantation of Dryobalanops aromatica.	77	69
6	- Integrating forest landscape management in land development.	120	106
7	- Visit to the premier research institutions - FRIM and MRB	154	154
8	- Mangrove forest and the community	120	120
9	- Cultural heritage of the aborigines and lowland tropical forest	80	67
	Total	**1123**	**1067**

Route 3: The Tropical Lowland Forest – Research and Recreation in the State of Negeri Sembilan

This tour took the participants through forested hills and valleys, oil palm and rubber plantations, rural villages and fruit orchards, to two tropical lowland rainforest reserves designated for research and recreation. Participants also had the opportunity to experience a unique cultural dimension of Negri Sembilan with the visit to the Sri Menanti Palace and Royal Museum. In general, most participants were satisfied with the programme. One participant came forward to the microphone to thank and congratulate the organizer for the excellent arrangements and preparation at the Pasoh Field Centre.

Route 4: Forest Management and Wildlife Conservation

The tour presented an introduction to the sustainable management of forest resources and the importance of conserving wildlife species and their habitats. Officers from the Forestry Department of Selangor gave the overview briefing about the forest management system in Malaysia while officers from the Department of Wildlife and National Parks Peninsular Malaysia briefed the participants on the vision, mission, objectives and research of the department. In general the programme was good except for the late departure.

Route 5: Plantation of Dryobalanops aromatica

The tour provided participants with a general view of the design concept of the Commonwealth Forest Park. Other facilities within the park were also introduced by the resource person from the Forestry Department of Selangor. Participants then visited the crystalware centre to see the production of unique crystalware in vibrant colours. Before heading back to PWTC the tour stopped at a batik factory to observe the production of batik for various uses such as attire, curtains, handbags and attractive souvenirs.

Route 6: Integrating Forest Landscape Management with Land Development

The main theme of the tour was to show the participants that land development in highland areas needs a proper planning in order to harmonize such a development with natural landscape. The tour ended with a visit to a mushroom farm. All in all, the programme was useful.

Route 7: Visit to Premier Research Institutions: FRIM and MRB

On this tour the historical background, philosophy, mandate, mission statement, objectives, clients' charter, quality, governing board, and organizational structure of the two

Table 9. Number of Participants in the Post-Congress Excursions by Routes

Excursion	Number	Excursion	Number
Route 1	6	Route 9	39
Route 2	15	Route 10	8
Route 3	67	Route 11 (Cancelled)	-
Route 4	40	Route 12 (Cancelled)	-
Route 5	20	Route 13	15
Route 6	35	Route 14 (Cancelled)	-
Route 7	37	Route 15	9
Route 8	26	TOTAL	317

research institutions were explained by the respective institute's resource person. Other than visiting the museum in FRIM, the participants were taken through two nature trails within FRIM. In MRB, the participants were exposed to the unrivalled collection of rubber products. Through the graphic-wall display at the Exhibition Centre in MRB, participants were reminded of the significant events of the rubber manufacturing industry and the major technological breakthroughs over the past centuries.

Route 8: Mangrove Forest and its Community

The participants visited the Kuala Selangor Nature Park and were briefed about the park by the appointed resource person. They were then taken on a tour visiting some interesting features of the park (Fig tree stand, watchtower, and bird watch bunker). The tour ended with a visit to Bukit Malawati which overlooks the green belt of mangroves along the Selangor coast, thus providing a unique panoramic view of the Kuala Selangor Nature Park.

Route 9: Cultural Heritage of the Aborigines and Lowland Tropical Forests

The main theme of the tour was to show the cultural heritage of the aborigines and a portion of the lowland tropical forests near Kuala Lumpur. This route gave an opportunity to participants to learn about the aborigines and have an insight into the their lifestyle and social cultures. Participants were also briefed by the resource person about the functions of Alang Sedayu Jungle Lodge and also the remains of the five underground tunnels built during World War II. All in all, the participants enjoyed the programme.

Post Congress Excursions

A total of 15 Post-Congress Excursions were planned involving nine destinations to the various states of Malaysia (Peninsular Malaysia, Sabah and Sarawak) and six destinations to the neighbouring ASEAN countries: Brunei, Indonesia, Thailand and Singapore. However, three routes had to be cancelled due to the insufficient subscription of participants. These were Route 11 (Agroforestry and Community Forest, Thailand); Route 12 (Teak Plantation in Central Java, Indonesia); and Route 14 (Pulp-Paper Industry in North Sumatra, Indonesia).

The duration of the excursions varied from three to five days and the excursion fees varied from USD 225 to USD 855 based on twin-sharing basis. The fees covered full board, admission to the respective places of interest, transportation and accommodation. The total number of participants in the Post-Congress Excursions was 317 representing 46 nationalities. The excursions were specially organized to include visits to tourist and cultural sites apart from visiting places of technical and professional interest.

Short Description of the Excursions

Route 1: Best Managed Mangrove in Malaysia

The main theme of this excursion was sustainable management of mangrove forest. The participants visited the Matang Mangrove Forest, the famous and largest single mangrove forest in Peninsular Malaysia estimated at 40,151 hectares. The forest has been acknowledged to be the best managed mangrove forest in this country and it plays an important role in fishery production, coastal habitats for specialized trees as well as for many common, threatened and endangered species. The participants were introduced to the replanting, thinning and harvesting activities in mangrove forests and witnessed the production of charcoal from neighbouring charcoal kilns.

In Kuala Kangsar, Perak, the participants visited buildings of architectural interest – the Royal Palace, the Royal Museum and the Ubudiah Mosque. Kuala Kangsar is known as the home of the rubber industry where the first rubber seedling was planted and has survived until today. The programmes were extended further in Penang where the participants visited the Pulau Pinang Forestry Museum and the popular Butterfly Farm, the first of it's kind in the tropical region. The Forestry Museum, which is located in the Telok Bahang Recreational Forest, is a specialized museum exhibiting various activities and items of forestry interest.

Route 2: Growing Trees for the Future

In this excursion, the participants were exposed to a Multi-storied Forest Management System at Chikus Forest Reserve, Bidor, Perak. The area comprises 2,000 hectares of tropical lowland forest, of which about 750 hectares were planted with Acacia mangium. Continuing with the technical visits, the participants visited a medium density fibreboard (MDF) plant located in Merbok, Kedah. This is the largest MDF factory in northern Peninsular Malaysia with sophisticated wood processing technology, established in 1993. The factory utilized timber from plantation as raw material.

The participants also visited FRIM's Teak Research Centre at Mata Ayer, Perlis. The Centre was established in 1953, covering an area of 455 hectares. In Langkawi, Kedah the participants visited the Eagle's Square (which houses the replica of all the legends and myths of Langkawi's historical events), the Langkawi Crocodile Farm (with more than 2,500 live crocodiles of different sizes and species from all over the world) and the Craft Cultural Complex (a collection of traditional crafts from all over Malaysia), as part of their tourist visit.

Route 3: Sustainable Forest Management of Natural Forest

The main emphasis of this excursion was sustainable forest management of natural forest in forest concessions at Pasir Raja, Terengganu. The concessionaire, the Kumpulan Pengurusan Kayu-Kayan Terengganu (KPKKT) Sdn Bhd specializes in log extraction and other forest development projects managed under a sustainable forest management system. Participants were briefed on the logging/extraction methods used and research work carried out by ITTO-FRIM-KPKKT, JIRCAS (Japan International Research Centre for Agricultural Sciences) and Oikawa Motor Company Limited, Japan. Later they visited a recreation park jointly managed by the State Forestry Department, Terengganu and the KPKKT. Several topics related to the economics, importance of forest management planning and bio-diversity in practical forestry operations were also discussed. In addition, the participants were also introduced to a forest checking station's operation, a downstream wood carving industry, a well known batik handicraft industry, a cultural market and a true holiday experience at the largest man-made lake in Malaysia, Tasik Kenyir Resort, surrounded by lush green tropical rain forest.

Route 4: National Park Management and Forestry Activities

The richness of the tropical rainforest's fauna and flora in their natural habitat was the theme of this excursion. The main emphasis of the excursion was the management of National Parks and the protection of wildlife. The participants took an active part in the prearranged programme in order to have a first-hand experience in nature-related activities in the National Park. A visit to the Orang Asli or the aborigines' settlement gave an added dimension to the excursion. The importance of commercial forest plantations for sustainable timber supply was also emphasized during a visit to the Kemasul Forest Plantation, Pahang. The participants also visited a woodcraft industry where manufacturing techniques of various items were demonstrated.

Route 5: Wood Processing Industry

The first stop of the excursion at the Taman Mini Malaysia and Mini ASEAN, Melaka allowed the participants to have a glimpse of the Traditional Malaysian and ASEAN Wooden Buildings Architecture. The participants visited rubberwood processing industries in Pagoh Industrial Area, Johor, where the timber was processed and manufactured into high quality and export-oriented products including settees, dining sets and other useful items. The participants also had the opportunity to witness solid rubberwood being processed into bent wood, an item commonly used in high-end furniture.

A visit to the Nasuha Enterprise Sdn Bhd, exposed the participants to the richness of Malaysian and exotic spices and herbal plants and products. At the Gunung Ledang (Mount Ophir) Resort, they experienced the splendour and exotic of the lush and green tropical rain forest. The last place of interest visited by the participants was the Singapore Botanical Garden, where they witnessed one of the world's biggest tropical orchid collections in terms of number of species and hybrids.

Route 6: Model of Certified Forest and Orang Utan Rehabilitation (Sabah)

The participants visted the Sepilok Orang Utan Rehabilitation Centre (SORC), Sandakan. After a short briefing, the participants went to the SORC Information Centre and later observed the feeding of the orang utan at Platform A. They were also briefed on the orang utan scientific rehabilitation techniques.

At the Deramakot Forest Reserve (DFR), the participants observed the various aspects and techniques of sustainable management of tropical rainforests in Sabah, and were given a demonstration on directional felling methods to minimize logging damage. The SGS-Forestry Malaysia has certified the DFR, which cover an area of 55,000 hectares, under the Qualifor Forestry Programme in 1977. In 1989, a sustainable forest management (SFM) project, supported by the German Agency for Technical Cooperation (GTZ) was launched with the objective to develop a model forest management plan within this forest reserve.

Route 7: Biodiversity in Sustainably Managed Forest (Sabah)

Danum Valley Field Centre (DVFC), Lahad Datu, covering an area of 438 square kilometres is a private protected area representing not only a natural treasure but also serving as an opportunity for land managers and conservationists to work together to sustain the biological resources unique to tropical habitat. DVFC provided the participants with an unparalleled ecological experience of the wild and wonders of ancient tropical forests. The participants also visited the Innoprise-FACE Foundation Rainforest Rehabilitation Project (INFAPRO), which is involved in the planting of indigenous tree species in logged-over forest areas. After a short briefing, the participants took part in the tree planting ceremony to commemorate their visit to INFAPRO.

A visit to the Tilawas Forestry and Recreational Centre (TFRC) gave the participants an insight into the sustainability of establishing a forest area with fast growing tree species. The participants continued their journey to the Kinabalu Park, where they enjoyed the majestic tip of South-East Asia's highest point - Mount Kinabalu, and the richness of endemic species of flora and fauna within the park’s vicinity.

Route 8: Peat Swamp Forest Management (Sarawak)

In this route, the participants were given one whole day to visit a logging site in the peat swamp forest at Loba Kabang, Sibu. The participants had the opportunity to experience a locomotive ride (used to transport both workers and logs in and out of the forest), and observed the "kuda-kuda" system of pulling logs from the stump to the log-landing site. They also visited a particleboard mill in Sibu, which uses offcuts from other sawmills as its main source of raw material.

Other technical visits included in the excursion were the Semenggoh Wildlife Rehabilitation Centre and the Semenggoh Botanical Research Centre. A visit to the Bako National Park allowed the sighting of a proboscis monkey at the Visitors’ Day Centre and observation of the various species of Nephanthes along the trail.

Interspersed with the technical visits, the participants were taken for a walk over the typical Night Market in Sibu. The participants also visited the Sarawak Cultural Village and the Sarawak Pottery Centre in Kuching.

Route 9: Role of Local People (Sarawak)

The excursion started with a visit to the Lambir Hill National Park, 7,000 hectares of forest covered with virgin rich stands of mixed dipterocarp forests, and continued with a visit to the Latak Waterfall. The participants also visited the Canopy Biology Plot and experienced an exhilarating climb of a 40-meter tree tower from which they viewed the typical canopy structure of the forests and the scenic beauty of the surrounding hills.

The participants visited the Niah Museum at the Niah National Park, which showcased the historical, archaeological and cultural heritage of the Niah Caves. In the Great Caves, they witnessed the local communities collecting guano and harvesting edible birds’ nests. They also visited the local Penan settlements along the Melinau River and had the opportunity to meet the local people living near the Mulu National Park. Visits to the Lang Cave and the Deer Cave gave the participants an opportunity to observe the beautiful limestone formations and the awesome underground passages.

Route 10: Forest Genetic Resources in Thailand

The participants observed nursery operations, vegetative propagation of forest trees, species diversity collection and herbs and medicinal plant collections at the Songkla Nursery Centre, and silvicultural research activities at the Silvicultural Research Centre, Royal Forestry Department of Thailand. They also observed birds’ conservation and species diversity of wetland area under the Wetland RAMSAR Programme at the Wildlife Nursing and Raising Centre, Pattalung.

The participants visited a rattan seed orchard where they witnessed seed production and species conservation activities. At Ranong Biosphere and Mangrove Forest Research Centre they were briefed on mangrove research programmes with Rhizophora apiculata and Rhizophora mucronata as the main research subjects, and learned about conservation efforts for shrimps, crabs, fishes and other marine fauna. In addition, they also witnessed a traditional southern custom at the Southern Study Centre and experienced a short stay in a fishing village at Pan Yee Island.

Route 11: Agroforestry and Community Forest in Thailand (cancelled)

Route 12: Teak Plantation in Central Java, Indonesia (cancelled)

Route 13: Botanical Garden and National Park in West Java

The first excursion destination was the Bogor Botanical Garden, a living museum with the most complete collection of tropical plants in the world. Covering a land area of 87 hectares, the Garden maintains about 3,600 species of plants belonging to over 1,290 genera and 200 families. The Centre for International Forestry Research (CIFOR), located also in Bogor was the next stop of the excursion. CIFOR is an independent scientific research institution established in 1993.

The participants visited the Gade Pangrango National Park, which was established in 1980. The Park covers an area of 15,196 hectares encompassing the Cibodas Nature Reserve, the oldest forest reserve in Indonesia. The participants also visited the Mount Halimun National Park covering an area of about 40,000 hectares of tropical forests. The Park provides protection for the hydrological system, conservation of flora and fauna, conservation of ecosystem diversity, and support and opportunity for research, education and eco-tourism.

Route 14: Pulp and Paper Industry in Riau, Indonesia (cancelled)

Route 15: National Park Management in Brunei Darussalam

The excursion started with a boat ride to the Selirong Island Mangrove Park, which is famous for its mangrove forest and the Kampung Air (Estuarine Village), which offers fascinating natural scenery. The excursion continued with another boat ride to Bangar Town in a meandering water channel that is lined with mangrove forests reputed to be the largest in the region.

A boat ride from Batang Duri to the Ulu Tembulong Natioanl Park gave the participants an opportunity to witness vegetation succession and transformation, birds and other wildlife. At the National Park, the participants climbed a 65-meter high canopy walkway in order to be above the crown of the trees. At the Kuala Belalong Field Study Centre the participants experienced jungle walking in the lush and green tropical rainforest. They also visited a waterfall area along the Apan River and later enjoyed shooting the rapids with inflatable rafts.

Accmpanying Persons' Programme

Organizational Preparation

The Accompanying Persons' Programme was a "tailor-made" tour package offered only to accompanying persons of IUFRO Delegates throughout the Congress week. Thus, each package was very special and unique in order to attract the interest of participants. In addition, these tours avoided competition with and duplication of those offered by normal tour operators.

In general, the sites selected for this programme largely complied with the Congress Theme "Forests & Society: The Role of Research." Even in the City tour, the participants were able to appreciate the forest environment during their visit to an urban Forestry Park in Kuala Lumpur City Centre. A total of ten tour packages were offered to accompanying persons and delegates.

Short Description of the Tours

Package 1: CITY TOUR …full day tour
Days: Tuesday, Wednesday & Friday

Malaysia presents an exotic blend of the old and the new. Despite the rapid change towards the modern lifestyle and advanced technology, Kuala Lumpur still retains its old world charm as depicted in the majestic buildings from the colonial era, quaint pre-war shop-houses and the way business is conducted. In order to get a first impression of KL, the participants took the opportunity of touring the city one day long and saw: Merdeka Square, National Monument, KL Lake Gardens, Orchid & Hibiscus Gardens, Kuala Lumpur Bird Park, National Mosque, King's Palace, National Museum, Commercial Centres, Kuala Lumpur City Centre (KLCC), Kuala Lumpur Tower and Central Market.

Package 2: FRIM & Batu Caves … Nature Tour I
Days: Tuesday, Wednesday, Friday & Saturday

About seventy years ago the Forest Research Institute Malaysia grounds were little more than abandoned tin mine pits, vegetable gardens and shrubby forest. Since 1926, foresters and scientists have nurtured the forest back to life into a serene forest with inspiring trees. Apart from the scientific value of the forest, shady park-like arboreta as well as nature trails are available for educational walks. Visitors were able to experience the Ethnobotanical Garden, an introductory of forestry in Malaysia, Keruing Nature Trail, FRIM Museum, Dipterocarp Arboretum/ Traditional Timber Houses and Sungai Kroh picnic area.

Besides, delegates also visited the limestone formation of the Batu Caves situated about 13km north of Kuala Lumpur. The best known of these caves is the Temple Cave, a large cavern with a vaulted ceiling about 100m above the floor. To reach it, one has to climb 272 steps, a feat performed by many Hindus to offer prayers to their revered deities.

Package 3 : Bukit Cahaya Seri Alam … Nature Tour II
Days: Tuesday, Wednesday & Saturday

The participants visited Bukit Cahaya Seri Alam Agricultural Park, the world's only agro-forestry park located at the Selangor State Capital, Shah Alam. It is a vast complex of landscaped floral gardens, agricultural plots, orchards, lakes and dense jungle. All these are set within a luscious tropical rainforest in a scenic 1,290-hectare site. On the theme of agriculture, the park also includes a rice-field where from time to time a demonstration of rice planting takes place. Here is a place to learn all about trees and their names! A rock garden, a formal garden and a kitchen garden are among the attractions that can be found in the park. As one of Malaysia's most popular parks, it has various facilities for accommodation, camping and picnic areas, public amenities and scenic natural trails throughout the area.

The tour then cruised around Shah Alam, the state capital of Selangor Darul Ehsan and the " Blue Mosque" - Masjid Sultan Salahuddin Abdul Aziz Shah (State Mosque).

Package 4 : Twinkle-twinkle Fireflies
Days: Tuesday, Wednesday & Friday

This tour started in the afternoon and included visits to the historical hill of Bukit Malawati and a boat ride along the Kuala Selangor riverbank to watch the fireflies displays in the late evening. The tour continued to Kampung Kuantan where the fireflies are found. As the sun sets, these fireflies begin to flash simultaneously at a rate of three flashes per second. In so doing a fascinating spectacle similar to a flashing Christmas tree is created. The participants enjoyed this wonderful sight.

Package 5: Alang Sedayu Jungle Lodge… a perfect getaway from the city.
Days: Tuesday, Wednesday & Friday

This is an attractive destination and also an ideal escape from the city where nature and tranquillity wait in a most unique setting. It was a perfect getaway for raw adventures and an intimate rendezvous with nature.

The Jungle Lodge, situated in a natural setting with primary forest on one side and the crystal clear stream on the other side, makes it an attractive blend of elegant kampong or village style surroundings and city convenience. The clean, cool, fresh air is matched by the quiet serenity of its natural surroundings and radiates a totally relaxed mood. The Jungle Lodge provides the sheer beauty of nature, the tropical forest with its varied flora and fauna, featuring waterfall amidst lush greenery and an insight into the cultural activities of the local people. Other features include a taste of Malay traditional games and pastimes, a lively performance of the aboriginal tribe, a blowpipe demonstration, fishing, the freedom fighter tunnel, collecting local tropical fruits, bird watching, refreshing swims in the river and a buffet lunch. After a gruelling adventure in the wild it is time to savour the delightful culinary creations of Malaysia served at the Jungle Lodge.

Package 6 : Malacca … a legacy of history and charm
Days: Tuesday, Wednesday & Friday

This was one of the popular tours. Malacca blends a rich historical past and a vibrant present. Many of its century-old buildings, some of them still in use, can be traced back to its early inhabitants. The tour gave the participants a unique opportunity to discover: Mini Malaysia, Ayer Keroh, the Peranakan Restaurant, the Baba & Nyonya Heritage Museum, Harmony Street, Antique Street/Jonker Street, Stadthuys – Dutch Town Hall, St. Paul's Cathedral/St. Paul's Hill, Porta De Santiago/A Famosa, Malacca's Sultanate Palace (a replica) and Padang Pahlawan/Proclamation of Independence Memorial.

Package 7 : Malaysian Handicrafts
Days: Wednesday & Friday

The legacy of Malaysia's arts and crafts springs from the mighty fountainhead of an age-old heritage of aesthetics and creative temperament. Arts and crafts are a mirror to the soul of the nation, giving shape and solidity. During this tour the participants visited Royal Selangor Pewter famous in the world for its manufacture of Malaysian Pewter, Embroidery Centre, Batik Factory, Handicraft Crystal and Glass Centre and Kompleks Budaya Kraf Kuala Lumpur.

Package 8 : Shopping Spree
Days: Friday & Saturday

Kuala Lumpur is a shopper's paradise, offering a wide variety of goods at reasonable prices. Modern shopping complexes provide numerous facilities for the comfort and convenience of shoppers. The stores display a wide range of goods rivalling that of major cities elsewhere, catering to every taste and budget. Delegates were able to experience shopping from the high-class shopping malls to bargaining stores. Among the places to go there are Suria KLCC, Lot 10, BB Plaza, Sungei Wang Plaza, Central Market, and China Town.

Package 9 : City Tour…a half-day tour
Days: Monday & Saturday

On this perfect half-day tour that only took three hours the participants passed through the busy centre of the town and visited some famous points of interest in Kuala Lumpur such as: Kompleks Budaya Kraf Kuala Lumpur , China Town, Central Market, Merdeka Square, National Monument, National Mosque, Railway Station and King's Palace.

Package 10: Banghuris … experience the country life
Days: Tuesday & Wednesday

The participants experienced the life of a typical villager, the hospitality, culture and tradition of the Malays at Banghuris. This place is made up of three neighbouring kampung (villages), namely Kampung Bukit Bangkong, Ulu Chuchuh and Ulu Teris. The participants were able to get to know the typical friendly villagers and their traditional way of life and were warmly greeted by the village folks. They were shown a performance of Malay martial art – silat, the cottage industry of making traditional Malay delicacies, press flower craft, an orchid farm, a medicinal landscape garden, "Jambu Air" (water apple) farm, an oil palm plantation, traditional 'tempe' making, and a local Malay house. Then they enjoyed the Bagan Lalang seaview.

Exhibitions and Events

Exhibitions

The World Forestry Exhibition was held from 7-9 August at Legar Putra, Level 2, the Putra World Trade Centre. This exhibition was jointly organized with a private event organiser, in conjunction with XXI IUFRO World Congress. A total of 42 organizations from the private sector, government institutions and non-government organizations participated in the exhibition (Table 10) representing 14 different countries. The exhibition was officially opened by the Minister of Primary Industries of Malaysia.

The response from delegates and the public was encouraging. This three-day event displayed on about 572 square meters exhibited many aspects of forestry and forest industries in terms of new products, technical publications, research findings and conservation activities. Besides the Congress delegates, this Exhibition was open to the general public. The IUFRO Secretariat and the Congress Organizing Committee were given six-exhibition booths to share their information and products.

Special Events

In conjunction with the Congress, several events were organized to mark the Congress. These special events included the launching of commemorative stamps, a tree planting ceremony, the Presidential Reception and the EB working luncheon.

Launching of commemorative stamps

A set of commemorative stamps was produced in cooperation with Pos Malaysia. The stamps were launched during the opening ceremony on 7 August 2000. The stamps are unique in the sense that they represent the major trees of the tropical forests. Both scientific and local names of the species were printed on the stamps. Stamps showing different shapes of trees (*Samanea saman, Fagraea fragrans, Dryrobalanops aromatica, Terminalia catappa* and *Dracontomelon dao)*, shapes of leaves (*Heritiera javanica, Endospermum diadenum, Macaranga gigantea, Licuala grandis* and *Johannesteijsmannia altifrons*), types of tree barks (*Shorea leprosula, Ochanostachys amentacea, Dryrobalanops aromatica, Pterocymbium javanicum* and *Dipterocarpus costulatus*) and types of seeds (*Hopea odorata, Adenanthera pavonina, Shorea macrophylla, Dyera costullata* and *Alstonia angustiloba*) were sold to the delegates and to the public. Brief information on the above stamps was contained in a special bi-lingual (English and Malay) Congress brochure, published by Pos Malaysia. The stamps printed were sold out within a week in Malaysia.

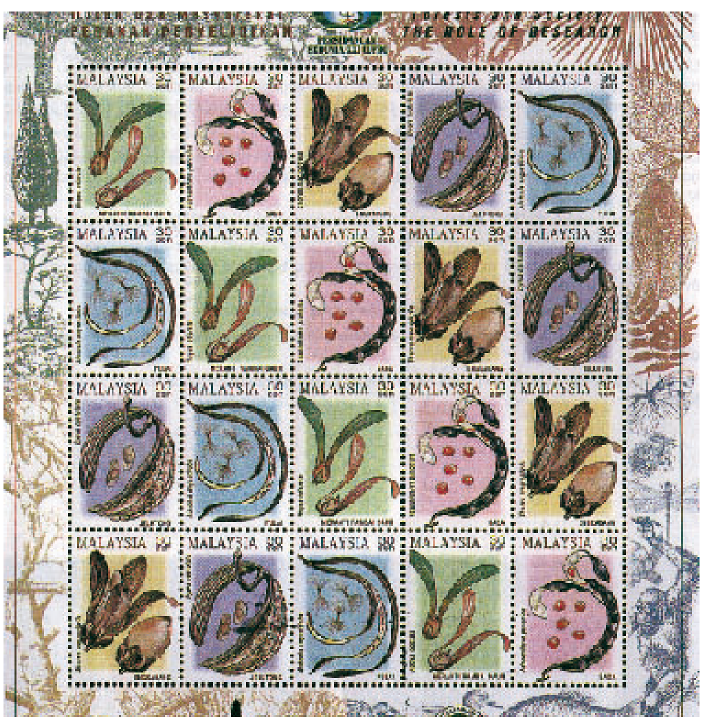

Table 10. Participating Agencies and Countries of Origin

No.	Exhibitor	Country
1.	APAFRI	Malaysia
2.	Asian Timber/First Asia Publishing Pte Ltd.	Singapore
3.	CABI Publishing	United Kingdom
4.	Canadian High Commission	Malaysia
5.	CIFOR	Indonesia
6.	CIRAD-FORET	France
7.	Delta-T Devices Ltd	United Kingdom
8.	Elsevier Science	Netherlands
9.	European Forest Institute	Finland
10.	FORAD	Australia
11.	Forestry Department of Peninsular Malaysia	Malaysia
12.	Forest Department Sarawak	Malaysia
13.	Forest Research Institute Malaysia	Malaysia
14.	Future Harvest/CGIAR	Malaysia
15.	GTZ GmbH	Malaysia
16.	Haglof Sweden AB	Sweden
17.	Innoprise Corporation Sdn Bhd	Malaysia
18.	International Foundation for Science	Sweden
19.	International Network for Bamboo and Rattan	China
20.	International Tropical Timber Organisation	Japan
21.	IUFRO	Austria
22.	Malaysian MDF Manufactures Association	Malaysia
23.	Malaysian Nature Society	Malaysia
24.	Malaysian Timber Council	Malaysia
25.	Malaysian Timber Industry Board	Malaysia
26.	METLA – Finnish Forest Research Institute	Finland
27.	National Board of Forestry, Sweden	Sweden
28.	National Timber Certification Council, Malaysia	Malaysia
29.	Palm Oil Research Institute of Malaysia	Malaysia
30.	Queensland Forestry Research Institute	Australia
31.	Regent Instruments Inc	Canada
32.	Regional Centre for Forest Management	Malaysia
33.	Relaskop – Technik	Austria
34.	Sabah Forestry Department	Malaysia
35.	Scandinavian Journal of Forest Research	Norway
36.	Stora Enso Forest Consulting	Finland
37.	Trelleborg SEA Pte Ltd	Singapore
38.	TropBio Group of Companies	Malaysia
39.	University Putra Malaysia	Malaysia
40.	Wageningen University	Netherlands
41.	WWF Malaysia	Malaysia
42.	YPJ Publications and Distributions Sdn Bhd	Malaysia

Tree Planting Ceremony

The Tree Planting ceremony has a long Congress tradition and was an auspicious way to mark the XXI IUFRO World Congress Kuala Lumpur. There were representatives from about 90 countries, and each of the International Council Members representing his/her country planted a tree. Invited honourable guests were Professor Jeffery Burley (The President of IUFRO), Tan Sri Rama Iyer (Chairman of the Malaysian Forestry Research and Development Board), and Mr Ishak Mohd Yusof (Senior Vice President, Bumiputra-Commerce Bank Berhad).

The Tree Planting was held at Taman Tasik Permaisuri, Kuala Lumpur, on 12 August 2000. Three buses were hired to ferry the members of IUFRO's International Council, EB members and members of the FRIM Directorate to the destination. This memorable event was jointly organized by the City Hall of Kuala Lumpur, FRIM, and the Congress Organizing Committee.

Five types of Malaysian native tree species were selected for this occasion: *Dyera costulata* (Jelutong), *Dryobalanops aromatica* (kapur), *Mesua ferrea* (Penaga Lilin), *Aqualaria malaccensis* (Karas/Aloes wood) and *Neolitsea zeylanica*
(Medang pasir).

Presidential Reception

This reception was held on 11 August 2000, one day before the closing ceremony. A total of 220 guests (EEB members, COC, Congress Secretariat, IUFRO Secretariat and other invited guests) attended this special function, hosted by the IUFRO President.

EB Working Luncheon

This special lunch took place on 12 August 2000, the last day of the Congress. It was a working lunch attended by the out-going and in-coming EB members. Pertinent matters and decisions were made during the meeting, including the appointment of Division Co-ordinators and their Deputies and the formation of new working parties. The President also handed the certificate of appreciation to COC and CS members for their contribution to the Congress organization.

Press and Publicity

Publicity in International Meetings

Congress promotion activities were carried out as early as in 1995, during the XX IUFRO World Congress in Tampere, Finland. A video presentation of Malaysia was shown to the delegates and information as well as souvenir items were given out. This was followed by the distribution of the first Congress announcement (1997), the Congress Information Package (1998), and the Congress Registration Package (1999). All the information was also distributed at major international/local meetings such the Commonwealth Forestry Congress (1997), World Forestry Congress (1997), and IUFRO Seed Symposium (1998).

IUFRO Tower in FRIM

A number of activities were organized to promote the Congress during the FRIM Open Day. Tree planting by corporate companies and individuals was carried out. There was the sale of balloons and used paper. In particular, the IUFRO Tower Aerial Runway was built of mangrove poles and ropes by the Petaling B Rover Crew. The construction of this tower was made possible with monetary contribution from the private sector. The charge was RM2 per ride and RM5 for 3 rides. In addition, the IUFRO Tower mangrove poles and leaves contest was held. Prizes included two "4 days and 3 nights" travel vouchers to Taman Negara, souvenir items and hampers. The money collected at all these activities was used to sponsor SAP candidates to attend the Congress.

Posters and car stickers

Two sizes of the IUFRO Congress posters were printed for distribution. A total of 1,000 big posters (50cm x 77cm) and 4,000 copies of A-4 size posters were disseminated to IUFRO Member Organizations and potential delegates.

A total of 3,000 car stickers (9cm x 35cm) and 20 bus stickers were also distributed to motorists, taxi drivers and bus drivers to promote the Congress.

IUFRO News and FRIM in Focus

Then newsletter IUFRO News played an important role in publicity as it carried news containing activities of the Congress. This is an important means of publicity as the News was circulated to about 15,000 persons in about 150 countries. Other than IUFRO News, FRIM in Focus provided an avenue to publicize the Congress. As FRIM in Focus, a quarterly brochure, is distributed free-of-charge, both the locals and foreigners were kept informed of the Congress updates.

Congress Information / Registration Packages

All information published in the first brochure (12,500 copies), Congress Information Package (12,000 copies) and Congress Registration Package (12,000 copies) were also placed on FRIM's and IUFRO's homepages. FRIM's homepage was also hyperlinked to Malaysia Airlines' homepage. In this manner, more people could access the Congress information through the Internet.

Press Releases

Six press releases were distributed at the following occasions: launching of the Congress Logo in conjunction with the IUFRO Seed Symposium (12 October 1998); signing of agreements with PCO, tour and exhibition organizers (31 March 1999); FRIM's Open Day (20 June 1999); cheque presentation for SAP at the British High Commission (12 May 2000); handing-over of stickers to bus and taxi drivers in a ceremony (18 July 2000); and a special media conference held by the Steering Committee Chairman (26 July 2000). Press releases were also distributed to the press at the media centre during the Congress week.

"Live" TV and Radio Talks

In 1999 and 2000, three TV 'live' talks on Radio Television Malaysia were arranged for the IUFRO President, the Steering Committee Chairman and the COC Chairman to elaborate on the Congress theme and the significance of the Congress. The Steering Committee Chairman and COC Chairman also gave 'live' talks on IUFRO over radio in March and July 2000.

Scientific Articles in Newspapers

A series of scientific articles written by FRIM's scientists were published in the New Straits Times, a leading local daily, one month before the Congress. At the end of each article, information on the Congress (such as theme, telephone, fax and e-mail) was also printed. Consequently, the Congress Secretariat received a number of enquiries on the Congress.

All news and scientific articles on the IUFRO Congress published in local dailies have been collected.

Souvenir Items

Sales of souvenir items were initiated as early as in March 1999 with a view to promote and publicize the Congress. T-shirts were available in six different designs, colours and sizes for both adults and children. Other items made available were mugs, neck-pens, lapel pins, umbrellas, table clocks and caps. Prior to the Congress, souvenir merchandise worth RM 45,000 was sold from the sale of 2,806 items. The souvenir items were also distributed to several forestry-related agencies in Malaysia including Malaysian Timber Industry Board, Forestry Departments of Sabah and Sarawak, FRIM's Club, and Malaysian Nature Society outlet at the Kuala Selangor Nature Park. Sale of souvenir items during the Congress started on Sunday morning, a day earlier than the expected date. Various items were on sale throughout the duration of the Congress from 0700 hrs daily until the eve of 13 August.

Banners

Banners were placed within FRIM a year before the Congress. Congress banners were also placed along the main road leading to the Congress venue one month before the Congress. A hot-air balloon was placed at the Congress venue a week before the Congress, informing the public of the Congress.

The Press Centre

The Press Centre was located on the second level of the Putra World Trade Centre at the second entrance to the building. The press centre was provided with facilities such as phones, computers and printers. Tea/coffee and snacks were served free-of-charge throughout the Congress. A total of 80 media journalists from eight local newspapers, eight foreign agencies, 15 journalists and 4 TV stations registered during the Congress. Invitations and reminders to cover the Congress were made two months and two weeks prior to the event, respectively. Letters of invitation were sent to each and every press agency identified in Malaysia and world-wide. The main Malaysian newspapers, news agencies, television and radio programmes were represented. Wide coverage on the Congress was reported in many Malaysian mass media, during and after the actual event.

Daily Bulletin - Belantara

In conjunction with the Congress, a daily bulletin entitled Belantara was published on five consecutive days and the maiden issue appeared in the morning of 13 August. 2000 copies of Belantara were distributed to inform and update participants on the Congress activities. Circulation of Belantara was done at 0830 hrs every day before the delivery of keynote addresses. The first issue was in full colour, whilst the second and consecutive issues were in two colours.

Three interviews (with Professor Jeffery Burley - the IUFRO President, DI. Heinrich Schmutzenhofer - the IUFRO Secretary, and Professor Risto Seppälä – the President elect) were conducted and published in the Belantara.

Press Conference

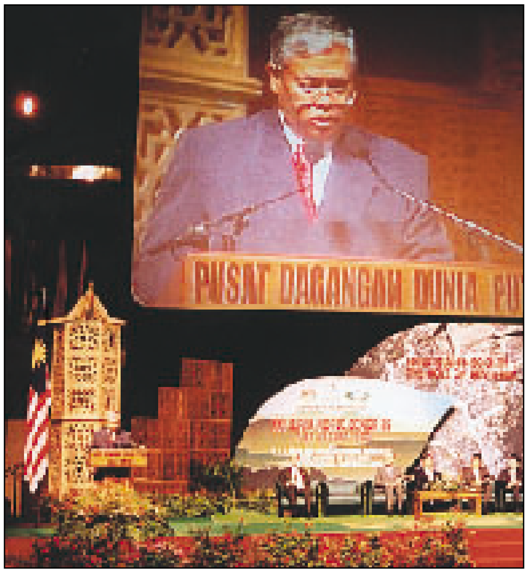
One special media conference was held in FRIM in July 2000 where the Chairman of the Steering Committee briefed the media representatives on the updates of the Congress.

Two press conferences were arranged for the IUFRO President on 7 and 9 August 2000. Another press conference was held on 9 August 2000 by the International Timber Trade Organisation (ITTO) because a new book was launched during its satellite meeting.

Addresses in the Opening and Closing Ceremonies

Addresses in the Opening Ceremonies

Address by



Dato' Dr. Abdul Razak Mohd Ali
Chairman of the Congress Steering Committee

YB Dato' Seri Dr Lim Keng Yaik,
Minister of Primary Industries,
Professor Jeffery Burley, President of IUFRO;
Distinguished guests, ladies and gentlemen;

It is truly an honour for me to welcome all of you to the XXI IUFRO World Congress on behalf of the Congress Steering Committee. Our special thanks goes to the Honourable Minister of Primary Industries of Malaysia for having agreed to attend and officiate the opening of this Congress on behalf of the Right Honourable Prime Minister who cannot be here this morning. To all delegates, and especially for those from abroad, 'Selamat Datang ke Malaysia' or 'Welcome to Malaysia'.

During the IUFRO Executive Board meeting in Madrid in April 1995, Malaysia bid to host this XXI IUFRO World Congress in Kuala Lumpur. The triumphant occasion that happened more than five years ago, remains fresh in my mind as I was then given the task to lead the delegation that presented Malaysia's proposal along with similar bids from South Africa, China and Indonesia.

Malaysia takes great pride in being the first developing country to host the IUFRO World Congress. The Congress is undoubtedly the largest ever forestry meeting organized in the country. In terms of the number of participants and accompanying persons registered, and papers and posters for presentation, it surpasses that of the 14th Commonwealth Forestry Conference held in Kuala Lumpur in September 1993.

We are indebted to the Government of Malaysia and the IUFRO International Council for having the confidence in entrusting this mammoth responsibility of organizing the IUFRO Congress to the Forest Research Institute Malaysia (FRIM). We wish to thank the IUFRO Secretariat in Vienna and the Malaysian Forestry Research and Development Board (MFRDB) for their invaluable guidance and support. The Congress Organizing Committee (COC) and its sub-committees have worked very hard to ensure that the progress of all aspects of the organization is closely monitored.

Ladies and gentlemen,

We are glad to announce that we have a total of 1906 registered participants and over 200 accompanying persons from 96 countries. Over the next few days, 5 keynote papers, 99 sub-plenary papers, 500 oral papers and 833 posters will be presented during the Plenary, sub-Plenary, Group and Poster Sessions, and Panel Discussions on posters. It is our intention that the poster presentations will provide opportunities for scientists to interact with their peers on subjects of interest.

Through the Scientist Assistance Programme (SAP), we are able to provide financial support for 138 scientists from 38 developing countries to attend the Congress. In addition, the Malaysian government has kindly provided funds to support another 31 scientists from Asia and the Pacific region to attend.

We are grateful to the Honourable Minister of Primary Industries of Malaysia who will be addressing us and declare the Congress open on behalf of the Prime Minister. Other highlights of the opening ceremony will include the launching of the XXI IUFRO World Congress commemorative stamps, a cultural show and the presentation of IUFRO awards. We also wish to thank the keynote speakers who will be delivering their speeches during the plenary sessions.

Ladies and gentlemen,

It is my sincere hope that the Congress will serve as a useful forum for scientists throughout the world to discuss the role of research in relation to forests and society. Traditionally, forests have been considered a source of timber. Research has indeed played a significant role in changing this perception and attitude that forests also provide a wide range of other goods and services pertinent to the well being of society.

Please take every opportunity during the course of this Congress to discuss research issues and needs and to forge beneficial R&D collaborations. The scheduled pre-congress, satellite and business meetings are intended to serve such purposes.

All said and done, I wish to apologize for any shortcomings in the organization of the Congress, on behalf of the Congress Steering Committee and the Congress Organizing Committee. Finally, do find the time during the in-Congress tours and post-Congress excursions to visit fascinating Malaysia, a country rich in biological and cultural diversity.

Thank you.

Address by

Professor Jeffery Burley

President of IUFRO

The Honourable Minister for Primary Industries,
Dato' Seri Dr. Lim Keng Yaik;
The Honourable Deputy Minister;
Mr. Secretary-General;
Dato' Dr Abdul Razak Mohd Ali,
Chairman of the Congress Steering Committee;
Dr Hosny El-Lakany,
Assistant Director General for Forestry in FAO;
Distinguished guests;
Ladies and gentlemen;

It is my great privilege and pleasure to welcome you to this 21st World Congress of the International Union of Forestry Research Organizations (IUFRO as it is widely known). Your Excellency, we are extremely sorry not to have the honour of the Prime Minister's presence but we recognize that reasons of State business have prevented his participation. However, we thank you for doing us the great honour of delivering the opening speech, which I am sure will be an address of welcome and exhortation to us. The theme of our Congress is "Forests and society: the role of research"; this is timely as we enter a new millennium of growing human populations, increasing demands on forests for their products, and increasing awareness of the many other environmental and social benefits that forests provide. It is particularly relevant here in Malaysia, a country of vast and variable forest resources and their associated services, and a country with a world-famous research tradition. Minister, you and I have known each other for many years and I know that you have always been an active and leading thinker and speaker on forestry and forest industries, particularly as they relate to Malaysia and South East Asia. We look forward with great interest to your presentation.

In the past five years it has been my continuing privilege to be the President of IUFRO and I would like to take a few minutes to tell you and our other guests something of the history and activities of the Union; in addition I will attempt to show why this should be of interest to a senior politician and why researchers and policy-makers should have increasingly closer dialogue.

IUFRO was founded in 1892 by a small number of European countries and for its first 80 years expanded to include most temperate countries. It was as late as 1971 that we created the first Working Party to deal specifically with a tropical subject (forest genetics and tree breeding). Since then IUFRO has actively sought to bring the benefits of its international collaboration to institutions and scientists in developing countries, including support for APAFRI, FORNESSA and a Latin American Network, and to involve them actively at all levels of its management; the Union now comprises nearly 700 member institutions in 110 countries with approximately 15,000 scientists working collaboratively and voluntarily in 276 Divisions, Research Groups and Working Parties. It is an international, non-governmental, non-profit and multi-disciplinary institution that seeks seriously to obtain the greatest value from government, industrial and private investment in research.

I should point out that the work of IUFRO is essentially voluntary; virtually all the officers of the Union and all collaborating scientists devote considerable efforts towards the success of IUFRO because they believe in the added value of collaboration. Only the Secretariat, generously provided by the Government of Austria, can be considered permanent "Civil Servants"of the Union. In addition the contractual staff of the Special Programme for Developing Countries (SPDC) are equally generously provided by Canada, Denmark and the USA. The European Union and the Governments of Japan, Switzerland and UK have provided great financial support to IUFRO. IUFRO maintains close ties with other organizations, particularly the International Council for Science, the Centre for International Forestry Research, the Food and Agricultural Organization of the United Nations, and the International Centre for Research in Agroforestry; it is an added privilege for us that the representative of the Director General of FAO will be giving a statement in this opening session.

Throughout this century the Union has stimulated and supported excellent research in a wide range of scientific topics. However, research is of no value when conducted independently; it should be seen as an integral part of the continuum from pure and applied research to adaptation and widespread application of new technological and social systems that address the issues of international and national policies. To this end, IUFRO has established Task Forces to encourage the integration of such research and to foster better understanding between researchers and policy-makers. At this Congress in Malaysia during the first year of the new millennium, IUFRO scientists will produce state-of-knowledge reports on many major issues to indicate the currently available information, the management implications of this research, and any need for new research.

In the past decade there has been a rapid expansion of political and public awareness of the importance of forests and trees in human welfare. They provide a vast number of social, environmental and economic products and services to a huge range of stakeholders. In addition to professional forestry books and journals, in most countries nowadays there are frequent publications in newspapers and magazines and programmes on television and radio relating to forests. There is a close interdependency and often competition between the various products and services demanded from forests; research embraces many disciplines that are not naturally cohesive. IUFRO is making strenuous efforts to encourage inter-disciplinary collaboration between biophysical and social scientists. The number 2000 is a nice round number, at least it is if you count by the mathematical base ten. It is also highly significant in certain religious calendars. However, it is totally significant to everyone alive and to unborn billions as the year in which international agencies, national governments, civil societal organizations, educators, researchers, businesses and resource managers must realize the urgent need to manage the world's resources in a wise, equitable, ethical and sustainable manner. Forests and trees will play a major role in such sustainable development and IUFRO will continue to do its utmost to encourage research and researchers to address relevant issues and to present their findings in ways that policy-makers and all stakeholders can understand and apply. The Executive Board of IUFRO feel sure that this Congress will do much to promote this.

Your Excellency, everyone attending IUFRO's 21st Congress is extremely grateful to the Government of Malaysia and the City of Kuala Lumpur for hosting it, for providing such friendly and generous hospitality, and for organizing such interesting and enjoyable study tours for both the scientists and their accompanying persons in your beautiful country. In relation to the organization I can only point out to you that staff of the Forest Research Institute, the Federal and State Forest Departments, and several Universities and other institutions have worked strenuously to support IUFRO in this quinquennial endeavour. While I am afraid that research in Malaysia may have been disrupted somewhat in recent years as a result, I am more concerned that it will disappear altogether in future as all these staff become professional conference organizers and tour operators.

Your Excellency, it will be our pleasure to have you open this 21st IUFRO Congress and to give us your views of the role and needs for forest research. I shall also ask you later to do us the honour of presenting IUFRO's highest award, Honorary Membership, to two outstanding leaders in our Union.

Address by

Dato' Seri Dr. Mahathir Bin Mohamad

The Prime Minister

Read by

Dato' Seri Dr. Lim Keng Yaik,

Minister of Primary Industries Malaysia;

Professor Jeffery Burley, President of IUFRO;
Datuk Haron Siraj, Secretary General of the Ministry of Primary Industries Malaysia;
Dato' Dr. Abd. Razak Mohd Ali, Chairman of the Congress Steering Committee;
Distinguished Guests;
Ladies and Gentlemen;

Let me, first of all, thank the organizers for inviting me to address and officiate the opening of this important forestry congress, the 21st International Union of Forestry Research Organizations, or IUFRO, World Congress. I would also like to extend a very warm welcome to all our guests and participants and wish you all a very fruitful meeting and pleasant stay in Malaysia.

I understand that IUFRO is a non-governmental and non-profit organization, established more than one hundred years ago, in 1892, and that its mission is to promote international cooperation in forestry research and related sciences. I also understand that although IUFRO has about 700 member institutions in 110 countries, this is the first time that the Congress is being held in a developing country. Therefore, it would be incumbent upon me to congratulate the organizers for having successfully bid to host this World Congress in Kuala Lumpur and for having undertaken the necessary preparations that have led us to be gathered here today at the biggest ever forestry meeting held in this country. I hope that this will mark the beginning for the IUFRO World Congress to be held in other developing countries as well.

As we all know, forests play a major role in the livelihood of citizens of many developing countries, contributing significantly towards the economic progress of these nations. I am extremely pleased, therefore, that Malaysia has blazed the trail for developing countries to bid and organize such a Congress, as forestry issues relate very closely to a large number of weak and impoverished citizens of the world. On this score, too, I wish to congratulate IUFRO on the very appropriate theme chosen for the Congress, linking society to forests through research.

I would be preaching to the converted if I were to embark on a discourse on the role and functions of forests. You are the experts on this subject. You are only too familiar with the fact that in the past, forests were considered separate from people who lived in or at their fringes and that forests were considered only for the timber that they supplied. In recent years, however, the trend globally has been towards recognizing that forests and society, both rural and urban, are but two sides of the same coin and that, beyond timber, forests provide a whole range of goods and services important for the well being of society.

But what lessons have we learned from the not-so-distant past, lessons in forestry that have triggered this change in perception and have set the stage for the current international debate on forests? We know that as the industrial revolution began in the early 1800s, vast tracts of temperate forests in Europe, already decimated in the preceding centuries, were further cleared to provide wood that was necessary for the industrialization process. Vast tracts of forests were also lost on the other side of the Atlantic Ocean, in America, in the 1800s. In just decades, millions of hectares of forest were destroyed for pasturage and cultivation, lumber and fuel.

The industrial revolution in the West led to massive negative effects on the environment. Pollution of the atmosphere and waterways as well as degradation of the soil accelerated. The rapid economic growth following the Second World War, in what are now the developed countries, provided the impetus for further environmental degradation. The United Nations Conference on the Human Environment of June 1972 in Stockholm came and went. However, environmental degradation continued unabated. Global warming, ozone layer depletion, marine pollution, acid rain, deforestation and soil degradation–mostly the result of industrial activities–had become a great cause for concern by the early 1980s.

Within this context, the Langkawi Declaration on the Environment of the Commonwealth Heads of Government Meeting (CHOGM) held in Kuala Lumpur in October 1989, planted the seed for a concept which took formal shape in subsequent global meetings. The concept of 'greening of the world' became enshrined as a principle in the Paris Declaration of the 10th World Forestry Congress held in 1991. Subsequently, at the United Nations Conference on the Environment and Development (UNCED) in Rio de Janeiro in June 1992, the Statement of Principles on Forests, accepted by all Governments, embodied this concept in full.

In this connection, just prior to the Earth Summit in Rio, Malaysia had in fact suggested that the world forest cover of 27.6% at the time be increased to 30% by the year 2000 through vigorous afforestation and reforestation programmes throughout the globe. We had envisaged that this increase would cover all types of forests–boreal, temperate and tropical – as there is no discrimination in the way different types of forest sequester carbon, stabilize climate, protect the environment, conserve biological diversity, produce industrial resources and provide sustenance for the livelihood of communities living within and in the vicinity of forests. We had also envisaged that the developed countries with low forest cover, a consequence of wanton forest destruction during the last few centuries, but now with strong economies, vast resources and technical know how, would spearhead efforts at greening the world. We had envisaged further, perhaps in our naivety, that these economically powerful countries would pool their vast resources to actively help implement afforestation and reforestation programmes in the poorer countries of the world.

However, eight years down the road from Rio, it is 'business as usual.' All the hype generated during the run-up to, and at Rio, has virtually dissipated almost overnight. There was no concerted movement to green the world, not even in the embryonic form. Each nation has been virtually left on its own to implement its forestry programmes. I am told that the average total annual cost required to implement the forestry programmes under Agenda 21 of UNCED was estimated at US$32 billion, a major portion of which was committed to come from developed countries. Despite the fact that Agenda 21 as well as the Forest Principles provided the framework for strengthening cooperation among countries, it is now clear that most of the funds required for forestry programmes would have to be generated by developing countries themselves.

Malaysia has always been and is proactive in global issues concerning forests and the environment. We participated actively in the negotiations leading to UNCED, encompassing Agenda 21, the Statement of Principles on Forests, the Convention on Biological Diversity and the Framework Convention on Climate Change, and have continued active participation in the developments since Rio. We adhere very much to the concept of greening of the world, although forests were cleared during the time of our colonial occupation for the purpose of establishing plantations. Nevertheless, natural forests still cover about 58% of our land area. With the inclusion of plantations of rubber and oil palm, the tree cover is about 72% of the land area. We have pledged and will continue to uphold this pledge, that forest cover will remain at a minimum level of 50% of the land area in perpetuity and this will be our contribution to the citizens of the world.

In this regard, we have also acted to strengthen our forestry practices, in line with the concept of sustainable forest management; for example, we have expanded the size of our permanent forest estate from 12.7 million hectares to 14.1 million hectares, revised the National Forestry Policy in 1992 and amended the National Forestry Act in 1993, strengthening its provisions and introducing stiffer penalties for forest offences. We are increasing our efforts in research and development in all relevant fields of forestry, including efforts to develop downstream forest-based industries that would operate sustainably. At the macro level, the National Policy on Biological Diversity, endorsed in 1998, will provide guidance for the conservation of biological diversity and sustainable utilization of its components.

Internationally, we have continued to provide input into the process of the Intergovernmental Panel on Forests (IPF) and the Intergovernmental Forum on Forests (IFF). We are also active participants in the present implementation phase of the Convention on Biological Diversity and the Framework Convention on Climate Change, both of which have direct relevance to forestry issues.

We acknowledge that forestry is important to a nation's economy and its society, as well as to the national and global environment. Consequently, it has become a dominant issue in both the domestic and international agenda on forestry relating to a legal instrument on forests. We are only too aware of the arguments that did not allow for such an instrument to be the subject of extensive debates; the issue of a legal instrument on forests has yet to be resolved. We are still no closer to a legal instrument than before.

Malaysia's position is that a legally binding instrument on all types of forests is a necessity for addressing a whole range of issues on forestry and timber, in a holistic, integrated and comprehensive manner. We believe that such a legal instrument would facilitate the achievement of sustainable forest for all forests, compared to the present 'ad hoc' non-legally binding international environment, which can be a hindrance to the best forestry practices. We also believe that such an instrument would enable international level action to be taken to address underlying factors for forest shrinkage and degradation in transboundary areas, such as international debt and unsustainable consumption patterns. The instrument would also encourage and accelerate cooperation in the transfer of technology.

Presently, the lack of consensus regarding the necessity of a legally binding instrument is due to the impasse concerning critical issues such as finance, transfer of technology and trade. In this regard, I would like to urge the developed countries to re-affirm and put into action their commitments to provide concrete financial assistance and technologies to developing countries to achieve sustainable management of their forests. In addition, sustainable forest management should be promoted through mutually supportive trade and environmental standards to market access. Such actions will only render forest valueless and will result in forests being cleared for other purposes. Trade and environmental restrictions will not reduce deforestation. In fact, greater market access will help promote sustainable forest management by providing the much-needed revenues for this purpose.

The dependence of society on forestry goes back to times immemorial, when society was primitive and societal needs simple. In many corners of the earth, mostly in developing countries, societal needs still remain simple. Elsewhere, needs have increased with development of societies and unsustainable lifestyles have contributed much to the increased and often insatiable needs of expanding societies. But needs are more than just material and hence the maxim that ‘forest resources and forest lands should be sustainably managed to meet the social, economic, ecological, cultural and spiritual human needs of present and future generations.’

I am gratified to have the chance to meet all of you today and to address this Congress of scientists who have committed their lives to forestry research, so that, directly or indirectly, you are contributing to societal needs of the present as well as of the future. Recent history has shown that investment in research and development in any field can lead to high returns. It is my sincere wish that your efforts will lead to returns that would improve the lot of society as a whole, and of the weak and poorer segments of society in particular. You represent both the developed and developing world and it is by way of this kind of North-South partnership that you are linked through IUFRO.

In this regard, I hope that your efforts will help towards building a more equitable forestry agenda in the international arena, whereby the technologies that you develop in your endeavours will be shared equitably and more magnanimously with the developing countries to improve forestry practices globally. If the world is to achieve sustainable forest management, the transfer of technology from the North to the South on preferential terms as agreed to in Rio, must be forthcoming. Unfortunately, this has not been so and developing countries, without access to these technologies, will be unable to meet their commitments on sustainable forest management, which works to nobody’s benefit. IUFRO can, therefore, play an important role to facilitate this transfer of technology. I hope that this Congress will help foster not just an exchange of research experiences but also develop more concrete networks which will serve as effective conduits for North-South transfer of technology. I therefore wish you all the best in your endeavors and hope that you will have a productive Congress.

In conclusion, let me once again extend our warm wishes to all delegates at this Congress. I hope that you will find time in the post-congress tours to savour not just the bio-diversity of our tropical forests but also the multi-racial, multi-cultural and multi-religious society of our country. In Malaysia you will see Asia.

With these remarks, I have great pleasure in declaring open the 21st IUFRO World Congress.

Address by

Prof. M. Hosny El-Lakany

Assistant Director-General,
Forestry Department, FAO

Honoured guests;
President and Members of the IUFRO Executive Board;
Ladies and Gentlemen;

On behalf of the Director-General and the rest of the staff of the Food and Agriculture Organization of the United Nations, and particularly my colleagues in the Forestry Department, I would like to extend warm greetings to all the participants in this twenty-first IUFRO World Congress. It is a great personal pleasure and an honour to be here with you in Kuala Lumpur today!

First of all, I would like to congratulate the Congress organizers and particularly our Malaysian hosts for the magnificent arrangements. Certainly Malaysia, with its long and strong tradition of forestry science contributing to development, is a most appropriate setting for this impressive gathering.

As I look around the hall this morning and see such an eminent and diverse group of participants, the fundamental value of IUFRO as an organization comes through strongly to me. IUFRO offers forestry scientists and researchers the means through which to share experience and knowledge both to advance the cause of sustainable forestry and to develop individually. The opportunity for young scientists at the beginning of their career to exchange ideas with and benefit from the most erudite members of the international forest research community is without parallel, and the possibility to tap the results of research from around the world is of immeasurable value. For how many of us here today, has this opportunity represented an auspicious occasion?

Certainly in my own case, this is so. I remember vividly my own first participation in a IUFRO Congress – in 1976 in Oslo and my direct encounter with many forest scientists; fortunately some of them are with us today. And part of my Ph.D. work was based on a seed collection made under the auspices of IUFRO – the Douglas Fir Provenance Collection of 1966.

Thus, I am particularly honoured to represent FAO at this important meeting – the first IUFRO World Congress of the new millennium. IUFRO has a special relationship with its members, and its relationship with FAO is also unique. At the institutional level, FAO and IUFRO have had a cooperative and symbiotic relationship since FAO was created – IUFRO being, of course, the “older sister” by nearly half a century. IUFRO links scientists and researchers, and FAO helps link IUFRO to the field, thus ensuring that the valuable results of forestry science and research are put into practice – and the “pulse” of the field is transmitted to researchers.

At FAO, all of our forestry officers have direct, ongoing contact with IUFRO and its Research Groups and Working Parties. In addition, through its Partnership Programme, FAO facilitates visits from academics, researchers and especially young professionals who might not otherwise have the opportunity to share experience and expertise on a face-to-face basis. Moreover, FAO, through its function as a neutral forum, helps countries to jointly identify areas where additional research is required, and thus to focus the efforts of forestry scientists world wide. In this regard, I am always pleased when national delegations to the biennial sessions of the FAO Committee on Forestry include forestry scientists and researchers. Thus, information and knowledge flows in a multi-channel network between FAO and IUFRO, to the benefit of all of our constituents.

From FAO’s perspective, the theme of this Congress, “Forests and Society: the Role of Research”, is particularly appropriate. In its work in forestry, FAO is fully committed to an approach based on maximizing the social as well as environmental and economic benefits of sustainable forest management. In fact this commitment is explicit in the FAO Strategic Vision for Forestry. Developed in collaboration with FAO member countries, partner institutions and organizations, including IUFRO, over a period of more than two years, and approved by the FAO Committee on Forestry in March 1999. The FAO Strategic Plan for Forestry describes the Organization's mission, goals, medium-term objectives, current priority activities and vision in forestry. That mission is “To enhance human well-being through support to member countries in the sustainable management of the world’s trees and forests.” It is people and society that come first.

Our priority activities are also focused on forests and society. For example, our effort in community and participatory forestry focuses on bringing a broader range of society more directly into the forest management and decision-making process. I should add that this concerns not only those who actually live in and around forest areas, but also others who depend on forest resources and products.

Another priority area for FAO that has direct relevance to the topic of forests and society is our work in helping countries pursue national forest programmes. These programmes – recognized by the intergovernmental processes that have emerged from UNCED – are aimed at establishing a workable social and political framework for the conservation, management and sustainable development of all types of forests.

A third priority area for FAO Forestry is strengthening world wide access to reliable and timely forestry information. The very first article of the FAO Constitution gives us a mandate to “collect, analyse, interpret and disseminate information.” In forestry, this involves the development of common terms and definitions, and the harmonization of definitions, the collection of statistics on production, consumption and trade, and our assessment of forest resources worldwide. In all of these aspects, we are collaborating closely with IUFRO. It is therefore particularly appropriate that we chose to launch the first results of the FAO Forest Resources Assessment 2000 here at this Congress. I would also mention our important forestry Web site and the collaboration between FAO and IUFRO in the development of the Global Forest Information Service.

Another important, and enduring area of FAO-IUFRO collaboration regards the Special Programme for Developing Countries – the SPDC. A month ago, on 7 July, the Forestry Research Network for sub-Saharan Africa (FORNESSA) was officially established and its first Chairman, Dr. Konuche from Kenya, was selected. In this context, I am happy to note that the SPDC Deputy Coordinator is hosted by the FAO Regional Office for Africa – thus close, ongoing relations with FAO are ensured.

At this Congress, several papers will be presented by FAO staff and many sessions have been co-organized with FAO participation.

By the examples I have provided, I hope it is evident that FAO has a long-term commitment to maximizing the positive relationship between forests and society. The theme of this Congress suggests strongly that IUFRO and its members are also oriented in this direction.

What then is the role of research in moving forward on this track as perceived by FAO. Certainly, we need a greater focus on social aspects of sustainable forestry development. We need to know more about how people can and do approach forest management, and especially about the tools and scientific developments that they need to take on this responsibility more effectively.

We need more research on how best to provide people with the information they need to better participate in forest decision making and specialized research into conflict management.

We especially need research into the potential and modalities of international cooperation in forestry. The past decade has seen a plethora of international agreements that are directly relevant to the future of world forestry, but those who are responsible for framing and implementing them are truly in a new territory. We must study, analyse and learn from the experiences of other sectors that have taken this path before us so that the agreements we forge for forestry are practical in scope as well as noble in intent.

These are challenging tasks indeed, and they will be made even more challenging by the fact that they must complement and not substitute research into other more traditional aspects of forestry. But, to my mind, they are essential if we are to achieve our common goal of sustainable use of forest ecosystems, and I can think of no organization more adroitly poised to take up this challenge than IUFRO.

In closing, Ladies and Gentlemen, I would like personally to congratulate the outgoing Executive Board and particularly the President – a close colleague and good friend, Professor Jeffery Burley, for their strong and competent direction. And permit me, as well, to express our full confidence in the incoming Board and the new President, Professor Risto Seppälä, and to extend warm greetings to Past Presidents, especially Dr. Salleh Mohd Nor.

Mr Chairman, on behalf of FAO Director-General, Jacques Diouf, on my own account, and particularly on behalf of the FAO Forestry Programme, I would like to express our sincere hopes that this will be a successful Congress, and a fitting start to a new millennium for world forestry.

Thank you.

Addresses in the Closing Ceremonies

Five-Year Review Speech
At the Closing Session

Professor Jeffery Burley
President of IUFRO

Distinguished guests, colleagues, ladies and gentlemen, as we come to the closing of this impressive and productive Congress, you will be addressed briefly by me as the current President and by Professor Risto Seppälä as the President-elect. I will summarize for you the activities and progress of IUFRO during the five years of my presidency while Professor Seppälä will outline to you his vision of future developments in forest research and in IUFRO.

The 1995 Resolutions and Challenges

At our 20th Congress in 1995 the following resolutions were accepted:- a) to maintain and enhance well targeted forestry and forest products research; b) to expand research capacity, especially in developing countries; c) to enhance partnerships that strengthen research and improve communications between scientific and general communities; and d) to increase policy and problem-oriented research in economic and social sciences. When I was elected President I offered to the Executive Board a personal view of IUFRO's role, development and activities and I would like to summarize that for you and indicate how IUFRO has responded to the challenges I posed and to the Congress resolutions.

I pointed out that, in the last decade of the last millennium, significant changes were occurring in forest policies, forest practices, and the forestry profession. Forestry issues had become globalized and internationalized with a wider policy-forming base of individuals and institutions that were not traditional foresters. Socio-economic sciences were making greater inputs to decision-making processes. There was global pressure to evaluate the role of forests for all benefits and to monitor their status. Policy-makers constantly sought (a) information on the roles, values and status of forests and trees in relation to conservation and development, (b) views on the linkages between forests, biodiversity, climate and other environmental issues, and (c) advice on sustainable management of forests including institutional issues.

I felt then (and feel now) that IUFRO should seek to respond to those changes while maintaining its primary role of networking among its member voluntary scientists. It should continue to be the principal source of knowledge and experience on forest research in specialized topics while increasing the intensity and frequency of inter-disciplinary cooperation within the Union itself and with organizations and disciplines outside its traditional membership.

Those links also publicized the work of IUFRO, ensured its relevance to modern needs, identified sources of funds for research, and sought productive collaboration while minimizing unnecessary duplication. Early recognition of emerging issues by the Executive Board proved vital and was facilitated by establishing strong links with a range of other institutions. IUFRO has attempted to support the Directors of Member Organizations themselves by undertaking and publishing policy-relevant science and by assisting the Directors in making the case for forests and forestry research to governments and agencies.

IUFRO's New International Role

The Executive Board of IUFRO has made strenuous efforts to advertise the existence, activities and relevance of the Union. The widely acclaimed IUFRO brochure was launched at the World Forestry Congress in Turkey during 1997 and the equally reputed IUFRO Web site has home pages for all research units that are mirrored on servers in several countries and linked to those of many other institutions. Many of these Web pages maintain space for statements of the state-of-knowledge in the particular discipline of the research unit; as you will have realized throughout this Congress, great attention has been given to the dissemination of research results and state-of-knowledge reports.

We have also sought to ensure a role for the Union in international debates and developments. I or other IUFRO officers have attended meetings of:- the Intergovernmental Panel on Forests (IPF); the Intergovernmental Forum on Forests (IFF); the World Forest Forum; the World Forestry Congress; the Committee on Forestry of the Food and Agriculture Organization of the United Nations (COFO/FAO); the IUCN General Assembly; various meetings of several international initiatives developing criteria and indicators for sustainable forest management; the

Board of Trustees of the Centre for International Forestry Research (CIFOR) and the International Centre for Research in Agroforestry (ICRAF); Centres Week of the Consultative Group for International Agricultural Research (CGIAR); the National Exposition at Kunming, China; and various meetings and exhibitions of other organizations. In particular we were delighted to see recommendations of the IFF 4th session calling for improved linkage between forest science and forest policy processes, funding for forest research (particularly in developing countries), enhance access to forest-related information and collaboration with IUFRO in the GFIS. IUFRO's own Special Project on Terminology (SilvaVoc), coordinated by Renate Prueller, and supported by Japan, contracted with FAO to provide definitions of major terms used in the international debates on sustainable forest management. I was delighted that my own Institute was able to represent IUFRO in preparing a document on researchable forest policy issues, financed by the UK Government's Overseas Development Administration (now the Department for International Development) for the World Commission on Forests and Sustainable Development.

The Union has also encouraged research units to pursue specific topics related to the new international concerns. An outstanding contribution of IUFRO to international processes was its role in organizing and publicizing the International Consultation on Research and Information Systems in Forestry (ICRIS) that was sponsored by the Governments of Austria and Indonesia in cooperation with CIFOR and the Forestry Department of FAO. This conference was an inter-sessional activity in support of the Intergovernmental Forum on Forests (IFF) of the United Nations Commission on Sustainable Development (UNCSD) and took place in Austria during September 1998; its major impacts on IUFRO itself were the establishment of Task Forces on the Global Forest Information Service (GFIS) and the Forest Science-Policy Interface.

IUFRO's Enhanced Structure and Activities

The primary role of IUFRO has continued to be the enhancement of the value of research through networking of nearly 700 Member Organizations and 15,000 scientists in their chosen fields; the 268 research units and 8 Task Forces have held 335 meetings in 65 countries, 41 of which were developing countries or emerging economies. Two new Divisions were created at the beginning of the Board period to recognize the great breadth of research activities and to reduce the workload on individual Division Coordinators and Deputy Coordinators (who, like all IUFRO officers, are volunteers). The Executive Board established a number of Special Programmes, Projects, Task Forces and Ad Hoc Committees to address particular topics or issues and it encouraged them to set significant specific goals including emphasis on capacity building. In a short speech it is clearly not possible to provide details or even adequate summaries of all of these but I will pick out some highlights.

As I indicated above, one of the major changes in the last decade has been the greater need for inter-disciplinary, problem-solving approaches to researchable issues and topics. IUFRO has always had wide coverage of sciences in individual biophysical and socio-economic research units. In the past five years we have encouraged interaction between these through inter-divisional meetings, through collaboration with other organizations, and through the work of the Task Forces. We all have to recognize the implicit difficulties of gaining mutual understanding of another person's discipline and of obtaining academic or professional recognition for such multi-disciplinary work, but this is clearly an outstanding need.

The Divisions

A major interdivisional meeting on forest ecosystem and land use in mountain areas took place in Seoul, Korea, in 1998 organized by Divisions 1, 4, 6 and 8; this attracted 350 participants from 24 countries. Within Division 1, Research Group 1.17.00 (Restoration of degraded sites) was closely involved in the international research programme jointly sponsored by the USDA Forest Service, the World Bank, CIFOR and the British Overseas Development Administration that examined the role and implications of plantations in accelerating natural forest recovery on degraded tropical lands.

Division 2 organized a major meeting on forest genetics in Beijing in 1998 and its Working Party 2.04.06 held a meeting on genetic modification in Oxford in 1999, demonstrating IUFRO's continual concern for and advice on current issues of public and political importance. Participants at these meetings recognized that classical genetic improvement still deserves major efforts in funding but should also use new technologies to increase efficiency; at present genetically modified organisms should be considered as laboratory tools, not for release until ethically accepted by the public.

Division 3 held a number of Divisional meetings and inter-Divisional meetings with Division 1 in Bolivia 1997; Division 6 in Japan 1997, Canada 1998 and Australia 2000; Division 8 in Japan 1998 and the Task Force on Sustainable Forest Management in Australia 1998. It also held a number of meetings with external organizations including CIFOR and FAO. Individual Research Groups produced state-of-knowledge reports.

Division 5 devoted considerable efforts to understanding the changing resource of materials in forests, extending the resource and implementing technologies that are environmentally and socially "friendly". The all-Division conference in 1997 focussed on forest products for sustainable forestry and was attended by 222 delegates from 42 countries.

Division 7 was created to address a specific resolution of the 1995 Congress that encouraged research on "… the extent, productivity and health of forests …". In the last five years the Division has convened major research meetings in Europe, North America and Asia dealing with entomology, pathology, air pollution and host-pest interactions.

Task Forces

A key issue throughout the world has been the development of criteria and indicators for sustainable forest management. The Task Force on Sustainable Forestry, coordinated by Alain Franc, collaborated with CATIE, CIFOR and FAO in organizing three major international meetings in Australia, 1998, Costa Rica, 1999, and France, 1999 (in association with Ecofor and EFI); each attracted 100-200 participants and bridged the gap between scientists and forest stakeholders while clarifying relationships between criteria, indicators, certification systems and biodiversity. Particular attention was given to the role of the social sciences.

Based on the contributions of many scientists, the Task Force on Environmental Change, coordinated by John Innes, developed outstanding state-of-the-art reports, two of which have already appeared in the IUFRO Research Series and the remainder will be completed during this year. Task Force officers also represented IUFRO interests at a number of meetings promoting the links between science and policy. The Task Force was specifically responsible for a resolution of the Ministerial Conference on the Protection of Forests in Europe known as "Helsinki 4" which deals with coordinating efforts to mitigate the effects of climate change on European forests.

The Task Force on Forests in Sustainable Mountain Development, coordinated by Martin Price, prepared the first state-of-knowledge report on this topic, bringing together 124 authors from around the world. A critical issue was the definition of the extent of the world's mountain forests; major elements were a map of the world's mountains (according to objective rules) and a map of the mountain forests which account for 28% of the world's forest area.

The Task Force on Water and Forests, coordinated by Rob Vertessy, was established to review the current scientific knowledge and existing hypotheses on fresh water ecosystems in forests and the implications of silviculture and forest management on water quantity and quality; it has produced a major publication on this topic.

The Task Force on Internet Resources, coordinated by Lauri Valsta, has developed a unique and invaluable resource for communication between scientists and for the dissemination of information about IUFRO worldwide.

The Task Force on Global Forest Information Service, coordinated by Risto Paivinen, is a consortium of international, regional and national organizations developing a strategy and implementing an Internet-based meta-data service to provide coordinated worldwide access to forest-related information. It has developed the basic concepts of collection policy and technical solutions including a working prototype, and an EU-funded project for Africa, Caribbean and the Pacific.

The Task Force on Management and Conservation of Forest Gene Resources, is coordinated by Veikko Koski and its committee includes representatives of most IUFRO Divisions, CIFOR, FAO and IPGRI; it gathers scientific information on interactions between all factors affecting the distribution, integrity and conservation of forest gene resources and it has prepared a state-of-knowledge report.

The Task Force on Forest Science-Policy Interface, coordinated by Rich Guldin, helped to shape the Division 6 conference on the contributions of science to the development of forest policies in South Africa and organized two Side Events at the third and fourth sessions of the IFF. Three conferences in the next three years will gather 40-50 case studies showing how research has successfully influenced forest policy.

IUFRO Supporting Developing Countries

The work of the Special Programme for Developing Countries (SPDC), coordinated until June this year by Bob Szaro, has consistently sought to assist in the development of human resource capacity in developing countries and emerging economies; additionally IUFRO has made every effort to support such scientists in participating in IUFRO science and management as officers of research units. The SPDC organized workshops on research management and planning, grant writing and proposal development, and strategic planning. It supported more than 200 scientists and 35 meeting organizers in more than 60 countries and initiated and published the first two volumes in a low-cost textbook series.

IUFRO greatly appreciates the contributions of the Government of the United States of America in providing the Coordinator, the Government of Canada in providing the Deputy Coordinator of the SPDC and the Government of Denmark for providing the Deputy Coordinator (Africa). The Japanese Government has been a generous supporter of the BIOREFOR programme, which has stimulated collaboration among many institutions in the Asia-Pacific region to contribute to our knowledge on how biotechnology can be used for reforestation efforts. We also appreciate the generous support of the European Commission of our GFIS-Africa project designed to foster forest related information sharing in Africa. Other agencies that provided generous support in cash or kind to IUFRO included AusAid (Australia), Deutscher Verb. FVA (Germany), the Royal Danish Embassy, the USDA Forest Service (USA), the Government of China Taipei, and the UK Government.

Disseminating Research Results

Research should not be conducted in a vacuum and its results should be widely disseminated. IUFRO has made valiant efforts to publicize the work, results, value and relevance of forestry research in general and of IUFRO specifically. In addition to the Web pages referred to earlier, and to 91 volumes of proceedings of meetings published by research units, we have continued to expand the IUFRO World Series and IUFRO Occasional Paper Series (published by the Secretariat), while adding the IUFRO Research Series (published by CAB International).

Review of IUFRO Structure and Management

Throughout its five years of office, the current Executive Board has constantly reviewed IUFRO's structure and activities, including commissioning an external review of the Secretariat, SPDC and Special Project. We have made strenuous efforts to attract funding, particularly in support of developing country members, but also to establish IUFRO's own projects such as the SilvaVoc Terminology Project. We have revised IUFRO's investment strategy, especially in view of the difficulties that some Member Organizations face in paying their subscriptions. Incidentally, in response to a recent decline in membership numbers, the Executive Board and International Council have approved the slight change of IUFRO's English name from "Forestry" to "Forest"; this recognizes the need to encompass the wider range of disciplines and institutions who would benefit from, and contribute to, IUFRO. It also recognizes a perception held by some members of the public that "forestry" only refers to massive removal of natural forests or to equally widespread development of plantations of exotic species; this is at a time when IUFRO is doing much more to provide research and advice on the social and environmental benefits of forests.

The Executive Board has encouraged Member Organizations and scientists to feel part of the IUFRO policy and planning processes. Many contributed to the development of the Strategic Plan that has guided the work on the Executive Board in the last five years. The International Council has also been closely involved in the development of IUFRO policy, the revision of IUFRO's Statutes and the election of your next Executive Board. The Executive Board has encouraged the regionalization of IUFRO management and scientific cooperation through the recognition of Chapters such as the Asia Pacific Association of Forest Research Institutes (APAFRI) for which the Secretariat is currently located here in Malaysia. In addition, IUFRO has been pro-actively supportive with FAO of other regional activities that seek to encourage cooperation between national institutions, including the Forestry Research Support Programme for Asia and the Pacific (FORSPA) and the Forestry Research Network for Sub-Saharan Africa (FORNESSA), the latter in close collaboration with the African Academy of Sciences (AAS).

Future Challenges

Ladies and gentlemen, I hope you realize from what I have said that IUFRO, led by the Executive Board and ably assisted by the Secretariat (generously supported by the Government of Austria), has flourished in the past five years and successfully responded to the resolutions of the last Congress; the EB itself responded very actively to the challenges I presented to it. As out-going President, it would be easy for me to offer challenges for the next President and Board to consider; among these I would include the following:-

- Continue the development of internationally acceptable standards for research methods.
- Strengthen networking among members.
- Develop GFIS, standardize terminologies and state-of-knowledge reports.
- Forge and enhance linkages between science, policy, management and use of forests, forest products and services.
- Identify and pursue disciplinary and inter-disciplinary research needs.
- Increase membership.
- Reorganize and enhance the Board and Secretariat to ensure financial security, increased support for members and expanded facilities for information dissemination.

Address by

Dr. Abdul Rahim Nik

Chairman of the Congress Organizing Committee

Professor Jeffery Burley, President of IUFRO;
Tan Sri G.K. Rama Iyer, Chairman of the Malaysian Forestry Research and Development Board;
Dato' Dr. Abdul Razak Mohd Ali, Director General of FRIM;
Professor Risto Seppala, President-Elect;
Honoured Guests and Distinguished Delegates;
Ladies and Gentlemen;

I am delighted that we have finally come to the closing of the XXI IUFRO World Congress. For the last 6 days, there has been a hive of activities at this Congress venue, ranging from scientific sessions, satellite and business meetings to exhibitions, receptions and tours. As organizers of this prestigious gathering, we have tried our very best to accommodate all your expectations and respond to your requests in order to ensure that your participation at the meetings and your stay over the last week or so was pleasant and comfortable.

It was five years ago that I was made the Chairman of the COC and given this monumental task of organizing this Congress. I did not have the slightest clue then as to the magnitude of the challenge and responsibility that was being entrusted to me. Three years down the road, we began to actually heat up and to accelerate the organizational pace. Finally, over the last six months before the Congress, we became fully engrossed in the real challenges. I must humbly admit that we have learnt a lot from organizing this Congress. In this regard, the currently available modern technologies have been very valuable and most helpful towards the preparations. I cannot imagine organizing this meeting without the use of the e-mail and facsimile facilities.

While the theme of the Congress "Forests and Society- the Role of Research" had been well elaborated and discussed in many of the technical sessions, we, the organizers also adopted for ourselves a motto in the process of organizing this congress. This motto is, "We are committed to ensuring a memorable and well organized Congress". You may have seen this motto displayed at all our service locations or stations. This simple motto embodies two important messages. Recognizing that this is the first time a Congress of this nature is being hosted by a developing country in more than one hundred years of IUFRO's history, we wanted to ensure that this XXI IUFRO World Congress, held here in Malaysia, will leave a strong, lasting impression and also pleasant memories in the minds of all the delegates who are present here today. Secondly, a large gathering like this Congress needs an efficient and well organized system in order to provide an impact to the participants and to give them their time and money's worth to participate. Charged and entrenched with this motto, we have worked whole-heartedly and with commitment to delivering the goods. It is up to you, distinguished delegates, to judge our performance!

At this closing session, I would like to share with you some important statistics associated with the Congress and some of our observations that may be useful for the next host of the Congress.

The total number of delegates registered for the Congress was 1906, from 96 countries. including the 209 participants who were registered as accompanying persons. We also received encouraging responses for all the tour and excursion programmes. A total of 1127 registered and participated in the nine In-Congress tour programmes on Thursday, and more than 700 persons participated in the Accompanying Persons' Programme. The tour to see the fireflies recorded the highest participation. Immediately after this Congress, a total of 324 delegates will be joining the 12 Post-Congress excursions covering most States in Malaysia and neighbouring countries including Brunei, Indonesia and Thailand over the next few days.

In terms of scientific presentations, most of the planned scientific sessions were conducted as scheduled. In some sessions, where speakers were unable to attend, the moderators were able to invite other participants in the sessions to cover the vacant slots. However, there were a few sessions that had to be cancelled, as none of the proposed speakers were present to expound on their findings. We noted that those who did not turn up were mostly from the developing countries where funding arrangements were a constraint. With regard to Poster presentations, of the 833 posters that were selected for presentation, only 55% of the poster presenters turned up. Most of the poster presenters who did not turn up were observed to be from developing countries that could not secure funds to attend the Congress. In terms of technical support for this Congress, we deployed 120 technical rapporteurs and almost 270 Congress assistants to facilitate its smooth running.

On a lighter note, to meet the needs of the Congress, we had produced about 6.6 million pages of printed matters including the early announcements and publicity materials. I am not sure of the equivalent number of trees that was needed for making these materials available. I sincerely believe that all this was worth the effort.

Allow me now to take a few moments to share my views with all of you on an issue that may be useful and that may be taken into consideration when the next Congress is convened. If a more active participation from developing countries is intended, then more efforts should be placed on securing sufficient funds for the Scientist Assistance Programme. For this meeting, out of the 169 SAP candidates, 91 had been partially and fully sponsored through funds made available by the Government of Malaysia. In my opinion, more efforts have to be focussed on securing sufficient funds from developed countries. This was not very much forth-coming at this Congress with the exception of funds from SPDC and a few countries like the United States of America, United Kingdom, Sweden and Finland. Some serious thought has to be given to this issue by the new Board and the next host.
I have to admit that it had been a great pleasure and a rich experience for us to organize this Congress, I do sincerely hope that this Congress has not only been beneficial to your scientific career but has also been a rewarding and useful experience. In spite of the great efforts we have put in to achieve perfection, there have still been some shortcomings and weaknesses here and there. For these, I seek your forgiveness and pardon. The time has now come for us to hand over the flag to the host of the XXII IUFRO World Congress.

As you may have noted, we have involved many organizations, agencies and sponsors in organizing this Congress. To all of them, I would like to extend by profound thanks and appreciation for all their kind support, cooperation and assistance without which we could not have succeeded in this difficult task. In particular, I wish to thank the Malaysian Forestry Research and Development Board and FRIM and especially their Chairman and DG for their encouragement and support throughout the entire planning and execution of this Congress. To the EB members and the IUFRO Secretariat, Vienna, I extend my sincere thanks for their advice and guidance towards making this Congress a success. Last, but not least, as the Chairman of the COC, I would like to thank all the members of the COC, Sub committees and Congress Assistants. They are the movers who worked strenuously behind the scene to make the Congress a success. Could you all join me in giving them a big hand…

To our overseas friends, I wish you all a pleasant and safe journey home.

BON VOYAGE AND THANK YOU.

Address by

Dr. Risto Seppälä
President-Elect

President Burley;
Your Excellencies, Members of IUFRO's International Council and Executive Board;
Distinguished Guests;
Fellow Scientists;
Ladies and Gentlemen;

It is a great honour for me to accept the election by the International Council to the post of IUFRO President. I promise to use my best efforts to fulfil the high expectations connected with this post.

In his acceptance speech five years ago our current President said that he had always had three ambitions for IUFRO: to have a President from the tropics, to have a World Congress in a developing country and to have a female President. We have now achieved the first two of these goals but if Jeff Burley wanted a female President as his own successor I am not the right person, although I can take the baton from him and bring it forward.

It is customary that an acceptance speech contains some visions of the incoming President's views of the future structure and activities of the organization. Because our current President presented earlier on this occasion an exhaustive list of future challenges, I pick up only two issues that I consider important. They are IUFRO's membership and IUFRO's role as a clearing house for forest research information and expertise.

IUFRO has now some 680 member organizations, which provide our basic funding. In recent years we have received new members, but at the same time too many of our old members are no longer able or willing to pay their fees. When we lose a member organization, we often also lose its scientists because for individuals it is troublesome and expensive to become a IUFRO member.

The time may be ripe to review the whole concept of IUFRO's membership. First we have to ask what we need members for. An obvious reason is money. Although IUFRO is a voluntary organization we would not survive now without membership dues. However, if we have money coming from sources other than from membership dues, do we still need members to fulfil our mission to promote international co-operation in forestry research and related sciences? The answer is yes. We need members also in this case because co-operation is not possible without co-operators, and our member institutions and their people form the best possible international network of co-operators in forest research.

According to a recent study of the European Forest Institute, in Western Europe alone there are more than a thousand institutions dealing with forest-related research. Out of these only 176 are IUFRO members. I guess that in other parts of the world the situation is similar. Thus, the potential for having new organizations join us is perhaps greater than we think. It is up to us how we use this potential to increase our institutional membership. There are many players, who are increasingly assuming important roles in the changing world of today, and with whom IUFRO has not yet established partnerships.

We need better direct links also with individual scientists. The fact that IUFRO is an organization of organizations does not guarantee that all scientists working in our member institutions know about IUFRO or get information about it. For scientists working in non-member institutions, the information flow was earlier practically non-existent. Now the situation has obviously improved considerably as most visitors to our web site and a considerable number of the participants in this Congress do not come from IUFRO's member organizations. To me this is again a sign of an enormous membership potential, because it shows how attractive IUFRO and its Congress are. An important precondition for increasing the number of individual members is that we make it easy for them to join IUFRO, especially for those in non-forestry disciplines. So far, IUFRO has used very modestly the knowledge and expertise of its member network. We have some non-refundable financed special projects and programmes, such as SPDC and SylvaVoc, but what we need to do is to mobilize the whole information and knowledge base of our scientists and experts, a unique but, for the time being, an underexploited resource. Good steps in this direction are the State-of-Knowledge Reports which have been presented here this week, and the Global Forest Information Service of which a prototype has been running during the Congress.

Ladies and Gentlemen,

My own vision for IUFRO is that we should become a clearing house for forest research information and expertise. Our office holders are key persons in this process but they only represent a fraction of our human resources. We must have direct links to all individuals who act in and are related to our research units. After having relevant information on their field of expertise, we will be able to function as a clearing house and respond to the requests of our clients when, for example, they want to know the state-of-knowledge in a specific field of forest research, or, when there is a need to create an international team to find a solution for a timely research problem.

If IUFRO acquires a good reputation as the clearing house of forest research information and expertise, it will greatly increase our visibility. This would appeal to sponsors and clients creating a snowball effect that would also lead to enhancing IUFRO's finances.

Dear Friends,

As the new President I see that one of my most important tasks is to act as IUFRO ambassador, who markets and sells our organization. The international forest sector community needs our expertise, and they are ready to pay for our services. We need marketing also for strengthening our membership. In addition to encouraging our current members to stay with us, we have to find new members, especially those who are outside the traditional forestry sector. An extensive and high-quality membership base is also an important precondition for selling our services to those, who need them and can pay for them.

Although I have now been expressing my views of the way ahead, I wish to spend a minute on the past. In my capacity as the current Vice-President for Programme I want to take this opportunity to thank all IUFRO office holders for your valuable work since the Tampere Congress. My special thanks go to the Congress Scientific Committee and the IUFRO Secretariat for their tremendous input in preparing the scientific programme of this Congress. Finally, I want to extend my gratitude to our Malaysian hosts. Because I was involved in hosting the previous Congress, I know precisely how much you have worked to make this event happen. I congratulate you on a very successful Congress. Saya ucapkan setinggi-tinggi tahniah kepada tuan rumah Malaysia di atas kejayaan kongres ini.

We Finns are known as people of few words - even when we have something to say. We prefer action to speeches, although speeches are also important when pointing the direction to where to go. I shall finish now, but you will hear from me later, perhaps not so much by what I say but rather and hopefully by what I do. Whatever I do for IUFRO, I want to do it together with all of you.

Address by
The representative of the host of the IUFRO Congress in 2005

Prof. Russell Haines

Queensland Forestry Research Institute

With a forty thousand-year history of utilization of forests and their resources in our country, Australians look forward to welcoming forest researchers internationally to the 22nd IUFRO World Congress in Brisbane in 2005.

Australia has a wide variety of forest types, from temperate to tropical to arid zone, and a rapidly expanding plantation estate. In the management of these forests, we face challenges similar to those faced by forest managers internationally and highlighted at this Congress.

Australia's Federal and State Governments have a strong commitment to the wise use of forest resources for the benefit of current and future generations, and recognize that such use must be based upon sound scientific knowledge. We have a strong commitment to participation in international forestry fora. In particular, we have a strong commitment to international scientific cooperation, and are strong supporters of the International Union of Forest Research Organizations. It is with some pride that I mention that it was my good friend and colleague, Dr Garth Nikles, recently retired after a 50 year contribution to forest science, who with Dr Jeff Burley in 1971 initiated IUFRO's first tropical Working Group.

I believe that we live in exciting times for forest researchers. Never before has there been a broader group of stakeholders with such a passionate interest in the management and utilization of forests and their resources. Never before has international cooperation among forest scientists been more important.

We hope that in 2005 we will be able to show delegates some Australian hospitality, and in particular to reciprocate the hospitality shown to us here in Malaysia.

Australian delegates have appreciated greatly the organizational excellence of the 21st IUFRO World Congress in Malaysia. We recognize that our Malaysian colleagues have set a very high standard for us to match, and the organization of Brisbane 2005 will be shaped significantly by the Malaysian experience.

We look forward to linking with the broader international IUFRO community in organizing the 22nd IUFRO World Congress, and to carrying the IUFRO flag forward for the next five years. In particular, we look forward to seeing all of you in Brisbane in 2005.

Closing Remarks by

Professor Jeffery Burley

President of IUFRO

Your Excellencies,
Distinguished Guests,
IUFRO Members, Colleagues and Friends,
Ladies and Gentlemen.

We come now to the formal closure of the 21st IUFRO World Congress in Kuala Lumpur, Malaysia. Although most people are always glad to return to their own homes, I know that many participants here will feel a tinge of sadness at leaving such a lovely country and people and at finishing such a comprehensive programme of exciting and challenging presentations, posters, discussions, exhibits and field visits. They will also regret leaving the old and new friends they have met here but I hope that professional and social contacts will be maintained in the century-old tradition of IUFRO's scientific and personal collaboration.

The organizers of every Congress are always worried at the outset that they cannot compete with the quality or quantity of the previous Congress but I have always believed that Congresses do not have to compete, just be different. After Montreal in 1990, the Finnish organizers of the Tampere Congress in 1995 initially felt that they could not match it but they did. After Tampere the Malaysians felt they could not possibly match it for this Congress in 2000 but I believe they have proved that they could. The quality of the administrative, political and technical arrangements has been superb, and the friendliness of all the supporting staff has been outstanding.

I have walked about the Congress site throughout the week and sought the views of many participants and have encountered none with any major criticisms. We shall see if this is borne out by the responses to the sample questionnaire survey but I am confident that it will be. Nevertheless the Executive Board of IUFRO will be anxious to hear your views after you have returned home and have had time to reflect on all aspects of the Congress.

It is clearly not possible for me to thank all the individuals and organizations that have contributed to the success of this Congress. On your behalf I will therefore thank collectively the Government of Malaysia; the Executive Board of IUFRO; the Congress Steering Committee chaired by Dr Razak; the Congress Organizing Committee chaired by Dr Rahim; the Congress Scientific Committee chaired by Dr Teissier du Cros; the IUFRO Secretariat led by Heinrich Schmutzenhofer; the many staff of FRIM, State and National Forest Departments, and Universities who have helped in so many ways; the photographers, information staff and Professional Congress Organizer's staff; the Press who reported so conscientiously throughout the week; the interpreters without whom the keynote speakers would not have been fully heard; the Master of Ceremonies without whom the opening and closing ceremonies and dinners would have been less efficient and less enjoyable; the sponsors of many participants; and, above all, the participants themselves. As with most activities in life, you get out of an event as much as you put in and I know that the majority of participants entered fully into the spirit and activities of the Congress and consequently gained much personal pleasure and professional benefit.

Personally I thank you all for your continued support over the past five years, particularly my wife Jean and the IUFRO Secretary, Heinrich Schmutzenhofer. Without them I could not have functioned as your President. Luckily I only have to go home with one of them. For the other I have a small present, an Oxford paper clock with the alarm permanently set at 6 p.m. so that he also will know it is time to go home to his equally supportive wife, Edith.

I wish you all safe onward journeys and may your God go with you. I now declare the 21st IUFRO World Congress closed.

Allocutions des cérémonies d'ouverture et de clôture

Allocution de

Dato' Dr. Abdul Razak Mohd. Ali

Président du Comité directeur du Congrès

Monsieur le Ministre, YB. Dato Seri Dr Lim Keng Yaik,
Ministre des Industries primaires
Monsieur le Professeur Jeffery Burley,
Président de l' IUFRO
Chers invités, Mesdames et Messieurs,

C'est vraiment un honneur pour moi d'accueillir vous tous au XXIème Congrès Mondial de l'IUFRO au nom du Comité directeur du Congrès. Nous sommes particulièrement reconnaissants au Ministre honorable des Industries primaires pour avoir accepté l'invitation à inaugurer ce congrès au nom du Premier ministre honorable qui ne peut pas être avec nous ce matin. À tous les délégués et particulièrement à ceux de l'étranger, „Selamat Datang ke Malaysia" ou „Bienvenue en Malaisie".

Au cours de la réunion du Bureau exécutif de l'IUFRO, tenue à Madrid en avril 1995, la Malaisie a offert d'accueillir ce XXIème Congrès Mondial de l'IUFRO à Kuala Lumpur. Ce sentiment de satisfaction éprouvé il y a plus de cinq ans demeure dans mon esprit puisque j'ai été alors confié la tâche de présider la délégation qui a présenté la proposition de Malaisie outre les offres semblables provenant de l'Afrique du Sud, de la Chine et de l'Indonésie.

La Malaisie est très fière d'être le premier pays en voie de développement qui accueille un Congrès Mondial de l'IUFRO. Ce congrès est certainement la plus grande réunion forestière jamais organisée dans le pays. En termes de nombre de participants et de personnes d'accompagnement inscrits, des exposés et des posters pour la présentation, le Congrès surpasse la 14ème Commonwealth Forestry Conference, tenue à Kuala Lumpur en septembre 1993.

Nous remercions le gouvernement de la Malaisie et le Conseil international de l'IUFRO pour avoir confié la responsabilité gigantesque d'organiser ce congrès de l'IUFRO à l'Institut de recherches forestières de la Malaisie (FRIM). Nous désirons remercier le Secrétariat de l'IUFRO à Vienne et le Comité directeur de la recherche forestière de la Malaisie (MFRDB) de leurs conseils et leur appui inestimable. Le Comité d'organisation du congrès (COC) et ses sous-comités ont travaillé de façon très dure pour assurer que les préparatifs du congrès se dérouleront comme prévus.

Mesdames et Messieurs,

C'est avec plaisir que nous vous informons que 1906 participants et plus de 200 personnes d'accompagnement provenant de 96 pays se sont inscrits. Dans les prochains jours 5 exposés principaux, 9 exposés sous-plénieres, 500 exposés de sessions de groupes et 833 posters ainsi qu'une discussion d'experts sur les posters auront lieu. La présentation de posters permettra un échange d'information entre les scientifiques et leurs collègues.

Grâce au Programme d'assistance aux scientifiques (SAP) nous pouvions financer la participation de 138 chercheurs provenant de 38 pays en voie de développement. Le gouvernement de la Malaisie a fourni des fonds financiers pour soutenir encore 31 scientifiques provenant de l'Asie et du Pacifique.

Nous remercions le Ministre honorable des Industries primaires de la Malaisie qui prononcera le discours d'ouverture au nom du Premier ministre. D'autres points culminants de la cérémonie d'ouverture incluront le lancement des timbres commémoratifs du congrès, une présentation culturelle et la présentation des récompenses de l'IUFRO. Nous aimerions également remercier les orateurs principaux pour leurs contributions pendant les sessions plénières.

Mesdames et Messieurs,

J'espère vraiment que le congrès servira de forum où les scientifiques du monde entier puissent discuter le rôle de la recherche et leur relation avec les forêts et la société. Traditionnellement, les forêts ont été considérées comme source de bois d'œuvre. La recherche a en effet joué un rôle significatif en changeant ces perceptions et attitudes en montrant que les forêts fournissent également un éventail d' autres biens et services pour assurer le bien-être de la société.

Veuillez profiter de l'occasion de ce congrès pour discuter des thèmes divers et des besoins de recherche et de forger des collaborations en matière de recherche et de développement. Les réunions avant le congrès, les réunions satellites et les réunions de travail programmées sont destinées à atteindre de tels objectifs.

Tout dit et fait, je vous demande pardon d'avance pour toutes les imperfections dans l'organisation du congrès, au nom du Comité directeur du Congrès et du Comité d'organisation du Congrès. En conclusion, j'espère que vous trouverez le temps pendant les excursions de visiter la Malaisie, pays fascinant et riche en diversité biologique et culturelle.

Merci.

Allocution du

Professeur Jeffery Burley

Président de l'IUFRO

Monsieur le Ministre honorable des Industries primaires,
Dato' Seri Dr. Lim Keng Yaik ;
Monsieur le ministre adjoint honorable ,
Monsieur le Secrétaire Général ,
Monsieur le Président du Comité directeur du Congrès ,
Dato' Dr Abdul Razak,
Monsieur le Directeur Général adjoint de la FAO ,
Dr. Hosny El-Lakany,
Chers invités ,
Mesdames et Messieurs,

C'est mon grand privilège et plaisir de vous accueillir à ce 21ème Congrès Mondial de l'Union Internationale des Organisations de Recherche Forestière (connue largement sous le nom de l'IUFRO). Votre Excellence, nous regrettons beaucoup de ne pas avoir l'honneur de la présence de Monsieur le Premier ministre mais nous comprenons que les affaires d'Etat ont empêché sa participation.

Cependant, nous vous remercions de nous faire le grand honneur de prononcer le discours d'ouverture qui, j'en suis sûr, sera une adresse de bienvenue et d'exhortation. Le thème de notre congrès est « La Forêt et la société : le Rôle de la science » ; cela est particulièrement important car nous écrivons un nouveau millénaire avec des populations humaines croissantes, des besoins croissants sur les produits de la forêt, et une sensibilisation prononcée pour les nombreuses prestations environnementales et sociales que les forêts fournissent. Cela est particulièrement vrai pour la Malaisie, un pays qui possède de vastes et riches ressources de forêt avec leurs services associés, et un pays avec une tradition de recherche réputée dans le monde entier. Nous sommes également très honorés de la présence de son Excellence, M. le Ministre des Industries primaires, Dato'Seri Dr. Lim Keng Yaik . Il a toujours été un penseur et un orateur actif et conscient en matière de recherche forestière et des industries forestières, notamment par rapport à la Malaisie et le Sud-Est Asiatique. C'est avec grand intérêt que nous attendons son discours.

Durant les cinq dernières années il a été toujours un privilège pour moi d'être le président de l'IUFRO et je voudrais profiter de votre attention pour vous raconter un peu de l'histoire et des activités de l'Union. J'aimerais montrer pourquoi ceci devrait être d'intérêt pour une haute personnalité de la vie politique et pourquoi les chercheurs et les décideurs politiques devraient chercher le dialogue.

L'IUFRO fut fondée en 1892 par un nombre restreint de pays européens, et au cours de ses 80 premières années d'existence la plupart des pays tempérés y ont adhéré. C'est seulement en 1971 que le premier groupe de travail traitant un thème spécifiquement tropical a été crée (génétique forestière et amélioration des arbres). Depuis lors l'IUFRO s'est empressée à faire profiter les institutions et les scientifiques dans les pays en voie de développement des avantages d'une collaboration internationale (y compris l'appui à l'APAFRI, au FORNESSA et au Réseau d'Amérique latine) et à les impliquer activement à tous les niveaux de sa gestion. L'Union comporte maintenant presque 700 organisations membres dans 110 pays avec approximativement 15,000 scientifiques travaillant en collaboration et volontairement dans 276 divisions, groupes de recherche et groupes de travail. C'est une organisation internationale, non-gouvernementale, sans but lucratif et multidisciplinaire qui cherche sérieusement à tirer les plus grands avantages de l'investissement que les gouvernements, les industries et les personnes privées font en matière de recherche.

J'aimerais souligner que le travail de l'IUFRO est essentiellement volontaire : pratiquement tous les cadres et coordonnateurs de l'Union et tous les chercheurs déploient des efforts considérables visant le succès de l'IUFRO parce qu'ils croient en la valeur ajoutée de la collaboration. Seulement le personnel du Secrétariat, généreusement financé par le gouvernement de l'Autriche, peut être qualifié de "fonctionnaires permanents" de l'Union. Le personnel contractuel du Programme spécial pour les pays en développement (SPDC) est généreusement financé par le Canada, le Danemark et les Etats-Unis. L'Union européenne et les gouvernements du Japon, de la Suisse et du Royaume-Uni ont aussi accordé une aide financière importante à l'IUFRO. L'IUFRO entretient des relations étroites avec d'autres organisations, en particulier le Conseil International pour la Science, le Centre pour la Recherche Forestière Internationale, l'Organisation des Nations Unies pour l'Alimentation et l'Agriculture et le Centre International pour la Recherche en Agroforesterie . C'est un privilège supplémentaire pour nous que le représentant du Directeur Général de la FAO va prononcer un discours au cours de cette séance d'ouverture.

Tout au long de ce siècle l'Union a encouragé et soutenu des travaux de recherche excellents abordant un éventail de thèmes scientifiques. Pourtant, la recherche est sans valeur une fois conduite indépendamment ; elle devrait être considérée comme partie intégrante du continuum de la recherche pure et appliquée destinée à l'adaptation et à l'application de grande envergure de nouveaux systèmes technologiques et sociaux qui abordent les grandes questions politiques internationales et nationales. A cet effet, l'IUFRO a mis en place des Groupes de réflexion afin d'encourager l'intégration d'une telle recherche et pour améliorer les relations entre les chercheurs et les décideurs politiques. Pour ce congrès de Malaisie qui a lieu dans la première année du nouveau millénaire, les scientifiques de l'IUFRO produiront des bilans scientifiques de connaissance sur beaucoup de questions d'intérêt faisant le point sur l'information actuellement disponible, sur les implications de la gestion de cette recherche, et sur tout besoin en nouveaux travaux de recherche.

Dans la décennie passée on pouvait noter une sensibilisation croissante au niveau de la politique et du grand public quant à l'importance des forêts et des arbres pour le bien-être de l'humanité. Ils fournissent un grand nombre de produits et de services sociaux, environnementaux et économiques au bénéfice de bon nombre de parties prenantes. Outre les livres et les journaux scientifiques, dans la plupart des pays, on note de plus en plus de contributions ayant trait à la forêt dans les journaux et les émissions à la télévision et à la radio. Il y a une interdépendance et souvent une compétition entre les divers produits et services exigés de la forêt. La recherche embrasse beaucoup de disciplines qui ne sont pas naturellement cohésives. L'IUFRO fait des efforts considérables afin d'encourager la collaboration interdisciplinaire entre les sociologues et les biophysiciens.

Le chiffre 2000 est un joli chiffre rond, du moins si vous appliquez le système décimal. Il est également fortement significatif dans certains calendriers religieux. Pourtant, il est totalement significatif pour tout être vivant et pour les milliards d'hommes pas encore nés car c'est l'année dans laquelle les agences internationales, les gouvernements nationaux, les organismes sociaux civils, les éducateurs, les chercheurs, les entreprises et les gestionnaires de ressources ont dû réaliser le besoin urgent de développer la gestion des ressources du monde d'une façon raisonnable, équitable, moralement impeccable et durable. Les forêts et les arbres joueront un rôle important dans un tel développement durable et l'IUFRO continuera à faire de son mieux pour encourager la recherche et les chercheurs à aborder les questions pertinentes et à présenter leurs résultats de sorte que les décideurs politiques et toutes les parties prenantes puissent les comprendre et appliquer. Le Bureau exécutif de l'IUFRO estime que ce congrès contribuera de manière décisive à cette approche.

Votre Excellence, tout participant au XXIème Congrès Mondial de l'IUFRO est extrêmement reconnaissant au gouvernement de la Malaisie et à la ville de Kuala Lumpur pour l'accueil chaleureux, l'hospitalité amicale et généreuse, et pour l'organisation des excursions intéressantes et agréables dans votre beau pays dont peuvent profiter les scientifiques et les personnes qui les accompagnent. Par rapport à l'organisation je tiens à souligner que le personnel de l'Institut de recherche, les Services des forêts et quelques universités et d'autres institutions ont travaillé durement pour appuyer l'IUFRO dans cet effort quinquennal. Ayant peur que cela a eu des conséquences pour la recherche en Malaisie je suis d'autant plus inquiet que les activités de recherche s'arrêtent complètement puisque les collaborateurs administratifs et scientifiques de l'institut sont devenus des organisateurs de congrès et de circuits touristiques.

Votre Excellence, nous vous prions maintenant d'inaugurer ce XXIème Congrès mondial de l'IUFRO et de partager avec nous votre avis du rôle et des besoins en recherche forestière. Je vous invite aussi à nous faire l'honneur de conférer le titre de membre honoraire, la distinction la plus haute de notre Union, à deux hauts cadres de l'IUFRO.

Allocution de

Y.A.B. Dato' Seri Dr. Mahathir bin Mohamad

Premier Ministre

prononcée par

Dato' Seri Dr. Lim Keng Yaik

Ministre des Industries primaires, Malaisie

Monsieur le Professeur Jeffery Burley , Président de l'Union Internationale de Recherches Forestières.
Monsieur le Secrétaire Général du Ministre des Industries primaires, Datuk Haron Siraj, Malaisie
Monsieur le Président du Comité directeur du Congrès, Dato' Dr. Abd. Razak Mohd Ali,

Chers invités, Mesdames et Messieurs,

Permettez-moi tout d'abord, de remercier les organisateurs de cet important congrès forestier qui m'ont invité à prononcer ce discours d'ouverture au 21ème Congrès Mondial de l'Union internationale des organisations de recherche forestière. J'aimerais aussi souhaiter la bienvenue à tous nos invités et participants en vous souhaitant des réunions couronnées de succès et un séjour agréable en Malaisie.

Autant que je sache, l'IUFRO est une organisation non-gouvernementale à but non lucratif, fondée en 1892, il y a plus de cent ans, et sa mission est de promouvoir la coopération internationale en matière de recherche forestière et sciences connexes. L'IUFRO compte environ 700 organisations membres dans 105 pays, et c'est la première fois que le congrès a lieu dans un pays en voie de développement. De ce fait, c'est ma tâche de féliciter les organisateurs pour avoir gagné le concours pour accueillir ce Congrès Mondial à Kuala Lumpur et pour avoir entrepris les préparations nécessaires qui nous ont permis à nous réunir ici à l'occasion de l'événement forestier le plus grand jamais organisé dans ce pays. J'espère que cela sera le début d'une série d'autres congrès qui se tiendront dans des pays en voie de développement.

Nul n'ignore que les forêts jouent un rôle majeur dans l'existence des peuples de beaucoup de pays en voie de développement tout en contribuant de manière significative au progrès économique de ces nations. Je suis extrêmement content que la Malaisie a ouvert la voie pour les pays en voie de développement de faire des offres pour organiser un tel congrès, puisque les thèmes forestiers concernent de plus près un grand nombre d'hommes et femmes dépourvus et pauvres dans le monde entier. Dans ce contexte, j'aimerais féliciter l'IUFRO pour avoir choisi un thème approprié, à savoir: la forêt et la société : le rôle de la science.

Mesdames et Messieurs,

J'enfoncerai des portes ouvertes si je vous parlais maintenant des rôles et des fonctions de la forêt. C'est vous qui sont les experts en cette matière. Vous savez très bien que les forêts ont été considérées toujours séparément des peuples qui habitent dans ou au bord de la forêt et que les forêts ont été considérées seulement pour le bois qu'elles fournissaient. Cependant, depuis des années on note une tendance vers la reconnaissance que les forêts et la société, tant rurale et urbaine, sont deux côtés de la même monnaie et qu'à part du bois, la forêt fournit une série de biens et de services importants pour le bien-être de la société.

Mais quelles sont les leçons que nous avons tirés de ce passé pas si lointain, des leçons qui ont déclenché ce changement de perception et qui ont marqué le début du débat international sur les forêts? Nous savons tous que lors du démarrage de la révolution industrielle au début du 19ème siècle, une grande partie des forêts tempérées de l'Europe, déjà décimées au cours des siècles précédents a été coupée pour fournir le bois nécessaire au processus de l'industrialisation. De grandes surfaces de forêts ont également été déboisées de l'autre côté de l'océan, aux Amériques, au cours du 19e siècle. Dans quelques décades seulement, des millions d'hectares de forêt ont été détruits pour gagner des pâturages et cultures, du bois d'œuvre et du bois de chauffage.

La révolution industrielle dans les pays occidentaux a provoqué des effets néfastes pour l'environnement. La pollution atmosphérique et des eaux ainsi que la dégradation du sol sont devenues plus importantes. La croissance économique initiée à grand pas après la Seconde Guerre Mondiale dans les pays maintenant développés a provoqué une dégradation continue de l'environnement. La Conférence des Nations Unies sur l'Environnement Humain tenue en juin 1972 à Stockholm n'a pas laissé de traces. Cependant, la dégradation de l'environnement continue comme avant. Le réchauffement du globe, la diminution de la couche d'ozone, la pollution des eaux marines, la pluie acide, le déboisement et la dégradation des sols - en grande partie conséquences des activités industrielles - sont devenues des causes importantes de préoccupation au début des années 80.

Dans ce contexte, la Déclaration de Langkawi sur l'Environnement issue de la réunion du Commonwealth des dirigeants de gouvernements (CHOGM) tenue à Kuala Lumpur en octobre 1989, a préparé le terrain pour un concept qui a pris forme au cours des réunions internationales subséquentes. La notion d'une "terre verte" sera désormais inscrite en tant que principe dans la Déclaration de Paris du 10ème Congrès Forestier Mondial tenu en 1991. Par conséquent, lors de la Conférence des Nations Unies sur l'Environnement et le Développement (CNUED) à Rio de Janeiro, en juin 1992, la Déclaration de Principe sur les forêts acceptée par tous les gouvernements traduit complètement cette notion.

Dans ce contexte, juste avant le Sommet de la Terre à Rio, la Malaisie a notamment proposé de porter la surface forestière mondiale qui était de 27.6 % à l'époque, à 30 % d'ici l'an 2000, et cela à l'aide de puissants programmes de reboisement à l'échelle mondiale. Nous avons envisagé que cette augmentation couvrirait tous les types de forêt - boréale, tempérée et tropicale – puisqu'il n'y a pas de différence dans la manière avec laquelle les forêts accumulent le carbone, stabilisent le climat, protègent l'environnement, conservent la diversité biologique, fournissent des ressources industrielles et la base de l'existence des communautés qui vivent dans et au bord de la forêt. Nous avons aussi pensé que les pays développés avec peu de surfaces boisées, ce qui est la conséquence de la mauvaise exploitation au cours des siècles écoulés, mais qui disposent maintenant des économies viables, de vastes ressources et du savoir-faire technologique, partageront nos efforts pour une "terre verte". Nous avions envisagé en plus, peut-être dans notre naïveté, que ces pays possédant de puissantes économies réuniront leurs vastes ressources pour la mise en œuvre des programmes de boisement et de reboisement dans les pays les plus pauvres du monde.

Cependant, huit ans après Rio, on note 'business as usual.' Toute euphorie engendrée par Rio s'est évaporée virtuellement du jour au lendemain. Aucun mouvement concerté pour une terre verte est né, même pas sous forme embryonnaire. Chaque nation a été pratiquement laissée à son propre chef pour mettre en œuvre ses programmes de reboisement. On m'a informé que, selon l'Agenda 21, le coût annuel moyen pour mettre en œuvre les programmes de reboisement a été estimé à US$32 milliards. Une partie importante devrait venir des pays développés. Malgré le fait que l'Agenda 21 et la Déclaration des Principes sur les forêts ont fourni le cadre pour renforcer la coopération des pays il s'est avéré que la plupart des fonds requis pour des programmes de reboisement devraient être trouvés par les pays en voie de développement eux-mêmes.

La Malaisie a toujours été et reste toujours proactive en ce qui concerne les questions globales au sujet des forêts et de l'environnement. Nous avons participé activement aux négociations menant à l'CNUED, y compris l'Agenda 21, le Rapport des Principes sur les forêts, la Convention sur la Diversité Biologique et la Convention-cadre sur les changements climatiques, et nous avons continué à participer activement aux développements depuis Rio. Nous préconisons le concept de la terre verte, bien que les forêts aient été détruites pendant la période de l'occupation coloniale dans le but de planter des cultures de rente.

Néanmoins, les forêts naturelles couvrent toujours environ 58% de notre terre. La couverture forestière est de 72% de la surface du pays, y compris les plantations du gommier et du palmier à huile. Nous avons mis en gage et continuerons à confirmer cet engagement, que cette couverture de forêt se stabilise à un niveau minimum de 50% de la surface à perpétuité. Cela sera notre contribution pour l'humanité.

À cet égard, nous nous sommes également efforcés de renforcer la sylviculture pratique, conformément au concept de la gestion forestière durable, par exemple, nous avons augmenté notre patrimoine forestier de 12,7 millions d'hectares à 14,1 millions d'hectares, nous avons révisé la politique nationale de sylviculture en 1992 et nous avons modifié la Loi nationale forestière en 1993, renforçant ses dispositions et prévoyant des pénalités plus strictes pour des réfractions en forêt. Nous augmentons nos efforts dans la recherche et le développement dans tous les domaines appropriés de la sylviculture, y compris des efforts de développer les industries du bois de manière durable. A l'échelle régionale, la politique nationale sur la diversité biologique, approuvée en 1998, fournira des conseils pour l'économie de la diversité biologique et de l'utilisation durable de ses composants.

Sur le plan international, nous avons continué à contribuer au processus du Groupe d'experts intergouvernemental sur les forêts (IPF) et du Forum intergouvernemental sur les forêts (FIF). Nous participons activement à la mise en place de la Convention sur la Diversité Biologique et de la Convention sur les changements de climat, tous les deux portent directement sur des thèmes forestiers.

Nous reconnaissons que le secteur forestier est important pour l'économie et la société d'une nation, aussi bien que pour l'environnement national et mondial. En conséquence, c'est devenu une question dominante aux ordres du jour forestiers locaux et nationaux notamment en ce qui concerne la mise en place d'un instrument législatif en matière forestière. Nous connaissons très bien les arguments qui n'ont pas permis qu'un tel instrument soit discuté largement; le problème d'un instrument législatif en matière forestière n'est pas encore résolu. Nous ne sommes pas plus près d'un tel instrument qu'avant.

La position de la Malaisie est telle qu'un instrument législatif obligatoire qui porte sur tous les types de forêts est nécessaire pour adresser une vaste gamme de thèmes forestiers d'une façon holistique, intégrée et complète. Nous croyons qu'un instrument légal faciliterait le développement d'une gestion durable pour toutes les forêts, par rapport aux solutions « ad hoc » qui peut être un obstacle à la mise en place de meilleures pratiques en matière de sylviculture. Nous croyons également qu'un tel instrument encouragerait les actions à niveau international destinées à adresser les facteurs responsables de la diminution et la dégradation de forêts telles que la dette internationale et la surconsommation. Un tel instrument encouragerait et accélérait la coopération dans le domaine du transfert de la technologie.

Actuellement, le manque de consensus sur la nécessité d'un instrument législatif obligatoire est dû à l'impasse au sujet des questions critiques telles que le financement, le transfert technologique et le commerce. À cet égard, je voudrais inviter les pays développés à réaffirmer et à réaliser leurs engagements pour fournir l'aide financière et les technologies concrètes aux pays en voie de développement en vue du développement de la gestion durable de leurs forêts. En outre, la gestion forestière durable devrait être encouragée à travers des pratiques commerciales plus souples et des normes environnementales. Les restrictions commerciales et environnementales ne réduiront pas le déboisement. Elles rendront la forêt inutile et auront comme conséquence que la forêt se voit détruite pour d'autres buts. En fait, un plus grand accès aux marchés aidera à favoriser la gestion forestière durable en fournissant les revenus si importants à cette fin.

La dépendance de la société à l'égard de la sylviculture remonte à la nuit des temps, quand la société était primitive avec des besoins simples. Dans beaucoup de parties de la terre, et notamment dans les pays en voie de développement, les besoins sociaux sont demeurés toujours simples. Ailleurs, le développement et les modes de vie gaspilleurs ont rendu souvent insatiables les besoins des sociétés. Mais, ces besoins ne sont pas simplement matériels, par conséquent il faut absolument appliquer la maxime que les ' ressources et les terres forestières devraient être gérées de façon durable pour répondre aux besoins humains sociaux, économiques, écologiques, culturels et spirituels des générations présentes et futures'.

Je suis content d'avoir l'occasion de rencontrer vous tous aujourd'hui et de vous parler lors de ce Congrès qui réunit des scientifiques ayant consacré leur vie directement ou indirectement à la recherche forestière. Ils contribuent aux besoins sociaux du présent aussi bien que du futur. L'histoire récente a prouvé que d'investir dans la recherche et le développement dans n'importe quel domaine peut entraîner des bénéfices importants. C'est mon souhait sincère que vos efforts aboutiront aux bénéfices qui amélioreraient le sort de la société dans l'ensemble, et des faibles de la société en particulier. Vous représentez les pays développés et en voie de développement du monde et c'est l'IUFRO qui assure la liaison Nord-Sud.

À cet égard, j'espère que vos efforts aideront à établir un ordre du jour plus équitable sur le plan forestier sur la scène internationale, par lequel les technologies que vous développez dans vos efforts soient partagées équitablement avec les pays en voie de développement pour améliorer les pratiques en matière de sylviculture globalement. Si le monde doit réaliser la gestion forestière durable, le transfert de la technologie du Nord au Sud à conditions préférentielles comme convenu à Rio doit être réalisé. Malheureusement, cela n'a pas été ainsi et les pays en voie de développement sans avoir accès à ces technologies, ne pourront pas assumer leurs responsabilités concernant la gestion forestière durable, cela n'apporte rien à personne. L' IUFRO joue donc un rôle important pour faciliter ce transfert de technologie. J'espère que ce congrès aidera non simplement à encourager un échange des expériences scientifiques mais qu'il développera également des réseaux plus concrets qui serviront des liens pertinents pour le transfert de la technologie en direction Nord-Sud. Donc, je vous souhaite que vos efforts soient couronnés de succès et que vous aurez un congrès productif.

En conclusion, laissez-moi saluer les délégués de ce congrès. J'espère que vous trouverez le temps au cours des excursions d'admirer non simplement la biodiversité de nos forêts tropicales mais de faire aussi la connaissance de la société multi-ethnique, multi-culturelle et multi-religieuse de notre pays. En Malaisie vous verrez l'Asie.

Ceci dit, j'ai le grand plaisir de déclarer ouvert le XXIème Congrès Mondial de l'IUFRO.

Allocution du

Professeur M. Hosny El-Lakany

Directeur Général Adjoint,
Département des Forêts, FAO

Chers invités,
Monsieur le Président,
Chers membres du Bureau exécutif de l'IUFRO,
Mesdames et Messieurs,

Au nom du Directeur Général et du personnel de l'Organisation pour l'Alimentation et l'Agriculture des Nations Unies, et tout particulièrement au nom de mes collègues du Département des Forêts, j'aimerais saluer cordialement tous les participants à ce 21ème Congrès Mondial de l'IUFRO. Il est pour moi un grand plaisir et un grand honneur d'être avec vous aujourd'hui, ici à Kuala Lumpur!

Tout d'abord, j'aimerais féliciter les organisateurs du Congrès et tout particulièrement nos hôtes Malaysiens pour leur organisation magnifique. Certainement, la Malaisie, avec sa longue tradition dans la recherche forestière, contribuant au développement est le cadre approprié pour un rassemblement tellement impressionnant.

En regardant autour de moi je vois un groupe divers et éminent de participants et je me rends ainsi compte de la valeur de l'IUFRO en tant qu'organisation. L'IUFRO offre aux scientifiques et chercheurs forestiers les moyens pour partager l'expérience et le savoir et ceci aussi bien pour avancer la cause d'une gestion forestière durable que celle de leur développement individuel. L'opportunité pour les jeunes scientifiques au début de leur carrière d échanger des idées et de profiter des membres savants de l'Union est sans égal et la possibilité d'exploiter des résultats des recherches du monde entier est d'une valeur immense. Combien parmi nous, présents aujourd'hui ici, n'ont pas saisi cette occasion unique?

Pour moi je peux le dire, c'était ainsi. Je me souviens très bien de ma première participation à un congrès de l'IUFRO – c'était en 1976 à Oslo, et de ma rencontre avec beaucoup de chercheurs forestiers dont quelques-uns sont heureusement avec nous aujourd'hui. Une partie de ma thèse de doctorat s'est appuyée sur la collection des semences réalisée sous l'égide de l'IUFRO – la collection de provenances de sapin de Douglas de 1966.

Ainsi, c'est un grand honneur pour moi de représenter la FAO lors de cette réunion importante – le premier Congrès Mondial de l'IUFRO du nouveau millénaire. L'IUFRO entretient des relations étroites avec ses membres, et les relations avec la FAO sont également uniques. A l'échelle institutionnelle, la FAO et l'IUFRO avaient entretenu des relations faisant preuve de coopération et de symbiose depuis la création de la FAO – l'IUFRO étant, bien entendu, « la sœur aînée" de près de presque d'un demi siècle. L'IUFRO établit des liens entre scientifiques et chercheurs et la FAO contribue à établir des liens entre l'IUFRO et le terrain, assurant ainsi que les résultats précieux de la recherche forestière soient appliqués – et les impulsions venant du terrain soient transmises aux chercheurs.

A la FAO, tous les fonctionnaires forestiers ont des contacts directs et continus avec l'IUFRO et ses groupes de travail et de recherche. En outre, à travers son programme de partenariat, la FAO facilite les visites et la communication directe entre personnel universitaire, chercheurs et tout particulièrement jeunes professionnels qui n'auraient pas autrement l'opportunité de partager l'expérience et l'expertise avec leurs collègues. De plus, la FAO, à travers son rôle de forum neutre, aide les pays à identifier conjointement les domaines où il faudrait des travaux de recherche supplémentaires, et de concentrer ainsi les efforts des scientifiques forestiers à l'échelle mondiale. Je suis toujours content de voir des scientifiques et chercheurs forestiers parmi les délégués nationaux dans les réunions bisannuelles du Comité des Forêts de la FAO. Ainsi, le flux d'informations et du savoir à travers les réseaux multiplies est assuré entre la FAO et l'IUFRO, au bénéfice de tous les intéressés.

Aux yeux de la FAO, le thème de ce Congrès « La forêt et la société : le rôle de la recherche » est particulièrement approprié. Dans son travail en matière de recherche forestière, la FAO se voit complètement engagée à une approche basée sur la mise en valeur maximale des bienfaits environnementaux et économiques de la gestion forestière durable. En effet, cet engagement est clairement inscrit dans la Stratégie pour les Forêts de la FAO, élaborée pendant plus de deux ans, en collaboration avec les pays membres de la FAO, les instituts et organisations partenaires, y compris l'IUFRO, et approuvée par le Comité des Forêts de la FAO en mars 1999. Le plan stratégique des forêts de la FAO décrit la mission, les buts, les objectifs à moyen terme, les activités actuelles prioritaires et sa vision pour le secteur forestier. Sa mission est "d'accroître le bien-être de l'humanité par l'appui aux pays membres pour développer une gestion durable des arbres et forêts du monde entier »." Ce sont les hommes et la société qui viennent en premier.

Nous aussi, nous concentrons nos activités prioritaires sur les forêts et la société. Nos efforts en matière de foresterie villageoise et participative ont pour but d'associer directement une partie plus grande de la société aux prises de décisions en gestion des forêts. Je devrais ajouter que l'objet de ces préoccupations sont non seulement ceux qui vivent dans et aux environs des forêts mais aussi ceux qui dépendent des ressources et produits forestiers.

Une autre priorité de la FAO ayant trait directement aux forêts et à la société, est notre appui aux pays pour poursuivre leurs programmes forestiers nationaux. Ces programmes – reconnus par les processus intergouvernementaux issus du CNUED – visent à établir un cadre social et politique propice pour la conservation, la gestion et le développement durable de tous les types de forêts.
Un troisième champ d'action du volet "forêts" de la FAO est la promotion de l'accès à l'échelle mondiale aux informations forestières fiables et actuelles. Le premier Article de la Constitution de la FAO nous donne le mandat de « Recueillir, analyser, interpréter and diffuser l'information." En matière forestière, cela implique le développement des termes communs et des définitions, l'harmonisation des définitions, la collection des statistiques sur la production, la consommation et le commerce, et notre évaluation des ressources forestières mondiales. Dans tous ces domaines, nous coopérons étroitement avec l'IUFRO. Pour cette raison, il est particulièrement important de lancer les premiers résultats de l'évaluation des ressources forestières 2000 de la FAO ici et à ce Congrès. J'aimerais aussi mentionner les pages forestières de notre site Web qui est très important et aussi la collaboration entre FAO et l'IUFRO dans le développement du Service mondial de l'information forestière.

Un autre domaine important est la collaboration de la FAO/IUFRO avec le Programme spécial pour les pays en développement – le SPDC. Il y a un mois, le sept juillet, le Réseau forestier de recherche pour l'Afrique subsaharienne (FORNESSA) fut crée officiellement et le premier président, Dr. Konuche du Kenya, fut nommé. Dans ce contexte, je suis heureux de voir que le Coordonnateur adjoint du SPDC s'est installé dans le Bureau régional de la FAO pour l'Afrique – ce qui est la garantie pour la continuation des relations avec la FAO.

Lors de ce Congrès, les collaborateurs de la FAO présenteront de nombreux exposés, et beaucoup de séances ont été co-organisées avec la participation de la FAO.

J'espère que par ces exemples donnés, il en ressort clairement que la FAO s'est engagée à long terme à maximiser les relations positives entre foresterie et société. Le thème de ce Congrès suggère que l'IUFRO et ses membres aillent dans cette direction.

Comment la FAO imagine le rôle de la recherche en poursuivant ce chemin? Certainement, il faut se concentrer encore plus sur les aspects sociaux d'une gestion forestière durable. Nous avons besoin de savoir plus comment on aborde ou peut aborder la gestion forestière et en particulièrement pour ce qui est des instruments et des développements scientifiques dont on a besoin pour assumer cette responsabilité plus efficacement.

Nous avons aussi besoin de plus de recherche sur la diffusion de l'information aux populations pour leur permettre de participer activement aux processus de prise de décision. Il faut aussi des travaux de recherche plus spécialisés concernant les questions de maîtrise des conflits.

Il faut que nous étudions le potentiel et les modalités de la coopération internationale en matière forestière. La décennie passée a vu une pléthore d'accords internationaux qui sont en relation directe avec le futur de la foresterie mondiale mais pour les responsables chargés de la mise en œuvre il s'agit là vraiment du nouveau terrain. Nous devons étudier, analyser et tirer des leçons des expériences des autres secteurs qui se sont lancés sur ce chemin avant nous, de sorte que les accords que nous concluons pour ces ressources soient en même temps raisonnables dans leur ampleur et noble dans l'intention.
Ce sont des véritables défis qui nous attendent, et ils sont d'autant plus intéressants par le fait qu'ils doivent compléter et non pas seulement substituer la recherche forestière traditionnelle. A mon avis, ils sont essentiels si nous voulons atteindre notre objectif commun ce qui est l'utilisation durable des écosystèmes forestiers. Et je pense qu'il y n'a pas une autre organisation plus appropriée que l'IUFRO à faire face à ces défis.

En conclusion, Mesdames et Messieurs, j'aimerais féliciter personnellement le Bureau exécutif et le Président sortant en particulier – qui est un collègue proche et un ami cher, le Professeur Jeff Burley, pour la direction compétente et forte. Et permettez-moi aussi d'exprimer ma confidence dans le Bureau et le Président, le professeur Risto Seppälä désigné, et de saluer tout cordialement les anciens présidents, et notamment le Dr. Salleh Mohd Nor.

Monsieur le Président, au nom du Directeur Général de la FAO, Jacques Diouf, et à mon propre nom, et tout particulièrement au nom du Programme des Forêts de la FAO, j'aimerais exprimer nos espérances sincères pour un Congrès couronné de succès, et pour un démarrage sans problèmes de la foresterie mondiale dans ce nouveau millénaire.

Merci.

Rapport quinquennal Séance de clôture Allocution du

Professeur Jeffery Burley
Président de l'IUFRO

Chers invités,
Chers collègues,
Mesdames et Messieurs,

Arrivant à la fin de ce congrès impressionnant qui a donné bien des résultats je vous parlerai brièvement en tant que président actuel et le professeur Risto Seppälä vous adressera quelques mots en tant que président désigné. J'aimerais faire le point sur les acquis que l'IUFRO a réalisé pendant les cinq années de ma présidence tandis que le professeur Seppälä vous tracera les grandes lignes de sa vision de futurs développements dans la recherche forestière et dans l'IUFRO.

Les Résolutions de 1995 et les défis
Lors du 20ème Congrès en 1995 les résolutions suivantes ont été adoptées : a) maintenir et renforcer la recherche appliquée à la forêt et aux produits forestiers ; b) accroître le potentiel de recherche, surtout dans les pays en développement, c) étendre le partenariat pour améliorer l'efficacité de la recherche en vue d'une meilleure communication entre la communauté scientifique et l'extérieur ; et d) encourager une recherche adaptée à la demande sociale. Lors de mon élection à la présidence de l'IUFRO j'ai proposé au Bureau exécutif une vue personnelle du rôle de l'IUFRO, du développement et des activités et j'aimerais vous en parler brièvement en montrant comment l'IUFRO a répondu à ces défis et aux résolutions du Congrès.

Je faisais alors état des changements importants qui se sont produits en politique forestière, en pratiques forestières et dans le métier du forestier. Les thèmes forestiers ont connu une expansion au niveau mondial et international avec une contribution toujours plus grande d'individus et d'institutions qui ne sont pas des forestiers traditionnels. Les sciences socio-économiques ont contribué encore plus aux processus de prise de décision. On notait une pression internationale pour évaluer le rôle des forêts en vue des services rendus et de surveiller sa condition. Les responsables ont cherché à recueillir (a) des informations sur les rôles, les valeurs et la condition des forêts et des arbres relatifs à leur conservation et leur évolution, (b) des vues sur les relations entre les forêts, la biodiversité, le climat et d'autres thèmes ayant trait à l'environnement, et (c) des conseils sur la gestion forestière durable, y compris des thèmes se rapportant au renforcement structurel.

Déjà en 1995, j'ai pensé (et je le pense toujours) que l'IUFRO devrait répondre à ces changements tout en conservant son rôle primaire de réseau de scientifiques volontaires membres de l'Union. Elle devrait continuer à être la source principale de connaissances et d'expériences en recherche forestière dans des sujets spécialisés tout en augmentant la coopération interdisciplinaire au sein de l'Union et avec des organisations et disciplines n'étant pas des membres traditionnels.

Ces relations ont également donné de la publicité au travail de l'IUFRO, elles ont assuré sa pérennité pour être à la page des besoins modernes, elles ont identifié des ressources pour la recherche, et recherché la collaboration productive tout en réduisant au minimum la duplication inutile. L'identification des besoins émergents par le Bureau exécutif s'est avérée essentiel et a été facilitée par l'établissement des liens forts avec bon nombre d'autres organismes. L'IUFRO a essayé de soutenir les directeurs des organisations membres eux-mêmes en encourageant des travaux de recherches orientés vers la politique et en aidant les directeurs à attirer l'attention des gouvernements et des agences sur les forêts et sur la recherche forestière.

Le nouveau rôle de l'IUFRO sur le plan international
Le Bureau exécutif n'a ménagé aucun effort pour afficher l'existence, les activités et l'importance de l'IUFRO. La brochure largement acclamée a été lancée au Congrès Forestier Mondial pendant 1997 et le site Web également réputé contient les pages d'accueil pour toutes les unités de recherches qui sont reflétées sur des serveurs dans plusieurs pays et jointes à ceux de beaucoup d'autres instituts. Beaucoup de ces sites incluent des pages pour accueillir des bilans scientifiques de connaissances dans les disciplines particulières des unités de recherche ; comme vous avez pu noter pendant ce congrès, l'accent a été mis sur la diffusion des résultats de recherche et des bilans scientifiques de connaissances.

Nous avons également essayé à renforcer le rôle de l'Union dans les discussions et les développements internationaux. Des cadres de l'IUFRO ou moi-même ont assisté aux réunions suivantes: - le Groupe d'experts intergouvernemental des forêts (IPF) ; le Forum intergouvernemental des forêts (IFF) ; le Forum mondial des forêts ; le Congrès forestier mondial ; le Comité sur les forêts de l'Organisation des Nations Unies pour l'Alimentation et l'Agriculture (COFO/FAO) ; l'Assemblée générale de l'UICN ; les réunions variées de plusieurs initiatives destinées à développer des critères et indicateurs pour la gestion forestière durable ; le Comité directeur du Centre international de la Recherche Forestière Internationale (CIFOR) et le Centre international pour la Recherche en agroforesterie (ICRAF) ; le Centres Week du Groupe consultatif pour la recherche agronomique (CGIAR) ; l'Exposition nationale à Kunming, Chine ; et plusieurs réunions et expositions d'autres organisations. En particulier, nous avons été satisfaits de voir les recommandations émanantes de la 4e Séance du Forum Intergouvernemental des Forêts (IFF) demandant le renforcement des liens entre la science de forêt et les politiques forestières, la mise à disposition des ressources financières pour la recherche forestière (aux pays en développement en particulier), l'amélioration de l'accès à l'information forestière et aux disciplines connexes et la collaboration avec l'IUFRO et le Service mondial d'information forestière (GFIS).

Le Projet spécial de l'IUFRO sur la terminologie (SilvaVoc), coordonné par Renate Prueller, et appuyé par le Japon, a signé un contrat avec la FAO pour fournir les définitions des termes principaux de la gestion forestière durable utilisés au cours des discussions internationales. Je suis content que mon propre institut pouvait représenter à l'IUFRO en préparant un document sur les aspects politiques de la recherche forestière, financé par l'Agence de développement d'outremer (ODA) du Royaume-Uni (maintenant le Département pour le développement international) pour la Commission mondiale sur les forêts et le développement durable.

L'Union a également encouragé les unités de recherches à se pencher sur les questions spécifiques en relation avec les préoccupations sur le plan international. Une contribution exceptionnelle de l'IUFRO aux processus internationaux était son rôle dans l'organisation et dans la diffusion des informations sur la Consultation internationale sur les systèmes d'information et la recherche forestière (ICRIS) tenue grâce à l'appui financier des gouvernements de l'Autriche et de l'Indonésie, en coopération avec le CIFOR et le Département forestier de la FAO. Cette conférence était une activité à l'appui du forum intergouvernemental sur les forêts (IFF) de la Commission des Nations Unies sur le développement durable (UNCSD) et a eu lieu en Autriche en septembre 1998. Ses retombées principales sur l'IUFRO étaient la mise en place du Groupe de réflexion sur le Service mondial de l'information forestière (GFIS) et du Groupe de réflexion de l'Interface entre sciences forestières et politiques forestières.

La structure améliorée de l'IUFRO et ses activités

Le rôle primordial de l'IUFRO a continué à être le rehaussement de la valeur de la recherche par son réseau de presque 700 organisations membres et de 15,000 scientifiques qui travaillent dans des domaines spécifiques ; les 268 Unités de recherche et les 8 groupes de réflexion ont tenu 335 réunions dans 65 pays, dont 41 étaient des pays en développement ou des pays défavorisés. Deux nouvelles divisions ont été créées au début du mandat du Bureau pour identifier l'ampleur des activités de recherches et pour réduire la charge de travail sur les coordonnateurs de divisions et leurs adjoints (qui, comme tout fonctionnaire de l'IUFRO, sont des volontaires). Le Bureau exécutif a établi un certain nombre de programmes spéciaux, de projets et de groupes de réflexion pour aborder des sujets ou des questions particulières. Dans un discours court il n'est certainement pas possible de fournir des détails ou même des sommaires adéquats de tout mais je sélectionnerai quelques points importants culminants.

Comme mentionné ci-dessus, l'un des changements principaux de la dernière décennie a été le besoin croissant d'approches interdisciplinaires pour résoudre les problèmes au niveau scientifique et social. L'IUFRO s'efforce sans cesse de couvrir tous les domaines scientifiques au sein des unités de recherche biophysique et socio-économique. Dans les cinq années écoulées nous avons encouragé l'interaction entre les divisions par des réunions interdivisionnaires, la collaboration avec d'autres organismes, et par les activités des Groupes de réflexion. Nous tous devons identifier les difficultés impliquées dans la compréhension mutuelle de la discipline scientifique de l'autre et d'obtenir la reconnaissance professionnelle pour un tel travail multidisciplinaire, mais c'est clairement un besoin exception nel.

Les Divisions

Une réunion importante sur les écosystèmes forestiers et l'utilisation des terres en montagne a eu lieu à Séoul, Corée, en 1998, organisée par les Divisions 1,4, 6 et 8 ; cet événement a réuni 350 participants de 24 pays. Le Groupe de recherche 1.17.00 (Réhabilitation des stations dégradées) a été étroitement impliqué dans le programme de recherche international financé par le Service forestier USDA, la Banque mondiale, le CIFOR et la British Overseas Development Administration qui ont examiné le rôle et les implications des plantations en accélérant la régénérations naturelle de la forêt naturelle sur les terres tropicales dégradées.

La Division 2 a organisé une importante réunion sur la génétique forestière à Beijing en 1998 et son Groupe de travail 2.04.06 a tenu une réunion sur la modification génétique à Oxford en 1999. Cela a montré l'intérêt continu de l'IUFRO pour les questions actuelles d'importance publique et politique. Les participants à ces réunions étaient tous d'accord qu'il faudra trouver des ressources financières pour l'amélioration génétique classique mais qu'il faudra également employer de nouvelles technologies pour augmenter l'efficacité; actuellement des organismes génétiquement modifiés devraient être considérés comme outils de laboratoire tant que les problèmes éthiques ne soient pas résolues.

La Division 3 a tenu bon nombre de réunions divisionnaires et interdivisionnaires avec la Division 1 en Bolivie en 1997 ; la Division 6 au Japon en 1997, le Canada en 1998 et en Australie en 2000 ; la Division 8 au Japon en 1998 et le Groupe de réflexion sur le rôle de la forêt dans le développement durable des montagnes en Australie en 1998. Elle a aussi organisé de nombreuses réunions avec des d'autres organisations, y compris le CIFOR et la FAO. Les différents groupes de recherche ont élaboré des bilans scientifiques de connaissances.

La Division 5 a consacré des efforts considérables à étudier la ressource changeante dans les forêts, à améliorer l'utilisation de cette ressource et à mettre en application des technologies qui ne nuisent ni à l'environnement ni à la société. La conférence de toute la division tenue en 1997 a porté sur les produits de la forêt pour la sylviculture durable et a réuni 222 délégués de 42 pays.

La Division 7 a été créée pour répondre à une résolution spécifique du congrès 1995 qui a encouragé la recherche sur "... l'ampleur, la productivité et la santé des forêts… ». Dans les cinq dernières années la Division a organisé des réunions principales de recherches en Europe, Amérique du Nord et Asie portant sur l'entomologie, la pathologie, la pollution atmosphérique et les interactions entre hôte et parasite.

Les Groupes de réflexion
Une question clé sur le plan international est le développement des critères et des indicateurs de la gestion forestière durable. Le Groupe de réflexion sur la gestion forestière durable, coordonné par Alain Franc, a coopéré alternativement avec le CATIE, le CIFOR et la FAO en organisant trois importantes réunions internationales en Australie, 1998, Costa Rica, 1999, et en France, en 1999 (conjointement avec l'Ecofor et l'EFI) qui réunissaient 100-200 délégués. Le but de ces réunions était de combler les lacunes et d'établir les liens entre les sociologues, les biophysiciens et les parties prenantes du secteur forestier.

Se basant sur les contributions de beaucoup de scientifiques, le Groupe de réflexion sur le changement de l'environnement coordonné par John Innes, a élaboré des bilans scientifiques de connaissance, dont trois ont déjà été publiés dans les « IUFRO Research Series ». Le reste sera publié au cours de cette année. Les fonctionnaires des Groupes de réflexion ont aussi défendu les intérêts de l'IUFRO lors d'une série de réunions en faveur des liens entre la science et la politique. Le Groupe de réflexion était responsable de la mise en œuvre d'une résolution issue de la Conférence ministérielle sur la protection des forêts en Europe connu sous le nom de « Helsinki 4 » qui s'occupe de la coordination des efforts pour atténuer les effets du changement du climat sur les forêts européennes.

Le Groupe de réflexion sur le rôle de la forêt dans le développement durable des montagnes, coordonné par Martin Price, a élaboré le premier bilan scientifique de connaissances sur ce sujet basé sur les contributions de 124 auteurs provenant du monde entier. Beaucoup d'importance a été consacrée à la définition de l'extension des ressources mondiales en forêts de montagne ; les travaux visaient la production d'une carte avec les montagnes du monde (d'après des critères objectifs) et une carte des forêts de montagnes qui représentent 28 % du couvert forestier du monde.

Le Groupe de réflexion sur les eaux et les forêts, coordonné par Rob Vertessy, a été mis en place pour faire le point sur la connaissance scientifique actuelle et les hypothèses existantes sur la valorisation des eaux douces dans la forêt et les effets de la sylviculture et de la gestion forestière sur la quantité et la qualité de l'eau. Ces efforts ont débouché sur une importante publication.

Le Groupe de réflexion sur les ressources Internet, coordonné par Lauri Valsta, a développé une ressource unique et de valeur inestimable pour la transmission et la diffusion de l'information sur l'IUFRO entre les scientifiques du monde entier.

Le Groupe de réflexion sur le Service mondial d'information forestière (GFIS), coordonné par Risto Päivinen, est un consortium d'organismes internationaux, régionaux et nationaux développant une stratégie et mettant en application un service de meta-données basé sur l'Internet pour offrir l'accès mondial coordonné aux informations relatives à la recherche forestière. Les concepts de base sur les méthodes de collecte de données et les solutions techniques ont été élaborés, y compris le prototype de la base de données. Un projet financé par la Commission européenne pour les pays de l'Afrique, les Caraïbes et le Pacifique couvre le volet pays en développement.

Le Groupe de réflexion sur la gestion et la conservation des ressources génétiques forestières est coordonné par Veikko Koski et son comité inclut des représentants de la plupart des Divisions de l'IUFRO, du CIFOR, de la FAO et de l'IPGRI ; il recueille l'information scientifique sur les interactions entre les facteurs effectuant la distribution, l'intégrité et la conservation des ressources génétiques forestières. Un bilan scientifique des connaissances a été élaboré.

Le Groupe de réflexion: Interface entre les sciences forestières et les politiques forestières, coordonné par Richard Guldin, a contribué à mettre l'accent de la conférence de la Division 6 sur la contribution de la science au développement des politiques forestières en Afrique du Sud. Deux réunions satellites ont été organisées à l'occasion de la troisième et quatrième Session du GIF. Trois conférences dans les prochaines trois années recueilleront 40-50 études de cas montrant comment la recherche a influencé avec succès la politique forestière.

L'IUFRO soutenant les pays en développement
Le travail du Programme spécial pour les pays en développement (SPDC), coordonné par Bob Szaro jusqu'en juin de cette année, a fait un effort considérable en vue du renforcement des compétences et des capacités en recherche forestière dans les pays en développement et les pays défavorisés. Le SPDC a organisé des ateliers sur la planification et la gestion de la recherche, il a entrepris la rédaction d'un manuel pour la soumission des propositions de projets de recherche et la planification stratégique. Il a subventionné plus de 200 scientifiques et 35 organisateurs d'ateliers se réunissant dans plus de 60 pays et lancé et publié les premiers deux volumes d'une série peu coûteuse de manuels de formation.

L'IUFRO aimerait remercier le gouvernement des Etats-Unis de l'Amérique pour mettre à disposition le coordonnateur, le gouvernement du Canada pour mettre à disposition le Coordonnateur adjoint du SPDC et le gouvernement du Danemark pour fournir le Coordonnateur adjoint (Afrique). Le gouvernement du Japon a soutenu généreusement le programme BIOREFOR qui a stimulé la collaboration parmi bon nombre d'établissements dans la région Asie-Pacifique et nous a montré comment la biotechnologie peut être utilisée pour le reboisement. Nous remercions aussi la Commission européenne qui a financé le projet GFIS Afrique destiné à améliorer la diffusion de l'information forestière en Afrique. D'autres agences ont aussi contribué des ressources financières ou du personnel au programme, y compris l'AusAid (Australie), l'Union allemande des organisations de recherche forestière (Allemagne), l'Ambassade royale du Danemark, le Service forestier de l'USDA (Etats-Unis), le gouvernement de Chine-Taipei, et le gouvernement du Royaume-Uni.

La diffusion des résultats de recherche
La recherche ne devrait pas se faire dans le vide et ses résultats devraient être diffusés largement. L'IUFRO a fait des efforts considérables de faire connaître le travail, les résultats, la valeur et l'importance de la science forestière en général et de l'IUFRO en particulier. Outre les pages Web mentionnées ci-dessus et les 91 volumes d'actes publiées par les unités de recherches, nous avons continué à publier les IUFRO World Series et les IUFRO Occasional Paper Series (éditées par le Secrétariat), tout en ajoutant les IUFRO Research Series (éditées par CAB international).

L'évaluation de la structure et de la gestion de l'IUFRO
Pendant son mandat de cinq années, le Bureau exécutif actuel s'interroge constamment sur la structure et les activités de l'Union. Ainsi une commission d'experts à été chargé d'une évaluation externe du Secrétariat, du SPDC et du projet spécial. Nous avons fait des efforts énormes pour attirer des fonds financiers pour appuyer des membres de pays en voie de développement mais nous avons aussi essayé d'établir des projets au sein de l'IUFRO tel que le projet de terminologie SilvaVoc. Nous avons examiné la stratégie d'investissement de l'IUFRO, en particulier sous l'angle des difficultés de nombreuses organisations membres de payer leurs cotisations. En réponse à un déclin récent du nombre de membres, le Conseil international a approuvé le changement du nom anglais de l'IUFRO « Forestry » à « Forest » ; ceci met en relief la nécessité d'entourer l'éventail de disciplines et d'institutions qui profiteront des prestations de l'IUFRO et qui y contribueront. Ce changement tient compte de la perception de l'opinion publique qui lie la notion « forestry » seulement avec les déboisements de grande envergure de la forêt naturelle ou des plantations artificielles des essences exotiques, et cela à une époque où l'IUFRO s'efforce sans cesse de mener des recherches et de tirer l'attention sur les services sociaux et environnementaux rendus par la forêt.

Le Bureau exécutif a encouragé les organisations membres et les chercheurs à contribuer aux processus de sensibilisation et de planification de l'IUFRO. Beaucoup de scientifiques ont contribué au développement du Plan stratégique qui a guidé le travail du Bureau exécutif pendant les 5 années écoulées. Le Conseil international était impliqué au développement des politiques de l'IUFRO, à la révision des Statuts de l'IUFRO et à l'élection du nouveau Bureau exé cutif.

Le Bureau exécutif a encouragé la régionalisation de la gestion et de la coopération scientifique de l'IUFRO par l'identification des Chapitres tels que l'Association pacifique de l'Asie des instituts de recherche (APAFRI) dont le Secrétariat se situe ici en Malaisie. En outre, l'IUFRO collabore étroitement avec la FAO en vue de la réalisation d'autres activités régionales destinées à encourager la coopération entre les institutions nationales, y compris le Programme de support de recherche forestière pour l'Asie et le Pacifique (FORSPA) et le Réseau de recherche en matière de recherche forestière pour l'Afrique du sud du Sahara (FORNESSA), le dernier en collaboration étroite avec l'Académie africaine des sciences (AAS).

Mesdames et Messieurs, j'espère que vous réalisez de ce que j'ai dit que l'IUFRO, dirigée par le Bureau exécutif et habilement aidée par le Secrétariat (avec l'appui généreux du gouvernement autrichien), a fait du progrès dans ces cinq années et qu'elle a avec succès répondu aux Résolutions du dernier Congrès. En tant que président sortant, il serait facile pour moi de mettre en évidence les défis à relever par le prochain Président et le Bureau; parmi ces derniers j'inclurai les suivants :

- continuer le développement des normes des méthodes de recherche sur le plan international
- promouvoir la création des réseaux parmi les membres
- développer le GFIS, standardiser les terminologies et les bilans scientifiques de connaissances
- améliorer les liens entre les sciences, les politiques, la gestion et l'utilisation des forêts, des produits et services forestiers.
- identifier et poursuivre les besoins en recherche disciplinaire et inter-disciplinaire
- augmenter les effectifs des membres
- réorganiser et renforcer le Bureau et le Secrétariat de sorte qu'ils soient en mesure d'assurer la sécurité financière, d'aider les membres et de mettre en place des moyens pour la diffusion de l'information.

Allocution du

Dr. Abdul Rahim Nik

Président du Comité d'organisation du Congrès

Monsieur le Professeur Jeffery Burley, Président de l'IUFRO,
Monsieur le Président du Comité directeur pour la recherche et le développement de la Malaisie,
Tan Sri G.K. Rama Iyer
Monsieur le Directeur-Général de FRIM, Dato' Dr. Abdul Razak Mohd Ali
Monsieur le Président désigné, Professeur Risto Seppälä,
Chers invités et délégués,
Mesdames et Messieurs,

Je suis très content que nous sommes arrivés à nous réunir pour la cérémonie de clôture du XXIème Congrès Mondial de l'IUFRO. Pendant les six derniers jours, nous avons assisté à une multitude d'activités allant des séances scientifiques, réunions satellite et de travail jusqu'aux expositions, réceptions et circuits touristiques. En organisant cette réunion prestigieuse nous avons essayé de faire de notre mieux pour satisfaire toutes vos espérances et demandes pour assurer un agréable séjour et le déroulement impeccable des réunions.

Il y a cinq ans, on m'a confié le rôle du président du Comité d'organisation du Congrès avec pour tâche gigantesque l'organisation de ce congrès. Je n'avais pas eu une idée de l'ampleur de ce défi et de la responsabilité qui m'attendaient. Trois ans plus tard les préparatifs ont pris forme. Enfin, six mois avant le congrès nous nous sommes vus impliqués aux défis véritables de l'organisation. Je dois avouer que nous avons beaucoup appris de l'organisation de ce congrès. Les technologies modernes disponibles aujourd'hui nous ont aidé beaucoup lors des préparatifs. Je n'aurais pas pu imaginer l'organisation d'une seule réunion sans l'utilisation du courrier électronique et des télécopies.

Tandis que le thème du congrès „La forêt et la société – le rôle de la recherche" a fait l'objet de nombreuses discussions au cours des sessions techniques, nous les organisateurs, ont choisi la devise suivante, soit „Nous avons pris l'engagement d'assurer un congrès mémorable et bien organisé". Vous avez du voir cette devise affichée aux murs de nos locaux et stations. Cette simple devise contient deux messages. En reconnaissant que c'est la première fois dans l'histoire centenaire de l'IUFRO qu'un congrès mondial ait lieu dans un pays en développement nous voulions assurer que ce XXIème Congrès Mondial, tenu ici en Malaisie fait grand effet dans la mémoire des délégués présents ici. Ensuite, un grand rassemblement comme ce congrès a besoin d'un système efficace et bien organisé pour assurer un impact durable aux participants et leur donner l'impression qu'ils n'ont pas dépensé leur temps et leur argent en vain. Ayant cette devise sous les yeux nous avons travaillé acharnement et dédiés pour achever un bon résultat. C'est à vous maintenant, chers délégués de juger si nous avons réussi.

Mesdames et Messieurs,

Lors de cette séance de clôture j'aimerais mettre en relief quelques données statistiques importantes relatives aux congrès et quelques-unes de nos observations qui devraient être utiles pour l'organisation du prochain congrès.

Au total, 1906 délégués provenant de 96 pays se sont inscrits à ce congrès, y compris les 209 participants inscrits en tant que personnes accompagnantes. Nous avons aussi reçu des réactions encourageantes en ce qui concerne le programme des excursions et des circuits touristiques. Un total de 1127 personnes était inscrit pour les neuf excursions organisées pour jeudi et plus de 700 personnes ont participé au programme des personnes d'accompagnement. Le tour pour voir les lucioles a vu la plus grande participation. Juste après ce congrès, un total de 324 délégués participera aux voyages d'études après le congrès, qui les conduiront dans les prochains jours aux différentes parties de la Malaisie et aux pays voisins tels que le Brunei, l'Indonésie et la Thaïlande.

Pour ce qui est des présentations scientifiques, la plupart des séances scientifiques programmées se sont déroulées comme prévues. Dans quelques-unes où les orateurs ne sont pas venus, les modérateurs ont réussi à inviter d'autres participants pour combler les lacunes. Cependant, quelques séances ont dû être annulées puisque les auteurs des contributions ne sont pas venus. Nous avons remarqué qu'il s'agissait surtout des auteurs des pays en développement qui ne pouvaient pas venir par manque de ressources financières. Pour ce qui est des présentations des posters, seulement 55 % des auteurs de posters d'un total de 833 posters sélectionnés est venu, dont la plupart des auteurs des pays en développement qui n'ont pas réussi à trouver des moyens financiers. Pour ce qui est de l'appui technique au congrès, nous avons mis à disposition 120 rapporteurs techniques et environ 270 assistants de congrès pour faciliter un déroulement sans problème.

Nous avons produit un total de 6,6 millions de pages d'imprimés, y compris les annonces et le matériel de publicité. Je n'ai aucune idée combien d'arbres étaient nécessaires pour produire ces documents. Je pense sincèrement que l'effort valait la peine.

Permettez-moi maintenant de consacrer quelques moments à un problème qui dû à l'importance qu'il revêt devrait être tenu en compte pour le prochain congrès. Si nous souhaitons un nombre plus important de participants de pays en développement nous devrions faire plus d'efforts pour chercher des fonds financiers pour le Programme d'assistance des scientifiques. Pour cette réunion, 169 candidats ont été financés, ou bien complètement ou bien partiellement à travers des ressources mises à la disposition par le gouvernement de la Malaisie. A mon avis, on devrait concentrer les efforts à chercher des ressources financières auprès des pays industrialisés. Cela n'était pas le cas pour ce congrès, exception faite du SPDC et de quelques pays comme les Etats-Unis, le Royaume-Uni, la Suède et la Finlande. Il faut que le Bureau désigné et le prochain pays d'accueil se penchent sur cette question.

Je dois avouer que c'était un plaisir et une expérience intéressante pour nous d'organiser ce congrès. J'espère que vous avez non seulement profité de ce congrès dans votre carrière scientifique mais qu'il était une expérience utile et fructueuse. Malgré les grands efforts il y avait des imperfections pour lesquelles je vous demande pardon. Le temps est venu pour passer le drapeau à l'hôte du prochain XXIIème Congrès mondial.

Enfin, Mesdames et Messieurs,

Comme vous avez pu noter, beaucoup d'organisations, agences et bailleurs de fonds étaient impliqués dans l'organisation de ce congrès. C'est à eux que j'aimerais exprimer mes remerciements pour leur soutien, leur coopération et leur appui sans lesquels nous n'aurions jamais réussi à s'embarquer sur cette tâche difficile. En particulier, j'aimerais remercier le Comité directeur pour la recherche et le développement de la Malaisie et le FRIM, et notamment son président et Directeur-Général pour leur encouragement et appui pendant les phases de planification et d'exécution de ce congrès. Grand merci aussi à tous les membres du Bureau exécutif et du Secrétariat dont le conseil et l'appui étaient très importants pour la réussite de ce congrès. Enfin, en ma qualité de président du Comité d'organisation du congrès, j'aimerais remercier tous les membres du COC, les sous-comités et les auxiliaires de congrès. C'est la force motrice qui en travaillant acharnement derrière la scène, a assuré le succès du congrès. Veuillez les applaudir avec moi…….

A nos amis d'outre-mer je souhaite un voyage de retour agréable, sain et sauf.

Bon voyage et Merci

Allocution du

Docteur Risto Seppälä

Président désigné de l'IUFRO

Monsieur le Président
Excellences,
Chers Membres du Conseil international de l'IUFRO et du Bureau exécutif
Chers invités, chers collègues
Mesdames et Messieurs

C'est un grand honneur pour moi d'accepter l'élection au poste de président de l'IUFRO par le Conseil international. Je promets de faire de mon mieux pour répondre aux hautes espérances liées à ce poste.

Dans son discours de réception il y a cinq ans notre président actuel a déclaré qu'il avait toujours eu trois ambitions pour l'IUFRO: avoir un président des tropiques, avoir un congrès mondial dans un pays en voie de développement et avoir un président féminin. Nous avons maintenant réalisé les deux premiers de ces buts mais si Jeffery Burley voulait un président féminin pour lui succéder, je ne suis pas la personne appropriée, cependant je peux prendre le bâton de lui et l'avancer.

Habituellement, un discours de réception contient des visions du président entrant sur la nouvelle structure et les activités futures de l'organisation. Puisque notre président actuel a présenté à cette occasion déjà une liste approfondie de futurs défis, je voudrai évoquer seulement deux thèmes que je considère importants. Ce sont les membres de l'IUFRO et le rôle de l'IUFRO comme centre de vérification pour l'information et l'expertise en matière de recherche forestière.

L'IUFRO compte maintenant environ 680 organisations membres qui fournissent les ressources financières de base. Ces dernières années bon nombre d'organisations ont adhéré à l'Union mais en même temps un trop grand nombre de nos anciens membres ne sont plus capables ou ne veulent plus payer les cotisations. Quand nous perdons une organisation membre, nous perdons souvent aussi ses scientifiques parce que pour le chercheur individuel il est ennuyeux et coûteux de devenir membre de l'IUFRO.

Il est peut être temps d'examiner de plus près le concept entier de membres de l'IUFRO. D'abord nous devons nous demander pourquoi nous avons besoin de membres. Une raison évidente est l'argent. Bien que l'IUFRO soit une organisation volontaire nous ne pourrions pas survivre maintenant sans cotisations. Cependant, si nous aurons de l'argent provenant des sources autres que les cotisations, aurions nous toujours besoin de membres pour accomplir notre mission qui consiste à encourager la coopération internationale en matière de recherche forestière et sciences connexes? La réponse est oui. Nous avons besoin de membres également dans ce cas-ci parce que la coopération n'est pas possible sans ceux qui coopèrent, et nos organisations membres et leurs collaborateurs forment le meilleur réseau international de coopérants dans la recherche forestière.

Selon une étude récente de l'Institut européen des Forêts, il y a en Europe de l'Ouest plus de mille organisations travaillant dans le domaine de la recherche forestière. Parmi elles, seulement 176 instituts adhèrent à l'IUFRO. J'estime que dans d'autres régions du monde la situation est semblable. Ainsi, le nombre de nouveaux membres potentiels est peut-être plus grand que nous imaginions. Il dépend de nous comment nous utiliserons ce potentiel pour augmenter les effectifs. Il y a beaucoup d'acteurs qui occupent des rôles importants dans le monde changeant d'aujourd'hui, et qui ne sont pas encore partenaires de l'IUFRO.

Nous avons besoin des relations plus étroites avec les chercheurs individuels. Le fait que l'IUFRO est une organisation parmi d'autres organisations ne garantit pas que tous les scientifiques travaillant dans nos organisations membres connaissent l'IUFRO ou obtiennent des informations sur elle. Avant, les scientifiques travaillant dans des établissements qui ne sont pas membres de l'IUFRO étaient exclus du flux d'information. La situation s'est maintenant améliorée considérablement car la plupart des visiteurs de notre site Web et un nombre considérable de participants à ce congrès ne viennent pas des organisations membres de l'IUFRO. Pour moi, cela est un signe pour un énorme potentiel de membres et il montre à quel point l'IUFRO est ses congrès sont attrayants. Faciliter l'adhésion à l'IUFRO, particulièrement pour ceux qui travaillent dans des disciplines non-forestières sera une condition préalable importante pour augmenter le nombre de membres.

Jusqu'ici, l'IUFRO a utilisé très modestement la connaissance et l'expertise de son réseau de membres. Nous avons quelques projets et programmes spéciaux financés à partir des sources extérieures, tels que le SPDC et SilvaVoc, mais ce que nous devons faire c'est de mobiliser l'information toute entière et toute la base de connaissance de nos scientifiques et nos experts, ce qui est une ressource unique mais sous-exploitée pour l'instant. Les bonnes étapes dans cette direction sont les bilans scientifiques de connaissance qui ont été présentés ici cette semaine, et le Service mondial d'information forestière dont le prototype avait été présenté pendant le congrès.

Mesdames et Messieurs,

Ma propre vision pour l'IUFRO est que nous devrions devenir un centre de vérification pour l'information et l'expertise en matière de recherche forestière. Nos fonctionnaires sont les protagonistes dans ce processus mais ils représentent seulement une fraction de nos ressources humaines. Nous devons avoir des liens directs avec tous les individus qui agissent dans et sont liés à nos unités de recherches. Ensuite, ayant l'information appropriée sur leur domaine d'expertise, nous pourrons fonctionner comme centre de vérification et répondre aux demandes de nos clients quand, par exemple, ils veulent savoir l'état-de-connaissance dans tel ou tel domaine spécifique de la recherche forestière, ou, quand il y a le besoin de créer une équipe internationale pour trouver une solution pour un problème scientifique.

Une bonne réputation comme centre de vérification pour l'information et l'expertise en matière de recherche forestière augmentera considérablement la visibilité de l'IUFRO. Cela rendra l'IUFRO plus intéressante pour les bailleurs de fonds et les clients en créant un effet multiplicateur pour engendrer les ressources financières nécessaires.

Chers amis,

En ma qualité de président désigné j'estime que l'une de mes tâches les plus importantes est d'agir en tant qu'ambassadeur de l'IUFRO, qui offre et vend notre organisation sur le marché. La communauté forestière internationale a besoin de notre expertise, et elle est prête à payer nos services. Nous avons besoin du marketing également pour renforcer nos effectifs de membres. Tout en encourageant nos membres actuels à rester avec nous, nous devons trouver de nouveaux membres, particulièrement ceux, qui ne font pas partie du secteur forestier traditionnel. Une base étendue et de haute qualité d'adhésion est également une condition préalable importante pour vendre nos services à ceux, qui en ont besoin et peuvent payer pour eux.

Bien que j'aie maintenant exprimé mes opinions pour le futur, j'aimerais faire le point du passé pour une minute. En ma qualité de vice-président programmes actuel je voudrais saisir cette occasion de remercier tous les fonctionnaires de l'IUFRO de leur travail précieux depuis le congrès de Tampere. Je remercie tout spécialement le Comité scientifique du congrès et le secrétariat de l'IUFRO pour leur contribution énorme lors de la préparation du programme scientifique de ce congrès. En conclusion, j'aimerais remercier nos hôtes en Malaisie. Puisque j'ai été impliqué dans l'organisation du congrès précédent, je sais exactement combien vous avez travaillé pour réaliser cet événement. Je vous félicite pour un congrès très réussi. Saya ucapkan setinggi-tinggi tahniah kepada tuan rumah Malaysia di atas kejayaan kongres ini.

On sait que nous, les Finlandais, nous sommes des personnes de peu de mots - même lorsque nous avons quelque chose à dire. Nous préférons l'action aux discours, bien que les discours soient également importants en montrant la direction où aller. Je terminerai maintenant, mais vous aurez des nouvelles de moi plus tard, peut-être pas tellement par ce que je dis mais plutôt - et si tout va bien - par ce que je fais. Tout ce que je ferai pour l'IUFRO j'aimerais faire avec vous tous.

Discours prononcé par le hôte du Congrès Mondial IUFRO 2005

Prof. Russell Haines
Queensland Forestry Research Institute

Vu les 40 ans d'utilisation des forêts et des ressources forestières dans notre pays, il nous fera un grand plaisir d'accueillir les chercheurs forestiers du monde entier au 22e Congrès Mondial IUFRO à Brisbane, en 2005.

L'Australie est riche en forêts les plus diverses, allant des zones tempérées aux zones arides en passant par les zones tropicales, et en plantations immenses qui ne cessent de croître. Les défis auxquels nous sommes confrontés en ce qui concerne la gestion de ces forêts sont les mêmes que ceux auxquels doit faire face le monde forestier et qui sont à l'ordre du jour de ce congrès.

Les gouvernements fédéraux de l'Australie et de ses Etats se sont engagés dans l'utilisation rationnelle des ressources forestières au profit des générations présentes et futures, reconnaissant qu'une telle utilisation demande des connaissances scientifiques solides. Nous avons pris l'engagement de participer aux fores forestiers internationaux et à la coopération scientifique internationale tout particulièrement. Nous appuyons à l'Union Internationale des Instituts de Recherche Forestière. Je suis fier de pouvoir mentionner que c'était mon cher ami et collègue, le Dr. Garth Nikles, retraité après 50 années de contribution à la science forestière qui, avec le Professeur Jeffrey Burley, a crée le premier Groupe de travail de l'IUFRO en 1971.

A mon avis, l'époque que nous vivons relève bien des défis intéressants pour les chercheurs forestiers. Jamais le groupe des parties prenantes n'a été aussi diversifié faisant preuve d'un intérêt passionné pour la gestion et l'utilisation des forêts et de leurs ressources. Jamais la coopération internationale entre les chercheurs forestiers n'a été plus importante.

Nous espérons qu'en 2005 nous pourrons montrer l'hospitalité australienne aux délégués, pour donner en retour un peu de l'hospitalité offerte par le peuple de Malaisie.

Les délégués australiens ont beaucoup apprécié les excellents arrangements du 21e Congrès Mondial IUFRO en Malaisie. Nous reconnaissons que nos collègues de Malaisie ont établi des standards très élevés et l'organisation du Congrès de Brisbane en 2005 aura recours aux expériences vécues en Malaisie.

Il sera un grand plaisir pour nous d'organiser le 22e Congrès Mondial IUFRO conjointement avec la grande communauté de l'IUFRO et de porter le drapeau de l'IUFRO haute dans les prochaines cinq années. En particulier, nous serons heureux de vous voir tous à Brisbane en 2005.

Séance de Clôture, Samedi 12 août 2000
Allocution du

Professeur Jeffery Burley

Président de l'IUFRO
Excellences,
Chers invités,
Chers Membres de l'IUFRO, Collègues et Amis,
Mesdames et Messieurs,

Nous arrivons maintenant à la séance de clôture du XXIème Congrès Mondial de l'IUFRO à Kuala Lumpur, en Malaisie. Bien que la plupart des participants soient heureux de rentrer dans leurs pays, je sais que beaucoup d'entre eux vont regretter un peu de quitter un pays si charmant, avec des gens extraordinaires et de voir s'achever un programme riche en exposés, posters, discussions, expositions et excursions intéressants. Ils vont aussi regretter d'être obligés de quitter les anciens et les nouveaux amis, mais j'espère que les contacts professionnels et sociaux nouvellement établis seraient maintenus selon l'ancienne tradition de l'IUFRO de collaboration scientifique et personnelle.

Les organisateurs de tout congrès se sont toujours inquiétés qu'ils ne puissent pas concourir avec le congrès antérieur tant par sa quantité ou par sa qualité, mais à mon avis, il n'est pas important qu'un congrès soit supérieur au précédant mais qu'il soit différent. En 1990, après Montréal, les organisateurs finlandais du Congrès de Tampere en 1995 ont pensé qu'ils ne pouvaient pas arriver à leur cheville, et pourtant ils y sont arrivés. Après Tampere, les organisateurs malaysiens ont pensé qu'ils n'arriveront non plus à atteindre le niveau du dernier congrès pour ce Congrès 2000, mais, à mon avis, ils y sont arrivés. La qualité des préparatifs sur le plan administratif, politique et technique a été superbe, et la gentillesse du personnel auxiliaire a été extraordinaire.

Pendant mes promenades aux lieux du congrès pendant toute la semaine j'ai demandé à beaucoup de participants de me faire savoir leur opinion ou leur critique. Nous allons voir si ces opinions sont identiques aux résultats du questionnaire mais j'en suis sur que cela sera le cas. Pourtant, le Bureau exécutif de l'IUFRO sera très intéressé à apprendre vos opinions une fois que vous avez eu le temps de réfléchir sur tous les aspects de ce congrès après votre retour.

Il n'est certainement pas possible de remercier individuellement toutes les personnes et organisations qui ont contribué au succès de ce congrès. Pour cette raison, j'aimerais remercier collectivement à votre nom le Gouvernement de la Malaisie ; le Bureau exécutif de l'IUFRO, le Comité directeur du Congrès présidé par le Dr. Razak, le Comité d'organisation du Congrès présidé par le Dr. Rahim Nik, le Comité scientifique du Congrès présidé par le Dr. Teissier du Cros, le Secrétariat de l'IUFRO géré par Heinrich Schmutzenhofer, le personnel nombreux de FRIM, les départements forestiers gouvernementaux et nationaux, les universités qui nous ont beaucoup aidé, les photographes, le personnel de liaison et les organisateurs professionnels du congrès, les journalistes pour leurs rapports conscients pendant cette semaine, les interprètes sans lesquels les orateurs principaux n'auraient jamais été entendus complètement, le maître des cérémonies sans qui les séances d'ouverture et de clôture n'aient pas été si efficaces et agréables, les bailleurs de fonds qui ont financé beaucoup de participants, et avant tout, les participants eux-mêmes. Comme avec la plupart des activités dans la vie, vous sortez d'un événement autant que vous mettez dedans et je sais que la majorité des participants se sont identifiés avec l'esprit et les activités du congrès profitant ainsi autant sur le plan personnel que professionnel.

Moi, personnellement, je vous remercie tous de votre appui pendant ces cinq dernières années, et tout particulièrement ma femme Jean et le Secrétaire de l'IUFRO, Heinrich Schmutzenhofer. Sans eux, je n'aurais jamais été en mesure d'assumer les responsabilités d'un président. Heureusement, je ne dois rentrer qu'avec l'un des deux. Pour l'autre, j'ai apporté un petit cadeau, un réveil d'Oxford mis sur 6 heures du soir, pour que Heinz sache qu'il est temps de rentrer pour joindre sa femme Edith.

Je vous souhaite tous un bon voyage de retour, et que Dieu vous bénisse. Le XXIème Congrès Mondial de l'IUFRO est clos.

Ansprachen in den Eröffnungs-und Abschlussfeierlichkeiten

Ansprache des Vorsitzenden desKongress Steuerungskomitees

Dato' Dr. Abdul Razak Mohd. Ali

Sehr geehrter Herr YB Dato Seri Dr Lim Keng Yaik, Minister für Primärindustrie,
vereehrter Herr Professor Jeffery Burley, Präsident von IUFRO
Geschätzte Gäste, sehr geehrte Damen und Herren,

Es ist wirklich eine Ehre für mich, Sie alle hier im Auftrag des Kongress-Steuerungskomitees am 21. IUFRO Weltkongress willkommen zu heissen. Unser besonderer Dank geht an den verehrten Herrn Minister für Primärindustrie, dafür, dass er zugesagt hat, an diesem Kongress teilzunehmen und diesen im Namen des ehrenwerten Herrn Premierministers, der leider heute morgen verhindert ist, feierlich zu eröffnen. Allen Delegierten und speziell jenen aus dem Ausland sage ich ein herzliches 'Selamat Datang ke Malaysia' oder 'Willkommen in Malaysia'.

Bei der IUFRO Direktoriumssitzung in Madrid im April 1995 hat sich Malaysia um die Abhaltung des 21. IUFRO Weltkongresses in Kuala Lumpur beworben. Dieser Augenblick des Triumphs vor fünf Jahren ist mir immer noch gegenwärtig und es war mir damals die Aufgabe übertragen worden, die Delegation anzuführen, die das malaysische Angebot zusammen mit ähnlichen Anboten von Seiten Südafrikas, Chinas und Indonesiens vorstellte.

Malaysia ist sehr stolz, das erste Entwicklungsland zu sein, in dem ein IUFRO Weltkongress stattfindet. Ohne Zweifel ist der Kongress die grösste forstliche Veranstaltung, die je in unserem Land stattfand. Die Anzahl der registrierten Teilnehmer und Begleitpersonen, sowie der Beiträge und Poster übersteigt bei weitem jene der 14. Commonwealth Forstkonferenz, die im September 1993 in Kuala Lumpur stattfand.

Wir sind der Regierung von Malaysia und dem Internationalen Rat IUFROs zu grossem Dank verpflichtet, dass sie dem Forstforschungsinstitut Malaysias (FRIM) die immense Verantwortung für die Organisation des IUFRO Kongresses übertragen haben. Wir möchten dem IUFRO Sekretariat in Wien und dem Malaysischen Beirat für Forschung und Entwicklung (MFRDB) für ihre unschätzbare Unterstützung und Führung danken. Das Kongress-Organisationskomitee (COC) und seine Subkomitees haben sehr hart gearbeitet, um den Erfolg dieses Kongresses auf allen Ebenen sicherzustellen.

Sehr geehrte Damen und Herren,

Wir freuen uns, bekanntzugeben, dass insgesamt 1906 Teilnehmer und über 200 Begleitpersonen aus 96 Ländern für diesen Kongress registriert sind. In den nächsten Tagen werden 5 Hauptvorträge, 9 Subplenarvorträge, 500 Vorträge und 833 Poster im Rahmen der jeweiligen Veranstaltungen und Sitzungen präsentiert werden. Unsere Absicht ist es, den Wissenschaftlern die Möglichkeit zu geben, mit Ihren Begutachtern Fachthemen zu diskutieren.

Mit Hilfe des Programms zur Unterstützung von Wissenschaftlern (SAP) konnte die Teilnahme von 138 Wissenschaftlern aus 38 Entwicklungsländern finanziert werden. Zusätzlich hat die Malaysische Regierung Geldmittel für die Unterstützung von weiteren 31 Wissenschaftlern aus Asien und der Pazifikregion zur Verfügung gestellt.

Wir möchten dem ehrwürdigen Herrn Minister für Primärindustrie, Malaysia, herzlich danken, der im Anschluss an seine Rede im Namen des Premierministers den Kongress feierlich eröffnen wird. Weitere Höhepunkte der Eröffnungszeremonie werden die Präsentation der Sonderbriefmarken zum 21. IUFRO Weltkongress, eine Folkloreshow und die Überreichung der IUFRO-Auszeichnungen sein. Wir möchten auch den Autoren der Hauptvorträge danken, die ihre Vorträge während der Plenarsitzungen halten werden.

Sehr geehrte Damen und Herren,

Ich hoffe sehr, dass der Kongress ein sinnvolles Forum für den Gedankenaustausch der Wissenschaftler untereinander zu den Themen Wald und Gesellschaft bieten wird. Schon immer wurden Wälder als Holzlieferanten betrachtet. Die Forschung hat bei der veränderten Wahrnehmung und Haltung dem Wald gegenüber eine massgebliche Rolle eingenommen, indem sie uns vor Augen führt, dass Wälder viele andere Güter liefern und Funktionen zum Wohl der Gesellschaft erfüllen können.

Bitte, nehmen Sie im Rahmen dieses Kongresses im Sinne der gegenseitigen Zusammenarbeit in Forschung und Entwicklung die Gelegenheit wahr, Forschungsbelange und Forschungsbedarf zu diskutieren. Die Nebenveranstaltungen vor und während des Kongresses sowie die Arbeitssitzungen der Forschungsgruppen sollen diesem Zweck dienen.

Nun ist alles gesagt und getan. Ich möchte mich, auch im Namen des Kongress-Steuerungskomitees und des Kongress-Organisationskomitees für eventuelle Pannen im vorhinein entschuldigen, die vielleicht bei diesem Kongress auftreten. Und schliesslich hoffe ich, dass Sie die Exkursionen während und nach dem Kongress nutzen können, um unser faszinierendes Land Malaysia zu entdecken, ein Land, das reich ist an biologischer und kultureller Vielfalt.

Ich danke Ihnen.

Eröffnungsansprache des IUFRO Präsidenten

Professor Jeffery Burley

Verehrter Herr Minister für Primärindustrie,
Dato'Seri Dr. Lim Keng Yaik,
Verehrter Herr Ministerstellvertreter,
Herr Generalsekretär,
Dato' Dr. Abdul Razak,
Vorsitzender des Kongress-Steuerungskomitees,
Dr. Hosny El-Lakany,
Stellvertretender Generaldirektor für Forstwirtschaft in der FAO,
Liebe Gäste,
Meine sehr verehrten Damen und Herren,

Es ist mir eine grosse Ehre und Freude, Sie hier bei diesem 21. Weltkongress des Internationalen Verbandes Forstlicher Forschungsanstalten (wohlbekannt unter dem Namen IUFRO) begrüssen zu dürfen. Eure Exzellenz, es tut uns sehr leid, dass der Herr Premierminister aufgrund seiner Staatsgeschäfte an der Teilnahme verhindert ist.

Ich danke Ihnen jedoch dafür, dass Sie uns die grosse Ehre erweisen, die Eröffnungsrede zu halten, die, dessen bin ich sicher, uns ein herzliches Willkommen vermitteln wird. Das Thema unseres Kongresses ist mit „Forstwirtschaft und Gesellschaft: die Rolle der Forschung" zeitgemäss, da wir ein neues Jahrtausend schreiben, in dem Bevölkerungswachstum, wachsende Ansprüche an den Wald und seine Produkte, wachsendes Bewusstsein um viele andere Leistungen des Waldes für die Umwelt und für die Gesellschaft grossen Raum einnehmen werden. Dies gilt auch besonders für Malaysia, ein Land mit ausgedehnten und vielfältigen Waldressourcen und Leistungen, ein Land mit einer international anerkannten Forschungstradition. Herr Minister, wir kennen uns seit vielen Jahren und ich weiss, dass Sie immer ein aktiver und fortschrittlicher Denker und Sprecher der Forstwirtschaft und Holzindustrie waren, insbesondere in bezug auf Malaysia und Südostasien. Wir erwarten mit grossem Interesse Ihre Rede.

In den letzten fünf Jahren war es ein besonderes Privileg für mich, Präsident von IUFRO zu sein, und ich möchte einige Minuten dazu verwenden, Ihnen und den übrigen Gästen etwas über die Geschichte und Aktivitäten von IUFRO zu erzählen; zusätzlich werde ich versuchen, Ihnen zu zeigen, warum dies für einen hohen Politiker von Interesse sein sollte und warum Wissenschaftler und politische Entscheidungsträger den Dialog suchen sollten.

IUFRO wurde 1892 von einer kleinen Zahl europäischer Staaten gegründet. In den ersten 80 Jahren seiner Existenz wurden die meisten Länder der gemässigten Zone Mitglied von IUFRO. Erst 1971 wurde die erste Arbeitsgruppe gegründet, die sich speziell mit einem Thema der Tropen befasste (Forstgenetik und Baumzüchtung). Seit damals hat IUFRO sich aktiv bemüht, an den Vorteilen der internationalen Zusammenarbeit auch Institutionen und Wissenschaftler aus Entwicklungsländern teilhaben zu lassen (einschliesslich der Unterstützung von APAFRI, FORNESSA und dem Netzwerk Lateinamerika) und sie aktiv auf allen Ebenen seiner Geschäftsführung zu beteiligen; der Verband umfasst nun fast 700 Mitgliedsorganisationen in 110 Ländern mit etwa 15,000 Wissenschaftlern, die auf freiwilliger Basis in 276 Abteilungen, Forschungs- und Arbeitsgruppen zusammenarbeiten. Es ist eine internationale, nicht gewinnorientierte, multidisziplinäre Nicht-Regierungsorganisation, deren ernsthaftes Bestreben es ist, den bestmöglichen Nutzen aus den von Regierung, Industrie und Privaten in die Forschung investierten Mitteln zu lukrieren.

Ich sollte darauf hinweisen, dass die Arbeit IUFROs im wesentlichen auf freiwilliger Basis geschieht; praktisch alle Funktionäre des Verbandes und alle mitarbeitenden Wissenschaftler unternehmen grosse Anstrengungen, um den Erfolg von IUFRO sicherzustellen, da sie an den Mehrwert ihrer Mitarbeit glauben. Nur die Mitarbeiter des Sekretariats, das grosszügigerweise von der österreichischen Regierung unterstützt wird, sind als ständige „Beamte" des Verbandes anzusehen. Das Vertragspersonal des Sonderprogramms für Entwicklungsländer (SPDC) wird aus grosszügigen Zuwendungen der Regierungen Kanadas, Dänemarks und den USA finanziert. Die Europäische Union und die Regierungen von Japan, der Schweiz und Grossbritannien leisteten ebenso grosszügige finanzielle Unterstützung für IUFRO. IUFRO unterhält enge Beziehungen mit anderen Organisationen, insbesondere mit dem Internationalen Rat für Wissenschaft, dem Zentrum für Internationale Forstliche Forschung, der Organisation der Vereinten Nationen für Ernährung und Landwirtschaft und dem Internationalen Zentrum für Agroforstwirtschaftliche Forschung. Es ist für mich ein Privileg mehr, dass der Repräsentant des Generaldirektors der FAO anlässlich dieser Eröffnungssitzung eine Rede halten wird.

In diesem Jahrhundert wurde der Verband nicht müde, ausgezeichnete und qualitativ hochwertige Forschung in vielen wissenschaftlichen Disziplinen zu fördern und zu unterstützen. Jedoch hat Forschung keinen Wert, wenn sie isoliert stattfindet; sie sollte als intergrierter Bestandteil des Kontinuums von theoretischer zu angewandter Forschung zur Anpassung und weit verbreiteten Anwendung neuer technologischer und sozialer Systeme angesehen werden, die Fragestellungen der internationalen und nationalen Politik aufgreifen. Hier wurde IUFRO aktiv und hat Sonderarbeitsgruppen ins Leben gerufen, die die Integration solcher Forschungsbemühungen fördern und zur Verbesserung des Dialogs zwischen Wissenschaftlern und Entscheidungsträgern beitragen sollen. Bei diesem Kongress in Malaysia, der im ersten Jahr des neuen Jahrtausends stattfindet, werden Wissenschaftler von IUFRO Berichte zum Stand der Wissenschaft zu vielen aktuellen Themen vorstellen, und so einen Überblick über verfügbare Informationen, die Problematik von Forschungsmanagement und den Bedarf an neuer Forschung geben.

In der Vergangenheit wurden wir Zeugen fortschreitender Sensibilierung der Politik und der Öffentlichkeit in Hinblick auf die Bedeutung des Waldes und der Bäume für das Wohl der Menschen. Unbestritten sind die Leistungen des Waldes für die Umwelt, die Wirtschaft und die Erholung für eine grosse Zahl von Menschen. Zusätzlich zu forstwissenschaftlichen Publikationen und Zeitschriften bringen heute in den meisten Ländern Zeitungen und Fernsehstationen Beiträge zu forstlichen Themen. Es gibt eine starke gegenseitige Abhängigkeit, ja sogar Konkurrenz zwischen den einzelnen Produkten und Leistungen, die vom Wald verlangt werden. Die Forschung umfasst viele Disziplinen, die nicht notwendigerweise kohäsiv sind. IUFRO macht hier unheimliche Anstrengungen, um die interdisziplinäre Zusammenarbeit zwischen Biophysikern und Soziologen zu fördern.

Die Zahl 2000 ist eine schöne runde Zahl, zumindest wenn man das Dezimalsystem anwendet. Sie ist auch in manchen religiösen Kalendern aussagekräftig. Jedoch ist sie für alle die Lebenden und die Milliarden Ungeborenen als das Jahr von Bedeutung, in dem internationale Organisationen, Unternehmen und Ressourcenmanager realisieren mussten, dass ein dringendes Bedürfnis besteht, die Ressourcen dieser Welt sinnvoll, gerecht, ethisch einwandfrei und in nachhaltiger Weise zu nutzen. Wälder und Bäume werden eine Hauptrolle bei einer nachhaltigen Entwicklung spielen, und IUFRO wird auch weiterhin sein möglichstes tun, um Wissenschaft und Wissenschaftler zu ermutigen, aktuelle Themen zu behandeln und ihre Ergebnisse so zu präsentieren, dass politische Entscheidungsträger und alle Interessensgruppen diese verstehen und anwenden können. Das Direktorium IUFROs ist sicher, dass dieser Kongress dazu beitragen wird.

Exzellenz, alle Teilnehmer am 21. IUFRO-Kongress sind der Regierung von Malaysia und der Stadt Kuala Lumpur sehr verbunden, dass sie sich als Gastgeber für diesen Kongress zur Verfügung gestellt haben, wir danken insbesondere für die grosszügige Gastfreundschaft und die äusserst interessanten und vergnüglichen Exkursionen, die für die Kongressteilnehmer und ihre Begleitpersonen in ihrem schönen Land organisiert wurden. Zur Organisation kann ich nur anmerken, dass das Personal des Forstforschungsinstituts, der Forstabteilung der Regierung und zahlreicher Universitäten keine Mühe gescheut hat, um die Bemühungen IUFROs für die Krönung seiner Fünfjahresperiode zu unterstützen. Ich fürchte nur, dass bei diesen Aktivitäten die Forschung in Malaysia nicht nur beeinträchtigt wurde, sondern dass sie auch bald nicht mehr da sein wird, wenn alle diese Forscher professionelle Kongressorganisatoren und Reiseleiter werden.

Exzellenz, ich bitte Sie nun, diesen 21. IUFRO-Kongress zu eröffnen und uns Ihre Sicht zur Rolle und zum Bedarf forstlicher Forschung darzulegen. In der Folge werde ich Sie bitten, uns die Ehre zu geben, die höchste Auszeichnung IUFROs, nämlich die Verleihung der Ehrenmitgliedschaft an zwei herausragende Wissenschaftler unseres Verbandes vorzunehmen.

Ansprache des

Premierministers
Y.A.B. Dato' Seri Dr. Mahathir bin Mohamad

Vorgetragen von

Dato' Seri Dr. Lim Keng Yaik,
Minister für Primärindustrie, Malaysia;

Professor Jeffery Burley, Präsident des Internationalen Verbandes Forstlicher Forschungsanstalten;
Sehr geehrter Herr Datuk Haron Siraj, Generalsekretär des Ministers für Primärindustrie, Malaysia
Dato' Dr. Abd. Razak Mohd Ali, Vorsitzender des Kongress-Steuerungskomitees

Verehrte Gäste, meine Damen und Herren,

Zuerst möchte ich den Organisatoren für die Einladung zur Eröffnung dieses wichtigen 21. Weltkongresses des Internationalen Verbandes Forstlicher Forschungsanstalten (IUFRO) danken. Ganz herzlich möchte ich auch alle unsere Gäste und Kongressteilnehmer begrüssen und Ihnen allen fruchtbringende Diskussionen und einen angenehmen Aufenthalt in Malaysia wünschen.

Soweit ich weiss, ist IUFRO eine nicht gewinnorientierte Nicht-Regierungsorganisation, die vor mehr als hundert Jahren, nämlich 1892, mit der Aufgabe gegründet wurde, die internationale Zusammenarbeit in der forstlichen Forschung und in verwandten Wissensgebieten zu fördern. Ich weiss auch, dass, obwohl IUFRO 700 Mitgliedsorganisationen in 105 Ländern zählt, es das erste Mal ist, dass ein Weltkongress in einem Entwicklungsland abgehalten wird. Deshalb möchte ich den Organisatoren gratulieren, dass es ihnen gelungen ist, die Ausschreibung für die Abhaltung dieses Weltkongresses in Kuala Lumpur zu gewinnen und dass sie die notwendigen Vorbereitungen getroffen haben, die es uns erlauben, uns hier anlässlich der grössten forstlichen Veranstaltung, die je in unserem Land abgehalten wurde, zu versammeln. Ich hoffe, dies wird der Beginn sein dafür, dass auch in anderen Entwicklungsländern in Zukunft IUFRO Weltkongresse abgehalten werden.

Wie wir wohl alle wissen, spielen Wälder im täglichen Leben vieler Menschen in den Entwicklungsländern eine sehr grosse Rolle und tragen massgeblich zum wirtschaftlichen Fortschritt dieser Nationen bei. Ich bin äusserst erfreut, dass Malaysia diese Ausschreibung gewonnen hat und somit den Weg geebnet hat für die Organisation derartiger Kongresse, da forstliche Themen in der Armutsbekämpfung von grosser Bedeutung sind. Auch möchte ich IUFRO zur gelungenen Wahl des Kongressthemas gratulieren, nämlich die Verknüpfung von Gesellschaft und Wald durch die forstliche Forschung.

Meine Damen und Herren,

Zu Ihnen von der Rolle und den Funktionen des Waldes zu sprechen würde wohl heissen: Eulen nach Athen tragen, denn Sie sind die Experten in diesem Bereich. Sie sind nur allzu vertraut mit der Tatsache, dass in der Vergangenheit die Wälder getrennt von ihren Bewohnern gesehen wurden und in den vergangenen Jahren nur als Holzlieferanten betrachtet wurden. Der globale Trend geht jedoch in Richtung Anerkennung der Tatsache, dass Wälder und Gesellschaft - und zwar sowohl im urbanen als auch im ländlichen Bereich - zwei Seiten derselben Medaille sind und dass die Wälder neben dem Nutzholz eine ganze Reihe von Gütern liefern und Funktionen erfüllen, die für das Wohl der Gesellschaft besonders wichtig sind.

Welche Lehren ziehen wir nun aus der nicht so weit entfernten Vergangenheit, Lehren, die dieses Umdenken mit sich gebracht hat und den Grundstein für die derzeitige internationale Debatte über die Wälder gelegt hat? Wir wissen, dass mit der industriellen Revolution im 19. Jahrhundert weite Teile der Wälder der gemässigten Zone in Europa, die bereits in den vergangenen Jahrhunderten dezimiert worden waren, einem nochmaligen Raubbau unterlagen, um das für die aufkeimende Industrie notwendige Holz zu liefern. Riesige Waldflächen fielen auch auf der anderen Seite des Ozeans, in Amerika, im 19. Jhdt dem Kahlschlag zum Opfer. Innerhalb von Jahrzehnten wurden Millionen Hektar Wald zerstört, um Weiden und Ackerland, Nutzholz und Brennstoff zu gewinnen.

Die industrielle Revolution im Westen hatte verheerende Konsequenzen für die Umwelt. Umwelt- und Wasserverschmutzung sowie Bodendegradierung nahmen weiter zu. Das rasche Wirtschaftswachstum am Ende des Zweiten Weltkrieges in den heutigen Industrieländern gaben Anlass zu neuerlicher Umweltzerstörung. Die Konferenz der Vereinten Nationen für die Menschliche Umwelt vom Juni 1972 in Stockholm kam und ging. Die Umweltzerstörung ging jedoch unvermindert weiter. Globale Erwärmung, Zerstörung der Ozonschicht, Verschmutzung der Weltmeere, saurer Regen, Entwaldung und Bodendegradierung - zumeist Auswirkungen der industriellen Aktivitäten - nahmen in den frühen 80er Jahren ein besorgniserregendes Ausmass an.

Vor diesem Hintergrund lieferte die Langkawi Erklärung für die Umwelt der Regierungsbeauftragten der Commonwealth

Konferenz (CHOGM), die im Oktober 1989 in Kuala Lumpur abgehalten wurde, den Anstoss für eine Konzept, dass in weiteren Treffen formell Gestalt annahm. Das Konzept der "Grünen Erde" wurde in der Pariser Deklaration des 10.. Welt-Forstkongresses 1991 zum Prinzip erhoben. In der Folge wurde mit dem bei der Konferenz der Vereinten Nationen für Umwelt und Entwicklung (UNCED) in Rio de Janeiro im Juni 1992 von allen Regierungen angenommenen Grundsatzerklärung über die Wälder dieses Konzept voll aufgenommen.

In diesem Zusammenhang und kurz vor der Abhaltung des Erdgipfels in Rio hatte Malaysia vorgeschlagen, dass die Waldfläche weltweit, die damals 27,6 % betrug, bis zum Jahr 2000 durch massive Aufforstungsmassnahmen und -programme auf 30 % erhöht werden solle. Wir hatten gemeint, dass die Massnahmen die Waldarten aller Zonen umfassen sollten - nämlich jene der borealen, gemässigten und tropischen Zonen – da es unerheblich ist, wie die verschiedenen Waldarten Kohlenstoff speichern, das Klima stabilisieren, die Umwelt schützen, die Artenvielfalt bewahren, Ressourcen für die Industrie liefern und die Existenz von im und am Rande des Waldes lebenden Bevölkerungsgruppen sichern. Wir hatten auch gemeint, dass Industrieländer mit wenig Waldbestand aufgrund des Raubbaus vergangener Jahrhunderte, die jedoch nun über eine starke Wirtschaft verfügen, auch Anstrengungen zur Begrünung der Erde unternehmen sollten. Wir hatten weiters gemeint, vielleicht in unserer Naivität, dass wirtschaftlich mächtige Länder, die über enorme Ressourcen verfügen, aktive Beiträge zu Aufforstungsprogrammen in den ärmeren Ländern leisten würden.

Acht Jahre nach dem Gipfel von Rio sind alle zur Tagesordnung übergegangen. Aller Enthusiasmus, der in Rio erzeugt worden und zu spüren war, ist beinahe über Nacht verschwunden. Nicht einmal das kleinste Anzeichen für eine gemeinschaftliche Bewegung für eine grüne Erde ist mehr zu sehen. Es wurde praktisch jeder Nation selbst überlassen, ihre Forstprogramme umzusetzen. Es wurde mir mitgeteilt, dass die jährlichen Durchschnittskosten, die notwendig sind, um die in der Agenda 21 von UNCED verlangten Forstprogramme umzusetzen, sich auf US$32 Mrd. belaufen. Davon sollte ein Grossteil von den Industrieländern aufgebracht werden. Trotz der Tatsache, dass die Agenda 21 sowie die Forstlichen Grundsätze die Rahmenbedingungen für die verstärkte Kooperation zwischen den einzelnen Ländern fördern sollen, ist es nun offensichtlich, dass der Grossteil der für die Aufforstungsprogramme notwendigen Geldmittel von den Entwicklungsländern selbst auftgebracht werden muss.

Malaysia ist und war immer proaktiv, was die Behandlung globaler Themen anlangt, wie Wald und Umwelt. Wir haben uns aktiv an den Verhandlungen beteiligt, die schliesslich zur UNCED, einschliesslich der Agenda 21, der Grundsatzerklärung über den Wald, der Konvention zur Artenvielfalt und der Rahmenkonvention über Klimaänderung führten. Wir haben aktiv an diesen Entwicklungen seit Rio mitgearbeitet. Wir sind dem Konzept einer “grünen Erde” stark verbunden, obwohl viele Wälder in der Zeit der Kolonialherrschaft gerodet wurden, und auf den so entstandenen Flächen Plantagen errichtet wurden. Trotzdem sind noch immer 58 % unserer Landesfläche von Naturwald bedeckt. Rechnet man auch Gummi- und Ölplamenplantagen dazu, so würden 72 % der Fläche von Wald bedeckt sein. Wir haben uns dafür eingesetzt und wir werden uns auch weiterhin dafür einsetzen, dass für immer mindestens 50 % der Landesfläche Malaysias mit Wald bedeckt sein sollen. Das wird unser Betrag für die Menschheit sein.

In diesem Zusammenhang haben wir alles unternommen, um die forstliche Praxis zu verbessern und diese nach den Grundsätzen der nachhaltigen Bewirtschaftung auszurichten. Wir haben z.B. die Grösse unseres permanenten Waldbesitzes von 12,7 auf 14,1 Millionen Hektar ausgedehnt, die Nationale Forstpolitik im Jahre 1992 neu gestaltet und das Nationale Forstgesetz 1993 novelliert. So wurden Gesetze verschärft und höhere Strafen für Vergehen im Zusammenhang mit dem Wald verhängt. Wir verstärken unsere Bemühungen im Bereich Forschung und Entwicklung, um die Holzindustrie auf eine Basis zu stellen, die das Prinzip Nachhaltigkeit berücksichtigt. Auf der Makroebene wird die 1998 verabschiedete Nationale Politik für Artenvielfalt die Richtung für die Bewahrung der Artenvielfalt und nachhaltigen Bewirtschaftung seiner Komponenten weisen.

Auf internationaler Ebene habe wir auch weiterhin versucht, zum Prozess des Zwischenstaatlichen Panels für Wälder (IPF) und des Zwischenstaatlichen Forums für Wälder (IFF) beizutragen. Wir sind auch aktive Teilnehmer an der derzeitigen Umsetzungsphase der Konvention für Artenvielfalt und der Konvention für Klimaänderung, die beide eng mit forstlichen Themen verbunden sind.

Wir sind wohl alle einer Meinung, dass Forstwirtschaft für Wirtschaft und Gesellschaft und auch für die Umwelt eines Landes und der Erde von grosser Bedeutung ist. Dementsprechend hat sich die Forstwirtschaft auch als Thema auf den nationalen und internationalen Tagesordnungen durchgesetzt, die sich mit der forstlichen Gesetzgebung befassen. Wir kennen nur allzugut die Argumente, die sich gegen eine solche Gesetzgebung aussprechen. Dieses Problem muss noch gelöst werden. Wir sind heute weiter denn je davon entfernt.

Malaysias Position ist die, dass gesetzlich bindende Instrumente für alle Waldarten eine Notwendigkeit darstellen, denn sie berücksichtigen die ganze Palette der Themen aus Forst- und Holzwirtschaft in einem ganzheitlichen, integrierten und umfassenden Ansatz. Wir glauben auch, dass derartige Gesetze eine nachhaltige Bewirtschaftung aller Wälder fördern würden, verglichen mit den aktuellen "ad-hoc" Massnahmen, in einer nicht gesetzlich bindenden internationalen Umwelt, die eigentlich eine Behinderung für die beste forstliche Praxis darstellt. Wir glauben auch, dass so ein Instrument Aktionen auf internationaler Ebene begünstigen würde, die sich verschärfenden Faktoren wie Waldrückgang und -degradierung in Übergangsbereichen sowie das Schuldenproblem und Konsumgewohnheiten, die die Nachhaltigkeit nicht fördern. Dieses Instrument würde auch die Kooperation bezüglich des Technologietransfers fördern und beschleunigen.

Derzeit ist der fehlende Konsens bezüglich der Notwendigkeit gesetzlich bindender Instrumente darin begründet, dass wir uns bei den kritischen Bereichen wie Finanzen, Technologietransfer und Handelsbeziehungen in einer Sackgasse befinden. Diesbezüglich möchte ich die Industrieländer dringend ersuchen, endlich ihre Verpflichtungen zu erfüllen und den Entwicklungsländern konkrete finanzielle Unterstützung und Technologien zu geben, die sie benötigen, um ihre Wälder nachhaltig bewirtschaften zu können. Überdies muss eine nachhaltige Waldbewirtschaftung durch gegenseitige Unterstützung durch den Handel und Umweltstandards für den Marktzugang gefördert werden. Alle anderen Aktionen werden den Wald nur wertlos machen und die Folge werden Kahlschläge für andere Zwecke sein. Handelsbeschränkungen und Umweltauflagen werden der Entwaldung nicht Einhalt gebieten können. Nur ein Zugang zum freien Markt wird nachhaltige Waldbewirtschaft fördern können durch die Erbringung der dafür notwendigen Einnahmen.

Seit Menschengedenken ist die Gesellschaft vom Wald abhängig. Die frühen Gesellschaften waren primitiv und die Ansprüche einfach. In vielen Teilen der Welt, zumeist in den Entwicklungsländern sind die Ansprüche der Gesellschaft immer noch einfach. Anderswo sind die Bedürfnisse gestiegen, der mit der Weiterentwicklung der Gesellschaft verbundene ressourcenverschwendende Lebensstil hat viel zum vermehrten und unstillbaren Verlangen von sich entwickelnden Gesellschaften beigetragen. Aber Bedürfnisse sind mehr als nur materiell und so lautet die Maxime, 'Waldressourcen und Waldflächen sollten nachhaltig bewirtschaftet werden, um die sozialen, wirtschaftlichen, ökologischen, kulturellen und geistigen Bedürfnisse des Menschen der heutigen und zukünftigen Generationen befriedigen zu können".

Ich bin sehr froh, dass ich heute die Gelegenheit habe, Sie alle hier zu treffen, und diese Rede an einem Kongress vor Wissenschaftlern zu halten, die ihr Leben der forstlichen Forschung verschrieben haben, sodass direkt oder indirekt, Sie es sind, die zur Deckung der Bedürfnisse der Gesellschaft beitragen, heute und in der Zukunft. Die jüngste Vergangenheit hat gezeigt, dass Investitionen in Forschung und Entwicklung in jedem Bereich gute Ergebnisse zeitigen. Es ist mein sehnlichster Wunsch, dass ihre Bemühungen zu Ergebnissen führen mögen, die eine bessere Gesellschaft zur Folge haben können und insgesamt auch den ärmeren Schichten der Bevölkerung zugute kommen. Sie vertreten hier sowohl die Industrie- als auch die Entwicklungsländer, und IUFRO fungiert als Bindeglied dieser Nord-Süd-Partnerschaft .

Ich hoffe, dass alle Ihre Bemühungen dazu beitragen mögen, eine gerechte Forstwirtschaft auf die Tagesordnung der internationalen Konferenzen zu bringen und die von Ihnen entwickelten Technologien in gerechter Art und Weise mit den Entwicklungsländern zusammen genutzt werden können, um die forstliche Praxis weltweit zu verbessern. Wenn die Welt eine nachhaltige Waldbewirtschaftung will, so muss sie auch den Technologietransfer von Norden nach Süden, wie in den Abkommen von Rio festgeschrieben, zulassen. Leider war dies bis jetzt nicht der Fall und die Entwicklungsländer werden ohne Zugang zu diesen Technologien nicht in der Lage sein, ihren Verpflichtungen zur nachhaltigen Waldbewirtschaftung nachzukommen. IUFRO kann daher eine wichtige Rolle bei diesem Technologietransfer spielen, und ich hoffe, dass dieser Kongress dazu beitragen wird, nicht nur den Austausch von Forschungsergebnissen zu fördern, sondern auch ein konkreteres Netz für den Technologietransfer Nord-Süd zu bilden. Ich wünsche Ihnen deshalb alles Gute bei Ihren Bemühungen und hoffe, dass Sie einen erfolgreichen Kongress erleben werden.

Abschliessend möchte ich noch einmal allen Teilnehmern dieses Kongresses alles Gute wünschen. Ich hoffe, dass Sie die Zeit finden werden, im Rahmen der Exkursionen nach dem Kongress nicht nur die Artenvielfalt unserer Tropenwälder sondern auch das multikulturelle, multiethnische und multikonfessionelle Malaysia kennenzulernen. In Malaysia werden Sie Asien finden.

Damit erkläre ich den 21. IUFRO-Weltkongress für eröffnet.

Ansprache von

Prof. M. Hosny El-Lakany

Stellvertr. Generaldirektor,
Forstabteilung, FAO

Sehr geehrte Gäste,
Sehr geehrter Herr Präsident,
Geehrte Mitglieder des IUFRO Direktoriums,
Meine Damen und Herren,

Im Namen des Generaldirektors und der Mitarbeiter der Organisation für Ernährung und Landwirtschaft der Vereinten Nationen, und im speziellen im Namen meiner Kollegen von der Forstabteilung möchte ich alle Teilnehmer an diesem XXI IUFRO Weltkongress sehr herzlich begrüssen. Es ist für mich persönlich eine grosse Freude und Ehre, dass ich heute hier bei Ihnen in Kuala Lumpur sein darf!

Zuerst möchte ich den Kongressorganisatoren und im speziellen unseren malaysischen Gastgebern für die hervorragende Organisation gratulieren. Gewiss ist Malaysia mit seiner langen und fundierten forstwissenschaftlichen Tradition ein Beitrag zur Entwicklung und ein äusserst geeigneter Rahmen für diese beeindruckende Zusammenkunft.
Wenn ich hier in die Runde blicke und diese vielfältige und hochkarätige Gruppe von Teilnehmern sehe, so wird mir immer mehr der grundlegende Wert von IUFRO als Organisation bewusst. IUFRO bietet ein Forum für Forstwissenschaftler zum gegenseitigen Austausch von Gedanken und Wissen im Sinne der Verbreitung der Sache der nachhaltigen Forstwirtschaft und des persönlichen Weiterkommens. Diese Gelegenheit für junge Wissenschaftler am Beginn ihrer Karriere einen Gedankenaustausch mit erfahrenen Forschern vorzunehmen und von diesen Kontakten zu profitieren, ist aussergewöhnlich und sucht ihresgleichen, und die Möglichkeit, Zugang zu Forschungsergebnissen aus der ganzen Welt zu bekommen, ist von unermesslichem Wert. Für wieviele von uns, die wir heute hier versammelt sind, war dies nicht ein grosser Vorteil!

Dies gilt auch für mich. Ich erinnere mich lebhaft an meine erste Teilnahme an einem IUFRO Kongress, und zwar war das 1976 in Oslo, und an mein Zusammentreffen mit vielen Forstwissenschaftlern, von denen glücklicherweise noch viele heute unter uns sind. Und ein Teil meiner Doktorarbeit beschäftigte sich mit Saatgutgewinnung im Rahmen des IUFRO – Douglasien- Herkunftsversuches von 1966.

Daher ist es eine grosse Ehre für mich, die FAO bei diesem wichtigen Ereignis – dem ersten IUFRO Weltkongress im neuen Millenium - vertreten zu dürfen. IUFRO hat eine besondere Beziehung zu seinen Mitgliedern und die Beziehungen zur FAO sind einzigartig. Seit der Gründung der FAO gibt es eine gute Kooperation und Symbiose zwischen FAO und IUFRO – wobei IUFRO die um ein halbes Jahrhundert „ältere Schwester" der FAO ist. IUFRO stellt die Verbindung zwischen Wissenschaftlern und Forschern her, und die FAO ist bei der Umsetzung der wertvollen Resultate der forstlichen Forschung in die Praxis behilflich – und auch dass der „Herzschlag" der Arbeit im Gelände auf die Wissenschaftler übertragen wird.

Alle Forstbeamten der FAO haben direkten und ständigen Kontakt mit IUFRO und den jeweiligen Forschungs- und Arbeitsgruppen. Zusätzlich fördert die FAO im Rahmen seines „Partnership Programmes" den Austausch von Wissenschaftlern, und speziell von jungen Wissenschaftlern, die sonst keine Gelegenheit zum direkten Erfahrungsaustausch haben. Auf Länderebene hilft die FAO durch seine Rolle als neutrales Forum bestimmte Bereiche gemeinsam zu erschliessen, wo weltweite zusätzliche Forschungsarbeit notwendig ist, und dadurch den Einsatz der Wissenschaftler weltweit auf ein gemeinsames Ziel zu konzentrieren. In dieser Hinsicht bin ich immer wieder erfreut, wenn den Nationalen Delegationen zu den zweimal pro Jahr stattfindenden Sitzungen des FAO Komitees für Forstwirtschaft auch Forstwissenschaftler angehören. Damit ergibt sich ein Informations- und Wissensaustausch über die Vielzahl der Adern des Netzwerks zwischen FAO und IUFRO zugunsten aller Beteiligten.

Aus der Sicht der FAO ist das Thema des Kongresses, „Wald und Gesellschaft: die Rolle der Forschung", besonders gelungen. In seiner forstlichen Arbeit ist die FAO einem Ansatz verbunden, der auf der bestmöglichen Nutzung der Umweltwirkungen und des wirtschaftlichen Potentials durch die nachhaltige Forstwirtschaft beruht. Tatsächlich entspricht diese Verpflichtung der FAO Strategie für die Forstwirtschaft, die in Zusammenarbeit mit FAO Mitgliedsstaaten, Partnerinstitutionen und –organisationen einschliesslich IUFRO, in mehr als zwei Jahren erarbeitet und vom Komitee der FAO für Forstwirtschaft im März 1999 angenommen wurde. Der Strategische Plan für Forstwirtschaft der FAO beschreibt das Aufgabengebiet, die Ziele und die mittelfristigen Zielsetzungen, laufende Schwerpunktaktivitäten und die Visionen für die Forstwirtschaft. Die Aufgabe besteht darin, "das Wohl der Menschheit zu fördern durch die Unterstützung der Mitgliedsstaaten bei der nachhaltigen Bewirtschaftung der Bäume und Wälder der Erde". Es sind der Mensch und die Gesellschaft, denen die grösste Bedeutung zukommt.

Unsere Schwerpunktaktivitäten konzentrieren sich auch auf den Wald und die Gesellschaft. Zum Beispiel bemühen wir uns, im Rahmen der partizipativen Forstwirtschaft grössere Anteile der Bevölkerung direkt an forstlichen Massnahmen und Entscheidungsprozessen zu beteiligten. Ich sollte hier noch hinzufügen, dass dies nicht nur jene betrifft, die in oder in der Nachbarschaft von Waldgebieten leben, sondern im speziellen auch andere, die vom Wald und seinen Leistungen abhängen.

Eine anderer Schwerpunkt der FAO hat direkte Relevanz für das Thema Wald und Gesellschaft in unserer Arbeit, Ländern dabei zu helfen, nationale Forstprogramme durchzuführen. Diese Programme, die aus den UNCED folgenden zwischenstaatlichen Prozessen hervorgegangen sind, zielen darauf ab, einen praktikablen sozialen und politischen Rahmen zu bilden für die Erhaltung, das Management und die nachhaltige Entwicklung aller Waldarten.

Eine dritte Priorität des forstwirtschaftlichen Bereichs der FAO unterstützt den weltweiten Zugang zu verlässlicher und aktueller forstlicher Information. Der erste Artikel der Verfassung der FAO gibt uns den Auftrag, Information zu sammeln, zu analysieren, auszuwerten und zu verbreiten. In der Forstwirtschaft beinhaltet dies die Entwicklung gemeinsamer Ausdrücke und Definitionen, und die Harmonisierung der Definitionen, die Sammlung von Statistiken im Bereich Produktion, Konsum und Handel, und unsere Beurteilung der forstlichen Ressourcen weltweit. Bei all diesen Aspekten arbeiten wir eng mit IUFRO zusammen. Es ist daher angebracht, dass wir die ersten Ergebnisse der Beurteilung der forstlichen Ressourcen 2000 durch die FAO hier bei diesem Kongress veröffentlichen. Ich möchte hier auch unsere umfassende Webseite und die Zusammenarbeit zwischen FAO und IUFRO bei der Entwicklung des Weltweiten Forstinformationsdienstes erwähnen.

Ein anderer wichtiger Bereich der Zusammenarbeit FAO-IUFRO betrifft das Sonderprogramm für Entwicklungsländer – das SPDC. Vor einem Monat, am 7. Juli, wurde das Netzwerk für forstliche Forschung für Afrika südlich der Sahara (FORNESSA) offiziell gegründet und Dr. Konuche aus Kenya übernahm die Leitung desselben. In diesem Zusammenhang bin ich sehr froh zu sehen, dass der stellvertretende Koordinator für Afrika des SPDC seinen Sitz im Regionalbüro für Afrika der FAO hat. Deshalb sind enge, ständige Beziehungen mit der FAO gesichert.

Bei diesem Kongress werden zahlreiche Vorträge von FAO Mitarbeitern gehalten werden und viele Veranstaltungen wurden zusammen mit der FAO organisiert.
Die gebrachten Beispiele zeigen, wie ich hoffe, die langfristige Verpflichtung der FAO zur bestmöglichen Förderung der positiven Beziehungen zwischen Wald und Gesellschaft. Und das Thema dieses Kongresses weist deutlich darauf hin, dass IUFRO und ihre Mitglieder auch in dieser Richtung tätig sind.

Welche Rolle nimmt die Forschung nun auf diesem Weg ein, aus der Sicht der FAO? Gewiss ist eine stärkere Konzentration auf die sozialen Aspekte der nachhaltigen Forstwirtschaft nötig. Wir müssen mehr über die Art der Durchführung der Waldbewirtschaftung erfahren und im speziellen über die Instrumente und die wissenschaftlichen Grundlagen, die nötig sind, um den Anforderungen so gut wie möglich gerecht zu werden.

Wir benötigen mehr Forschung auch darüber, wie die Informationen am effizientesten an diese Menschen weitergegeben werden können, um sie in die Lage zu versetzen, besser an den Entscheidungsprozessen in der Forstpolitik teilhaben zu können. Ebenso brauchen wir spezielle Forschungsarbeiten zum Bereich Konfliktmanagement.

Und wir brauchen auch besonders Forschung zum Potential und zu den Modalitäten internationaler Kooperation in der Forstwirtschaft. Die vergangene Dekade war gekennzeichnet von einer Unmenge von internationalen Abkommen, die sich direkt auf die Zukunft der Weltforstwirtschaft beziehen, aber jene, die mit der Einbindung und Umsetzung der Forschung betraut sind, bewegen sich auf Neuland. Wir müssen aus den Erfahrungen der anderen Sektoren, die diesen Weg vor uns beschritten haben, lernen, sie studieren und analysieren, sodass die Abkommen, die wir für die Forstwirtschaft schliessen, sowohl praktikabel in der Umsetzung als auch ehrlich in der Absicht bleiben.

Es sind dies grosse Herausforderungen und sie werden umso grösser, wenn man bedenkt, dass sie Forschung ergänzen, jedoch nicht traditionelle forstliche Forschung ersetzen sollen. Meiner Meinung nach sind sie jedoch wesentlich für die Erreichung unseres gemeinsamen Ziels der nachhaltigen Nutzung von Waldökosystemen. Und ich kann mir keine andere Organisation vorstellen, die besser für diese Aufgabe geeignet ist als IUFRO.

Zum Schluss, meine Damen und Herren, möchte ich dem scheidenden Direktorium und insbesondere seinem Präsidenten, der ein enger Kollege und guter Freund ist, Professor Jeff Burley für ihre kompetente Kollaboration danken. Und erlauben Sie mir auch, dem neuen Vorstand und dem neuen Präsidenten, Professor Risto Seppälä, mein Vertrauen auszusprechen sowie die Altpräsidenten und hier besonders Dr. Salleh Mohd Nor herzlich zu begrüssen.

Herr Vorsitzender, im Auftrag des Generaldirektors der FAO, Jacques Diouf, und in meinem eigenen Namen, und besonders im Namen des Forstprogrammes der FAO, hoffe ich sehr, dass dies ein erfolgreicher Kongress sein wird und ein gelungener Start für die Weltforstwirtschaft im neuen Millenium.

Ich danken Ihnen.

Fünfjahres Bericht
Schlusssitzung

Professor Jeffery Burley

IUFRO Präsident

Sehr geehrte Gäste, liebe Kollegen, meine Damen und Herren,
am Ende dieses beeindruckenden und produktiven Kongresses möchte ich mich kurz als amtierender Präsident an Sie wenden. Professor Risto Seppälä wird als designierter Präsident eine Rede halten. Ich werde Ihnen einen Überblick über die Aktivitäten und Erfolge IUFROs in den letzten fünf Jahren meiner Präsidentschaft geben, während Professor Seppälä Ihnen seine Visionen zukünftiger Entwicklungen in der forstlichen Forschung und in IUFRO darlegen wird.

Die Resolutionen von 1995 und ihre Herausforderungen
Bei unserem 20. Kongress, der 1995 stattfand, wurden die folgenden Resolutionen akzeptiert: - a) Erhaltung und Verstärkung zielgerichteter Forschung in den Bereichen Forstwirtschaft und Forstprodukte; b) Steigerung der Forschungskapazität, speziell in den Entwicklungsländern; c) Förderung breitgefächerter Partnerschaften zur Erhöhung der Forschungseffizienz und verbesserte Kommunikation zwischen wissenschaftlichen und nichtwissenschaftlichen Gruppen; d) Verbesserung der politik- und problemorientierten Forschung in den Wirtschafts- und Sozialwissenschaften. Als ich zum Präsidenten gewählt wurde, habe ich dem Direktorium meine persönliche Sicht der Rolle IUFROs dargelegt, der Entwicklungen und Aktivitäten, und ich möchte diese nun für Sie zusammenfassen und Ihnen zeigen, wie IUFRO auf die von mir gestellten Herausforderungen und Kongress-Resolutionen reagiert hat.

Ich habe darauf hingewiesen, dass im letzten Jahrzehnt des letzten Milleniums einschneidende Änderungen im Bereich Forstpolitik, forstliche Praxis und forstliches Berufsbild stattgefunden haben. Forstliche Themen wurden zum globalen und internationalen Anliegen und betrafen immer mehr auch Bevölkerungsgruppen, die nichts mit der traditionellen Forstwirtschaft zu tun haben. Sozioökonomische Wissenschaften gewannen an Einfluss in den Entscheidungsprozessen. Ein globaler Druck war zu bemerken, die Rolle des Waldes zu überdenken und zu evaluieren und seinen Zustand zu überwachen. Entscheidungsträger bemühten sich nun (a) um Informationen über die Rolle, die Werte und den Zustand der Wälder und Bäume in bezug auf Erhaltung und Entwicklung, (b) um neue Sichtweisen zu den Zusammenhängen zwischen Wäldern, Artenvielfalt, Klima und anderen Umweltfragen und (c) um Beratung hinsichtlich nachhaltiger Waldwirtschaft einschliesslich Strukturförderung.

Schon damals war mir klar (und ich bin noch immer dieser Meinung), dass IUFRO auf diese Änderungen reagieren sollte, jedoch unter Beibehaltung seiner Vorreiterrolle als ein Netzwerk von auf freiwilliger Basis arbeitenden Wissenschaftlern, IUFRO sollte auch weiterhin die wichtigste Quelle von Wissen und Erfahrungen im Bereich forstlicher Forschung für spezielle Themen sein, wobei auch die Intensität und Häufigkeit interdisziplinärer Zusammenarbeit innerhalb des Verbandes selbst und mit anderen Organisationen ausserhalb des traditionellen Forstbereichs erhöht werden sollte.

Aufgrund dieser Verbindungen konnte auch die Arbeit IUFROs unter Anwendung moderner Technologien bekanntgemacht werden, Geldquellen erschlossen und eine produktive Zusammenarbeit zur Vermeidung von Überschneidungen etabliert werden. Schwerpunktthemen wurden früh durch das Direktorium erkannt und erwiesen sich als äusserst wichtig für die Herstellung von Kontakten mit einer Reihe anderer Institutionen. IUFRO hat versucht, die Leiter der Mitgliedsorganisationen zu unterstützen durch die Durchführung und Vebreitung von politik-orientierter Forschung und durch die Unterstützung der Direktoren für die Sensibilisierung von Regierungen und Organisationen für forstliche Themen.

Die neue Rolle IUFROs auf der internationalen Bühne
Das Direktorium machte grosse Anstrengungen, um die globale Bedeutung IUFROs herauszustreichen. Die hochgelobte IUFRO Broschüre wurde am Weltkongress in der Türkei 1997 verteilt und die gleichermassen anerkannte IUFRO Webseite hat Homepages für alle Forschungseinheiten, die auf Servern in einzelnen Ländern gespiegelt und mit anderen Internetseiten verküpft sind. Viele dieser Webpages enthalten Raum für Berichte über den Stand der Wissenschaft in der jeweiligen Disziplin der Forschungseinheit. Wie Sie wahrscheinlich bei diesem Kongress bemerkt haben, wurde grosses Augenmerk auf die Verbreitung von Forschungsresultaten und Berichten über den Stand der Wissenschaft gelegt.

Wir haben uns auch bemüht, die Rolle des Verbandes in der internationalen Debatte und Entwicklung zu stärken. Ich und andere IUFRO Funktionäre haben Tagungen von anderen Organisationen besucht, so z.B.: - das Zwischenstaatliche Forum für Wälder (IFF); das Weltwaldforum; den Weltforstkongress; das Komitee für Forstwirtschaft der Organisation der Vereinten Nationen (COFO/FAO); die Generalversammung von IUCN; zahlreiche Tagungen einer

Reihe von internationalen Initiativen zur Ausarbeitung von Kriterien und Indikatoren für nachhaltige Waldbewirtschaftung; das Direktorium des Zentrums für internationale forstliche Forschung (CIFOR) und das internationale Zentrum für agroforstliche Forschung (CGIAR); die Nationale Ausstellung in Kunming, China; und zahlreiche Treffen und Ausstellungen anderer Organisationen. Mit besonderer Genugtuung haben wir die Empfehlungen der 4. Sitzung des IFF wahrgenommen, die zur Verbesserung der Beziehungen zwischen forstlicher Forschung und forstpolitischen Prozessen, zur besseren Förderung der forstlichen Forschung (speziell in den Entwicklungsländern) und zu einem besseren Zugang zu forstlich-orientierter Information und Zusammenarbeit mit IUFRO im Rahmen von GFIS aufrief.

Das von Renate Prüller koordinierte und von Japan finanzierte Terminologieprojekt IUFROs (SilvaVoc) hat sich gegenüber der FAO vertraglich verpflichtet, Definitionen zu den wichtigsten Ausdrücken, die bei den internationalen Debatten zum Thema „nachhaltige Forstwirtschaft“ verwendet werden, bereitzustellen. Es hat mich auch sehr gefreut, dass mein eigenes Institut in der Lage war, im Namen von IUFRO für die Weltkommission für Wälder und Nachhaltige Entwicklung ein Dokument über forstpolitische Fragen auszuarbeiten, das von der Overseas Development Administration von Grossbritannien (nun Abteilung für Internationale Entwicklung) finanziert wurde.

IUFRO hat seine Forschungseinheiten ermutigt, aktuelle Schwerpunktthemen aufzugreifen. Ein aussergewöhnlicher Beitrag IUFROs zu den internationalen Prozessen war seine Rolle bei der Organisation und Bekanntmachung der Internationalen Konsultation über Forschung und Informationssysteme in der Forstwirtschaft (ICRIS), die von den Regierungen von Österreich und Indonesien in Zusammenarbeit mit CIFOR und der Forstabteilung der FAO finanziert wurde. Diese Konferenz war eine Aktivität zur Unterstützung des Zwischenstaatlichen Forums für Wälder (IFF) der Kommission der Vereinten Nationen für nachhaltige Entwicklung (UNCSD) und fand im Sepember 1998 in Österreich statt. Eines der wichtigsten Ergebnisse für IUFRO waren die Gründung der Sonderarbeitsgruppe für den weltweiten forstlichen Informationsdienst (GFIS) und die Sonderarbeitsgruppe über die Verknüpfung von forstlicher Forschung mit der Politik.

IUFROs verbesserte Struktur und Aktivitäten

IUFRO nimmt auch weiterhin eine Vorreiterrolle bei der Förderung forstlicher Forschung durch die Zusammenarbeit im Rahmen des Netzwerkes von fast 700 Mitgliedsorganisationen und 15.000 Wissenschaftlern in ihren jeweiligen Disziplinen ein; 268 Forschungseinheiten und 8 Sonderarbeitsgruppen hielten 335 Tagungen in 65 Ländern ab, darunter befinden sich 41 Entwicklungsländer oder Reformstaaten. Zu Beginn der Amtsperiode des Direktoriums wurden zwei neue Abteilungen gegründet, um dem wachsenden Forschungsbedarf gerecht zu werden und das Arbeitsvolumen der einzelnen Abteilungskoordinatoren und ihrer Stellvertreter zu reduzieren (die ja, wie alle IUFRO-Funktionäre, Freiwillige sind). Das Direktorium hat eine Reihe von Sonderprogrammen, Projekten und Sonderarbeitsgruppen ins Leben gerufen, die spezielle Themen oder Fragestellungen aufgreifen. Sie wurden ermutigt, Schwerpunkte zu setzen, besonders im Bereich Ausbau der Forschungskapazität. In einer so kurzen Rede ist es natürlich nicht möglich, auf alle Einzelheiten einzugehen oder auch nur Kurzdarstellungen dieser Aktivitäten zu geben, aber ich werde einige besondere Errungenschaften der Sonderarbeitsgruppen herausstreichen.

Wie bereits erwähnt, war eine der grössten Veränderungen im vergangenen Jahrzehnt der vermehrte Bedarf an interdisziplinären Ansätzen zur Lösung von Forschungsproblemen. IUFRO hat immer versucht, alle wissenschaftlichen Bereiche in einzelnen Forschungseinheiten (Biophysik und Sozioökonomie) abzudecken. In den letzten fünf Jahren wurde die Verflechtung untereinander durch die Abhaltung interdivisionärer Veranstaltungen in Zusammenarbeit mit anderen Organisationen und durch die Arbeit der Sonderarbeitsgruppen gefördert. Wir müssen einsehen, wie schwierig es ist, fremde Fachdisziplinen zu verstehen und universitäre oder berufliche Anerkennung für multidisziplinäre Arbeit zu bekommen, aber das ist klar ein wichtiges Ziel, das wir anstreben müssen.

Die Abteilungen

In Seoul, Südkorea, fand 1998 eine interdivisionäre Tagung über forstliche Ökosysteme und Landnutzung im Gebirge statt. Sie wurde von den Abteilungen 1,4,6 und 8 organisiert. 350 Delegierte aus 24 Ländern nahmen daran teil. Innerhalb der Abteilung 1 war die Forschungsgruppe 1.17.00 (Wiederherstellung degradierter Standorte) sehr stark in einem vom USDA Forstdienst, der Weltbank, CIFOR und der British Overseas Development Administration finanzierten internationalen Forschungsprogramm involviert, das sich mit der Rolle und den Auswirkungen beschleunigten natürlichen Waldwuchses auf degradierte tropische Flächen auseinandersetzte.

Abteilung 2 organisierte eine grosse Veranstaltung zum Thema Forstgenetik in Peking, 1998 und ihre Arbeitsgruppe

2.04.06 hielt 1999 eine Tagung über genetische Veränderungen in Oxford ab, wobei IUFROs kontinuierliche Auseinandersetzung mit aktuellen Themen von politischer Relevanz besonders zum Tragen kam. Die Teilnehmer an dieser Tagung waren sich darin einig, dass der Bereich genetischer Veränderungen immer noch nicht über genügend Finanzmittel verfügt, jedoch auch neue Techologien zur Erhöhung der Effizienz verwendet werden sollen. Derzeit sollten genetisch veränderte Organismen nur für Laborzwecke verwendet werden und solange der ethische Gesichtspunkt in der Öffentlichkeit nicht abgeklärt ist, keine sonstige Verbreitung erfahren.

Abteilung 3 organisierte eine Reihe von Abteilungstreffen und interdivisionären Treffen mit der Abteilung 1 in Bolivien, 1997; der Abteilung 6 in Japan, 1998, Kanada, 1998 und Australien, 2000; der Abteilung 8 in Japan, 1998 und der Sonderarbeitsgruppe für Nachhaltige Waldbewirtschaftung in Australien, 1998. Sie hielt auch eine Reihe von Treffen mit externen Organisationen wie CIFOR und FAO ab. Einzelne Forschungsgruppen erarbeiteten Berichte über den Stand der Wissenschaft.

Abteilung 5 bemühte sich sehr um mehr Verständnis um die sich ändernde Ressourcenbasis im Wald, um die vermehrte Ausnutzung von Ressourcen und um den Einsatz von umfreundlichen und sozial verträglichen Technologien. Die Konferenz der gesamten Abteilung 1997 legte den Schwerpunkt auf Waldprodukte für nachhaltige Waldwirtschaft und wurde von 222 Teilnehmern aus 42 Ländern besucht.

Abteilung 7 wurde geschaffen, um spezifisch eine Resolution von 1995 anzusprechen, die sich mit Forschung zum „…..Ausmass, der Produktivität und der Gesundheit von Wäldern…“ auseinanderzusetzt. In den letzten fünf Jahren hielt die Abteilung Veranstaltungen in Europa, Nordamerika und Asien ab, die mit sich mit Entomologie, Pathologie, Luftverschmutzung und den Wechselwirkungen Wirt-Schädling befassen.

Sonderarbeitsgruppen

Ein Schlüsselthema weltweit war die Entwicklung von Kriterien und Indikatoren für die nachhaltige Waldbewirtschaftung. Die von Alain Franc koordinierte Sonderarbeitsgruppe für die nachhaltige Forstwirtschaft hat wechselweise mit CATIE, CIFOR, Ecofor, EFI und der FAO bei der Organisation von drei grossen internationalen Veranstaltungen in Australien 1998, Costa Rica 1999 und Frankreich 1999 (in Kooperation mit Ecofor und EFI) zusammengearbeitet. Jede dieser Veranstaltungen vereinte 100-200 Teilnehmer mit dem Ziel, Wissenslücken zwischen Wissenschaflern und Interessensgruppen zu schliessen und gleichzeitig die Beziehungen zwischen Kriterien, Indikatoren, Zertifizierungssystemen und Biodiversität zu klären. Besonderes Augenmerk wurde dabei auf die Rolle der Sozialwissenschaften gelegt.

Aufgrund der Beiträge vieler Wissenschaftler entwickelte die von John Innes koordinierte Sonderarbeitsgruppe für Umweltveränderungen herausragende Berichte zum Stand der Wissenschaft. Zwei davon wurden in der IUFRO Research Series veröffentlicht, der Rest wird im Laufe des Jahres fertiggestellt werden. Die Sonderarbeitsgruppe war im speziellen verantwortlich für eine Resolution der Ministerkonferenz zum Schutz der Wälder in Europa, auch als „Helsinki 4“ bekannt, die sich mit der Koordination von Massnahmen zum Klimaschutz in Europa befasst.

Die von Martin Price koordinierte Sonderarbeitsgruppe über die Bewirtschaftung von Gebirgswäldern hat den ersten Bericht zum Stand der Wissenschaft zu diesem Thema geliefert, mit Beiträgen von 124 Autoren aus der ganzen Welt. Ein kritischer Punkt war die Definition, wie gross die Waldfläche weltweit ist; Schwerpunkte waren die Erstellung einer Weltwaldkarte (nach objektiven Kriterien) und einer Karte mit Bergwäldern, die 28 % der Weltwaldfläche ausmachen.

Die von Rob Vertessy koordinierte Sonderarbeitsgruppe für Wasser und Wald wurde ins Leben gerufen, um den aktuellen Wissensstand und Hypothesen über Süsswasserökosysteme in Wäldern und die Auswirkungen von Waldbau und Waldbewirtschaftung auf Wasserquantität und –qualität zu überprüfen. Zu dem Thema wurde eine umfangreiche Publikation verfasst.

Die von Lauri Valsta koordinierte Sonderarbeitsgruppe über Internet-Ressourcen hat ein einzigartiges Instrument von unschätzbarem Wert für die Kommunikation zwischen Wissenschaftlern untereinander und für die weltweite Verbreitung von Information über IUFRO entwickelt.

Die von Risto Päivinen koordinierte Sonderarbeitsgruppe für den weltweiten forstlichen Informationsdienst ist ein Konsortium von internationalen, regionalen und nationalen Organisationen, die eine Strategie für eine internet-gestützte Metadatenbank entwickelt, die weltweiten Zugriff auf forstlich relevante Informationen bieten soll. Die Sonderarbeitsgruppe hat Grundkonzepte für Datensammlung und technische Lösungen inklusive eines Prototyps erarbeitet. Ein von der Europäischen Kommission finanziertes EU-Projekt für Afrika, die Karibik und den Pazifischen Raum deckt den Bereich Entwicklungsländer ab.

Die Sonderarbeitsgruppe für die Bewirtschaftung und Erhaltung forstlicher Genressourcen wird von Veikko Koski koordiniert und besteht aus Vertretern der meisten IUFRO-Abteilungen, von CIFOR, FAO und IPGRI. Sie sammelt wissenschaftliche Informationen über Wechselwirkungen zwischen allen Faktoren, die die Verteilung, Integrität und Erhaltung forstlicher Genressourcen beeinflussen. Es wurde ein Bericht über den Stand der Wissenschaft erstellt.

Die von Rich Guldin koordinierte Sonderarbeitsgruppe für die Verknüpfung von forstlicher Forschung und Forstpolitik trug zur Gestaltung der Konferenz der Abteilung 6 über die Beiträge der Wissenschaft zur Entwicklung der Forstpolitik in Südafrika bei und organisierte zwei Nebenveranstaltungen bei der dritten und vierten IFF-Sitzung. Drei Konferenzen, die in den nächsten drei Jahren stattfinden sollen, werden 40-50 Fallstudien durchführen, die zeigen sollen, wie Forschung erfolgreich auf die Forstpolitik Einfluss nimmt.

IUFRO unterstützt Entwicklungsländer

Die Arbeit des bis zum Juni dieses Jahres von Bob Szaro koordinierten Sonderprogramms für Entwicklungsländer (SPDC) war immer darauf ausgerichtet, den Aus- und Aufbau fachlicher Kapazitäten in Entwicklungs- und Reformstaaten zu fördern. Zusätzlich wurden Anstrengungen unternommen, um Wissenschaftler, die in den Bereichen Wissenschaft und Management als Funktionäre von Forschungseinheiten tätig sind, zu unterstützen. Das SPDC organisierte Workshops zum Thema Management und Planung von Forschung, Formulierung von Forschungsanträgen und Strategische Planung. Mehr als 200 Wissenschaftler und 35 Veranstaltungen in mehr als 60 Ländern wurden durch dieses Programm finanziert und die ersten zwei Bände einer Reihe kostengünstiger Handbücher wurden publiziert.

IUFRO dankt für Zuwendungen der Regierungen der Vereinigten Staaten von Amerika, von Kanada und von Dänemark, die jeweils den Koordinator, den stellvertretenden Koordinator und einen stellvertretenden Koordinator für Afrika für das SPDC finanzierten. Das BIOREFOR-Programm wurde grosszügig von der Japanischen Regierung unterstützt. Dieses Programm trug zur Förderung der Zusammenarbeit zwischen vielen Institutionen in der Asien-Pazifik-Region auf dem Gebiet der Nutzung der Biotechnologie für Aufforstungsvorhaben bei. Wir sind gleichfalls verbunden für die grosszügige Unterstützung, die die Europäische Kommission unserem GFIS-Afrika Projekt angedeihen liess. Dieses Projekt soll die Verbreitung forstlicher Information in Afrika fördern. Andere Agenturen, die Unterstützung in Form von Finanz- oder Personalmitteln für IUFRO zur Verfügung stellten, waren: AusAid (Australien), der Deutsche Verband forstlicher Versuchsanstalten (Deutschland), die Königliche Dänische Botschaft, der USDA Forstdienst (USA), die Regierung von China Taipei, und die Regierung von Grossbritannien.

Verbreitung von Forschungsresultaten

Forschung sollte nicht im luftleeren Raum betrieben werden und es ist anzustreben, die Ergebnisse dieser Forschung so weit wie möglich zu verbreiten. IUFRO hat sich sehr bemüht, die Arbeit, die Ergebnisse, den Wert und die Bedeutung forstlicher Forschung im allgemeinen und von IUFRO im speziellen bekanntzumachen. Zusätzlich zu den bereits erwähnten Webseiten und zu insgesamt 91 Tagungsberichten, die von den Forschungseinheiten herausgegeben wurden, haben wir auch versucht, die IUFRO World Series und die IUFRO Occasional Paper Series fortzusetzen (vom Sekretariat herausgegeben) sowie auch die IUFRO Research Series zu ergänzen (von CAB International herausgegeben).

Evaluierung von IUFRO-Struktur und Management

Das im Amt befindliche Direktorium ist ständig mit der Evaluierung der Struktur und der Aktivitäten IUFROs befasst. Zu diesem Zweck wurde auch eine externe Expertenkommission beauftragt, das Sekretariat, das SPDC und das Sonderprojekt zu evaluieren. Wir haben uns sehr bemüht, Zuwendungen für die Unterstützung von Mitgliedern aus Entwicklungsländern zu bekommen und gleichzeitig auch IUFROs eigene Projekte wie das Terminologie-Projekt SilvaVoc zu etablieren. Einer eingehenden Prüfung wurde auch die Investitionspolitik in Hinblick auf die Probleme, die manche Mitgliedsorganisationen bei der Aufbringung des Mitgliedsbeitrags haben, unterzogen. Als Reaktion auf den kürzlich zu verzeichnenden Rückgang der Anzahl der Mitgliedsorganisationen hat der Internationale Rat die Änderung des englischen Namens IUFROs von „Forestry“ auf „Forest“ genehmigt. Hier wird der Bedarf sichtbar, die breite Palette der Disziplinen und Institutionen, die Leistungen von IUFRO erhalten oder die Beiträge leisten, zu erfassen. Es wird auch der unterschiedlichen Wahrnehmung des Begriffes „Forstwirtschaft“ durch Teile der Öffentlichkeit Rechnung getragen, die diesen nur mit massiven Abholzungen oder Plantagen mit fremdländischen Baumarten in Zusammenhang bringen. Und das zu einer Zeit, wo IUFRO alles unternimmt, um auf die überwirtschaftlichen Funktionen des Waldes wie Erholungs- und Umweltwirkung hinzuweisen.

Das Direktorium hat die Mitgliedsorganisationen und Wissenschaftler angewiesen, sich als Teil des Politik- und

Planungsprozesses von IUFRO zu verstehen. Viele haben zur Entwicklung des Strategischen Planes beitragen, der die Arbeit des Direktoriums in den letzten fünf Jahren begleitet hat. Der Internationale Rat wurde auch zur Entwicklung der IUFRO-Politik, der Neufassung der Statuten IUFROs und der Wahl des nächsten Direktoriums herangezogen.

Das Direktorium hat die Regionalisierung des IUFRO Managements und der wissenschaftlichen Kooperation durch die Anerkennung von Kapiteln wie der Asia Pacific Association of Forest Research Institutes (APAFRI), dessen Sekretariat derzeit in Malaysia seinen Sitz hat, ermutigt. Zusätzlich leistete IUFRO zusammen mit der FAO proaktive Unterstützung für andere regionale Aktivitäten, die die Kooperation zwischen nationalen Institutionen wie dem Forestry Research Support Programme for Asia and the Pacific (FORSPA) und dem Forestry Research Network for Sub-Saharan Africa (FORNESSA) unterstützen, wobei letztere in enger Zusammenarbeit mit der African Academy of Sciences (AAS) erfolgen.

Herausforderungen für die Zukunft

Meine Damen und Herren, ich hoffe, Sie erkennen aus dem Gesagten, dass IUFRO, geführt vom Direktorium und kompetent unterstützt vom Sekretariat (mit der grosszügigen Unterstützung der österreichischen Bundesregierung), sich in den letzten fünf Jahren weiter entfaltet und mit Erfolg die Resolutionen des letzten Kongresses vertreten hat. Als scheidender Präsident möchte ich dem nächsten Präsidenten und Vorstand eine Reihe von Herausforderungen mit auf dem Weg geben:
∑ Weiterführung der Entwicklung von internationel akzeptablen Standards für Forschungsmethoden

- Unterstützung der Netzwerkbildung zwischen den Mitgliedern
- Entwicklung von GFIS, Normung von Terminologien und Berichte zum Stand der Wissenschaft
- Verbesserung der Beziehungen zwischen Wissenschaft, Politik, Management und Nutzung von Wald, Holzprodukten und Waldfunktionen.
- Identifizierung und Weiterverfolgung des disziplinären und interdisziplinären Forschungsbedarfs
- Gewinnung neuer Mitglieder
- Reorganisation des Direktoriums und Sekretariats zur Verbesserung der finanziellen Sicherheit, mehr Unterstützung für Mitglieder und Verbesserung der Möglichkeiten zur Verbreitung von Information.

Ansprache des
Vorsitzenden
des Kongress-Organisationskomitees

Dr. Abdul Rahim Nik

Sehr geehrter Herr Professor Jeffery Burley, Präsident von IUFRO,
Sehr geehrter Herr Tan Sri G.K. Rama Iyer, Vorsitzender des Malaysischen Beirats für Forstliche Forschung und Entwicklung,
Sehr geehrter Herr Dato' Dr. Abdul Razak Mohd Ali, Generaldirektor von FRIM,
Sehr geehrter Herr Professor Risto Seppälä, designierter IUFRO Präsident,
Geschätzte Gäste und Kongressteilnehmer,
Meine Damen und Herren,

Ich bin sehr froh, dass wir nun bei der Schlusssitzung des 21. IUFRO Weltkongresses angelangt sind. In den vergangenen sechs Tagen fanden an diesem Kongressort eine Fülle von Aktivitäten statt, angefangen von den Fach- und Arbeitssitzungen, Nebenveranstaltungen bis hin zu Ausstellungen, Empfängen und Exkursionen. Als Organisatoren dieser hochkarätigen Veranstaltung haben wir unser bestes versucht, alle Ihre Erwartungen und Anforderungen zu erfüllen, um sicherzustellen, dass Ihre Beteiligung an den Sitzungen und Ihr Aufenthalt in der letzten Woche so angenehm und bequem wie möglich werden.

Vor fünf Jahren wurde ich zum Vorsitzenden des Kongress-Organisationskomitees (COC) ernannt und es wurde mir die monumentale Aufgabe übertragen, diesen Kongress zu organisieren. Ich hatte nicht die leiseste Ahnung von der Grösse der Herausforderung und Verantwortung, die auf mich zukommen würde. Drei Jahre später kam die Sache ins Rollen und die Organisation nahm Formen an. Schliesslich wurden wir sechs Monate vor dem Kongress mit den tatsächlichen Herausforderungen konfrontiert. Ich muss gestehen, dass wir aus der Organisation dieses Kongresses eine Menge gelernt haben. In diesem Zusammenhang waren die verfügbaren modernen Technologien von unschätzbarem Wert und hilfreich während der Vorbereitungsarbeiten. Ich kann mir nicht vorstellen, wie wir diese Veranstaltung ohne elektronische Kommunikationstechnologien hätten organisieren können.

Während das Thema des Kongresses "Wald und Gesellschaft – die Rolle der Forschung" in vielen Fachsitzungen erschöpfend diskutiert wurde, haben wir, die Organisatoren, für uns ein Motto für die Organisationsarbeit festgesetzt. Dieses Motto lautet: "Wir haben uns verpflichtet, einen denkwürdigen und guten Kongress zu organisieren". Sie haben wahrscheinlich den Aufdruck dieses Mottos überall bei den Kongressständen gesehen. Dieses einfache Motto enthält zwei Botschaften. In Anerkennung der Tatsache, dass dies der erste Kongress in der hundertjährigen Geschichte IUFROs ist, der in einem Entwicklungsland abgehalten wird, wollten wir sichergehen, dass dieser XXI IUFRO Weltkongress, der hier in Malaysia stattfindet, einen lang anhaltenden Eindruck und auch angenehme Erinnerungen bei den Teilnehmers, die heute hier anwesend sind, hinterlassen wird. Zweitens benötigt eine grosse Veranstaltung wie diese hier ein effizientes und gut organisiertes System, um auf die Teilnehmer einen guten Eindruck zu machen und ihnen das Gefühl zu geben, dass sie ihr Geld und ihre Zeit nicht umsonst aufgewendet haben. Angesichts dieses Mottos haben wir mit grossem Engagement gearbeitet, um diesen Auftrag zu erfüllen. Es ist nun an Ihnen, verehrte Kongressteilnehmer, über die Leistungen zu urteilen!

Meine Damen und Herren,

Bei dieser Schlusssitzung möchte ich Ihnen einige wichtige statistische Daten nennen, die mit dem Kongress in Zusammenhang stehen, sowie einige unserer Beobachtungen, die nützlich für den nächsten Kongress sein könnten.

Am Kongress nahmen insgesamt 1906 Delegierte aus 96 Ländern teil, einschliesslich 209 Teilnehmer, die als Begleitpersonen registriert waren. Wir haben auch positive Reaktionen auf alle Exkursionsveranstaltungen erhalten. Insgesamt nahmen 1127 Personen an den neun Kongressexkursionen am Donnerstag und mehr als 700 Personen nahmen am Begleitprogramm teil. Die Leuchtkäfertour zählte die meisten Teilnehmer. Unmittelbar nach diesem Kongress werden 324 Delegierte an den 12 mehrtägigen Exkursionen teilnehmen, die hauptsächlich in die Provinzen von Malaysia und Nachbarstaaten einschliesslich Brunei, Indonesien und Thailand führen werden.

Die wissenschaftlichen Präsentationen wurden wie geplant abgehalten. Bei einigen Sitzungen waren die Vortragenden verhindert, doch die Moderatoren konnten andere Teilnehmer einladen, um die Lücken zu füllen. Jedoch gab es eine Reihe von Sitzungen, die abgesagt werden mussten, da keiner der vorgeschlagenen Vortragenden anwesend war, um über die Themen zu sprechen. Es fiel uns auf, dass vorwiegend in den Entwicklungsländern die Finanzierung ein Problem war. Von den 833 ausgewählten Postern wurden nur 55 % präsentiert. Die meisten Absagen kamen von Forschern aus Entwicklungsländern, die nicht genug Reisemittel auftreiben konnten. Die technische Unterstützung des Kongresses bestand in 120 Rapporteuren und beinahe 270 Kongresshelfern, die dazu beitrugen, dass der Kongress problemlos über die Bühne gehen konnte.

Um den Anforderungen des Kongresses gerecht zu werden wurden 6,6 Millionen Seiten gedruckt, wobei auch die früheren Ankündigungen und Werbematerial inkludiert sind. Ich bin nicht sicher, wieviele Bäume dafür gefällt werden mussten. Trotzdem glaube ich, dass es der Mühe wert war.

Erlauben Sie mir, ihre Aufmerksamkeit auf ein Thema zu lenken, dass mir besonders wichtig erscheint und dass beim nächsten Kongress berücksichtigt werden sollte. Wenn wir wollen, dass Teilnehmer aus Entwicklungsländer sich aktiver beteiligen, so sollten wir versuchen, schwerpunktmässig die Bereitstellung von Geldmitteln für das Programm zur Unterstützung von Wissenschaftlern zu forcieren. Für diese Veranstaltung wurden 91 von den gemeldeten 169 SAP-Kandidaten teilweise oder ganz mit Hilfe von Geldmitteln der malaysischen Regierung gesponsert. Meiner Meinung nach sollte die Bereitstellung von genügend Mitteln aus den Industrieländern gefördert werden. Bei diesem Kongress war dies nicht der Fall, mit Ausnahme der Geldmittel, die vom SPDC und einigen Ländern wie den Vereinigten Staaten von Amerika, dem Grossbritannien, Schweden und Finnland bereitgestellt wurden. Das neue Direktorium und das nächste Gastgeberland sollten ernstlich über dieses Thema nachdenken.

Ich muss zugeben, dass es ein grosses Vergnügen und eine reiche Erfahrung für uns war, diesen Kongress zu organisieren, und ich hoffe sehr, dass dieser Kongress nicht nur Ihrer wissenschaftlichen Karriere zugute kommen wird, sondern auch eine sinnvolle und zufriedenstellende Erfahrung ist. Trotz der grossen Anstrengungen, einen perfekten Kongress zu erreichen, gab es immer noch hie und da Schwachstellen und Pannen. Dafür hoffe ich auf Ihre Nachsicht. Die Zeit ist nun gekommen, um die Fahne an den Gastgeber des nächsten 22. IUFRO Weltkongresses zu übergeben.

Wie Ihnen wohl aufgefallen ist, waren viele Organisationen, Institutionen und Sponsoren an der Organisation dieses Kongresses beteiligt. Ihnen allen möchte ich meinen tiefsten Dank und meine Wertschätzung für Ihre freundliche Unterstützung, Zusammenarbeit und Hilfe aussprechen, ohne die wir diese schwierige Aufgabe nicht hätten bewältigen können. Im besonderen möchte ich dem Malaysischen Beirat für Forschung und Entwicklung sowie FRIM, und hier im speziellen ihrem Vorsitzenden und Generaldirektor für die Unterstützung und Ermutigung während der Planungs- und Durchführungsphase dieses Kongresses aussprechen. An alle Mitglieder des Direktoriums und des IUFRO-Sekretariats in Wien geht mein herzlichster Dank für Ihre Beratung und Hilfe bei der Aufgabe, diesen Kongress erfolgreich zu gestalten. Und nicht zuletzt danke ich als Vorsitzender des COC allen COC-Mitgliedern, den Subkomitees und Komitees und Kongresshelfern. Sie sind die Motoren, die unglaubliche Arbeit hinter der Bühne leisteten, um dem Kongress zum Erfolg zu verhelfen. Ich bitte Sie alle um einen grossen Applaus……..

Ich wünsche allen Freunden aus Übersee eine angenehme und sichere Heimreise.

Bon Voyage und vielen Dank.

Ansprache des designierten IUFRO-Präsidenten

Dr. Risto Seppälä

Vereehrte Mitglieder des Internationalen Rates und des Direktoriums von IUFRO,
sehr geehrte Gäste, Kollegen,
Meine Damen und Herren.

Es ist mir eine grosse Ehre, die Wahl zum IUFRO Präsidenten durch den Internationalen Rat annehmen zu können. Ich verspreche, dass ich mein bestes tun werde, um die hohen Erwartungen, die mit dieser Position verbunden sind, voll zu erfüllen.

Bei seiner Antrittsrede vor fünf Jahren sagte der amtierende Präsident, dass er drei Wünsche für IUFRO hätte: nämlich einen Präsidenten aus den Tropen, einen Weltkongress in einem Entwicklungsland und eine Frau als IUFRO-Präsident. Zwei dieser Wünsche haben sich erfüllt, aber wenn Jeff Burley als seinen Nachfolger eine Frau als Präsident wollte, so bin ich wohl nicht die richtige Person, obwohl auch ich gerne eine Frau als meine Nachfolgerin sehen würde und dieses Ziel mit aller Kraft anstreben werde.

Bei einer Antrittsrede ist es üblich, dass der gewählte Präsident seine Visionen über die zukünftige Struktur und Aktivitäten der Organisation vorstellt. Da der amtierende Präsident bei dieser Gelegenheit bereits eine umfassende Liste mit zukünftigen Herausforderungen präsentierte, werde ich nur zwei Punkte herausheben, die ich für besonders wichtig erachte. Es sind dies die IUFRO Mitgliedschaft und die Rolle IUFROs als Informationszentrale für forstliche Forschung und Fachwissen.

IUFRO umfasst nunmehr 680 Mitgliedsorganisationen, die das Fundament des Verbandes darstellen. In den vergangenen Jahren gewannen wir zwar viele neue Mitglieder dazu, aber zur gleichen Zeit können oder wollen viele unserer früheren Mitglieder nicht mehr für ihre Mitgliedsbeiträge aufkommen. Wenn wir eine Mitgliedsorganisation verlieren, so verlieren wir auch die dazugehörigen Wissenschaftler, da es für einzelne Wissenschaftler mühsam und teuer ist, IUFRO Mitglied bei IUFRO zu werden.

Es mag wohl an der Zeit sein, das Gesamtkonzept der IUFRO-Mitgliedschaft zu überdenken. Zunächst einmal müssen wir uns fragen, wozu wir Mitglieder haben wollen. Geld ist ein einleuchtender Grund. Obwohl IUFRO eine Organisation von Freiwilligen ist, können wir nicht ohne Mitgliedsbeiträge überleben. Wenn sich der Verband jedoch aus externen Quellen finanzieren kann, brauchen wir dann immer noch Mitglieder, um unsere Aufgabe als Förderer der internationalen Zusammenarbeit in der forstlichen Forschung und auf verwandten Gebieten zu erfüllen? Die Anwort ist ja. Wir brauchen Mitglieder auch in diesem Fall, da Zusammenarbeit nicht möglich ist ohne jene, die zusammenarbeiten und unsere Mitgliedsorganisationen und ihre Mitarbeiter bilden das effizienteste Netzwerk internationaler Kooperation in der forstlichen Forschung.

Laut einer kürzlich veröffentlichten Studie des Europäischen Forstinstitutes (EFI) gibt es allein in Westeuropa mehr als tausend Institutionen, die mit forstlicher Forschung und verwandten Gebieten befasst sind. Davon sind 176 IUFRO Mitglieder. Ich glaube, dass in anderen Teilen der Welt die Situation ähnlich ist. So ist das Potential für den Beitritt neuer Organisationen grösser als wir uns vorstellen können. Es liegt nun an uns, zu überlegen, wie wir dieses Potential nutzen sollen. In der im Wandel begriffenen Welt von heute gibt es viele Spieler, mit denen IUFRO noch keine Partnerschaften eingegangen ist.

Wir brauchen engere Beziehungen auch zu den einzelnen Wissenschaftlern. Die Tatsache, dass IUFRO ein Verband von Organisationen ist, ist keine Garantie dafür, dass alle Wissenschaftler, die in unseren Mitgliedsorganisationen beschäftigt sind, über IUFRO Bescheid wissen oder Informationen über IUFRO bekommen. Für Wissenschaftler, die in Nicht-Mitgliedsorganisationen arbeiten, gibt es praktisch keine Kommunikation mit IUFRO. Nun hat sich die Situation offenbar beträchtlich geändert, da viele Besucher unserer Internetseiten und eine grosse Anzahl Teilnehmer an diesem Kongress nicht von einer Mitgliedsorganisation kommen. Mir scheint, dass dies wiederum ein Zeichen für ein enormes Potential ist, da es zeigt, wie attraktiv IUFRO und seine Kongresse sind. Eine wichtige Voraussetzung für die steigende Zahl von Einzelmitgliedern ist, dass wir ihnen den Beitritt zum Verband erleichtern, im speziellen jenen, die nicht aus der Forstwirtschaft kommen.

Bis jetzt hat IUFRO das Wissen und die Expertise seines Netzwerkes nur marginal genutzt. Wir haben extern finanzierte Sonderprojekte und –programme wie das SPDC oder Silvavoc, aber wir müssen das gesamte Informations- und Wissenspotential unserer Wissenschaftler und Experten mobilisieren, das einzigartig und derzeit noch nicht ausgeschöpft ist. Erste Schritte in diese Richtung sind die Berichte über den Stand der Wissenschaft, die in dieser Woche präsentiert werden und der Weltweite Forstliche Informationsdienst, dessen Prototyp hier auf diesem Kongress vorgestellt wurde.

Sehr geehrte Damen und Herren,

Meine eigene Vision ist, dass IUFRO eine Zentrale für forstliche Information und Expertise werden soll. Unsere Funktionäre nehmen Schlüsselstellungen in diesem Prozess ein, aber sie stellen nur einen Bruchteil des Potentials an Menschen dar. Wir müssen einen direkten Kontakt zu allen Personen aufnehmen, die in den Forschungsgruppen tätig sind oder Beziehungen mit ihnen haben. Erst wenn wir relevante Informationen über ihr Fachgebiet haben, sind wir in der Lage, als Vermittlungsmechanismus zu fungieren und auf die Anfragen von Interessenten zu antworten, die z.B. den Stand der Wissenschaft in einem speziellen Gebiet forstlicher Forschung wissen wollen, oder wenn ein internationales Team zusammengestellt werden soll, um Lösungsmöglichkeiten für ein aktuelles Problem der forstlichen Forschung zu finden.

Die Rolle IUFROs als Zentrale für forstliche Information und Expertise wird den Bekanntheitsgrad IUFROs noch erhöhen. Es würde IUFRO auch für Sponsoren und Interessenten attraktiv machen, indem es einen Schneeballeffekt hervorruft, der auch zu einer Ressourcenvermehrung IUFROs führen würde.

Liebe Freunde,

Als neuer Präsident sehe ich eine meiner wichtigsten Aufgaben darin, als IUFRO Botschafter zu agieren, der unsere Organisation und ihre Leistungen auf dem Markt anbietet und verkauft. Die internationale forstliche Gemeinschaft braucht unser Fachwissen und ist auch bereit, dafür zu bezahlen. Wir brauchen eine gute Marketingstrategie, um neue Mitglieder zu gewinnen. Zusätzlich zu unserem Bemühen, unseren jetzigen Mitgliederstand zu halten, müssen wir neue Mitglieder werben, im speziellen jene, die nicht dem Forstsektor angehören. Ein ausgedehnter und qualifizierter Mitgliederstock ist eine wichtige Voraussetzung, um unsere Dienstleistungen an jene zu verkaufen, die sie brauchen und die dafür bezahlen können.

Obwohl ich nun meine Ansichten über eine mögliche Zukunft für IUFRO dargelegt habe, möchte ich doch noch eine Minute in der Vergangenheit verweilen. In meiner Eigenschaft als amtierender Vizepräsident für Programme möchte ich die Gelegenheit wahrnehmen, um allen IUFRO Funktionären für die wertvolle Arbeit, die sie seit dem Tampere Kongress geleistet haben, zu danken. Mein besonderer Dank geht an das Wissenschaftliche Kongress-Komitee und das IUFRO-Sekretariat für ihren enormen Einsatz bei der Vorbereitung des wissenschaftlichen Programmes des Kongresses. Und schliesslich möchte ich den malaysischen Gastgebern herzlich danken. Gerade weil ich mit dem vorherigen Kongress befasst war, weiss ich genau, wieviel Arbeit notwendig ist, um eine solche Veranstaltung zu realisieren. Ich möchte Ihnen hiermit zu diesem äusserst erfolgreichen Kongress gratulieren. Saya ucapkan setinggi-tinggi tahniah kepada tuan rumah Malaysia di atas kejayaan kongres ini.

Wir Finnen sind bekannt als wortkarge Menschen – auch wenn wir etwas zu sagen haben. Wir ziehen es vor zu handeln, obwohl auch Reden wichtig sind, um den Weg in eine Richtung vorzuzeigen. Ich werde hier Schluss machen, aber Sie werden noch von mir hören, vielleicht nicht sosehr durch meine Reden, sondern hoffentlich durch meine Taten. Was ich auch für IUFRO tue, möchte ich zusammen mit Ihnen allen tun.

Ansprache von

Prof. Russell Haines

Queensland Forestry Research Institute
Organisator des nächsten IUFRO Weltkongresses 2005

Die Bevölkerung Australiens mit seiner vierzigjährigen Geschichte der Nutzung von Wäldern und ihrer forstlichen Ressourcen freut sich, alle Forstwissenschaftler zum XXII IUFRO Weltkongress in Brisbane im Jahre 2005 willkommen zu heissen.

Australien hat eine grosse Vielfalt anWäldarten, von der gemässigten über die tropische zur ariden Zone und rasch wachsende Plantagenbestände. Bei der Bewirtschaftung dieser Wälder begegnen wir ähnlichen Herausforderungen wie jenen, mit denen auch Forstmanager weltweit befasst sind und die bei diesem Kongress schwerpunktmässig hervorgehoben wurden.

Die australische Bundesregierung und die Regierungen der einzelnen Staaten haben sich voll und ganz der nachhaltigen Nutzung der Waldressourcen zugunsten der jetzt lebenden und der zukünftigen Generationen verschrieben und anerkennen, dass diese Nutzung auf einer fundierten wissenschaflichen Grundlage geschehen muss. Wir haben uns verpflichtet, in internationalen forstlichen Foren mitzuarbeiten und uns an der internationalen wissenschaftlichen Zusammenarbeit zu beteiligen. Wir unterstützen insbesondere auch den Internationalen Verband Forstlicher Forschungsanstalten. Mit einigem Stolz möchte ich erwähnen, dass mein guter Freund und Kollege, Dr. Garth Nikles, der kürzlich nach 50 Jahren Wirken für die Forstwissenschaft in den Ruhestand trat, zusammen mit Professor Jeffrey Burley 1971 die erste Arbeitsgruppe im Bereich der Tropen initiierte.

Ich glaube, dass wir in einer für Forstwissenschaftler spannenden Zeit leben. Niemals zuvor haben sich Beteiligte aus so unterschiedlichen Bereichen so leidenschaftlich für die Bewirtschaftung und Nutzung der Wälder und Waldressourcen interessiert. Niemals zuvor hatte internationale Zusammenarbeit einen derart hohen Stellenwert unter den Forstwissenschaftlern.

Wir hoffen, dass wir im Jahre 2005 den Delegierten die australische Gastfreundschaft nahebringen können, und im besonderen möchten wir die Gastfreundschaft, die wir hier in Malaysia erfahren haben, erwidern.

Die australischen Delegierten haben die ausgezeichnete Vorbereitung des 21st IUFRO Weltkongresses in Malaysia sehr genossen. Wir sehen nun, dass unsere malaysischen Kollegen die Latte hoch gelegt haben und die Erfahrungen in Malaysia werden uns bei der Organisation des Kongresses in Brisbane im Jahr 2005 gute Dienste leisten.

Wir freuen uns schon darauf, zusammen mit der internationalen IUFRO Gemeinschaft den 22. IUFRO Weltkongress zu organisieren, und die IUFRO Flagge für die nächsten 5 Jahre voranzutragen. Und ganz besonders freuen wir uns darauf, Sie alle in Brisbane im Jahr 2005 begrüssen zu dürfen.

Schlussrede, Samstag, 12. August 2000,

Professor Jeffrey Burley
IUFRO Präsident

Exzellenzen, verehrte Gäste,
Liebe IUFRO Mitglieder,
Kollegen und Freunde,
Meine Damen und Herren,

Wir kommen nun zur Schluss-Sitzung des XXI IUFRO Weltkongresses in Kuala Lumpur, Malaysia. Obwohl die meisten Teilnehmer wohl froh sein werden, nach Hause zu fahren, so weiss ich doch, dass bei vielen auch bisschen Wehmut dabei ist, ein so schönes Land mit so netten Leuten zurückzulassen umso mehr als auch das zu Ende gehende Programm voller interessanter Vorträge, Postersessions, Diskussionen, Ausstellungen und Exkursionen war. Sie werden auch bedauern, dass Sie ihre alten und neu gewonnenen Freunde zurücklassen müssen, aber ich hoffe, dass die beruflichen und persönlichen Kontakte nach der alten IUFRO-Tradition der wissenschaftlichen und persönlichen Zusammenarbeit fortgeführt werden.

Die Organisatoren jedes Kongresses sind immer etwas besorgt darüber, dass ihr Kongress nicht mit dem letzten, sowohl was die Qualität als auch, was die Quantität betrifft, mithalten könne. Ich war jedoch immer der Meinung, dass es hierbei nicht darum geht, mitzuhalten, sondern einfach anders zu sein. Nach dem Montreal-Kongress 1990 dachten die finnischen Organisatoren, dass der Tampere-Kongress 1995 nicht dem vorherigen das Wasser würde reichen können. Nach Tampere dachten die malaysischen Organisatoren, dass dieser Kongress 2000 nicht so erfolgreich werden könne wie der vorherige. Ich glaube jedoch, dass es ihnen gelungen ist, dieses Ziel zu erreichen. Die Vorbereitungen sowohl auf administrativem als auch auf politischem und technischem Gebiet waren ausgezeichnet, und das Hilfspersonal aussergewöhnlich freundlich.

Bei meinen Rundgängen am Kongressort in dieser Woche habe ich viele Teilnehmer nach ihren Eindrücken oder ihrer Kritik gefragt. Wir werden nun sehen, ob sich diese Meinungen mit dem Fragebogen decken, den wir ausgesandt haben. Ich glaube jedoch, dass dem so ist. Doch wird das Direktorium immer an Ihrer Meinung interessiert sein, auch nachdem Sie bereits zu Hause sind und Zeit hatten, das Gesehene und Gehörte nachwirken zu lassen.

Es ist wohl nicht möglich, jedem von Ihnen einzeln und jeder Organisation dafür zu danken, dass sie zum Erfolg dieses Kongresses beigetragen haben. Aus diesem Grund möchte ich kollektiv in Ihrem Namen der Regierung von Malaysia danken, dem Direktorium der IUFRO, dem Kongress-Steuerungskomitee unter der Leitung von Dr. Razak, dem Kongress-Organisationskomitee unter der Leitung von Dr. Rahim Nik, dem Wissenschaftlichen Kongress-Komitee unter der Leitung von Dr. Teissier du Cros, dem IUFRO-Sekretariat unter der Führung von Heinrich Schmutzenhofer , den zahlreichen Mitarbeitern von FRIM, den nationalen und staatlichen Forstabteilungen, den Universitäten, die uns in vielen Bereichen unterstützt haben, den Photographen, der Presse, für Ihre verantwortungsbewusste Berichterstattung, den Dolmetschern, ohne die man die Hauptredner wahrscheinlich nicht so gut verstanden hätte; dem Zeremonienmeister ohne den die Eröffnungs- und Schluss-Sitzungen wahrscheinlich nicht so effizient und vergnüglich abgelaufen wären, und nicht zuletzt Ihnen, den Teilnehmern selbst. Wie dies so oft der Fall ist im Leben, bekommt man das zurück, was man investiert, und ich weiss, dass sich die meisten Teilnehmer voll und ganz mit den Aktivitäten des Kongresses identifiziert haben und deshalb auch sowohl persönlich als auch beruflich davon profitieren konnten.

Ich persönlich möchte allen für die Unterstützung in den letzten fünf Jahren danken, allen voran meiner Frau Jean und dem IUFRO-Sekretär, Heinrich Schmutzenhofer. Ohne sie wäre ich nie in der Lage gewesen, das Amt des Präsidenten zu bekleiden. Glücklicherweise muss ich nur einen von ihnen nach Hause mitnehmen. Für den anderen habe ich ein kleines Geschenk, einen Oxford-Wecker, der immer auf 18.00 abends eingestellt ist, sodass er weiss, wann er nach Hause zu seiner Frau Edith gehen soll.

Ich wünsche Ihnen allen eine gute Heimreise, möge Gott mit Ihnen sein. Der XXI IUFRO Weltkongress ist hiermit offiziell beendet.

Discursos en las ceremonias de inauguración y de clausura

Discurso de bienvenida pronunciado por el
Presidente del Comité Directivo de Congreso,

Dato' Dr. Abdul Razak Mohd. Ali

YB Dato' Seri Dr Lim Keng Yaik, Ministro de Industrias Primarias,
Profesor Jeff Burley, Presidente de IUFRO,
Distinguidos huéspedes, señoras y señores:

Es un verdadero honor para mí dar la bienvenida a todos Uds. al XXI Congreso Mundial de IUFRO en nombre del Comité Directivo del Congreso. Quisiéramos expresar nuestra gratitud particular al Honorable Sr. Ministro de Industrias Primarias de Malasia por haber consentido en participar e inaugurar oficialmente este Congreso en nombre del Honorable Sr. Primer Ministro que no puede estar con nosotros esta mañana. Me gustaría decir a todos los delegados y especialmente a los que vienen de lejos 'Selamat Datang ke Malaysia' o 'Bienvenidos a Malasia'.

Durante la reunión del Comité Ejecutivo de IUFRO en Madrid en abril 1995, Malasia sometió su oferta para ser el anfitrión del XXI Congreso en Kuala Lumpur. Recuerdo todavía muy vivamente el momento de triunfo de hace más de cinco años cuando me encargaron con la tarea de encabezar la delegación de Malasia para presentar nuestra oferta junto con las ofertas de Sudáfrica, China e Indonesia.

Malasia se enorgullece mucho de ser el primer país en desarrollo que es anfitrión de un Congreso Mundial de IUFRO. El congreso es, sin duda, la reunión forestal mayor en toda la historia del país. En cuanto a los números de participantes y personas acompañantes registrados y en cuanto a los discursos y pósters que se presentarán, excede la XIV Conferencia Forestal de la Mancomunidad celebrada en Kuala Lumpur en septiembre de 1993.

Estamos agradecidos al Gobierno de Malasia y al Consejo Internacional de IUFRO por haber tenido la confianza de encargar el Instituto de Investigación Forestal de Malasia (FRIM) con esta responsabilidad enorme de organizar el Congreso de IUFRO. Quisiéramos dar las gracias a la Secretaría de IUFRO en Viena y al Comité de Investigación y Desarrollo Forestales de Malasia (MFRDB) por su apoyo y consejo inestimables. El Comité Organizador de Congreso (COC) y sus sub-comités han trabajado duramente para asegurar que el progreso en todos los aspectos de organización sea controlado exactamente.

Señoras y señores:

Celebramos anunciar que tenemos 1906 participantes registrados en total y más de 209 personas acompañantes de 96 países. En los días siguientes se presentarán 5 discursos keynote, 99 ponencias subplenarias, 500 ponencias y 833 pósters en las sesiones plenarias y subplenarias, sesiones de grupos, de pósters y discusiones paneles de pósters. Quisiéramos que las presentaciones de pósters dieran la oportunidad a los científicos de intercambiar sus ideas y experiencias con sus pares sobre temas de interés común.

A través del Programa de Asistencia Científica (SAP) podemos dar apoyo financiero a 138 científicos de 38 países en desarrollo para que pueden asistir al Congreso. Además, el gobierno de Malasia nos ha generosamente dado los fondos para que otros 31 científicos más de Asia y la región del Pacífico puedan participar.

Estamos agradecidos al Honorable Sr. Ministro de Industrias Primarias de Malasia que va a dirigirse a nosotros e inaugurar el Congreso en nombre del Primer Ministro. Otros momentos culminantes en el curso de esta ceremonia inaugural serán la presentación del sello conmemorativo del XXI Congreso Mundial de IUFRO, el show cultural y la presentación de los premios y distinciones de IUFRO. Quisiéramos también dar las gracias a los conferenciantes que presentarán los discursos keynote durante las sesiones plenarias.

Señoras y señores:

Espero sinceramente que este Congreso sirva de foro útil para los científicos de todo el mundo para discutir el papel de la investigación en relación con los bosques y la sociedad. Tradicionalmente, los bosques han sido considerados como fuente de madera. La investigación ha de veras desempeñado un papel importante en cambiar esta percepción y actitud acerca de los bosques que ofrecen una gran cantidad de bienes y servicios indispensables para el bienestar de la sociedad.

Por favor, aprovechen toda oportunidad durante este Congreso para discutir cuestiones y necesidades de investigación y forjar colaboraciones beneficiosas para la investigación y el desarrollo. Las reuniones pre-Congreso, satélite y administrativas en el programa sirven precisamente a este fin.

Como todo queda dicho y hecho, les ruego perdonar cualquier deficiencia de organización en nombre del Comité Directivo del Congreso y del Comité Organizador del

Congreso. Finalmente, espero que encuentren el tiempo durante las excursiones en medio del Congreso y después del Congreso para visitar el país fascinante de Malasia con su riqueza y diversidad biológica y cultural.

Gracias.

Discurso pronunciado por el
Presidente de IUFRO

Profesor Jeffery Burley

Ministro Honorable de Industrias Primarias,
Dato' Seri Dr. Lim Keng Yaik,
Sr. Ministro Adjunto Honorable,
Sr. Secretario General,
Dato' Dr. Abdul Razak,
Presidente del Comité Directivo del Congreso,
Dr. Hosny El-Lakany,
Director General Adjunto del Departamento Forestal de la FAO;
distinguidos huéspedes;
señoras y señores:

Es un gran honor y placer para mí darles la bienvenida a este XXI Congreso Mundial de la Unión Internacional de Organizaciones de Investigación Forestal (IUFRO, como es el acrónimo bien conocido). Excelencia, lo sentimos mucho no tener el honor de la presencia del Primer Ministro, pero entendemos que no pudo participar por asuntos de Gobierno.

No obstante, me complazco en darle las gracias a Ud. por el gran honor de pronunciar el discurso inaugural que seguramente será un discurso de bienvenida y exhortación para nosotros. El tema de nuestro Congreso es "Bosque y Sociedad: el Papel de la Investigación"; este tema es muy oportuno al entrar en el nuevo milenio caracterizado por el crecimiento demográfico, la demanda creciente por los productos de los bosques, y una conciencia cada vez mayor de los muchos otros beneficios medioambientales y sociales que los bosques pueden prestar. Este tema es de relevancia especial aquí en Malasia, un país de gran riqueza y variedad en recursos forestales y sus servicios asociados y un país de una tradición de investigación forestal reconocida en todo el mundo. Sr. Ministro, nosotros nos conocemos personalmente desde hace muchos años y sé que Ud. siempre ha sido un pensador y hablador activo e importante en el campo forestal y en la industria forestal, sobre todo en lo que se refiere a Malasia y el Sudeste de Asia. Estamos esperando su presentación con mucho interés.

Durante los últimos cinco años he tenido el privilegio continuo de ser el Presidente de IUFRO, y me gustaría familiarizar a Uds. y a nuestros huéspedes en pocos minutos con la historia y las actividades de la Unión. Además, trataré de demostrar por qué esto debe ser de interés para un político superior y por qué los investigadores y los políticos deberían entrar en diálogos aun más estrechos.

IUFRO fue establecida en 1892 por un número pequeño de países europeos. Durante los primeros 80 años de su existencia, IUFRO creció hasta incluir la mayoría de los países de la zona templada. Sólo fue en el año 1971 que establecemos el primer Grupo de Trabajo que se dedicara exclusivamente a un tema tropical (genética forestal y mejora de árboles). Desde entonces, IUFRO se ha esforzado activamente por hacer llegar los beneficios de su colaboración internacional a instituciones y científicos en países en vías de desarrollo, incluyendo apoyo para APAFRI, FORNESSA y una Red para América Latina y el Caribe, e involucrarlos activamente en todos los niveles de su gestión. Actualmente, la Unión abarca casi 700 Organizaciones Miembros en 110 países con aproximadamente 15'000 científicos que cooperan voluntariamente en 276 Divisiones, Grupos de Investigación y Grupos de Trabajo. IUFRO es una institución internacional, no gubernamental, sin fines de lucro y multi-disciplinaria que trata seriamente de obtener el máximo valor de las inversiones de gobiernos, industrias y personas privadas en la investigación.

Me gustaría subrayar que el trabajo de IUFRO es básicamente voluntario, es decir que prácticamente todos los oficiales de la Unión y los científicos cooperantes trabajan con gran dedicación para el éxito de IUFRO porque creen en el valor añadido por esta colaboración. Solamente los miembros de la Secretaría, apoyada generosamente por el Gobierno de Austria, pueden ser considerados como "funcionarios" permanentes de la Unión. Además, los coordinadores contratados para el Programa Especial para Países en Desarrollo (SPDC) son pagados con el apoyo igualmente generoso de Canadá, Dinamarca y EEUU. La Unión Europea y los gobiernos de Japón, de Suiza y del Reino Unido han prestado también un apoyo financiero considerable a IUFRO. IUFRO mantiene relaciones estrechas con otras organizaciones, especialmente con el Consejo Internacional por la Ciencia, el Centro de Investigación Forestal Internacional, la Organización de Alimentación y Agricultura de las Naciones Unidas, y el Centro Internacional de Investigación Agroforestal; es un privilegio adicional para nosotros que el representante del Director General de FAO tomará la palabra en esta sesión inaugural.

Durante este siglo, la Unión ha estimulado y apoyado la investigación excelente en una gama amplia de temas científicos. Sin embargo, la investigación no vale nada cuando pasa independientemente; debe ser considerada como parte integral de un proceso continuo desde la ciencia pura y aplicada a la adaptación y aplicación amplia de nuevos sistemas tecnológicos y sociales que se dirigen a las cuestiones de la política internacional y nacional. A este fin, IUFRO ha establecido Grupos Especiales de Intervención para animar la integración de tal investigación y fomentar el mejor entendimiento entre investigadores y políticos. En este Congreso en Malasia que se celebra en el primer año del nuevo milenio, los científicos de IUFRO producirán informes sobre el estado actual de los conocimientos en muchos temas importantes para indicar la información que existe en este momento, las cuestiones de gestión que implica esta investigación y cualquier demanda por nuevas investigaciones.

En la década pasada hubo un aumento rápido en la conciencia política y pública de la importancia de los bosques y árboles para el bienestar humano. Los bosques y árboles suministran un número enorme de productos y servicios sociales, medioambientales y económicos para un gran grupo de interesados. Además de los libros y revistas forestales profesionales, muchos países tienen una cantidad de publicaciones en diarios y revistas, programas de televisión y radio sobre temas forestales. Hay una interdependencia estrecha y a menudo hasta una competencia entre la variedad de productos y servicios exigidos por los bosques; la investigación abarca muchas disciplinas que no son cohesivas por naturaleza. IUFRO se esfuerza fuertemente por estimular la colaboración interdisciplinaria entre los científicos biofísicos y sociales.

El número 2000 es un hermoso número redondo por lo menos según el sistema matemático decimal. También es altamente importante en ciertos calendarios religiosos. Sin embargo, es de suma importancia para todos los vivos y billones que están por nacer, porque es el año en que las agencias internacionales, los gobiernos nacionales, las organizaciones civiles de la sociedad, los educadores, investigadores y gerentes de negocios y recursos deben realizar la necesidad urgente de manejar los recursos del mundo de manera sabia, equilibrada, ética y sostenida. Los bosques y árboles jugarán un papel mayor en el desarrollo sostenible, e IUFRO va a continuar a hacer lo posible para animar la investigación y los investigadores a dirigirse a cuestiones relevantes y presentar sus resultados en una forma que los políticos y todos los interesados puedan comprender y aplicar. El Comité Ejecutivo de IUFRO está seguro que este Congreso va a contribuir mucho a la promoción de estos objetivos.

Excelencia: todos los participantes del XXI Congreso IUFRO están muy agradecidos al Gobierno de Malasia y la Ciudad de Kuala Lumpur por ser nuestros anfitriones y ofrecer su hospitalidad tan amable y generosa, y por organizar excursiones tan interesantes y agradables en su país tan hermoso para los científicos y sus acompañantes. Me gustaría dar las gracias también a todos los empleados del Instituto de Investigación Forestal, los Departamentos Forestales Federales y Estatales, y varias Universidades y otras instituciones que han trabajado intensamente para asistir IUFRO con la organización de este acontecimiento de cada cinco años. Mientras temo que la investigación en Malasia haya sufrido un poco de esto en los últimos años, me preocupo aun más ahora que desaparezca completamente si todos estos empleados trabajarán como organizadores profesionales de conferencias y excursiones de ahí en adelante.

Excelencia: tengo el placer de dirigirme respetuosamente a Ud. para que inaugure este XXI Congreso IUFRO y nos presente sus puntos de vista sobre el papel y la necesidad de la investigación forestal. Además, me gustaría preguntarle más tarde el honor de presentar el premio supremo de IUFRO, la distinción de Miembro Honorario, a dos líderes destacados de nuestra Unión.

Discurso pronunciado por
el Primer Ministro

YAB Dato' Seri Dr Mahathir bin Mohamad

Presentado por

Dato' Seri Dr. Lim Keng Yaik,

Ministro de Industrias Primarias de Malasia

Profesor Jeffery Burley, Presidente de IUFRO,
Datuk Haron Siraj, Secretario General del Ministerio de Industrias Primarias de Malasia,
Dato' Dr. Abd. Razak Mohd Ali, Presidente del Comité Directivo del Congreso,

Distinguidos Huéspedes, Señoras y Señores:

En primer lugar me gustaría dar las gracias a los organizadores de este congreso forestal importante por invitarme y darme la oportunidad de inaugurar oficialmente el XXI Congreso Mundial de la Unión Internacional de Organizaciones de Investigación Forestal (IUFRO). También quisiera dar una bienvenida muy cordial a todos nuestros huéspedes y participantes y desear a todos una reunión muy productiva y una estancia muy agradable en Malasia.

Entiendo que IUFRO es una organización no gubernamental y sin fines de lucro que fue establecida hace más de cien años en el 1892, y que tiene como misión la promoción de la cooperación internacional en la investigación forestal y las ciencias relacionadas. Entiendo también que, aunque IUFRO tiene alrededor de 700 Organizaciones Miembros en 105 países, ésta es la primera vez que se celebra el Congreso en un país en desarrollo. Por lo tanto debería felicitar a los organizadores por el éxito que ha tenido la oferta de Malasia para ser anfitrión de este Congreso Mundial y por las preparaciones necesarias que nos permiten reunirnos ahora en el mayor evento forestal que ha tenido lugar en nuestro país. Espero que de ahí en adelante más Congresos Mundiales de IUFRO se celebren en países en desarrollo.

Como sabemos todos, los bosques juegan un papel importante para la vida de los ciudadanos de muchos países en desarrollo y contribuyen al progreso económico de estos países. Por lo tanto es un gran placer para mí que Malasia haya abierto el paso para los países en desarrollo para presentar sus ofertas como anfitriones de tales congresos, porque los asuntos forestales son importantes para muchos ciudadanos débiles y pobres en todo el mundo. En este sentido me gustaría felicitar IUFRO por el tema muy oportuno para este Congreso que une la sociedad con los bosques mediante la investigación.

Señoras y señores:

Sería echar agua en el mar si yo les hablara sobre el papel y las funciones del bosque. Uds. son los expertos en este tema. Uds. conocen muy bien el hecho de que en el pasado los bosques fueron vistos separados de la gente que vivió en ellos o en sus lindes y que los bosques sólo fueron considerados por la madera que suministraron. En los últimos años, sin embargo, se ha notado una tendencia mundial hacia el reconocimiento de que los bosques y las sociedades, tanto rural como urbana, representan dos caras de la misma moneda y que, además de la madera, los bosques suministran una cantidad de bienes y servicios importantes para el bienestar de la sociedad.

¿Cuáles son, pues, las lecciones que hemos aprendido del pasado no tan lejos, lecciones forestales que han causado este cambio de vista y han preparado el terreno para el debate actual internacional sobre bosques? Sabemos que al comienzo de la revolución industrial a principios del siglo XXI se cortaron aun más vastas áreas de bosques de la zona templada en Europa después de haber reducido los bosques en los siglos anteriores para obtener la madera necesaria para el proceso de industrialización. En el mismo siglo IXX, se perdieron también grandes superficies de bosques al otro lado del Océano Atlántico, en América. En pocas décadas, millones de hectáreas de bosques fueron destruidos para obtener pastos, cultivar tierras, y tener madera y leña.

En el mundo occidental, la revolución industrial produjo efectos muy negativos para el medio ambiente. Se aceleraron la contaminación del aire y del agua así como también la degradación del suelo. El crecimiento económico rápido después de la Segunda Guerra Mundial en los países desarrollados de hoy dio impulso a una degradación medioambiental ulterior. La Conferencia de las Naciones Unidas sobre el Medio Ambiente Humano en 1972 en Estocolmo vino y fue, pero la degradación medioambiental continuó incesantemente. El aumento mundial de la temperatura, la reducción de la capa de ozono, la contaminación de los mares, la lluvia ácida, la deforestación y la degradación de la tierra – en la mayoría de los casos a consecuencia de las actividades industriales – llegaron a convertirse en grandes preocupaciones a principios de los años ochenta.

En este contexto, la Declaración de Langkawi sobre el Medio Ambiente de la reunión de los Jefes de Gobierno de la Mancomunidad (CHOGM) en Kuala Lumpur en octubre de 1989, plantó la semilla para un concepto que vino formándose en las reuniones mundiales que siguieron. El concepto de “hacer el mundo verde” fue adoptado como principio de la Declaración de París en el X Congreso Forestal Mundial en 1991. Luego, en la Conferencia de las Naciones Unidas sobre el Medio Ambiente y el Desarrollo (UNCED) en Río de Janeiro en junio de 1992, la Declaración de Principios sobre Bosques fue aceptada por todos los gobiernos y captó este concepto completamente.

Poco antes de la Cumbre de Río, fue Malasia que sugirió que la superficie cubierta de bosques sea aumentada del 27,6% al 30% hasta el año 2000 mediante programas vigorosos de forestación y reforestación en todo el mundo. Hemos pensado en aumentar la superficie de todos los tipos de bosques – boreales, templados y tropicales - porque no hay discriminación en la manera de cómo los diferentes tipos de bosques secuestran carbono, estabilizan el clima, protegen el medio ambiente, conservan la biodiversidad biológica, producen recursos industriales y forman la base de subsistencia para la vida de las comunidades en o cerca de los bosques. También tuvimos la idea de que los países desarrollados que tienen una pequeña superficie de bosques a consecuencia de una destrucción forestal desconsiderada, pero que tienen economías fuertes, vastos recursos y los conocimientos técnicos ahora deberían encabezar el esfuerzo de hacer el mundo más verde. Además, nos hemos imaginado, tal vez por ingenuidad, que estos países económicamente fuertes reunirían sus recursos amplios para ayudar activamente a implementar los programas de forestación y reforestación en los países más pobres del mundo.

Sin embargo, después de haber pasado ocho años desde Río, todo sigue igual. Todo el entusiasmo antes de Río y en Río mismo ha prácticamente desaparecido de la noche a la mañana. No existe ningún concepto ni siquiera embrionaria para hacer el mundo más verde. Cada nación queda prácticamente aislada para implementar sus programas forestales. Según mi información, el costo medio total por año que se necesita para implementar los programas forestales bajo la Agenda 21 de UNCED fue estimado a US$32 billones, y una parte mayor de esto debe haber venido de los países desarrollados. A pesar del hecho de que la Agenda 21 y los Principios Forestales suministraron un marco para fortalecer la cooperación entre los países, queda claro ahora que la mayoría de los fondos necesarios para los programas forestales debería ser generado por los países en desarrollo mismos.

Malasia ha siempre sido y sigue siendo proactivo en las cuestiones mundiales que conciernen los bosques y el medio ambiente. Hemos participado activamente en las negociaciones que llevaron a la Conferencia UNCED, abarcando la Agenda 21, la Declaración de Principios sobre Bosques, la Convención sobre la Diversidad Biológica y la Convención de Marco sobre el Cambio Climático; hemos continuado a participar activamente en los desarrollos desde Río. Nos aferramos mucho al concepto de hacer el mundo más verde. Aunque durante nuestro período de ocupación colonial, bosques fueron cortados para establecer plantaciones, el 58% de nuestra tierra está todavía cubierta de bosques. Cuando incluimos las plantaciones de árboles de caucho y palmas oleíferas, el 72% de nuestra tierra está cubierta de bosques. Nos hemos comprometido y seguimos comprometiéndonos a que la cobertura forestal nunca caiga bajo un nivel mínimo del 50% de toda nuestra tierra y que este compromiso será nuestra contribución para los ciudadanos del mundo.

En este respecto nos hemos esforzado también por reforzar nuestras prácticas forestales lo que queda en línea con el concepto del manejo forestal sustentable. Por ejemplo, hemos expandido la superficie de la propiedad forestal estatal permanente de 12,7 millones de hectáreas a 14,1 millones de hectáreas; hemos revisado la Política Forestal Nacional en 1992 y enmendado la Ley Forestal Nacional en 1993 para fortalecer sus estipulaciones e introducir penas más rígidas para ofensas forestales. Estamos potenciando nuestros esfuerzos en la investigación y el desarrollo en todos los campos forestales relevantes, incluyendo esfuerzos para desarrollar industrias de base forestal que trabajarían de manera sustentable. En el macro nivel, la Política Nacional sobre la Diversidad Biológica que fue aprobada en 1998 va a dar la dirección para la conservación de la diversidad biológica y la utilización sustentable de sus componentes.

A nivel internacional hemos continuado a hacer contribuciones a los procesos del Panel Intergubernamental sobre Bosques (IPF) y el Foro Intergubernamental sobre Bosques (IFF). Participamos también activamente en la fase actual de implementar la Convención sobre Diversidad Biológica y la Convención sobre el Cambio Climático, ambos siendo de relevancia directa para los asuntos forestales.

Reconocemos que el sector forestal es importante tanto para la economía y la sociedad de una nación como para el medio ambiente nacional y mundial. Consiguientemente, la creación de un instrumento legal para los bosques se ha convertido en un tema dominante tanto a nivel doméstico como internacional. Estamos demasiado conscientes de los argumentos que no permitieron largas debates sobre tal instrumento; pues, la cuestión de legislación para bosques está todavía por resolver. Todavía no nos hemos acercado a ningún instrumento legal.

Malasia representa la posición de que una legislación obligatoria para todo tipo de bosque sería una necesidad para dirigirse a una gama amplia de asuntos relacionados con el sector forestal y la madera en una manera holística, integral y comprensiva. Creemos que un instrumento legal facilitara lograr el manejo sustentable para todos los bosques mientras que la situación actual internacional de decisiones “ad hoc” sin legislación obligatoria puede ser un obstáculo para las mejores prácticas forestales. Creemos también que tal legislación posibilitaría tomar acciones a nivel internacional para dirigirse a los factores que están detrás de la reducción y degradación de bosques en áreas transnacionales, como, por ejemplo, la deuda internacional y los modelos de consumo no sustentable. Tal instrumento estimularía y aceleraría también la cooperación en la transferencia de tecnología.

En la actualidad, la falta de consenso frente a la necesidad de una legislación obligatoria se debe al empate en los asuntos cruciales como las finanzas, la transferencia de tecnología y el comercio. En este respecto me gustaría invitar a los países desarrollados a reafirmar y poner en acción sus compromisos para dar ayuda financiera concreta y suministrar tecnologías a los países en desarrollo para que logren el manejo sustentable de sus bosques. Además, el manejo forestal sustentable debería ser fomentado por negocios de apoyo mutuo y por estándares medioambientales para el acceso al mercado. De otra forma, los bosques perderían su valor y serían taladas por otros fines. Restricciones comerciales y medioambientales no van a reducir la deforestación. Es más bien el acceso mejorado al mercado que va a ayudar a fomentar el manejo forestal sustentable suministrando los ingresos tan necesarios para este fin.

La dependencia de la sociedad de los bosques existe desde los tiempos inmemoriales cuando la sociedad fue primitiva y sus necesidades fueron sencillas. En muchos lugares del mundo, sobre todo en los países en desarrollo, las necesidades de la sociedad son todavía sencillas. En otras partes, las demandas han crecido con el desarrollo de las sociedades, y formas de vida no sustentables han contribuido mucho a las necesidades mayores y muchas veces insaciables de las sociedades crecientes. Pero las necesidades no sólo son materiales, y por lo tanto vale el lema de que “los recursos forestales y las tierras forestales deberían ser manejados de una manera sustentable para cumplir con las necesidades sociales, ecológicas, económicas, culturales y espirituales de la humanidad a favor de las presentes y futuras generaciones.”

Es un honor para mi encontrarme con Uds. aquí y dirigirme a este Congreso de científicos que se han dedicado a la investigación forestal de manera que contribuyen directa o indirectamente a las necesidades de la sociedad en el presente y en el futuro. La historia reciente ha demostrado que la inversión en la investigación y el desarrollo en cualquier campo puede dar altas ganancias. Deseo sinceramente que sus esfuerzos den un buen rendimiento que mejoraría el destino de la sociedad en general y de sus partes más pobres y débiles en particular. Uds. son representantes tanto del mundo desarrollado como del mundo en desarrollo e IUFRO les vincula por este tipo de relación entre el Norte y el Sur.

En este respecto espero que sus esfuerzos ayuden a elaborar una agenda forestal más justa en la arena internacional y que las tecnologías que Uds. desarrollarán en su trabajo sean compartidas de forma más justa y más generosa con los países en desarrollo para mejorar las prácticas forestales en todo el mundo. Si el mundo debe llegar a manejar los bosques de manera sustentable, la transferencia de tecnología del Norte al Sur debe efectuarse bajo condiciones de preferencia como fue acordado en Río. Desgraciadamente, esto no es el caso por el momento, y por lo tanto los países en desarrollo que no tienen acceso a estas tecnologías no serán capaces de cumplir con sus compromisos en el ámbito del manejo forestal sustentable de lo que no se beneficiará nadie. IUFRO puede, pues, jugar un papel importante para facilitar esta transferencia de tecnología. Espero que este Congreso ayude a fomentar no sólo el intercambio de experiencias sino también a desarrollar redes más concretas que servirán de canales para el transporte de la tecnología del Norte al Sur. Por eso les deseo todo lo mejor para sus esfuerzos y espero que tengan un congreso productivo.

Finalmente me gustaría expresar otra vez mis mejores deseos a todos los delegados del congreso. Espero que encuentren el tiempo en las excursiones post-congreso para conocer no sólo la biodiversidad de nuestros bosques forestales sino también da diversidad de razas, culturas y religiones de nuestro país. En Malasia Uds. verán Asia.

Ahora tengo el gran honor de inaugurar el XXI Congreso Mundial de IUFRO.

Discurso del Director General Adjunto,
Departamento de Montes, FAO

Prof. M. Hosny El-Lakany

Distinguidos huéspedes,
Sr. Presidente y Miembros del Comité Ejecutivo de IUFRO,
Señoras y señores:

En nombre del Director General y de los demás empleados de la Organización de Alimentación y Agricultura de las Naciones Unidas, y particularmente en nombre de mis colegas del Departamento de Montes, me gustaría saludar cordialmente a todos los participantes de este XXI Congreso Mundial IUFRO. Es un gran privilegio y un gran honor para mí poder estar aquí en Kuala Lumpur con Uds. hoy.

Ante todo quisiera felicitar a los organizadores del Congreso y sobre todo a los anfitriones de Malasia por las preparaciones magníficas. Naturalmente, Malasia con su tradición larga y fuerte de una ciencia forestal que contribuye al desarrollo del país es el lugar perfecto para celebrar este evento impresionante.

Al mirar a los participantes en esta sala y al ver este público tan eminente y diverso, siento fuertemente el valor fundamental de la organización de IUFRO. IUFRO ofrece a los científicos e investigadores forestales los medios para compartir experiencia y conocimientos tanto para el avance del manejo forestal sostenible como para su desarrollo individual. Es una oportunidad sin igual para científicos jóvenes que están al principio de su carrera poder intercambiar ideas con y beneficiar de los miembros más eruditos de la comunidad forestal internacional. Además, la posibilidad de tener acceso a resultados de investigación de todo el mundo es de valor inconmensurable. ¿Cuántos de nosotros pueden confirmar que esta oportunidad ha sido una ocasión propicia para ellos?

En mi caso es ciertamente así. Tengo memorias muy vivas de mi primera participación en un Congreso IUFRO en 1976 en Oslo y de mi encuentro directo con muchos científicos forestales, algunos de los cuales están con nosotros hoy, afortunadamente. Además, una parte de mi tesis doctoral se basó en una colección de semillas hecha bajo los auspicies de IUFRO – la Colección de Procedencia de Abeto Grande en 1966.

Por lo tanto es un gran honor para mi representar la FAO en esta reunión importante – el primer Congreso Mundial de IUFRO del nuevo milenio. IUFRO tiene una relación especial con sus miembros, y la relación con FAO es también extraordinaria. A nivel de institución, FAO e IUFRO han mantenido una relación cooperativa y simbiótica desde la fundación de FAO cuando IUFRO, por supuesto, fue la "hermana mayor" con más de medio siglo de edad. IUFRO entrelace a científicos e investigadores, y FAO entrelace IUFRO con el campo, es decir que asegura que los resultados valiosos sean puestas en práctica y que el "pulso" del campo sea transmitido a los investigadores.

En FAO, todos los oficiales forestales tenemos contacto directo y permanente con IUFRO y sus Grupos de Investigación y Trabajo. A través de su Programa de Socios, FAO facilita también visitas de académicos, investigadores y sobre todo de profesionales jóvenes que probablemente no tuvieran otra oportunidad de compartir experiencia y pericia de cara a cara. Además, la FAO en su función de foro neutral, ayuda a países a identificar conjuntamente las áreas que requieren más investigación y concentrar de esta manera los esfuerzos de los científicos forestales en todo el mundo. En este respecto es siempre un gran placer para mí cuando se encuentran científicos e investigadores forestales en las sesiones bianuales del Comité de FAO. De esta manera, la información y el conocimiento pueden fluir en una red de múltiples canales entre FAO e IUFRO en beneficio de todos nuestros componentes.

Desde el punto de vista de la FAO, el tema de este Congreso "Bosque y sociedad: el papel de la investigación" es especialmente apropiado. En su trabajo forestal, la FAO se compromete completamente a aumentar al máximo los beneficios sociales, ambientales y económicos del manejo forestal sostenible. De hecho, este compromiso consta explícitamente en la Visión Estratégica Forestal de la FAO que ha sido desarrollado en cooperación con los Estados Miembros de FAO, instituciones asociadas y organizaciones, entre ellas IUFRO, en un período de más de dos años, y aprobado por el Comité Forestal de FAO en marzo de 1999. El Plan Estratégico Forestal de la FAO describe la misión, las metas, los objetivos a medio plazo, las actividades prioritarias actuales y la visión para el sector forestal de la organización. He aquí la misión: "Aumentar el bienestar de los seres humanos mediante el apoyo a los Estados Miembros en la ordenación sostenible de los árboles y bosques del mundo." La gente y la sociedad vienen primero.

Nuestras actividades prioritarias enfocan también los bosques y la sociedad. Nuestros esfuerzos en el campo de las actividades forestales participativas y comunitarias se centran en involucrar a un grupo más amplio de la sociedad más directamente en el proceso del manejo forestal y de la toma de decisiones. Debería añadir que esto afecta no sólo a las personas que viven actualmente dentro o cerca de los bosques sino también a los que dependen de los recursos y productos forestales. Otra prioridad de la FAO que es de relevancia directa para el tema de los bosques y la sociedad es nuestro apoyo para los países en seguir un programa forestal nacional. Estos programas son reconocidos por procesos intergubernamentales emergidos de UNCED y aspiran a establecer un marco social y político funcional para la conservación, el manejo y el desarrollo sostenible de todos los tipos de bosques.

Una tercera prioridad para la FAO es fortalecer el acceso a información forestal fidedigna y oportuna en todo el mundo. El primer artículo de la Constitución de la FAO nos da el mandato para "coleccionar, analizar, interpretar y diseminar información.". En el sector forestal, esto abarca el desarrollo de términos y definiciones comunes y la armonización de definiciones, la colección de estadísticas sobre producción, consumo, y negocios, y nuestra evaluación de los recursos forestales del mundo. En todos estos aspectos estamos colaborando estrechamente con IUFRO. Por lo tanto es muy oportuno que hayamos decidido publicar los primeros resultados de la Evaluación de los Recursos Forestales Mundiales 2000 de la FAO aquí en este Congreso. Me gustaría mencionar también nuestro sitio Web forestal importante y la colaboración entre FAO e IUFRO en el desarrollo de un Servicio Mundial de Información Forestal.

Otro área importante y duradera de la cooperación entre FAO e IUFRO es el Programa Especial para Países en Desarrollo, el SPDC. Hace un mes, el 7 de julio para ser preciso, se estableció oficialmente la Red de Investigación Forestal para la África Sub-sahariana (FORNESSA), y se eligió al Dr. Konuche de Kenia como primer presidente. En este contexto me complazco en notar que el Coordinador Adjunto del SPDC tiene su oficina en la Oficina Regional de la FAO para África, lo que asegura aun más la continuación de las relaciones estrechas entre FAO e IUFRO.

En este Congreso, miembros de FAO presentarán varias ponencias, y muchas sesiones han sido organizadas conjuntamente con FAO.

Espero que los ejemplos que les he dado hagan manifiesto que FAO se ha comprometido a largo plazo a aumentar las relaciones positivas entre los bosques y la sociedad a un máximo. Y el tema de este Congreso sugiere fuertemente que IUFRO y sus miembros hayan tomado el mismo rumbo.

¿Cuál es, pues, el papel de la investigación en avanzar en este camino como lo percibe la FAO? Por supuesto, necesitamos enfocar más los aspectos sociales del desarrollo de un manejo forestal sostenible. Debemos saber más sobre la manera en que la gente puede acercarse al manejo forestal y como lo hace, y es de importancia especial conocer las herramientas y desarrollos científicos que la gente necesita para cumplir con esta responsabilidad más eficazmente.

Necesitamos más investigación sobre la mejor manera de suministrar la información a la gente que la necesita para poder participar mejor en la toma de decisiones forestales. También hace falta una investigación especial sobre el manejo de conflictos.

Sobre todo necesitamos investigación sobre el potencial y las modalidades de la cooperación internacional en el sector forestal. En los últimos diez años hemos visto una cantidad de acuerdos internacionales de relevancia directa para el futuro del sector forestal en el mundo, pero los que tienen la responsabilidad de ponerlos en un marco e implementarlos se encuentran verdaderamente en nuevos territorios. Debemos estudiar, analizar y aprender de las experiencias de otros sectores que han tomado este camino antes de nosotros para que los acuerdos que forjamos sean prácticos de alcance y nobles de intención.

Estas son tareas exigentes, de veras, y serán aun más exigentes dado el hecho de que deben complementar en vez de sustituir la investigación en otras áreas forestales más tradicionales. Sin embargo, creo que son tareas esenciales si debemos lograr nuestra meta común del uso sostenible de los ecosistemas forestales. Y no veo ninguna otra organización que esté más capaz y lista para asumir este desafío que IUFRO.

Finalmente, señoras y señores, quisiera dar mis gracias personales al Comité Ejecutivo saliente y, particularmente, al Presidente Profesor Jeff Burley, que es un muy buen colega y amigo mío, por su dirección fuerte y competente. Les ruego permiso también para expresar mi plena confianza en el nuevo Comité y el nuevo Presidente, el Profesor Risto Seppälä, y saludar cordialmente a los Presidentes anteriores, especialmente al Dr. Salleh Mohd Nor.

Sr. Presidente, en nombre del Director General de FAO, Jacques Diouf, en mi propio nombre, y especialmente en nombre del Programa Forestal de la FAO, me gustaría expresar mis sinceros deseos que este Congreso tenga éxito y sea un comienzo apropiado del nuevo milenio para el sector forestal del mundo.

Gracias.

Discurso de análisis de cinco años de Presidencia
Sesión de Clausura

Profesor Jeffery Burley

Presidente de IUFRO

Distinguidos huéspedes, colegas, señoras y señores:
Al llegar a la clausura de este Congreso impresionante y productivo, escucharán breves discursos de mí como Presidente actual y de Risto Seppälä, el Presidente electo. Me gustaría hacer un resumen de las actividades y del progreso de IUFRO en los cinco años de mi Presidencia, mientras el Profesor Seppälä trazará su visión de los desarrollos futuros en la investigación forestal y en IUFRO.

Las resoluciones y los desafíos de 1995

En nuestro XX Congreso en 1995 se aceptaron las siguientes resoluciones: -a) mantener y fomentar la investigación aplicada a los bosques y a los productos forestales con objetivos bien definidos; b) potenciar la capacidad de investigación, sobre todo en países en desarrollo; c) ampliar la colaboración para fomentar la eficacia de la investigación y mejorar la comunicación entre las comunidades científicas y la sociedad; y d) fomentar la investigación orientada hacia problemas y políticas concretas en las ciencias económicas y sociales. Cuando fui elegido Presidente, presenté mi vista personal del papel de IUFRO y de su desarrollo y actividades al Comité Ejecutivo, y ahora me gustaría hacer un resumen para Uds. con el fin de mostrar cómo IUFRO ha respondido a los desafíos que expresé y a las resoluciones de Congreso.

Destaqué el hecho de que en la última década del último milenio hubo cambios significantes en la política forestal, la práctica forestal y la profesión forestal. Los asuntos forestales se convirtieron en asuntos mundiales e internacionales y tuvieron una base política más amplia formada por personas e instituciones que no eran forestales tradicionales. Las ciencias socioeconómicas hicieron cada vez mayor contribuciones a los procesos de decisión. Hubo una presión mundial exigiendo que se evalúe el papel de los bosques a la luz de todos sus beneficios y monitorear su estado. Los políticos buscaron siempre (a) información sobre el papel, el valor y el estado de los bosques y árboles en relación a la conservación y el desarrollo, (b) opiniones sobre los vínculos entre bosques, biodiversidad, clima y otros asuntos medioambientales, y (c) consejos sobre el manejo sustentable de los bosques incluyendo cuestiones institucionales.

Pensé (y sigo pensando) que IUFRO debería tratar de responder a estos cambios manteniendo al mismo tiempo su papel primordial como red de sus científicos voluntarios afiliados. Debería continuar a ser la fuente principal de conocimientos y experiencia sobre la investigación forestal en temas especializados y aumentar simultáneamente la intensidad y la frecuencia de su cooperación interdisciplinaria dentro de la Unión misma y con organizaciones y disciplinas fuera del grupo de sus miembros tradicionales.

Estos vínculos contribuyeron también a hacer el trabajo de IUFRO más público, asegurar su relevancia a las necesidades modernas, identificar fuentes de fondos para la investigación y buscar colaboración productiva reduciendo toda duplicación innecesaria. Fue de importancia vital que el Comité Ejecutivo reconociera los asuntes emergentes muy temprano, lo que le resultó más fácil gracias a los contactos fuertes con un número de otras instituciones. IUFRO ha intentado a apoyar a los Directores de las Organizaciones Miembro directamente por realizar y publicar ciencia relevante para la política y asistir a los Directores con sus argumentos en favor del bosque y la investigación forestal ante los gobiernos y agencias.

El nuevo papel internacional de IUFRO

El Comité Ejecutivo de IUFRO se ha esforzado extremamente por hacer publicidad para la existencia, las actividades y la importancia de la Unión. El folleto IUFRO fue recibido con gran éxito cuando fue presentado en el Congreso Forestal Mundial en Turquía en 1997. Igualmente, el sitio Web de IUFRO con sus páginas para cada unidad de investigación copiado en servidores espejos en muchos países y relacionado con muchas instituciones más tiene muy buena reputación. Muchas de las páginas Web reservan espacio para informes sobre el estado de los conocimientos en la disciplina correspondiente a la unidad de investigación; como Ud. se habrá dado cuenta en el curso de este Congreso, se ha prestado mucha atención a la divulgación de los resultados de investigación y los informes sobre el estado de conocimientos.

Hemos tratado también a asegurar un papel para IUFRO en los debates y desarrollos internacionales. Yo u otras personas que desempeñan cargos dentro de IUFRO asistieron a reuniones tales como: el Panel Intergubernamental sobre Bosques (IPF); el Foro Intergubernamental sobre Bosques (IFF); el Foro Forestal del Mundo; el Congreso Forestal Mundial; el Comité Forestal de la Organización para Alimentación y Agricultura de las Naciones Unidas (COFO/FAO); la Asamblea General de IUCN; varias reuniones de iniciativas internacionales para desarrollar criterios e indicadores para el manejo forestal sustentable; el Comité de Síndicos del Centro de Investigación Forestal Internacional (CIFOR); el Centro Internacional para la

Investigación Agroforestal (ICRAF); la Semana de Centros del Grupo Consultativo para Investigación Agricultural (CGIAR); la Exposición Nacional en Kunming, China; y varias reuniones y exposiciones de otras organizaciones. Estuvimos especialmente encantados con que las recomendaciones de la IV sesión del IFF abogaron por mejores vínculos entre los procesos de ciencia y política forestales, por financiamiento de la investigación (sobre todo en los países en desarrollo), por mejorar el acceso a información sobre bosques y colaboración con IUFRO en el GFIS (Servicio Mundial de Información Forestal).

El Proyecto Especial de IUFRO sobre Terminología (SilvaVoc), coordinado por Renate Prüller y apoyado por Japón, entró en contrato con FAO para suministrar definiciones de términos importantes usados en los debates internacionales sobre el manejo forestal sustentable. Me encantó ver que mi propio Instituto pudo representar IUFRO en la preparación de un documento sobre asuntos de política forestal aptos para ser investigados. Aquel documento fue financiado por la Overseas Development Adminstration (ahora el Departamento para Desarrollo Internacional) del Gobierno Británico para la Comisión Mundial sobre Bosques y Desarrollo Sostenible.

La Unión ha también estimulado las unidades de investigación a dedicarse a temas específicos relacionados con las nuevas cuestiones internacionales. El papel que IUFRO desempeñó en la organización y publicidad de la Consulta Internacional sobre Sistemas de Investigación e Información Forestales (ICRIS), patrocinada por los Gobiernos de Austria e Indonesia en cooperación con CIFOR y el Departamento Forestal de FAO, fue una contribución destacada a los procesos internacionales. Aquella conferencia fue una actividad internacional en apoyo del Foro Intergubernamental sobre Bosques (IFF) de la Comisión de las Naciones Unidas sobre el Desarrollo Sostenible (UNCSD) y tuvo lugar en Austria en el mes de septiembre de 1998: sus repercusiones mayores para IUFRO mismo fueron el establecimiento de los Grupos Especiales de Intervención sobre el Servicio Mundial de Información Forestal (GFIS) y sobre la Interface entre Ciencia y Política Forestales.

La estructura y las actividades avanzadas de IUFRO

El papel principal de IUFRO sigue siendo el avance del valor de la investigación a través de su red de casi 700 Organizaciones Miembros y 15’000 científicos en sus especialidades correspondientes; las 268 unidades de investigación y 8 Grupos Especiales de Intervención tuvieron 335 reuniones en 65 países, 41 de ellos países en desarrollo o con economías emergentes. Se crearon dos Divisiones nuevas al principio del período del Comité Ejecutivo para reconocer la gran amplitud de actividades de investigación y reducir la carga de trabajo de ciertos Coordinadores y Coordinadores Adjuntos de División (que son, como todos los que desempeñan cargos dentro de IUFRO, voluntarios). El Comité Ejecutivo estableció un número de Programas Especiales, Proyectos, Grupos especiales de intervención y comités ad hoc para dirigirse a temas o asuntos especiales y les estimuló a ponerse metas significantes específicas incluyendo más énfasis sobre la creación de capacidades. En un discurso corto es prácticamente imposible dar los detalles o hasta resúmenes adecuados para todas estas iniciativas, pero me gustaría escoger algunos puntos culminantes.

Como he indicado antes, uno de los cambios mayores de la última década ha sido el aumento de la necesidad de enfocar asuntos y temas capaces de ser investigados desde un punto de vista interdisciplinario y con el objetivo de solucionar problemas. IUFRO ha siempre tenido un amplio rango de unidades de investigación biofísicas y socio-económicas. En los últimos cinco años hemos tratado de animar la interacción entre aquellas unidades a través de reuniones interdivisionales, colaboración con otras organizaciones, y el trabajo de los Grupos Especiales de Intervención. Todos tenemos que reconocer las dificultades implícitas de aprender a entender el uno la disciplina del otro y de recibir reconocimiento académico o profesional para tal trabajo multi-disciplinario, pero existe claramente una obvia necesidad.

Las Divisiones

Hubo una mayor conferencia interdivisional sobre ecosistemas forestales y el uso de tierras en zonas montañosas en Seoul, Korea, en el 1998. Esta conferencia fue organizada por las Divisiones 1, 4, 6 y 8 y atrajo a 350 participantes de 24 países. Dentro de la División 1, el Grupo de Investigación 1.17.00 (Restauración de sitios degradados) fue involucrado estrechamente en el programa de investigación internacional patrocinada conjuntamente por el Servicio Forestal del USDA, el Banco Mundial, CIFOR, y la British Overseas Development Administration, que examinaron el papel y las implicaciones de plantaciones para acelerar la recuperación natural del bosque en tierras tropicales degradadas.

La División 2 organizó una gran conferencia sobre genética forestal en Beijing en 1998, y su Grupo de Trabajo 2.04.06 organizó una reunión sobre modificación genética en Oxford en 1999, demostrando cómo IUFRO se ocupa continuamente de asuntos actuales de importancia pública y política y cómo da consejos. Los participantes de estas reuniones reconocieron que la mejora genética clásica sigue careciendo esfuerzos mayores de financiamiento mientras debe usar nuevas tecnologías para aumentar la eficiencia; actualmente, los organismos modificados genéticamente deben ser considerados como herramientas de laboratorio y no deben ser difundidas hasta que el público les acepte desde el punto de vista de la ética.

La División 3 celebró algunas reuniones divisionales e interdivisionales: con la División 1 en Bolivia en 1997, con la División 6 en Japón, 1997, en Canadá 1998 y Australia 2000; con la División 8 en Japón en 1998; y con el Grupo Especial de Intervención sobre Manejo Sustentable Forestal en Australia en 1998. También se celebraron varias reuniones con organizaciones externas como CIFOR y FAO, por ejemplo. Algunos Grupos de Investigación elaboraron informes sobre el estado de conocimientos.

La División 5 se dedicó intensamente a comprender el cambio de recursos forestales extendiendo los recursos e implementando tecnologías que estén en armonía con el medio ambiente y la sociedad. La conferencia de toda la División en 1997 se centró en los productos forestales a favor de un manejo forestal sustentable y tuvo 222 delegados de 42 países.

La División 7 fue creada como respuesta a una resolución específica del Congreso en 1995 que impulsó la investigación sobre“…la extensión, productividad y estado sanitario de los bosques …”. En los últimos cinco años, la División ha celebrado importantes reuniones de investigación en Europa, Norteamérica y Asia sobre entomología, patología, contaminación atmosférica e interacciones entre huésped y plaga.

Grupos Especiales de Intervención

Un asunto clave en todo el mundo ha sido el desarrollo de criterios e indicadores para el manejo forestal sustentable. El Grupo Especial de Intervención sobre el Manejo Forestal Sustentable, coordinado por Alain Franc, colaboró con CATIE, CIFOR y FAO para organizar tres reuniones internacionales importantes en Australia (1998), Costa Rica (1999) y Francia (1999), en asociación con Ecofor y EFI; cada una de las reuniones atrajo entre 100 y 200 participantes y tendió un puente entre los científicos y otros grupos interesados en el bosque mientras clarificó las relaciones entre criterios, indicadores, sistemas de certificación y biodiversidad. Se prestó mucha atención al papel de las ciencias sociales.

El Grupo Especial de Intervención sobre el Cambio Medioambiental, coordinado por John Innes, desarrolló informes excepcionales sobre el estado de conocimientos basados en las contribuciones de muchos científicos. Dos de estos informes han sido publicados ya en la serie de investigación IUFRO Research Series, y el restó será terminado durante este año. El Grupo Especial de Intervención representó también los intereses de IUFRO en muchas reuniones promoviendo los vínculos entre la ciencia y la política. El Grupo especial de intervención tenía, en especial, la responsabilidad para una resolución de la Conferencia Ministerial sobre la Protección de los Bosques en Europa, conocida como “Helsinki 4”, que se ocupa de coordinar los esfuerzos para mitigar los efectos del cambio climático sobre los bosques europeos.

El Grupo Especial de Intervención sobre el papel del Bosque en el Desarrollo Sostenible de las Zonas Montañosas, coordinado por Martin Price, preparó su primer informe sobre el estado actual de conocimientos basado en las contribuciones de 124 autores de todas partes del mundo. Un punto crítico fue la definición de la extensión de los bosques en zonas montañosas en el mundo; los elementos más importantes del informe fueron un mapa con las montañas del mundo (según reglas objetivas) y un mapa de los bosques en zonas montañosas que forman el 28% del área total de bosques en el mundo.

El Grupo Especial de Intervención sobre Agua y Bosques, coordinado por Rob Vertessy, fue establecido para revisar el conocimiento científico actual y las hipótesis existentes sobre ecosistemas de agua potable en bosques y las implicaciones de la selvicultura y el manejo forestal para la cantidad y calidad de agua. El Grupo ha producido una publicación importante sobre este tema.

El Grupo Especial de Intervención sobre los Recursos en Internet, coordinado por Lauri Valsta, ha desarrollado un medio único e inestimable para la comunicación entre los científicos y la diseminación de información sobre IUFRO en todo el mundo.

El Grupo Especial de Intervención sobre el Servicio Mundial de Información Forestal, coordinado por Risto Paivinen, es un consorcio de organizaciones internacionales, regionales y nacionales que están desarrollando una estrategia e implementando un servicio de meta-datos basado en Internet para suministrar en todo el mundo el acceso coordinado a información relacionada con los bosques. Se han desarrollado ya los conceptos básicos para la colección y las soluciones técnicas incluyendo un prototipo en función y un proyecto financiado por la Comunidad Europea para África, el Caribe y el Pacífico.

El Grupo Especial de Intervención sobre Gestión y Conservación de Recursos Genéticos Forestales es coordinado por Veikko Koski. Su comité se compone de representantes de la mayoría de las Divisiones de IUFRO, de CIFOR, FAO e IPGRI. Colecciona información científica sobre interacciones entre todos los factores que afecten la distribución, integridad y conservación de recursos genéticos forestales y ha escrito un informe sobre el estado de conocimientos.

El Grupo Especial de Intervención sobre la Interface entre Ciencia y Política, coordinada por Rich Guldin, ayudó a realizar la conferencia de la División 6 en Sudáfrica sobre las contribuciones de la ciencia al desarrollo de políticas forestales y organizó dos eventos satélites en la tercera y la cuarta sesión del IFF. Tres conferencias planeadas para el año que viene van a unir unos 40-50 estudios de casos que demostrarán cómo la investigación ha tenido una buena influencia en la política forestal.

IUFRO en apoyo de países en desarrollo

El trabajo del Programa Especial para Países en Desarrollo (SPDC), coordinado por Bob Szaro hasta junio de este año, ha tratado consistentemente a ayudar con el desarrollo de los recursos humanos en los países en desarrollo y países con economías en transición. Además, IUFRO se ha esforzado mucho por apoyar a científicos de tales países para que puedan desempeñar cargos en la ciencia y la gestión de las unidades de investigación de IUFRO. El SPDC organizó talleres de trabajo sobre la gestión y planificación de la investigación, la redacción de solicitudes de subvenciones, y el desarrollo de propuestas, y sobre la planificación estratégica. El Programa dio apoyo a más de 200 científicos y 35 organizadores de reuniones en más de 60 países e inició y publicó los dos primeros tomos de una serie de libros de texto a bajo costo.

IUFRO está muy agradecida al Gobierno de los Estados Unidos de América por haber puesto a disposición a un Coordinador, al Gobierno del Canadá por haber mandado a un Coordinador Adjunto del SPDC, y al Gobierno de Dinamarca para hacer posible que haya un Coordinador Adjunto en África también. El Gobierno de Japón ha sido muy generoso en apoyar el programa BIOREFOR que ha estimulado la colaboración entre muchas instituciones en la región Asia-Pacífica para contribuir conocimientos sobre el uso de la biotecnología para la reforestación. Estamos también muy agradecidos a la Comisión Europea por su apoyo generoso para nuestro proyecto GFIS-África que quiere mejorar la forma de compartir información relacionada con los bosques en África. Otras agencias también dieron contribuciones generosas en forma de dinero o en especie a IUFRO: AusAid (Australia), Deutscher Verb. FVA (Alemania), la Embajada Real de Dinamarca, el Servicio Forestal de EEUU (USDA), los Gobiernos de China-Taipei y del Reino Unido.

Diseminación de los resultados de la investigación

La investigación no debe realizarse en un vacío sino es importante que se divulguen sus resultados ampliamente. IUFRO se ha esforzado valiosamente por hacer publicidad para el trabajo, los resultados, el valor y la relevancia de la investigación forestal en general y de IUFRO en particular. Además de las páginas Web mencionadas anteriormente y los 91 tomos de memorias publicadas por las unidades de investigación, hemos seguido expandiendo las series de IUFRO como IUFRO World Series y IUFRO Occasional Papers (publicadas por la Secretaría), y añadido la serie IUFRO Research Series (publicada por CAB International).

Revisión de la estructura y gestión de IUFRO

Durante sus cinco años de función, el Comité Ejecutivo actual ha revisado constantemente la estructura y las actividades de IUFRO y ha encargado también un grupo externo para revisar la Secretaría, el SPDC y el Proyecto Especial. Nos hemos esforzado fuertemente por atraer subvenciones, sobre todo para apoyar miembros de países en vías de desarrollo, pero también para establecer los propios proyectos de IUFRO como el Proyecto de Terminología Silvavoc. Hemos revisado la estrategia de inversiones de IUFRO, sobre todo en vista de las dificultades que tienen algunas Organizaciones Miembros con el pago de sus cuotas. Como una respuesta a la reducción del número de miembros últimamente, el Comité Ejecutivo y el Consejo Internacional han aprobado un ligero cambio del nombre de IUFRO en la versión inglesa de “Forestry” a “Forest”; esto reconoce la necesidad de abarcar una gama más amplia de disciplinas e instituciones que sacaran beneficios de IUFRO y contribuyeran a la Unión. Reconoce también la percepción de algunos miembros del público de que “forestry” sólo se refiere a la eliminación masiva de bosques naturales o el desarrollo igualmente amplio de plantaciones de especies exóticas; esto pasa en un tiempo en que IUFRO está haciendo mucho más para suministrar investigación y consejo sobre los beneficios sociales y medioambientales del bosque.

El Comité Ejecutivo ha invitado a las Organizaciones Miembros y científicos a sentirse más integrados en los procesos de política y planificación de IUFRO. Muchos contribuyeron al desarrollo del Plan Estratégico que ha guiado el trabajo del Comité Ejecutivo en los últimos cinco años. El Consejo Internacional también ha sido involucrado estrechamente en el desarrollo de la política de IUFRO, la revisión de los Estatutos de IUFRO y la elección de su futuro Comité Ejecutivo.

El Comité Ejecutivo ha estimulado una regionalización de la gestión y cooperación científica de IUFRO mediante el reconocimiento de Capítulos como la Asociación de Institutos de Investigación Forestal de la Asia Pacífica (APAFRI), la secretaría de la cual se encuentra actualmente en Malasia. Adicionalmente, IUFRO ha sido pro-activa en apoyar, junto con FAO, otras actividades regionales que quieren fomentar la cooperación entre instituciones nacionales, incluyendo el Programa de Apoyo de la Investigación Forestal en Asia y el Pacífico (FORSPA) y la Red de Investigación Forestal para la Africa Sub-sahariana (FORNESSA) en la que coopera también estrechamente la Academia Africana de Ciencias (AAS).

Desafíos del futuro

Señoras y señores, espero que se den cuenta después de haber escuchado mis palabras, que IUFRO, bajo el liderazgo del Comité Ejecutivo y con la asistencia valiosa de la Secretaría (con el apoyo generoso del Gobierno de Austria), ha florecido en los cinco años pasados y ha respondido con éxito a las resoluciones del Congreso anterior. El Comité Ejecutivo mismo ha contestado muy activamente a los desafíos con que yo lo confronté. Como Presidente saliente sería fácil para mí ofrecer al futuro Presidente y el Comité Ejecutivo los desafíos que tendrán que considerar. Entre ellos, yo destacaría los siguientes:

- Continuar con el desarrollo de estándares de métodos de investigación que pueden ser aceptados a nivel internacional.
- Fortalecer la red de miembros.
- Desarrollar GFIS, normalizar terminologías e informes sobre el estado de conocimientos.
- Forjar y reforzar los vínculos entre ciencia, política, gestión y uso de los bosques, productos forestales y servicios.
- dentificar y cumplir con las necesidades de investigación disciplinarias e interdisciplinarias.
- Aumentar el número de miembros.
- Reorganizar y reforzar el Comité y la Secretaría para asegurar una seguridad financiera, un apoyo mayor por parte de los miembros y mejores facilidades para la divulgación de información.

Discurso de bienvenida pronunciado por
el Presidente del Comité Organizador del Congreso,

Dr. Abdul Rahim Nik

Profesor Jeffery Burley, Presidente de IUFRO,
Tan Sri G.K. Rama Iyer, Presidente del Comité de Malasia para la Investigación y Desarrollo Forestales,
Dato' Dr. Abdul Razak Mohd Ali, Director General de FRIM,
Dr. Risto Seppälä, Presidente electo,
Distinguidos huéspedes y delegados,
Señoras y señores:

Celebro mucho que hayamos llegado a la clausura del XXI Congreso Mundial de IUFRO. Durante los 6 días pasados hubo una abundancia de actividades en este sitio de Congreso de las sesiones científicas, reuniones satélite y administrativas a las exposiciones, recepciones y excursiones. Como organizadores de este evento prestigioso, hicimos todo lo posible para cumplir con todas sus esperanzas y deseos para asegurar que su participación en las reuniones y su estancia durante la semana pasada fuesen muy agradables y cómodas para Uds.

Hace cinco años que fui nominado Presidente del Comité Organizador de Congreso (COC) y que fui encargado con la tarea monumental de organizar este Congreso. Entonces no tuve ni la mínima idea sobre el tamaño del desafío y de la responsabilidad que ha sido confiado a mí. Tres años más tarde empecemos realmente a acalorarnos y acelerar nuestra velocidad de organización. Finalmente, en los últimos seis meses antes del Congreso estuvimos completamente absortos en los desafíos reales. Tengo que admitir humildemente que hemos aprendido mucho organizando este Congreso. En este respecto, la tecnología moderna de la que disponemos hoy en día nos ha venido muy valiosa y nos ha ayudado mucho en la preparación. No puedo imaginarme organizar esta reunión sin facilidades como el correo electrónico y el fax.

Mientras el tema del Congreso de "Los Bosques y la Sociedad – El Papel de la Investigación" ha sido bien elaborado y discutido en muchas sesiones técnicas, nosotros los organizadores adoptamos un lema propio en el curso de las preparaciones del Congreso. El lema es "Nos comprometemos a asegurar un Congreso memorable y bien organizado". Uds. habrán visto este lema en todas nuestras estaciones de servicio. Este lema sencillo transporta dos mensajes importantes. Reconociendo que esta es la primera vez que un Congreso de este carácter sea celebrado en un país en desarrollo en los más de cien años de la historia de IUFRO, queríamos asegurar que este XXI Congreso Mundial de IUFRO celebrado aquí en Malasia dejaría una impresión fuerte y duradera y también recuerdos agradables en las memorias de los delegados que están presentes hoy. En segundo lugar, una reunión tan grande como ésta necesita un sistema bien organizado para impresionar a los participantes y compensar el valor de tiempo y dinero que han invertido para participar. Fijados en este lema hemos trabajado con todo entusiasmo y gran dedicación para rendir los servicios. Uds., estimados delegados, deben juzgar nuestro trabajo ahora.

Señoras y señores:

En esta sesión de clausura me gustaría compartir con Uds. algunos datos estadísticos importantes acerca de este Congreso y algunas de nuestras observaciones que pueden ser de interés para el anfitrión del próximo Congreso.

El número total de delegados registrados para el Congreso fue 1906 de 96 países, entre ellos 209 participantes registrados como personas acompañantes. Recibimos también un eco muy alentador para todos los programas de visitas y excursiones. En total, 1127 personas se registraron y participaron en los nueve programas de excursiones durante el Congreso el jueves, y más de 700 personas asistieron al programa para acompañantes. La visita de los luciérnagas tuvo el mayor éxito. Inmediatamente después del Congreso, 324 delegados en total van a participar en los próximos días en las 12 excursiones post-Congreso que les llevarán a casi todos los estados de Malasia así como también a países vecinos como Brunei, Indonesia y Tailandia.

En cuanto a las presentaciones científicas constatamos que la mayoría de las sesiones tuvieron lugar según el programa. En algunas sesiones hubo vacíos por conferenciantes que no podían asistir, pero los moderadores de las sesiones pudieron invitar a otras conferenciantes para llenar estos vacíos. Hubo, sin embargo, pocas sesiones que tenían que ser canceladas porque ninguno de los conferenciantes apareció para presentar sus investigaciones. Nos dimos cuenta de que la mayoría de los que no aparecieron fueron científicos de países en desarrollo que tenían problemas financieros. En cuanto a las presentaciones de pósters, sólo el 55% de los presentadores de los 833 pósters seleccionados estuvieron presentes. La mayoría de los presentadores de pósters que no llegaron fueron también de países en desarrollo y no tuvieron los fondos para asistir al Congreso. En lo que se refiere al personal técnico empleado en este Congreso, hubo 120 especialistas técnicos y casi 270 asistentes para asegurar que no hubiera inconvenientes.

Por si les interesa saber, hemos producido 6.6 millones de páginas de impresos, incluyendo los anuncios previos y el material de publicidad. No conozco exactamente cuántos árboles necesitamos para todo esto pero estoy convencido que ciertamente valió la pena.

Permítanme ahora que comparte con todos Uds. brevemente mi punto de vista sobre un tema que puede ser útil y que puede tomarse en consideración para lo organización del próximo Congreso. Si se quiere una participación más activa por parte de los países en desarrollo es necesario hacer mayores esfuerzos para asegurar los fondos suficientes para el SAP o Programa de Asistencia Científica. Para esta reunión, la participación de 91 de los 169 candidatos SAP fue financiada parcialmente o completamente por el Gobierno de Malasia. En mi opinión, es importante esforzarse más por asegurar fondos suficientes de países desarrollados, lo que no fue el caso en este Congreso, con algunas excepciones como fondos del SPDC y de países como los Estados Unidos de América, el Reino Unido, Suecia y Finlandia. El nuevo Comité de IUFRO y el próximo anfitrión de Congreso deberían reflexionar sobre esta situación.

Tengo que admitir que ha sido un gran placer y una excelente experiencia para nosotros haber organizado este Congreso. Espero sinceramente que este Congreso no sólo haya sido beneficioso para su carrera científica sino que ha sido también una experiencia valiosa y útil. A pesar de los grandes esfuerzos que hicimos para tenerlo todo perfecto, hubo algunas faltas y puntos débiles que les ruego disculpar, por favor. Ahora es tiempo ya para pasar la bandera a los próximos anfitriones del XXII Congreso Mundial de IUFRO.

Por fin, señoras y señores, se habrán dado cuenta de que muchas organizaciones, agencias y muchos patrocinadores han tomado parte en este Congreso. Tengo el gusto de expresar mi profunda gratitud y apreciación por todo su apoyo, cooperación y asistencia sin el cual no hubiéramos conseguido cumplir con nuestra tarea tan difícil. Particularmente, quisiera dar las gracias al Comité de Malasia para la Investigación y el Desarrollo Forestales y a FRIM, y sobre todo a su Presidente y Director General por su apoyo estimulante durante toda la planificación y realización de este Congreso. Gracias también a los miembros del Comité Ejecutivo y a la Secretaría de IUFRO en Viena por sus consejos y su dirección para asegurar el éxito de este Congreso. Los últimos, pero no por orden de importancia, a los que quisiera dar las gracias como Presidente del Comité Organizador de Congreso son los miembros del Comité y los Sub-comités y los asistentes de Congreso. Les invito a todos a darles fuertes aplausos conmigo.

A todos que tienen que viajar lejos para llegar a casa les deseo un buen y seguro viaje.

Bon Voyage y Gracias.

Discurso pronunciado por
el Presidente electo

Dr. Risto Seppälä

Presidente Burley,
Excelencias, Miembros del Consejo Internacional de IUFRO y del Comité Ejecutivo de IUFRO,
Distinguidos Huéspedes, Colegas Científicos,

Señoras y Señores,

Es un gran honor para mí aceptar la elección como Presidente de IUFRO por el Consejo Internacional. Les prometo que voy a hacer los mejores esfuerzos para cumplir con las grandes esperanzas vinculadas con esta posición.

En su discurso de aceptación hace cinco años, el Presidente actual dijo que siempre tenía tres ambiciones para IUFRO: que IUFRO tenga un Presidente de los trópicos; que se celebre un Congreso Mundial en un país en desarrollo, y que haya una mujer como Presidenta. Ahora hemos alcanzado las dos primeras metas, pero si Jeff Burley quería que una mujer le siga en la posición de Presidente, yo no soy la persona justa. Sin embargo, puedo seguir obrando en su sentido para alcanzar esta tercera meta.

Es por tradición que un discurso de aceptación contenga algunas de las visiones que el Presidente entrante tiene acerca de la estructura y las actividades de la organización en el futuro. Dado que nuestro Presidente actual les ha presentado ya en esta misma ocasión una larga lista de desafíos para el futuro, me gustaría escoger sólo dos asuntos que me parecen muy importantes: son la afiliación a IUFRO y el papel que juega IUFRO como “clearing house” o centro de información y pericia en la investigación forestal.

IUFRO tiene actualmente 680 Organizaciones Miembros que nos proveen con los fondos básicos. Aunque hemos acogido a nuevos miembros en los últimos años, demasiado de nuestros miembros antiguos ya no podían o querían pagar sus cuotas de miembro. Cuando perdemos una Organización Miembro, sin embargo, perdemos también a muchos científicos porque para personas individuales resulta más difícil y caro hacerse miembro de IUFRO.

Probablemente ya es tiempo para revisar todo el concepto de la afiliación a IUFRO. Primero debemos preguntar para qué necesitamos los miembros. Una razón obvia es el dinero. Aunque IUFRO es una organización voluntaria, no pudiéramos sobrevivir sin las cuotas de los miembros. Sin embargo, si recibiéramos dinero de otras fuentes que las cuotas, ¿necesitaríamos todavía los miembros para cumplir con nuestra misión de promover la cooperación internacional en la investigación forestal y las ciencias relacionadas? La respuesta es que sí. Necesitamos los miembros para eso también porque no hay cooperación sin cooperadores, y nuestras instituciones miembros y sus científicos forman la mejor red posible de cooperadores en la investigación forestal a nivel internacional.

Según una investigación realizada recientemente por el Instituto Forestal Europeo, solamente en la Europa Occidental hay más de mil instituciones que se ocupan de investigaciones relacionadas con los bosques. De este número, sólo 176 son miembros de IUFRO. Me imagino que en otras partes del mundo la situación será semejante. Por eso el potencial para reclutar nuevas organizaciones miembros es probablemente más grande que pensamos. Depende de nosotros cómo aprovechamos este potencial para aumentar el número de Organizaciones Miembros. Hay muchos actores que juegan papeles cada vez más importantes en este mundo en cambio y con los que IUFRO no ha todavía establecido relaciones.

También necesitamos establecer mejores vínculos con los científicos individuales. El hecho de que IUFRO es una organización de organizaciones no garantiza automáticamente que todos los científicos que trabajan en nuestras Organizaciones Miembros sepan de IUFRO y reciban información sobre la Unión. Para los científicos que trabajan en instituciones fuera de IUFRO, el flujo de información fue prácticamente nulo antes. Ahora, pues, la situación ha mejorado considerablemente porque la mayoría de los visitantes de nuestro sitio Web y un número considerable de los participantes de este Congreso no vienen de Organizaciones Miembros de IUFRO. Para mí, esto es también una indicación de un potencial enorme de miembros porque muestra el gran interés por IUFRO y su Congreso. Una condición previa muy importante para aumentar el número de miembros individuales será facilitar su afiliación a IUFRO, especialmente cuando no vienen de las disciplinas forestales.

Hasta ahora, IUFRO ha aprovechado muy modestamente los conocimientos y la pericia de su red de miembros. Tenemos algunos proyectos y programas especiales de financiación no reembolsable como, por ejemplo, el SPDC y SilvaVoc, pero lo que necesitamos hacer es movilizar la base entera de información y conocimiento de nuestros científicos y expertos que es un recurso único pero actualmente muy poco aprovechado. Los Informes sobre el Estado de los Conocimientos que fueron presentados en el curso de la semana de Congreso son un buen paso hacia esta dirección, y el Servicio Mundial de Información Forestal del que hemos visto un prototipo durante este Congreso es otro.

Señoras y Señores:

Mi propia visión de IUFRO es que se vuelva en “clearing house” o centro de información y pericia de la investigación forestal. Las personas que tienen cargos dentro de IUFRO son las personas claves en este proceso, pero representan solamente una pequeña fracción de nuestros recursos humanos. Tenemos que establecer vínculos directos con todos los individuos que actúan en nuestras unidades de investigación o son relacionados con ellas. Después de recibido información relevante en sus especialidades, podremos servir como “clearing house” y contestar a las solicitudes de nuestros clientes cuando, necesitan un informe sobre el estado de conocimientos en un cierto campo de la investigación forestal, por ejemplo, o cuando hace falta establecer un grupo internacional para solucionar un problema actual de investigación.

Si IUFRO recibe una buena reputación como “clearing house” de información y pericia forestales, nuestra visibilidad aumentará considerablemente. Esto atraería a donantes y clientes y produciría un efecto de bola de nieve que adelantaría también las finanzas de IUFRO.

Estimados amigos:

Como Presidente nuevo veo que una de mis tareas más importantes es servir como embajador de IUFRO que hace publicidad para nuestra organización y vende nuestros productos. La comunidad del sector forestal internacional necesita nuestra pericia y está dispuesta a pagar para nuestros servicios. También necesitamos el márketing para reforzar la afiliación a IUFRO. Además de animar a nuestros miembros actuales a quedarse con nosotros, tenemos que encontrar nuevos miembros, sobre todo en áreas fuera del sector forestal tradicional. Una base de miembros amplia y de alta calidad es también la condición previa para vender nuestros servicios a aquellos que los necesitan y pueden pagar para ellos.

Aunque he estado ahora en medio de presentar mi vista del camino que tenemos adelante, me gustaría dedicarme por un minuto al pasado. En mi capacidad de Vice Presidente actual de Programas, quisiera aprovechar esta oportunidad para decir las gracias a todos que desempeñan un cargo dentro de IUFRO por su trabajo valioso desde el Congreso de Tampere. Me gustaría dar mis gracias particulares al Comité Científico del Congreso y la Secretaría de IUFRO por sus contribuciones extraordinarias a la preparación del programa científico de este Congreso. Finalmente, quisiera expresar mi gratitud a nuestros anfitriones de Malasia. De mi experiencia personal con la organización del Congreso anterior sé exactamente cuánto trabajo Uds. han invertido para que este evento pueda tener lugar. Les felicito a Uds. por el gran éxito de este Congreso. Saya ucapkan setinggi-tinggi tahniah kepada tuan rumah Malaysia di atas kejayaan kongres ini.

Los finlandeses somos conocidos como gente de pocas palabras aun cuando tengamos algo que decir. Preferimos las acciones a las palabras sabiendo que los discursos también son importantes cuando se trata de mostrar la dirección para ir adelante. Me gustaría concluir mi discurso ahora pero Uds. oirán de mí tal vez no tanto a través de lo que digo sino, ojalá, a través de lo que hago. Todo lo que haga por IUFRO lo quisiera hacerlo junto con todos Uds.

Discurso pronunciado por
el anfitrión del Congreso IUFRO en 2005

Prof. Russell Haines
Queensland Forestry Research Institute

En vista de la historia de cuarenta mil años de utilización de bosques y recursos forestales en nuestro país, será un gran placer para nosotros los australianos dar la bienvenida a los investigadores forestales de todo el mundo en el XXII Congreso Mundial IUFRO en Brisbane en 2005.

Australia tiene una gran variedad de tipos de bosques tanto de la zona templada como tropical y árida y una superficie de plantaciones que está creciendo rápidamente . Los desafíos que se nos plantean en el manejo de estos bosques son semejantes a los de otras partes del mundo que se han puesto de relieve en este Congreso.

El gobierno federal y los gobiernos de los estados de Australia se han comprometido fuertemente al uso sabio de los recursos forestales en beneficio de las generaciones actuales y futuras reconociendo que hace falta una base de conocimientos científicos profundos. Nos hemos comprometido fuertemente a participar en foros forestales internacionales. Particularmente, nos hemos comprometido fuertemente a la cooperación científica a nivel internacional y apoyamos vigorosamente la Unión Internacional de Organizaciones de Investigación Forestal. Tengo cierto orgullo en mencionar que fue mi buen amigo y colega Dr. Garth Nikles, recién jubilado después de haber contribuido 50 años a la ciencia forestal, quien, junto con el Dr. Geoff Burley, inició el primer Grupo de Trabajo IUFRO tropical en 1971.

Creo que vivimos en tiempos muy interesantes para la investigación forestal. El grupo de personas interesadas ávidamente en el manejo y la utilización de los bosques y sus recursos ha nunca sido mayor, y la cooperación internacional entre los científicos forestales ha nunca sido más importante.

Esperamos para el 2005 que podamos mostrar a los delegados nuestra hospitalidad australiana y particularmente devolver la hospitalidad con que nos han acogido aquí en Malasia.

Los delegados de Australia han apreciado mucho la organización excelente del XXI Congreso Mundial IUFRO en Malasia. Reconocemos que nuestros colegas de Malasia han establecido estándares muy altos para el próximo Congreso y estamos convencidos de que la organización del Congreso en Brisbane en 2005 se orientará mucho en la experiencia de Malasia.

Esperamos con gran alegría unirnos con la comunidad internacional amplia de IUFRO en la organización del XXII Congreso Mundial IUFRO y llevar la bandera de IUFRO adelante en los próximos cinco años. Sobre todo, por supuesto, nos alegraríamos verlos a todos Uds. en Brisbane en 2005

Discurso de Clausura pronunciado por el Presidente de IUFRO,

Profesor Jeffery Burley

Excelencias, Distinguidos Huéspedes,
Miembros de IUFRO, Colegas y Amigos
Señoras y Señores:

Estamos llegando a la clausura formal del XXI Congreso Mundial de IUFRO en Kuala Lumpur, Malasia. Aunque la mayoría de la gente siempre se alegra de poder volver a casa, sé que hay muchos participantes que son un poco tristes por haber que despedirse de un país tan hermoso y un pueblo tan amable y terminar un programa tan lleno de presentaciones, pósters, discusiones, exposiciones y excursiones de campo interesantes y estimulantes. También serán tristes por tener que despedirse de amigos antiguos y nuevos a que encontraron aquí, pero espero que los contactos profesionales y sociales sean mantenidas en la tradición de un siglo de colaboración científica y personal dentro de IUFRO.

Los organizadores de cada Congreso siempre están preocupados al principio por saber si pueden competir con el Congreso anterior en cuanto a la calidad y la cantidad, pero yo siempre he pensado que no tienen que competir sino que tienen que diferir. Después de Montreal en 1990, los organizadores finlandeses del Congreso de Tampere en 1995 pensaron inicialmente que no pudieran competir pero lo lograron. Después de Tampere, los organizadores de Malasia pensaron que no hubiera manera de competir, pero creo que demostraron que sí lo pudieron. La calidad de los arreglos administrativos, políticos y técnicos ha sido estupenda, y la amabilidad de todos los empleados de apoyo ha sido extraordinaria.

He caminado por el sitio del Congreso durante toda la semana buscando las opiniones de muchos participantes y no he encontrado a ninguno que hubiera expresado críticas graves. Vamos a ver si esto se refleja también en el resultado del cuestionario aleatorio, pero estoy convencido que sí. No obstante, el Comité Ejecutivo de IUFRO tendrá mucho interés por conocer sus puntos de vista una vez que hayan vuelta a casa y hayan tenido el tiempo para reflejar sobre todos los aspectos del Congreso.

Por supuesto, no es posible para mí dar las gracias a todas las personas y organizaciones que han contribuido al éxito de este Congreso. Por lo tanto me permito dar las gracias colectivamente en nombre de todos Uds. al Gobierno de Malasia; al Comité Ejecutivo de IUFRO; al Comité Directivo de Congreso encabezado por el Dr. Razak; al Comité Organizador del Congreso presidido por el Dr. Rahim; al Comité Científico del Congreso presidido por el Dr. Teissier du Cros; a la Secretaría de IUFRO encabezada por Heinrich Schmutzenhofer; a los empleados de FRIM, a los Departamentos Forestales nacionales, a las Universidades que han ayudado en muchas maneras; a los fotógrafos, a las personas de información y los empleados del organizador profesional de Congreso; a la prensa que informó tan concienzudamente durante toda la semana; a los intérpretes sin los cuales no todos hubieran podido escuchar bien a los discursos keynote; al maestro de ceremonias sin el que las ceremonias de inauguración y clausura así como las cenas hubieran sido menos eficientes y menos agradables; a los patrocinadores de muchos participantes; y, sobre todo, a los participantes mismos. Como es el caso con la mayoría de las actividades en la vida, se extrae de un evento tanto como se invierte, y sé que la mayoría de los participantes sumergieron completamente en el espíritu y las actividades del Congreso y sacaron, por consecuencia, mucho placer y muchos beneficios personales.

Me gustaría extender mis gracias personales a todos Uds. por su apoyo continuo durante los últimos cinco años, especialmente a mi esposa Jean y al Secretario de IUFRO, Heinrich Schmutzenhofer. Sin ellos no hubiera podido servir como su Presidente. Por suerte, sólo tengo que volver a casa con uno de los dos. Para el otro tengo un pequeño regalo, un reloj de Oxford con despertador fijado en las 6 de la tarde para que sepa siempre cuando es tiempo para irse a casa a su esposa Edith a que igualmente agradezco su apoyo.

Quisiera desearles a todos Uds. un buen viaje y que su Dios esté con Uds. Declaro el XXI Congreso Mundial de IUFRO terminado.

Congress Resolutions

RESOLUTIONS

of the 21st Congress
International Union of Forestry Research Organizations
12 August 2000

	CONSIDERATIONS	RESOLUTIONS
Role of forests and trees in human welfare	**Recognizing** the great contributions made by forests, trees, industries and the forestry profession to human, environmental, economic and socio-cultural welfare, **further recognizing** the contributions to poverty alleviation, the stimulating of development and reversing environmental decline, **further recognizing** the importance of cultural diversity, and **further recognizing** that research is undertaken at different intensities depending on the geographical extent of a problem, the level at which it is approached, and the inter-relationships with other problems,	IUFRO should continue and expand its stimulation and support for research, and provide the knowledge necessary to achieve sustainable forest management within differing physical and social landscapes; it should seek to reconcile conflicting demands for wood and non-wood products, environmental services and social benefits; IUFRO should also seek appropriate knowledge, particularly from indigenous people.
Attention by policy-makers	**Noting** the increasing attention paid to forests by international and national agencies, international NGOs, commercial enterprises and academic institutions, and the need for reliable information by decision-makers in such organizations,	research should be increasingly directed towards forest policy-related issues in the major environmental and social conditions including urban, mountain and dry environments; IUFRO has a major role in enhancing the interface of science, policy and industry, aiming at better provision of all forest benefits, goods and services.
Role in inter-governmental processes	**Being** aware of the place of forestry in the considerations of several inter-governmental processes, and of IUFRO's unique capacity to mobilize a broad range of individual and collective expertise,	IUFRO should strengthen its contributions to international debates and political processes, specifically those relating to:- genetic resources and biotechnology; biodiversity; sustainable forest management; climate change and carbon sequestration; soil; water; fire; deforestation, forest degradation and desertification. It should promote the transfer of socially acceptable, environmentally sound techniques.
Research and the impacts of forestry activities	**Considering** the public concern for the possible impacts of forestry activities on global and local environments, social welfare and biodiversity, and **remembering** that IUFRO's research traditionally focuses and progresses in major disciplines,	research should increase within single disciplines while simultaneously moving towards an interdisciplinary, problem-solving approach; IUFRO should seek closer collaboration with other research organizations, while bringing its experience and networking powers to assist other research networks and consortia.

	CONSIDERATIONS	RESOLUTIONS
Information	**Appreciating** the research undertaken and the forest and forest products technologies developed, especially by IUFRO member institutions and individual scientists, **realizing** that much of this information is available in scattered sources and forms, and **observing** the rapid development and availability of information technologies,	existing information should be made available in accessible and appropriate forms for the wide range of users; forest research institutions should strive to divulge their research results; use of the IUFRO Net, and development of the Global Forest Information Service led by IUFRO, should be intensified and IUFRO research units should continue to disseminate statements of the current state of knowledge in their specific fields.
Research capacity	**Believing** that forest research capacity is low in countries with developing and emerging economies, and that women scientists are underrepresented and insufficiently supported in forest research,	IUFRO should expand its collaboration with other organizations that seek to enhance biophysical and social research capacity in countries with developing and emerging economies; it should encourage the role of women and disadvantaged researchers in forest sciences.

Congress Resolutions (French)

RESOLUTIONS
DU 21ème Congrès de
l'Union Internationale des Instituts de Recherches Forestières
12 août 2000

	CONSIDERATIONS	RESOLUTIONS
Importance des forêts et des arbres pour le bien de l'humanité	**Reconnaissant** la contribution importante apportée au bien-être environnemental, économique et socio-culturel de l'humanité par les forêts, les arbres et l'industrie forestière, **Reconnaissant** aussi les contributions à la lutte contre la pauvreté, à l'encouragement du développement et au renversement du processus de destruction de l'environnement, **Reconnaissant** aussi l'importance de la diversité culturelle, et **Reconnaissant** aussi le fait que les travaux de recherche sont menés en fonction de la portée géographique du problème, du niveau de l'approche et de leur interaction avec d'autres problèmes,	l'IUFRO devrait poursuivre et étendre ses encouragements et son soutien à la recherche, et produire la connaissance nécessaire pour concevoir une gestion forestière durable dans tout environnement social ou biophysique; elle cherchera a dépasser les conflits entre demande de produits ligneux et non-ligneux et la satisfaction des besoins environnementaux et des bénéfices sociaux; l'IUFRO devrait aussi recueillir la connaissance des peuples indigènes.
Intérêt des décideurs politiques	**Considérant** l'attention croissante apportée aux forêts par les agences internationales et nationales, les ONG internationales, les entreprises commerciales et les institutions universitaires ainsi que le besoin d'une information fiable pour les décideurs de telles organisations,	la recherche devrait de plus en plus être orientée vers les questions politiques concernant les principales conditions environnementales et sociales, y compris l'espace urbain, les zones de montagne et les zones sèches ; l'IUFRO a un rôle majeur à jouer en promouvant l'interface entre la science, la politique et l'industrie, tout en visant la sauvegarde des bienfaits et des services rendus par la forêt.
Rôle dans les processus intergouvernementaux	**Etant** conscient de la place que la foresterie occupe dans les préoccupations de plusieurs processus intergouvernementaux, et de la capacité unique de l'IUFRO de mobiliser un grand nombre d'experts,	l'IUFRO devrait maintenir et intensifier sa présence dans les débats et processus politiques internationaux, notamment ceux qui se rapportent aux thèmes suivants : ressources génétiques et biotechnologie, biodiversité, gestion forestière durable, changements climatiques, séquestration du carbone ; sols, eaux ; incendies ; déboisement, dégradation des forêts et désertification. Elle devrait promouvoir le transfert des techniques n'ayant pas d'effets nuisibles ni pour la société ni pour l' environnement
La recherche et l' impact des activités forestières	**Considérant** l'inquiétude publique quant aux retombées possibles des activités forestières sur l'environnement mondial et local, l'humanité et la biodiversité,	la recherche devrait s'éloigner de plus en plus de l'actuelle approche disciplinaire pour résoudre les problèmes par une approche interdisciplinaire; ainsi l'IUFRO devrait collaborer plus étroitement

	CONSIDERATIONS	RESOLUTIONS
	Rappelant que la recherche menée au sein de l' IUFRO est centrée traditionnellement sur les disciplines majeures où les progrès sont le plus visibles,	avec d'autres organismes de recherche tout en mettant en valeur son expérience et ses capacités de gestion de réseaux pour renforcer d'autres réseaux et consortia de recherche
Information	**Reconnaissant** la recherche entreprise et les technologies développées en matière de foresterie et de produits forestiers, notamment par les institutions membres de l'IUFRO et par les scientifiques individuels, réalisant qu'une grande partie de ces informations est disponible sous des formes diverses et disséminées, et **observant** le développement rapide et la disponibilité des technologies de l'information,	l'information existante devrait être mise à disposition du plus grand nombre d'utilisateurs de manière appropriée et accessible ; les instituts de recherche devraient s'efforcer sans cesse de diffuser leurs résultats de recherche; l'utilisation du réseau de l'IUFRO et le développement du Service mondial d'information forestière (GFIS) entrepris par l'IUFRO devraient être encouragés et les unités de recherche de l'IUFRO devraient continuer à diffuser les bilans de connaissances de leurs champs de recherche respectifs.
Compétences	**Estimant** que les moyens de la recherche forestière sont faibles dans les pays en développement et émergeants, et que les femmes dans la recherche forestière sont sous-représentées et pas assez soutenues,	l'IUFRO devrait étendre sa collaboration avec d'autres organisations qui s'efforcent de renforcer les moyens pour la recherche – en sciences sociales ou biophysiques – dans les pays en voie de développement ou émergeants.

Congress Resolutions (German)

RESOLUTIONEN DES XXI Weltkongresses des
Internationalen Verbandes forstlicher Forschungsanstalten (IUFRO)

	ERWÄGUNGEN	ENTSCHLIESSUNGEN
Die Bedeutung des Waldes und der Bäume für das Wohl der Menschheit	**In Anerkennung** der enormen Beiträge des Waldes, der Bäume und der Forstberufe für eine gesunde Umwelt, wirtschaftlichen und sozialen Wohlstand, **In weiterer Anerkennung** der Beitraege des Waldes im Kampf gegen die Armut, bei der Foerderung von Entwicklung und Umkehrung der Zerstoerungsprozesse, **In weiterer Anerkennung** der Bedeutung kultureller Vielfalt, und **In weiterer Anerkennung** der Tatsache, dass Forschung, je nach geographischer Tragweite, mehr oder weniger intensiv betrieben wird, des Niveaus der betriebenen Forschungsarbeiten und der Wechselbeziehungen mit anderen Problemfeldern,	sollte IUFRO forstliche Forschung zunehmend fördern und die nötige Wissensgrundlage zur Verfügung stellen, um eine nachhaltige Bewirtschaftung von Wäldern zu erreichen, damit diese alle Funktionen in ihrem jeweiligen physischen und sozialen Umfeld erfüllen können; IUFRO sollte einander widersprechende Ansprüche an den Wald wie Nutzung von Holz und anderen Produkten, Umweltschutz und Wohlfahrtswirkung auf einen Nenner bringen und auch das Wissen indigener Völker einbeziehen.
Beachtung durch politische Entscheidungsträger	**Eingedenk** der zunehmenden Beachtung durch internationale und nationale Institutionen, internationale Nicht-Regierungsorganisationen, kommerzielle Unternehmungen, akademische Einrichtungen und des Bedarfes an zuverlässigen Informationen für die Entscheidungsträger in solchen Organisationen,	sollte Forschung immer öfter zur Lösung politisch relevanter Fragestellungen zu den wichtigen natürlichen und sozialen Gegebenheiten, Stadt, Gebirge und Trockenzonen eingeschlossen, verwendet werden. IUFRO muss bei der Verknüpfung von Wissenschaft, Politik und Industrie eine grosse Rolle spielen und trachten, alle Wirkungen, Güter und Leistungen des Waldes sicherzustellen.
Rolle in zwischenstaatlichen Prozessen	**Im Bewußtsein** der Stellung der Forstwirtschaft bei den einzelnen zwischenstaatlichen Prozessen, und des einzigartigen Potentials IUFROs, eine grosse Zahl unterschiedlichster Wissenschaftler zu mobilisieren,	sollte IUFRO zur internationalen Debatte und politischen Prozessen auch weiterhin beitragen und diese Präsenz noch verstärken, insbesondere in den Bereichen genetische Ressourcen und Biotechnologie, Biodiversität, nachhaltige Waldwirtschaft, Klimawandel und Komplexbildung, Boeden, Wasser, Brandbekämpfung, Entwaldung, Waldzerstörung und Desertifikation. IUFRO sollte den Transfer von umweltfreundlichen und sozial verträglichen Techniken foerdern.
Auswirkungen forstlicher Eingriffe	**In Erwägung** der öffentlichen Sorge bezüglich möglicher Auswirkungen forstlicher Eingriffe auf die Umwelt, sowohl in globaler als auch in lokaler Hinsicht, auf den Wohlstand und auf die Biodiversität,	sollte Forschung sich zunehmend vom derzeitigen fachspezifisch-orientierten Ansatz entfernen und interdisziplinäre Forschung mit problemlösungs-orientierten Ansätzen verfolgen. IUFRO sollte unter Einbringung seiner Erfahrung und seines Netzwerkes eine engere Zusammenarbeit

	ERWÄGUNGEN	ENTSCHLIESSUNGEN
	In Erinnerung daran, dass IUFRO traditionell Forschung in den Hauptdisziplinen durchfuehrt,	mit anderen Forschungsorganisationen und die Einbindung in Forschungsnetzwerke und –konsortien anstreben.
Information	**In Wertschätzung** der Forschung im Bereich Forst- und Holzwirtschaft und der dabei von IUFRO Mitgliedsinstitutionen und einzelnen Wissenschaftlern entwickelten Technologien, **in der Erkenntnis**, daß ein Großteil dieser Information erhältlich ist über verschiedene Informationsquellen und –formen, und **in der Beobachtung** der raschen Entwicklung und Verfügbarkeit von Informationstechnologie,	sollte bestehende Information leicht und bequem für einen großen Anwenderkreis verfügbar sein, sollten Forstforschungsorganisationen versuchen, ihre Forschungsresultate zu verbreiten; das IUFRO Netzwerk zu nutzen, die Entwicklung des von IUFRO geleiteten weltweiten forstlichen Informationsdienstes sollte verstärkt werden und IUFRO Forschungseinheiten sollten auch weiterhin den aktuellen Wissensstand in ihren Fachdisziplinen für ein breiteres Publikum dokumentieren.
Forschungskapazität	**In der Überzeugung**, daß die forstlichen Forschungskapazitäten in Entwicklungsländern und Reformstaaten niedrig sind, und daß Frauen in der Wissenschaft unterrepräsentiert sind und in der Forstwissenschaft ungenügend unterstützt werden,	sollte IUFRO die Zusammenarbeit mit anderen Organisationen forcieren, die sich bemuehen, Forschungskapazitäten im Bereich Biophysik und Soziologie in Entwicklungs- und Schwellenländern auf- und auszubauen und Frauen und benachteiligte Forscher in der Forstwissenschaft fördern.

Congress Resolutions
(Spanish)

RESOLUCIONES
del XXI Congreso
de la Unión Internacional de Organizaciones de Investigación Forestal

12 de agosto de 2000

	CONSIDERACIONES	RESOLUCIONES
La importancia de los bosques y árboles para el bienestar humano	**Reconociendo** las grandes contribuciones de los bosques y árboles y de la profesión forestal al bienestar medioambiental, económico y socio-cultural de la humanidad, **Reconociendo** además la contribución a la lucha contra la pobreza, el estímulo al desarrollo así como a contrarrestar la degradación ambiental, y **Reconociendo** además la importancia de la diversidad cultural, **Reconociendo** además que la investigación se desarrolla con distintas intensidades dependiendo de la extensión geográfica de un problema, el nivel al cual se lo trata de solucionar, y de la relación con otros problemas,	IUFRO debería continuar y aumentar su estimulación y apoyo a la investigación, así como proporcionar los conocimientos necesarios para lograr una ordenación forestal sostenible dentro de diferentes contornos físicos y sociales; debería aspirar a conciliar las demandas de productos leñosos y productos forestales no leñosos, servicios ambientales y beneficios sociales. IUFRO también debería aspirar a obtener conocimientos apropiados, especialmente de pueblos indígenas.
La atención de los políticos	**Notando** tanto la atención creciente que las agencias internacionales y nacionales, las ONGs internacionales, empresas comerciales e instituciones académicas están prestando a los bosques, como la demanda de información confiable por parte de las personas que toman las decisiones en tales organizaciones,	la investigación debería dirigirse cada vez más a solucionar asuntos relacionados con políticas en los principales ámbitos medioambientales y condiciones sociales, incluyendo regiones urbanas, montañosas y secas. IUFRO debe desempeñar un papel clave de fomentar la interface entre la ciencia, las políticas y la industria, con el objetivo de proporcionar todos los beneficios de los bosques, los bienes y los servicios.
El papel en los procesos intergubernamentales	**Teniendo en cuenta** el rango de los temas forestales en las consideraciones de varios procesos intergubernamentales, y la capacidad excepcional de IUFRO para movilizar una amplia gama de experiencias individuales y colectivas.	IUFRO debería mantener y aumentar sus contribuciones a los debates internacionales y procesos políticos, particularmente sobre recursos genéticos y biotecnología; biodiversidad; la ordenación sostenible de los bosques; cambio climático y captura de carbono; suelo; agua; incendios; deforestación; degradación de los bosques y desertificación. Debería promover la transferenica de tecnologías sociales y ambientalmente aceptables.
Los impactos de las actividades forestales	**Considerando** las preocupaciones públicas por los posibles impactos de las actividades forestales sobre el medio ambiente a nivel mundial o local, el bienestar social y la biodiversidad,	la investigación debería aumentar en el ámbito de cada disciplina, pero simultáneamente ir evolucionando hacia un enfoque interdisciplinario dirigido a la solución de problemas; IUFRO debería tratar de colaborar más estrechamente con otras organizaciones de investigación y con-

	CONSIDERACIONES	RESOLUCIONES
	Teniendo presente que la investigación realizada por IUFRO tradicionalmente se ha orientado y desarrollado en torno a las disciplinas de mayor importancia,	tribuir con su experiencia y su gran capacidad para establecer redes en apoyo de otras redes y consorcios de investigación.
La información	**Reconociendo** la investigación realizada y las tecnologías desarrolladas, tanto en relación a los bosques como a los productos forestales, especialmente por las organizaciones miembros de IUFRO y científicos individuales, **Viendo** que gran parte de la información sobre investigación está disponible en varias fuentes y formas dispersas, y **Observando** el rápido desarrollo y la disponibilidad de tecnologías de información,	la información existente debería estar disponible en formas accesibles y apropiadas para los diversos usuarios; las instituciones forestales deberían aspirar a divulgar sus resultados de investigación; debería intensificarse el desarrollo del Servicio Mundial de Información Forestal dirigido por IUFRO, y las unidades de investigación de IUFRO deberían seguir haciendo declaraciones sobre el estado actual de los conocimientos en sus áreas específicas.
La capacidad de investigación	**Reconociendo** que la capacidad de la investigación forestal en los países en desarrollo y con economías emergentes es baja, y que las mujeres están representadas inadecuadamente entre los científicos y con apoyo insuficiente en la investigación forestal,	IUFRO debería aumentar su colaboración con otras organizaciones que aspiran a mejorar la capacidad de investigación biofísica y social en países en desarrollo y con economías emergentes; debería reforzar el papel de la mujer y de los investigadores con menos recursos en la ciencia forestal.

Report on President's Panel Discussion Friday 11 August 2000, 14.30 - 16.00

International Research Policy - Forestry and Wood Industries Comments on Congress Resolutions

Chair: Professor J Burley
Rapporteur: Mr D J Macqueen

The IUFRO President invited a Panel of distinguished persons representing several donor agencies and international organizations that had been long-term supporters of IUFRO, to offer their views on a number of major issues. To focus the discussion, the Panel members were provided with a draft version of the Congress Resolutions; at the time of the Panel meeting these Resolutions had not formally been confirmed by the International Council (although they were subsequently confirmed by the IC and published at the closing ceremony).

The Panel included Dr Yves Birot (France), Dr Robert Lewis (USA), Professor Jeff Sayer (CIFOR), Dr Yvan Hardy (Canada), Dr Peter Poschen (ILO), Dr Jacques Valeix (France) and Mr Duncan Macqueen (UK). The Panel was asked to address the six Resolutions that referred to:- the role of forests and trees in human welfare; attention by policy-makers; the role of IUFRO in inter-governmental processes; research and the impacts of forestry activities; the role of information; and strengthening research capacity. It is not possible to include all the points raised in over an hour's discussion of these major issues, but the following summary emphasizes the major views.

IUFRO's mission statement is: "To promote international co-operation in forestry research and related sciences". It is a mission statement that requires amplification. Why does IUFRO wish to promote co-operation in research? How will IUFRO achieve this? Because of this, these resolutions are extremely important; they define IUFRO's vision - not just research for research's sake, but research with a clear objective.

The first Congress Resolution is the foundation, for it defines why IUFRO promotes collaboration in research - it seeks to enhance human welfare. This is the common currency that unites us all, whether for the long-term opportunities of biodiversity and a stable environment, or for short-term commercial interests or poverty eradication, recreational interests or spiritual value. Human welfare is that common currency; it is a language understood by policy and land use decision-makers, by business, by environmental activists and by the poor. It explains why sustainable forest management and IUFRO's research activities are important.

The Panel noted that perceptions are changing, from seeing people as the problem to recognizing them as the solution. The Panel saw the need for clarity in defining who should be helped and how. The Panel discussed the need to question whether and to what degree forests can be used to eradicate poverty. They also noted that different types of forestry (from industrial to community management) have different effects on human welfare. Researchers have a pivotal role in clarifying these issues. A question from the floor questioned how IUFRO intends to address the agendas of different people, particularly of the poor and women, in defining its activities. The IUFRO President outlined a number of initiatives that IUFRO has implemented, including the Special Programme for Developing Countries, the creation of a number of Task Forces, and the establishment of a new research unit dealing with gender issues.

The Congress had highlighted the complexity of the forest sector - a complexity of agendas, of forest products and forest services. The second Resolution sought to address this complexity to enhance human welfare and recognized that IUFRO, with its broad membership base, was equal to this task. Starting at the policy level, this Resolution begins to define the "how" of IUFRO's mission statement. The Panel believed that researchers have a responsibility to link research results with policy formulation. They talked about the need for care to maintain credibility in doing this, and the important role that IUFRO might play in this regard. They also noted the communication gap between science and policy and discussed the importance of finding ways to communicate uncertainty, rather than making unsubstantiated generalizations.

The third Resolution recognizes that this is a time of opportunity for IUFRO to contribute to international debates and political processes. Never before has the value of forests been so widely recognized. For the first time we are seeing payments for carbon sequestration, environmental protection and watershed conservation. We are seeing payments for biodiversity knowledge through Intellectual Property Rights under the Convention on Biological Diversity. This Resolution charges IUFRO with seizing the initiative at the international level in the interests of human welfare. The Panel noted the importance of IUFRO in terms of intellectual input but felt that this potential was under-utilized. The sphere of relevance for forestry had become broader. IUFRO must face the challenge and engage with inter-governmental fora in order to address these current issues.

The fourth Resolution highlights the need for a problem-solving approach. Recognizing the opportunities, how does IUFRO make this a reality while keeping quality science? The answer is through collaboration - linking research organizations with each other and with a wider group of application-orientated institutions. The Panel emphasized IUFRO's role in supporting scientific break-throughs and innovation. They discussed the need for a balance between maintaining the quality of research within any single discipline and the need to engage in multi-disciplinary partnerships to address all aspects of a problem. It was recommended that IUFRO builds its Divisions around the production of tools for decision making.

In the fifth Resolution the Panel discussed one of IUFRO's principal comparative advantages - the compilation and dissemination of information. If IUFRO is to achieve its mission, it will be essential to synthesize what is already known, through state-of-knowledge papers and the Global Forest Information Service (GFIS), and to identify gaps and future research priorities. The Panel noted that the demand for forest information is increasing. At the same time they observed that newer information technologies such as the Internet were diluting the quality of research information. IUFRO can play an important role through SilvaVoc, GFIS and its state-of-knowledge papers in restoring the credibility of forest science.

In considering the sixth Resolution, the Panel recognized that the united vision or common currency of IUFRO (and ideas of how this might be accomplished), will stand or fall on the institutional and individual capacity of its members. Finding ways to enhance this capacity will be a major challenge for IUFRO over the next five years. The Panel noted the importance of encouraging equity between north and south countries and between genders but it drew attention to a bigger problem - the huge gap in investment in research between industrialized and developing countries. The Panel noted that this was self-perpetuating leading to a vicious cycle of under-investment and lack of new recruitment. IUFRO should urge donors to address this fundamental problem. It must highlight ways in which sustainable capacity development can be encouraged:- through training in writing research proposals; through increasing equity in the sharing of research finance; and through the creation of young scientist fellowships at international centres. Comments from the floor noted the pressure on developing country researchers to demonstrate impact with scarce funds and the role IUFRO could play by giving a greater platform for developing country research results.

The Panel covered a wide range of topics. We hope that the discussion, both from the Panel and the floor, has helped to clarify IUFRO's vision. It is a vision that defines why IUFRO wishes to promote collaboration in research and how it intends to do this.

Keynote Addresses

Sustainable Management of Natural Resources

Tan Sri Razali Ismail
Special Adviser to the Prime Minister of Malaysia

Mr. Chairman, Distinguished Guests,
Ladies and Gentlemen,

Introduction

Let me commence by thanking the organizers of this prestigious 21st IUFRO World Congress for inviting me to give a keynote address. It is with a mixture of delight and apprehension that I stand here. While I take enormous pleasure in being among you all, the world's leading thinkers, scientists and foresters, at the same time I feel humbled by your erudition and achievements. What can I, once a simple career diplomat, now dabbling uneasily with the corporate world and dealing with human industry and his waste too, offer here? I pretend to be no scientist, I can offer you nothing in that realm, and therefore, my remarks here will stay away from areas that I know little of. I can, however, speak from my heart, and even that only hesitatingly (although as a diplomat, we were taught to say things consistently and convincingly.)

Distinguished Guests, Ladies and Gentlemen,

The theme of the Congress, addressing issues of forests and society, especially how research can guide us through the uncertain course we are sending this planet through, is indeed apt and timely. When I say this, I am only reminding myself, and feel equally guilty, that we are destroying this planet.

Human activity is radically altering or destroying nature's support systems everywhere. The world's original forest area, about 6 billion hectares, or 40% of the world's land area has been steadily declining. In the last few hundred years we have lost one-third of it. And most of it happened in the last 50 years. Forest depletion is most significant in the tropics at present. Annually we are losing some 20 million hectares. The loss of tropical forests is a double-edged sword. Over 2 billion people depend on these forests for survival and more than half of all plants and species on earth occur within them. The rapid loss of tropical forests means both the impoverishment of more people and the rapid disappearance of our plants and animals. Scientists have estimated that at the present rate of extinction, 20% of the 10 million estimated species on earth would disappear in 15 years' time. Another way of saying it, we are killing 50 or more species every day.

More people are hungry now than ever before, and the numbers are increasing. This is partly because we are rapidly losing arable land. As a result of erosion, 6 million hectares of agricultural land are made unproductive each year. Waterlogging, salinization and alkalinization are reducing the productivity of another 1 million hectares each year.

Life on earth also depends on water. Our use of water is reaching crisis levels. Global water withdrawals have grown 35-fold in the past three centuries. Current patterns of freshwater use cannot be sustained if human populations reach 10 billion. Throughout the world, pollution and misuse have impaired water quality. Oceans cover more than two-thirds of our planet's surface. Their vastness gives the impression no harm can come to them. While we have destroyed the mangroves, saltmarshes, and coral reefs, and threw much pollution into the ocean, we are at the same time over-harvesting the oceans for fish, 100 million tonnes annually, and clearly threatening the fisheries industries. Because of our profligate use of energy derived from burning fossil fuels, "greenhouse" gases are accumulating in the atmosphere. These heat trapping gases are believed to result in global warming, by about 1 to 3 degrees in this century. This may not sound much, but it is a faster change than has occurred in the past 10,000 years. If it continues, sea levels will rise, climatic regions will shift, rain patterns will change, and droughts and storms may increase in frequency and intensity. I can go on listing many more of the problems, but suffice to say the list is long and lamentable. So, it is appropriate that we gather here and re-examine the way we manage our forests, and ultimately our environment.

More than that, it is no more an academic exercise to study this problem or that – it is now a matter of survival. Why? For an explanation, I can offer a simple analogy. When we are mildly indisposed with a cough or fever, we usually go to a pharmacist for an inexpensive drug. If the condition deteriorates further, we seek a physician, but unfortunately our earth has no such recourse. It has no pharmacist to go to, and no physician to turn to. We humans have only one place, this earth, and no where else to go. Therefore, we must make sure it remains healthy and habitable, for all, forever.

Natural Resources – The Forests

It would be far too much to talk in breadth about sustainable management of all the natural resources. Let me therefore confine myself to the forests, the one that is of concern for all of us here, and one that is closest to my heart. I however, am of the view that the principles enunciated here with the case of forests will in general apply to all natural resources. Here I wish to depart from my earlier statement that I will veer away from science, which I again claim no knowledge of.

For a change let me borrow some of your ideas, which you all know so well anyway.

Forests and woodlands occur from the seafront to the uplands, and from the tropics to the subarctic. They exist in an extraordinary diversity of forms – evergreen to deciduous, coniferous to broad-leaved, wet and dry, and open woodlands to closed-canopy forests. Most of the land that is cultivated today was once clothed in forests. Forests, natural and modified, provide a huge wealth of benefits. The forests maintain the earth's life support system. They regulate the atmosphere and climate, store carbon, and warm the subarctic zone by absorbing heat from the sun. Tropical forests play an even bigger role; they probably drive the general circulatory system of the atmosphere and distribute heat to temperate zones. Forests moderate local climate as well, making it milder, moister and less variable. Forests regulate the hydrological cycle, protecting soils from erosion, reducing silt loads in rivers, slowing runoff, and moderating floods.

Besides being a life-support system, forests also provide a variety of goods. Annually, the world obtains more than $ 300 billion dollars worth of lumber, veneer and pulpwood. In poorer countries, 20% of the energy is obtained from fuelwood. The forests also yield large amounts of forage, animal and plant food, medicines, non-wood fibers, furs, skins, essential oils, gums, latex, resins and innumerable number of other products. For example, Burkill published the Dictionary of the Economic Products of the Malay Peninsula in 1935, after a gestation of 14 years. The majority of the thousands of items mentioned in the dictionary came from the natural forests. Just to mention a few, it included: chewing gum from jelutong (Dyera), damar resin for varnishes from keruing (Dipterocarpus), gutta percha from nyatoh (Palaquium), camphor from kapur (Dryobalanops), and benzoin from kemenyan (Styrax). Many of the products have been replaced by synthetics, but some still remain, fortunately. Our ladies would like to know that their lipstick remains where it is meant to be because of a special fat that is obtained from the fruit of the engkabang tree (Shorea) from Borneo. From the first century A.D. Chinese and Indian traders were regularly coming to Malaya for gharu wood (Aquilaria), amber, camphor, and other non-timber forest products. Marco Polo's chronicles of 1299 mention the trade of camphor from the region by Arabs since the 6th century.

While the value of these non-timber goods cannot be reliably verified, they provide significant income and employment, especially for the rural poor. Of course, the forests yield fresh water, and many tropical countries depend totally on this source alone. Besides all these, forests are also a source of genetic material. All the fruit trees in Malaysia came from the forests, including durian (Durio), duku (Lansium), mangis (Garcinia), nangka (Artocarpus), petai (Parkia), and rambutan (Nephelium) to name a few . The wild ones provide the genetic material for crop improvement. Another increasingly recognized value, forests provide the resource base for tourism, and of course they are inestimable in view of their cultural value in terms of beauty, recreation, amenity, religion, art, music and poetry.

Another feature of forests that deserves special mention is the biodiversity, especially in the tropical forests. Forests do not just support life systems; they actually generate and hold the life. Life in terms of variety and form have probably reached their acme in the wet tropical forests of the world, Malaysian forests being among the top record holders for terrestrial species diversity. Typically, one hectare of the Malaysian lowland dipterocarp forest has about 230 or so tree species alone. An enumeration of a 50-hectare plot in Peninsular Malaysia unearthed about 830 tree species. This does not include the herbs, shrub and epiphytes, nor all the animal species. The numbers are astounding, and we need not go further than 30 km from this spot to reach these amazing and incredible forests. How did this myriad of plants and animals come to exist in such small areas of land when only 7% of the earth's surface is covered with wet tropical forests? Biologists say that these forests have existed without much perturbation for almost 100 million years, and the plants and animals specialized more and more, and occupied every niche available. The relationships have become so intricate and interdependent that removing one will lead to the extinction of another or a series of them. Let me switch to a South American example to illustrate this. The Brazil nut tree (Bertholettia excelsa) is pollinated by several Euglossine bees. The male bees gather organic compounds from certain species of tree-dwelling orchids to attract females before mating, but they depend on flowers of trees like Brazil nut for food. The Brazil nuts are pollinated in the process. A large rodent, the Agouti, breaks open the nut seed to allow dispersal and germination. This biological chain links the tree, bee, orchid and rodent. Is this not a reminder that we cannot exist by ourselves?

In case some of you are thinking that these are minor curiosities that excite only biologists, let me halt you. These plants and animals are incredibly important for us. In the 1990s medical doctors were surprised to learn that a chemical important in human brain activity and valuable in the control of high blood pressure is similar to the poison obtained from an Amazon forest tree which Amerindians use for hunting. Several well-known medicines were discovered from the rainforests: anticancer drugs from rosy periwinkle (Catharanthus roseus), steroids from Mexican yams

(Dioscorea composita), and antihypertensive drugs from serpent-wood (Rauwolfia serpentina). The discoveries continue to grow.

Management or Destruction

You have just heard me extolling the virtues of the forests, not just their beauty, but also their utilitarian value, and the promises they hold for mankind in the future. However, I am not here for that. I am here because all is not for the best in the best of all possible worlds.

I have already pointed out the rate of forest loss worldwide to be alarming. There are several factors behind this unparalleled destruction and loss of forests. I must state quite frankly that forest loss and degradation are not confined to just the tropics – it is a worldwide problem. Old growth forests everywhere are threatened. The principal cause, particularly in the poorer nations is due to agricultural expansion. Subsistence farmers in developing countries account for more than 60% of the loss of tropical forests annually, but that is not to say all forest openings have bad impacts. Malaysia opened up quite a bit of its land, especially the rich lowland forests for agriculture and plantation crops, and they remained the bulwark for our economic growth. Today such agricultural expansions are still going on. The method of forest opening is still torch and fire. Because of the scale of the openings, forest fires and associated haze problems are becoming common. Whether or not all these are perpetuated further is the important question.

Opening lands for cattle ranching is devastating the forests in tropical America and Africa. Overgrazing has resulted in further degradation of the land. Fuelwood gathering is another cause. About half the world's population depends on wood as their main source of household energy. Much of the wood comes from natural forests and trees outside forest areas. Infrastructure development, especially building of dams has covered millions of hectares of forests. A World Bank Report stated that in 1950 there were 5,270 large dams; today there are over 36,500. The price is most often paid by forests – they are flooded out.

Lastly, let me touch on about the most contentious issue, viz. commercial logging. Another factor behind deforestation is commercial logging. Annually about 5 million hectares of commercially productive closed forests are logged. However, it is not the leading cause for deforestation, only accounting for about 20 % of total deforestation. In most tropical countries selective logging is used. I have been told that this is resulting from highgrading, whereby all the commercially valuable trees of high quality are removed, and the remaining crop is impoverished. Moreover the method of logging, using heavy ground machinery, causes much damage to the residual trees left behind, as well as to the soils and waterways. The loggers return too early to remove the residuals as well. Following logging, there is very little reinvestment in terms of planting, releasing regeneration, and protecting the forests from illegal encroachment. Even more disturbing is the fact that while the poor people suffer the consequences of logging, such as loss of minor forest produce, game, fish, flooding problems downstream and erosion of soils, the wealth accruing from logging flow into the hands of a few only.

Sustainable Management – The Solution:

In the first place what do we mean by sustainability? There are numerous definitions, and all seem to be on the basis of what we know about it at that time. Distilled to its simplest form, if an activity is sustainable, for all practical purposes, it can continue forever. On this basis, we certainly cannot say we are managing and utilizing our forest resources sustainably, even using the simplest of definitions. In this context, I asked my forestry friends how to achieve sustainable forest management. They had no difficulty or hesitation in giving a prescription. The following would be the actions:
First, plan the allocation of land for the different purposes. Land must be allocated according to its ecological suitability, while taking into account the social and economic factors. Nations should put aside forests for maintaining their water supply, preserving genetic resources, protecting their soils, and also demarcating forests which have the potential for yielding timber and other products. Also ensure lands set aside for agriculture are suitable for sustainable agriculture.

The second would be the need to establish a comprehensive system of protected natural forests. They should represent the full range of forest types, and the areas should be large enough to buffer them from disturbances from outside. Such legally protected areas would maintain the ecological functions, conservation of species, maintenance of genetic resources, provide opportunities for scientific research, allow indigenous cultures to maintain their life-styles, and offer opportunities for wilderness appreciation.

As a third action, nations should establish and maintain an adequate permanent production forest estate. This would, besides conserving the life-support systems and biological diversity, provide a sustainable yield of timber and non-timber products. They should be variably managed, from those that are lightly harvested to others that are intensively managed to enhance their yields of timber. The harvesting should be done on a sustainable basis by using methods and techniques that will not impair the productivity of the forests. These forests provide resources, money and employment, while retaining the ecological services and biological diversity.

The fourth action would be increasing the area of planted forests. With the growth in human populations and rising demand for better quality of life, we will never meet all the needs adequately from the natural forests. Planted forests can concentrate timber production in areas close to markets and the yields are many fold higher. Plantations should also be located on degraded lands and those retired from agriculture.

The penultimate action would be increasing the national capacity to manage forests sustainably. I have been told that the most reasonable production from natural forests cannot exceed 1.5 cubic meters of timber per hectare per year. The annual volume of tropical timber in the international timber trade is in excess of 60 million cubic meters. This would mean 40 million hectares of forest should be under sustained yield management. The demonstrated area under sustainable management is only 1 million hectares. This does not include domestic consumption of industrial wood. Clearly, there is a huge gulf to be crossed. Everyone agrees that this unsustainable industrial exploitation of tropical forests must end. The same may be said of even the forests in the United States, Canada and Russia. Some of the conditions that require greater attention for sustainable management include: i) creating legally guaranteed permanent forest estates, ii) training of staff in ecology and management, iii) applying the appropriate local cutting cycles or allowable cuts, using suitable harvesting techniques, ensuring environmental safeguards, iv) imposing adequate controls on all aspects of harvesting and forest treatments after harvesting, v) adopting environmental policies that protect the ecological services and biological diversity, and vi) effective monitoring to make sure all the above are met.

The last action for achieving sustainable forest management would be involving the communities that live in or near forests in decisions about forest conservation and development. Because they live in the forests, they have a strong incentive to maintain the forest and use it sustainably. However, in most tropical countries governments have taken authority for managing forests from local and indigenous communities who used to manage them in their own ways formerly. If these communities' needs are not met, and they are denied a fair share of the wealth from the forests, they will have no incentive to conserve the forests.

What is Missing?

If the mantra for sustainability is so simple, and so easily met, how come we have not achieved it? In fact, most of the basic information for managing forests on a sustainable basis is already available. Yet, as noted earlier, only a small percentage of the tropical forests are managed sustainably. What went wrong? What is missing?

Simply stated, our hearts are not in the right place. Further, we use a number of economic theories to justify our heartless actions. The people of every country have a right to exploit their natural resources for economic development. There can be no argument on this count. It is the manner in which we pursue this that we should be concerned with. If a forest is to be cleared for providing land for the poor, to increase their opportunities, few can quibble about it. The concerns would be issues like the suitability of the land for agriculture and setting aside adequate lands for protection and production functions. The FELDA schemes in Malaysia are about the finest examples of such development. They seem to have exceeded the original goals, and some of the settlers have become wealthier than most of us.

However, more often than not this is not the case. Take a look at industrial logging. Usually a few individuals, mostly in the upper-income group and in possession of financial and political clout, end up getting logging concessions. The wealth of the state, which belongs to the people, passes to these few individuals. What do the people get – ruined forests, reduced game and fruit and other products, silted up rivers, muddy waters, flooding downstream, increased incidence of disease, and so forth. The future generations are denied the opportunity. Why should the poor take the brunt of such activity? Why should society pay the social costs? The polluter should pay principle was never implemented, run away profits are frequent, and common people suffer.

Having looked further into some more issues, I have cause to think that the developed countries are hypocritical when they carry on protesting about the loss and destruction of tropical forests worldwide. They argue relentlessly about the value of the tropical forests, which indeed belong to the global community, which contain most of the earth's biodiversity, which are the major carbon sinks that if lost would lead to global warming, and which are the earth's life support systems. No one denies this. But there is a flip side to it too. One hectare of oil palm earns more money than a similar area of forest at present. Are we going to deny the citizens of tropical countries the right to a better quality of life? Who will pay for the opportunity costs which will be the case if the forests are left undisturbed? Or is the developed world having a free ride at the expense of the tropical countries? In this equation the poor will end up supporting the profligate and non-sustainable life-styles of the rich.

The issue of biodiversity takes us further down the path of insincerity. For thousands of years, people in the tropics have learned the medicinal and pesticidal properties of a number of plants and animals and conserved them. Chemical and pharmaceutical companies from the industrialized countries have suddenly "discovered" them, and artificially synthesized the chemical compounds. While these companies have built huge fortunes from them, what have the people who preserved the plants and the traditional knowledge gained? Nothing. The industrialized countries, instead of punishing the tropical countries with timber boycotts, instead of arguing about market forces and demand and supply, should instead value the tropical forests for what they represent and find ways to pay for their conservation and preservation.

Let me give you another tragic but comical example of how the industrialized world conducts its business of saving the forests. The G7 (now G8) group of countries met in Italy in 1987, and underlined its "own responsibility" toward tropical forests. In 1990 they met in the USA and declared "to take action to increase forests while protecting existing ones." In 1991, they met in the United Kingdom where they "remained concerned." In 1993, in Tokyo they wanted "international agreement" to protect forests. In 1997, in Denver, they called on all countries to "eliminate illegal logging," and stated that forests "continue to be destroyed and degraded at alarming rates." In 1998, in Birmingham, they called for an "Action Program on Forests." Like so many UN resolutions, there is sound but no action. Since the Denver summit, an area the size of Germany has been destroyed.

At this point, I would like to move away from litigious issues and look at each and everyone of us, whether from poor, emerging or rich countries. We are part of this earth, and we all have a role in sustaining the natural resources on earth, whether it be forests, wood, water, or wildlife. We all are earnest to see improvements in the quality of human life while conserving the vitality and diversity of the earth, its forests, its creatures, and its regenerative and sustaining capacity. We have no options but to live sustainably. It means living in harmony with other people and with nature. We must share with each other and care for the earth. We can not take more from nature than nature can replenish. It means adopting life-styles that are sustainable.

Finally, no nation is today self-sufficient. We have to learn to protect the globally shared resources, the oceans and forests, the atmosphere and the biosphere. Therefore, we need to develop an ethic of care at the global, national and individual levels. All nations stand to gain from worldwide sustainability, or will be threatened if we fail. We have to change. A famous philosopher once remarked, "To pluck a flower is to kill a star." Let us reverse it, "To plant a tree is to rekindle the universe."

Thank you.

Science in Service to Society
Matching Research to Society's Needs

Peter Farnum*, Christine A. Dean, Mark L. Plummer
Weyerhaeuser Company, Washington, U.S.A.

This past July, vandals trampled a few acres of cornfield in a New York agricultural research station, another in a long series of attacks around the world on genetic engineering research. The vandalism took place at the Cold Spring Harbor Laboratory, and the field was where Dr. Barbara McClintock conducted her pioneering studies of plant genetics in the 1940s. Fortunately, the attack set back the current research, which focuses not on genetically modified crops but on natural plant breeding, by only a few weeks (Cooper 2000).

This attack exemplifies a growing problem. Scientific research finds itself embroiled in an increasing variety of social controversies: human genetics, global warming, endangered species and worldwide deforestation. These are but a few of the fields where science plays an active role in setting national and sometimes global policy. Debates over these policies scrutinize the supporting and opposing scientific work for the slightest defect, and sometimes go beyond rhetorical attacks, as the researchers in New York and others have learned.

The romanticized idea of the scientist in her ivory tower, working to better all humankind but unfettered by social, economic or political concerns, leaves her, and other scientists who hold to that paradigm, ill-prepared to deal with these controversies. Even a casual reading of the history of science clearly indicates this model was never true (e.g., Galileo's trial, recantation and house arrest, noted in Bradbury 1999). Indeed, as Robert Merton (1957) noted more than forty years ago, the attempt to cloak oneself in the purity of science may simply exacerbate these problems:

Precisely because scientific research is not conducted in a social vacuum, its effects ramify into other spheres of value and interest. Insofar as these effects are deemed socially undesirable, science is charged with responsibility. The goods of science are no longer considered an unqualified blessing. Examined from this perspective, the tenet of pure science and disinterestedness has helped to prepare its own epitaph.

Yet the tenets, methodology and disinterestedness of science are a fundamental part of a broader set of behaviors that constitute the conduct of scientific research, and have made it possible for science to make significant contributions to social progress. Scientific research such as Dr. McClintock's, for example, helped fuel the remarkable increases in agricultural productivity over the past several decades and holds the same potential for forestry. This presents scientists with a dilemma — in a world where people have conflicting values and look to science for guidance, how can scientists discharge their social responsibility while remaining true to the model of science that has made so much progress possible?

In our paper, we argue that the social responsibility of the scientist is to develop better ways for society to achieve its goals, and to elucidate and quantify the tradeoffs society faces so better policy choices can be made in the pursuit of these goals. We then resolve the dilemma by offering a model of science for today's contentious world. Our model retains the tenets of science that most researchers hold dear: systematically examining a situation, repeated testing which attempts to reject hypotheses through rigorous experimentation, and, because of an understanding of the limitations of their method, cautiously drawing conclusions from the results (Hempel 1996). However, we supplement these characteristics with two new ones: being "cognizant" (and, in fact, making use) of social concerns and aware of the limitations of "pure science and disinterestedness"; and being "transparent" in the description of her research methods and open to review and replication. If today's scientist is cognizant and transparent, we argue, she will be able to discharge her social responsibilities while remaining true to the tenets of science.

The remainder of our paper presents our argument for the "cognizant and transparent" scientist. In the next section, we present two examples of how science has become entangled in the real world. These examples underscore how scientific research can contribute to social progress, but also illustrate how social values and interests can affect that research. We then present two responses to the lessons drawn from our examples. The first incorporates the precautionary principle into a model of a precautionary scientist; the second is an elaboration of our model of the "cognizant and transparent" scientist. We argue in conclusion that the first model presents insurmountable problems, while the second has the potential to strengthen the conduct of scientific research.

The Perils of Science in the Real World

In their simplest form, the fruits of scientific research contribute to social progress in two ways: they offer us "better" methods or products, and they help us identify and quantify the consequences of our actions. Finding better methods and products enables society to make technical progress by improving the utilization of its scarce resources; identifying and quantifying consequences promotes social progress by clarifying the possible ways society can utilize those resources. In taking this rather limited view, we do not deny the value of basic scientific research whose goals are not immediately connected to social concerns. Those forms of research, however, often end up contributing practically to social welfare through one of the two categories.

The connection between scientific research and society is not just from the former to the latter, of course. Social concerns frequently help determine the direction and extent of research through such avenues as funding and governmental mandates. Those concerns can work in more subtle ways, however, and make the scientist's task of fulfilling her social responsibilities more complex. Below, we offer two examples of this complexity.

Getting More from Less: Genetics and Industrial Forestry

In 1996, the world consumed almost 1.5 billion cubic meters of industrial wood products (Food and Agriculture Organization 1999). Until the latter half of this century, most of this wood production came from harvesting natural forests, often as part of the conversion of the land from forest to agricultural use. Today, about one third of the total supply comes from these natural forests, while more than half comes from actively managed forests (Sedjo and Botkin 1997).

Over the next decade, industrial wood demand is expected to grow to about 1.9 billion cubic meters (Food and Agriculture Organization 1999). Meeting this demand will be a challenge, but not one that is unmanageable. The important question is not if but how the demand will be met. Different approaches to forestry can produce equivalent amounts of wood with very different impacts on world forests (Farnum et al. 1983). For example, meeting today's demand only through harvests of natural forests would require up to 1.5 billion hectares of forestland, or up to 40 percent of the world's forests. Growing and harvesting wood from managed forests could decrease the amount of land needed tenfold; switching to high-yield plantations could decrease it still further, reducing the forestland devoted to industrial production to 2 percent (Sedjo and Botkin 1997).

This is one way that scientific innovations have contributed to technical progress: getting more from less. For a given amount of land dedicated to industrial forestry, scientific advances have allowed us to meet a growing demand for wood products; future research has the potential to do the same from an even smaller land base. Each increase in the production rates of industrial forests creates the potential for more land remaining in its "natural" state.

One method of getting more from less is forest genetics. Most genetics programs in forestry are based largely on traditional breeding methods with the goals of gene conservation, adaptability, growth production and wood quality. Typically, these programs identify large initial base populations for most commercial species, followed by extensive breeding, testing and selection efforts. Consider the incremental changes possible when selection emphasis is placed primarily on increasing forest growth in a generalized population, as shown in Figure 1. The solid bars on the left side of Figure 1 show changes in growth expected over successive generations of traditional breeding and increasing control of pedigree in the material to be outplanted. Research associated with genetics programs has targeted orchard, nursery and operational field performance to ensure the genetic populations are well managed and genetic potential is fully expressed and captured in the plantation.

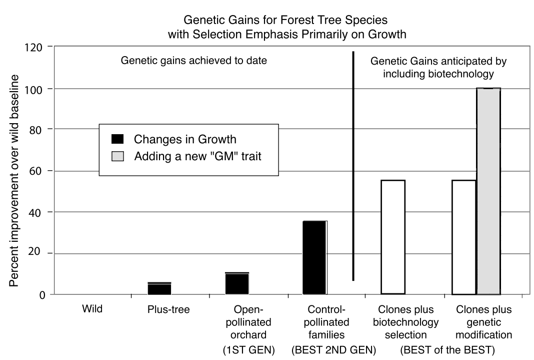

Figure 1. Realized and potential gains from forestry genetics programs.

The right side of Figure 1 shows the genetic gains that are anticipated by including the new tools offered by forest biotechnology in conjunction with clonal deployment. Biotechnology holds the promise of gene identification and transformation processes that will allow more efficient selection and transfer of entirely new desirable traits to existing superior genotypes. Some of the traits of interest currently being investigated for forest trees include: lignin composition, herbicide and insect resistance, climatic adaptability (drought and cold), and wood quality; i.e., specific gravity or fibril angle (Sedjo 1999).

Increased yield from applied forest genetics is but one example of what societies have done for centuries: managed their forest resources to pursue the goal of getting more from less. The transformation of forestry from a practice to a science arguably boosted our ability to pursue that goal (Farrell et al. 2000). Some elements of society, however, often led by strong special interest groups, question whether current scientific advances, particularly those described above, will lead to further progress or to ecological disaster. As Merton (1957) noted, scientific research cannot be isolated from the social passions of the day, passions that at times threaten to slow or even derail that research.

Genetic engineering, and even natural plant breeding, have been particularly vulnerable to this situation. In the first six months of 2000, for example, vandals broke into research facilities almost a dozen times, destroying experimental wheat crops and strawberry plants in California, oat crops in Minnesota, canola and maize crops in Belgium, grass plots in Oregon, potato crops in New Zealand, pineapple crops in Australia, and forest plots in Canada (Bioengineering Action Network 2000). In another case, this vandalism amounted to a tragic farce — the "genetically engineered poplars" destroyed in a 1999 attack were, in fact, raspberry plants being used in cane disease research (McOmber 1999). The facility, located in Washington State, now sports a sign — "NO GMOs" — in the hope of warding off future attacks.

These examples illustrate how a simple case of getting more from less is rarely simple in today's complex society. The genetic researcher is intent on straightforward tasks — how to increase the accuracy of selection, decrease the time to breed and select, increase overall yield, ensure adaptability, or reduce rotation age. These are appropriate and valid scientific questions, of course, but they are also inextricably bound to other questions of a less benign nature — will the genetic manipulations affect nearby, unmanipulated stands, or have possible adverse effects on wildlife (Losey et al. 1999)?

Dismissing these questions as "alarmist" misses the point. To the extent that scientific research materially affects the rest of the world, unintended consequences of that research are always possible and sometimes detrimental. Indeed, they have been common throughout history as the scientific method has evolved. As long as scientists fail to consider and understand the passions that these consequences sometimes evoke, they will continue to be surprised by reactions such as the attacks by anti-genetic engineering vandals. This misconstruction of the concept of scientific "detachment" will slow progress both in social and scientific endeavors.

In no way do we support vandalism or persecution as a constructive reaction — attacks like the one in New York are criminal and should be stopped, period, - but surely there are better responses than to post "NO GMOs" signs; indeed, exactly what kind of sign should be posted by researchers who do conduct GMO research?

Getting More and Less: Modeling and Forestry Regulation

Consider a second example from a different aspect of forestry. In Washington State, a government agency — the Forest Practices Board (hereafter referred to as the Board) — regulates forestry practices. Because of the effects forestry can have on fish habitat, the Board pays special attention to riparian areas, with greater constraints placed on forestry practices adjoining fish-bearing streams. Beginning in the 1970s, the Board used aerial photography to type the waters of the state, including a designation as fish-bearing or fish-nonbearing, and promulgated regulations protecting riparian areas based on this typology. For two decades, this system remained in place despite the absence of any study of its accuracy.

This changed in 1997, on the basis of evidence on the system's errors gathered by a team of biologists from Native American tribes, who have fishing and other rights established by treaties with the U.S. government. In response to this data, and with the support of the industry, the Board passed an "emergency" rule specifying a new typing system. The "emergency" system relies on a simple set of stream characteristics, measured on the ground, to predict the presence or absence of fish. (Measuring the actual presence or absence of fish is a much more difficult data-gathering task which may in fact entail some danger to the fish.) Recently, this emergency system has come under criticism, leading to development of a third system by scientists from Weyerhaeuser. This model consists of a broader set of predictive variables, uses more sophisticated mathematical techniques, and incorporates geomorphic information gathered from Geographic Information Systems (Fransen et al. in preparation).

Because all three systems implicitly or explicitly consist of a predictive model, they inevitably produce two types of errors: a false positive occurs if the system predicts the presence of fish when fish are absent, and a false negative occurs when the system predicts the absence of fish when fish are present. The sum of these two types of errors is a measure of the system's accuracy.

As noted above, our story covers three models: the original system, based on aerial photography; the current ("emergency") one, based on a simple predictive model; and a proposed one, based on a more sophisticated predictive model. In the table below, we list the total error associated with each system, but keep their identities hidden for the moment to help illustrate our argument:

System	Total Error
A	12.3%
B	5.9%
C	5.6%

At first glance, the "best" system is obvious: System C has the greatest accuracy, making an incorrect prediction only 5.6% of the time. Under our first notion of science — trying to get more from less — that system would be the "best," wouldn't it?

This conclusion, however, would be based on a concept of "best" that implicitly assumes the two components of total error are equivalent — a judgment that lies outside the purview of science, and one that, in general, is wrong. Errors in a model's predictions are not simply tallied in an experimental notebook. In Merton's words, they "ramify into other spheres of value and interest." A false positive triggers regulatory protections that are, by this system's internal logic, more than necessary; the costs of those protections are borne by the forest landowner. Conversely, a false negative fails to trigger enough protection and leaves fish at potential risk; the costs of this failure are borne by the fish, the public-at-large and, importantly, the Washington state Native American tribes. (In making these statements, we are assuming that the protective prescriptions are "correct" if applied where fish are present. Another important error, whether the prescriptions themselves are correct even if applied in these places, is beyond our current scope.)

Because these parties have different values and interests, each has a stake in not just the overall accuracy of the predictive model used in the regulatory system, but in the distribution of the error as well. This stake illustrates a second way that science contributes to social progress: identifying and quantifying the consequences of different policy choices. In this case, the choice is between three systems for determining stream types. These consequences include the two types of errors, not just their sum. In the table below, we list each of the systems in chronological order and identify the components of the overall errors (recall that a false positive imposes costs on the forest landowners, while a false negative imposes potential risk to the fish):

System	Model	Error	
		False Positive	False Negative
B	Original Model	0.0%	5.9%
A	Current ("Emergency") Model	11.9%	0.4%
C	Proposed Model	4.1%	1.5%

As the table clearly shows, the distributions of the errors in the three cases are significantly different. Once viewed in this way, the "best" system is no longer obvious. If yet another predictive model lowered both types of errors, for example, to no false positives and 0.2% false negatives, this fourth system would obviously be better than the current three. This model would be an example of science getting more from less, which we have already discussed. However, sometimes the best science can do is to clarify the consequences of actions for social policy makers, not improve the range of those consequences. In this case, science can illustrate how society can get more and less: fewer false positives but only at the cost of more false negatives, or vice-versa. In cases such as the three systems above, determining the "best" system is not possible on a scientific basis alone. The values and interests of the recipients of the individual errors must be consulted, which is a social process, not a scientific one.

This example also illustrates how the results of research, given the political and social conditions, can redound to impact the researchers themselves. The parties bear different benefits and costs of an action — the typing of streams — under scientific scrutiny. The incentive to conduct further research is, in part, determined by those benefits and costs as perceived by the organizations which fund those scientists. When the evidence showed that the original system imposed potential risks to the fish, advocates for the fish used scientific data to put pressure on the Board to adopt a system that would rectify this imbalance. The Board did just that, but the system it adopted turned out to move the errors toward the opposite extreme, one in which the costs were borne largely by the forest landowners.

Because the emergency rule is still in effect, the advocates for the fish are quite content with the current system, despite its relatively low accuracy, because they do not bear the burden of those errors. Further research, then, is not a high priority for them. For the forest landowners, the opposite is the case.

As a result, they have pursued a new system that would bring the regulations back toward a balance. This model, which we have labeled System C, is currently under consideration by the regulators. If adopted, it would lessen the errors borne by forest landowners but would increase, albeit by a small amount, the errors borne by the fish. The resolution of this situation remains unclear.

By one reckoning, the examples above illustrate the danger of mixing science and politics. Let the scientists do their research, this point of view would say, and sort out the political, social and economic implications later. Only then can science find its true voice and serve society to its fullest capacity. By another reckoning, these examples illustrate the shortsightedness of that view. Scientific research often takes place not in a vacuum but in a lively cauldron of values and interests. Isolating the former from the latter is impossible; pretending otherwise will indeed help write the scientist's epitaph. In the next section, we discuss how the model of "good" science can incorporate this reality.

The Promise of Science in the Real World

We are, therefore, back to the dilemma: whither scientific research? If not a retreat to the ivory tower, then where? One response is for the scientist to embrace the social values and interests that affect the research environment but lie outside the formal sphere of science. This response has its advocates and detractors within both scientific and policy circles. Below, we offer an example of responding in this manner: "precautionary science," in which the precautionary principle is incorporated into scientific practice (Barrett and Raffensperger 1999). We then offer a critique of this model, followed by our own proposal for what can be called "cognizant and transparent science."

The Precautionary Scientist

Although expressed in various ways, the precautionary principle is captured in the following statement: "When an activity raises threats of harm to human health or the environment, precautionary measures should be taken even if some cause-and-effect relationships are not fully established scientifically" (Wingspread Consensus Statement on the Precautionary Principle 1999). This principle has found numerous applications in international law, including the Rio Declaration on Environment and Development. Through the fruits of its research or sometimes through research itself, science arguably can be an activity that "raises threats of harm to human health or the environment." For that reason, we consider one way of responding to our dilemma: precautionary science.

What would a precautionary scientist look like? One view is given in Barrett and Raffensperger (1999, all quotes below), who describe a precautionary scientist as one who:

- enlists individuals beyond disciplinary and even scientific bounds as "co-problem-solvers";
- focuses her investigations on "indirect, secondary, cumulative and synergistic interactions" rather than on direct effects;
- emphasizes "indirect and acausal relationships, such as correlation, pattern and association";
- addresses "uncertainties … which render precise experimental replication problematic if not meaningless";
- does not insist "that all valid data are quantifiable and replicable and that all theories are predictive across wide-ranging circumstances"; and
- prefers to conclude "there is an effect when there is none than to falsely claim there is no effect."

Extrapolating from these characteristics, how would the precautionary scientist fare in our two examples above?

In the first case, a precautionary genetics researcher would begin with a presumption that any experimental products will be harmful in some way and seek evidence of the product's safety. She might define safety as "absence of harm," which practically speaking would set the burden of proving the product's safety quite high. In contrast, she would accept evidence of a product's harm from a broad spectrum of sources, not just classic experimental work. Such evidence would not have to address cause and effect, and would not have to be either quantifiable or replicable.

In the second case, the precautionary stream-type modeler would push the distribution of error toward false positives — better to claim there are fish when there are none than falsely claim there are no fish. She would enlist the broader community of interests as co-modelers and accept individual exceptions and anecdotal evidence as data of quality on a par with that gathered through formal survey protocols.

Clearly, this model takes the scientist far afield. By choosing different levels of rigor for evidence which indicates safety or harm, she usurps society's authority to make this decision with her own scientific investigations; and by skewing the distribution of error in a particular direction, she is taking sides in a dispute among stakeholders. In short, the precautionary scientist as advocated by Barrett and Raffensperger is quite content to dissolve the barrier between science and social values and interests by actively embracing the latter.

This approach, therefore, encounters a fundamental problem — whose values and which interests should the precautionary scientist embrace? For every activist intent on forestalling the deleterious effects of genetically engineered crops, there is a nutritionist interested in providing nourishment at a lower cost. And for every person whose livelihood derives from harvesting fish, there is an architect touting the environmental benefits of wood as a building material. Because scientific research impinges on a diverse set of values and interests, incorporating a particular subset into the conduct of science is itself a value choice — one that the scientist has no license to make.

We believe this complete merger of social values with scientific technique is an ill-advised response to the dilemma we have posed in this paper because it inevitably undermines the scientific method employed and thus diminishes the contribution which science can make. Applied literally and rigorously this approach cannot properly be called science.

Retaining the Tenets of Science

In contrast to merging social values with science, acknowledging the importance of values, interests and passions, as well as the wisdom of proceeding cautiously, does not overthrow the existing tenets of science. Indeed, these acknowledgments point to a stronger role for science, not a weaker one. By helping to form a social consensus on what possibilities exist, science lays the foundation for a more informed, democratic debate over which of those possibilities should to be pursued. Further, by improving the set of possibilities itself, science can reduce clashes that stem from conflicting values and interests.

In short, to borrow from the age-old distinction made by David Hume (1888), the strength of science lies in its ability to promote social consensus over what "is"; beyond that, society, not the scientist, must determine what "ought" to be. Consider, for example, the following characteristics of the scientific method (which do not exhaust the full set, of course).

A scientist:

- understands the necessity of the testability of a hypothesis, of repeatedly trying to prove her hypotheses wrong; and that a test result which does not reject her hypothesis in no way constitutes proof of its correctness (i.e., she understands the fallacy of affirming the consequent);
- directs her research toward the formation and testing of theories which go beyond prediction and help explain underlying mechanisms;
- recognizes the importance of testing under a wide variety of environmental conditions, and does not make claims that extend beyond the inference space of her testing;
- insists that all ancillary assumptions are clearly stated and have been widely tested, and she makes these assumptions transparent in her documentation;
- is rigorous in estimating both false positive and false negative errors (more generally Type I and Type II errors), and she designs experiments with sufficient precision to address both; and
- documents her results, submits them to rigorous and critical peer review, and encourages others to repeat her work.

These characteristics give scientific research an almost mechanistic quality, with the individual scientist as interchangeable as any standardized part in a machine. Yet the reason this model is so attractive is exactly that quality: if any scientist anywhere can run the same experiment and produce, statistically speaking, the same result, society's confidence in that result is bolstered.

This is why the model of the precautionary scientist, in our view, is a step backward. The precautionary scientist expands the boundaries of science into the sphere of social values and interests — into the realm of the "ought." If her values perfectly mirrored those of the rest of society, such an incursion would save us all time and energy — why not let the scientists tell us what we ought to do? However, the diversity of values in society makes this happenstance impossible, and so the scientist's injection of her own values into her science undercuts confidence in its accuracy and hinders the ability of scientific research to make its contributions to society.

The Cognizant and Transparent Scientist

As we have continually noted, purging scientific research of all values and interests is a futile, often counterproductive task. Because scientists are human, not mere mechanisms, their work will always involve choices, and those choices will always be informed and shaped by that humanity. Acknowledging the inseparability of science and social values and interests, however, does not prevent us from striving to keep the two spheres distinct. Unable to remain solely within the sphere of science, the scientist can still use her incursions into the other spheres to enhance the quality of her science, and take care to signal how her research has been shaped in the process.

She can conduct research in a manner that we call "cognizant and transparent." Our scientist is "cognizant" because she is aware of the social context in which research takes place, and is diligent in cautiously approaching choices that have important social consequences. She is informed by the challenges of the other spheres, and uses the knowledge she gains to explore new paradigms, test different hypotheses, and examine her results in even more self-critical ways.

In her own sphere, our scientist is "transparent" in how she conducts her research because, like Hansel and Gretel in the ancient fairy tale, she leaves a trail of "bread crumbs" — clear documentation — for others to follow. She identifies at each step the choices made in experimental design, data-gathering protocols, significance thresholds, and so forth. This transparency allows for independent verification of her results, a cornerstone of science, which her "precautionary" counterpart would let crumble.

Drawing a parallel to the precautionary scientist, what would a cognizant and transparent scientist look like? She would certainly be diligent in following the elements of the scientific method we have just listed above. In contrast to the precautionary scientist she would be one who:

- enlists individuals beyond disciplinary and even scientific bounds to help frame problems, but retains a scientific focus for identifying and testing solutions;
- focuses her investigations on measurable effects but acknowledges the possible existence of immeasurable effects;
- emphasizes relationships underpinned by theoretical or causal relations, but remains open to investigating relationships expressed through correlation, pattern and association;
- addresses uncertainties which may not be subject to precise experimental replication but distinguishes them from uncertainties that are subject to such testing;
- characterizes data by their ability to be quantified and replicated, assigning higher confidence in a greater ability but reporting the gamut of data types collected; and
- is equally rigorous in quantifying the potential level of both false negatives and false positives; and emphasizes one over the other only at the direction of social policy-makers leaving clear documentation of how this emphasis is achieved.

So, how would this second type of scientist handle our two examples?

In the first case, the cognizant and transparent scientist would use constructive social criticism to formulate, for example, hypotheses covering the effectiveness and safety of genetically modified organisms. In research on genetic modifications, the null hypothesis can be expressed either as "the treatment is not effective in producing the desired result" or it could be expressed as "the treatment has no unsafe impact on the environment." In contrast to the precautionary scientist, who would skew the choice toward the "unsafe" side, the cognizant and transparent scientist would recognize and test for both effects, using the appropriate experimental and statistical techniques. This scientist would be open to new measurements that would be useful in directing further research and forming new hypotheses. She would conduct her tests in a wide variety of places and over many years before claiming credibility for her results.

In the second case, the cognizant and transparent scientist would strive to improve the accuracy of stream-typing models, but not weigh errors against fish (that is, the environment) more heavily than errors against landowners, as the precautionary scientist would. She would consider the errors separately rather than summing the two because she is aware of the different implications of each; and she would push her research in one direction or the other only to serve an explicit social policy decision. She would seek the guidance of tribal, industrial and governmental individuals in shaping questions; and, while retaining leadership and control over the process of gathering data and testing hypotheses in her own experiments, she would encourage others to test her models in new watersheds and in different years. She would understand and accept the correlative nature of the models she produces, but would use current knowledge and theory in their formation in order to have them explain mechanisms for the results as well as just predicting them.

What distinguishes the cognizant and transparent scientist is simply a greater understanding of the geography of the modern world of science and policy. This understanding brings with it an awareness of the gray areas where the sphere of science and the sphere of social values and interests intersect with each other. There is never a clear dividing line between the two spheres, of course, but neither do they overlap completely. Being both cognizant and transparent, our scientist combines social awareness with the tenets of rigorous science. As a result, she treads carefully in the gray areas but does not shy away from them. The result does not magically make the controversies over science and policy disappear, of course, but it helps build greater confidence in the science itself and may even lessen the degree of controversy.

Erasing the Epitaph

When scientists and their research become embroiled in a controversy, we believe they should avoid the temptation to retreat back into their laboratory; neither should they go to the opposite extreme, abandoning the tenets of science by infusing their research with a particular set of values and interests. The choice of one set of values inevitably comes at the expense of others, and places the scientist beyond the boundaries of her training and discipline; it undermines society's confidence in all science, a discouraging and damaging side effect.

The conflicts facing science today are not historically unique. When Merton (1957) warned scientists against writing their own epitaph forty years ago, he could not have known that his advice would still apply today, perhaps with greater force. The scientific method has evolved for the past few centuries under conditions similar to the ones we are experiencing today — indeed, scientific research has rarely been conducted in an environment free of controversy. Having adapted to fit these conditions, science will always have much to contribute. If its practitioners follow the model we offer, they can strengthen the practice of science and, we hope, continue the long history of scientific contributions to social progress.

Acknowledgements

Changes in Environment and Society

How did changes in forests influence society?

Prof. Antonio Andaluz Westreicher,
Santa Cruz de la Sierra, Bolivia

It is quite plain; let us start at the very beginning, when our primitive ancestors lived in the canopies of trees and in caves, when forests, prairies, and a few natural deserts covered the entire planet. It can be said that there was too much forest for so few people, until the first great revolution of human history took place: the agriculture, that started with the clearing of forests or, in other words, destroying trees as the first act of civilization. Man was not only the father of this revolution, but very much its child; Domesticating plants and animals not only supplied the nutrients that helped to build the human brain, but also because the shift from gathering, hunting, and fishing to a farmer that uses tools –beginning with his head– around a more productive and continuous source of food and bio-protective supplies (clothing and housing), compels the function of thinking to build the organ of thought. As stated by the rules of physiology, an organ not only performs functions, but also the lack of functioning implies its atrophy; (The need to respond to environmental pressures effectively triggered the evolution of such organs.)

So human civilization began cutting down trees; and the first way in which the biped cave dweller became man was destroying the forest. Now we recognize that solar energy is directed to the industrious entrepreneur of the photo-chemical industry called the chloroplast with domesticated plants' leaves converting light and carbon dioxide, as the sole raw materials, but supported by the soil as a physical support and supplier of some mineral salts, water as a solvent, and air for breathing.

However, let us consider the admonition of Paracelsus –who was also an alchemist– in the sense that the dose makes the poison. This is because now the major threat to humanity is widespread deforestation resulting from the advance of agriculture into forestlands in the name of development and the welfare of humanity; this is not only putting at risk the forests and the different goods and services they provide to allow life on the planet, but also agriculture itself, which closely depends on them.

As a matter of fact, landing with these concepts on the splendid cultural artifact that is a city with all the facilities as now we are (Putra World Trade Center, Kuala Lumpur), simultaneously to the clearing of forests for croplands, the care of plants and animals forced man to settle down on what will become the germ of urban phenomenon: cradle of civilization and human culture, although it always said under the reserve of Paracelsus' dose, in the meaning that it is already the city that is threatening to become the grave of both.

What are the implications of deforestation for society?

To start, I would like to highlight what I stated at the International Symposium on Possibilities for Sustainable Forest Management in Tropical America, held in Santa Cruz de la Sierra, Bolivia, from July 15 to 20, 1997, and sponsored by BOLFOR, CIFOR and IUFRO:

"Before anything, let me tell you that when I was a child, there was no greater pleasure for me than walking through the "real forest" –which was the way the virgin forest was called– and playing with my brothers. This is similar to what the Nobel Prize winner for Literature, Pablo Neruda, describes in his memoirs "I Confess I have Lived" about the forests of Temuco and his childhood in Chile……. William Cordero has introduced me as a poet and, in fact, I do write poetry or, at least and this is not my fault, I feel like a poet; so I have always asked myself, with the obvious differences taken into account, whether Neruda was fascinated by forests because he was a poet, or if he became a poet due to his fascination with forests.

From my point of view and –I repeat– with the obvious differences taken into account, I just say in De Profundis (a poem which in Latin means from very deep inside) that I came to this world gifted with too many blessings / that I became indebted / for ever / with life:

in the middle of coffee plantations and trees
at the shore of a shady stream
of giant blue butterflies
with the elemental vapors of weeds
the evanescent steams of rain
and the savage fragrance of cosmogony in the
wild rotten matter
with its mushrooms added
with its bugs added
with its intrusive and gluttonous roots
its enigmas
its mysteries
the humid and fleshy offspring that engender
the serene forest
royal residency of true fantasies

under the brilliant mess of birds
and the tender pestilence of the crib
where Mom used to milk the daily cow”.

“At the shore of a shady stream / of giant blue butterflies”, the verses went and, in fact, these were two literal things: a shady stream and giant blue butterflies. I remember that my brothers and I used to spend whole mornings in the river and its tunnels of trees and mysterious meanders, fishing or catching strings of crabs… this is what I translate in “El Yangunturo” (one of my books of poems) as the Grace of innocent times / parenthesis of circumstance / habitat of transparent joy / den of the elementary being. Well, the fact is that many years later I returned to my hometown and that same stream, now completely stripped of its vegetation, had become a sewer and with it a part of me also died. Therefore, if anyone wants to point an accusing finger at the person who designated the banks of streams and other water bodies, as well as the hills, as ecological easements in the new Bolivian forestry legislation, that finger should be pointed at not other than me, and my lost stream somewhere in Peru.

At any rate, there certainly is not a better representation of the different manifestations of the miracle of life than forests. Obviously, there is also the ocean, but it is easier to walk into a forest than to dive into the sea. The tragedy lies in that there is no real forest anymore, either surrounding Temuco or my hometown, and the same has happened all over the world around cities, towns, villages. As a result, we have literally generated, in only fifty years, billions of human beings that are born and die without having the chance to what I call the “experience of the forest”, which is like dying without God or without having been born.

This is the root of human tragedy: when we speak to people about the need, as a mandate of intelligence, for conservation and sustainable use of forests, it is as if we were talking about the beauty of colors and the subtlety of tones to blind people, or about the music of Vivaldi or Debussy to deaf people. Naturally, politicians could be included among those blind and deaf people; politicians who have never been in a forest, as a source for basic goods and services for the people whose world they rule, but who, nevertheless, make decisions, every day, that affect the future of forests (or even better said and what is actually the worst as a fact, about no future for forests, and always, of course, in the name of a better future for the world).

A practical piece of advice would be: Stop talking to people about protection and environmentally sound use of forests; instead, take them into such forests, where they can get the “experience of the forest” that will make to grow in them eyes to see and ears to hear.

Undoubtedly, the main value of forests lies in their spiritual significance for the human soul, since a genuine quality of life has to become being genuinely vital. This is something that does not have a price in the market and is not a commodity, but it is indeed the most priceless service, since there is no way to pay for it. So this is, I say, a gift of forests: and only for that they already merit legal protection, since they are the most vital resource that we have at our disposal on Earth.

The Existential Categories of Man

Before continuing, let me explain something that is apparently obvious and thus it is assumed to be a tacit universal topic shared by all human beings, although it seems to have been completely forgotten by everyone, just because no one uses anymore to make emphasis about it. The question is: “Which are the existential categories of man as a distinct being, if not from the universe, certainly from the planet?”.

First, it is obvious that man is a living being –no matter how much he really behaves as such and enjoys each of the daily miracles that life offers–, and that is what makes man different from inert or motionless objects; but also, and together with his other existential categories, different from the nature and purpose of life forms in animals and plants.

Second, man is an intelligent being and, as such, is able to plan, decide, and build his destiny; to the point that awaking and developing his potential capacities looks like the inherent epitome of human understanding. Well, man is an intelligent being: and what is at stake regarding the concerns we are addressing, is that man is the only species, among more or less ten million other species conservatively estimated as human partners in the planet, who can do things in a deliberated way and, therefore, the only one with environmental responsibilities. As time passed and taking into account the environmental record of the world, there is no doubt that this is just the field of his less intelligent performance.

Third, man is a historical being, a being that creates history and cultural heritage, as well as he inherits it from his ancestors; and, as soon as he can be a hand-maker of himself, a being that develops his own capabilities at the same time that contributes to that social process we know as human history. This is the difference between this builder-man or homo faber and other builders in the animal kingdom, such as bees, for example, and whose architect of perfect symmetry is the genetic code drafted by the nucleic acid as a mere brunch of responses stimulated by environmental factors and fitted in the framework of survival instinct. However, let us remember here that bees never forget that there are no beehives without flowers and no flowers without plants and no plants without soil, water, breathable air, and other animals to disperse and pollinate the plants. This means that the bees' instinctive understanding prevents them from forgetting that negative changes in the environment are closely linked to negative changes in their society. This is the point we are going to address later on, talking about this builder-man as the best reflection of the historical existential category of human beings –and jointly with asking ourselves how much intelligence is really an intelligence that is increasingly going down even below the proper instinct of survival; precisely as we rush to build our beehives –the cities–, we are forgetting that we are completely dependent on nature.

Fourth, man is a cultural being, because he produces culture and has to live in time and place according to inherited culture, giving social answers in its range of permeability to atypical behaviors.

Fifth, man has needs, which means that he requires external elements, just as animals and plants do, but with additional needs that evolve together with his cultural and historical character. And the relevant issue regarding the topic that joins us here is that, as Karl Marx warned, man is a machine that generates needs; where the historical increase of needs –and even mere desires whose worse expression is the phenomenon of consumerism– produces an environmental impact on the natural resources of the planet, that is greater than demographic explosion itself. So do not ask only how much has human population increased since 1950, but also how much human needs and desires have also augmented in the same period, charging the incremental costs in the natural resources of "our only earth" (as was the motto for the 1972 Stockholm United Nations Conference, followed by "act locally think globally" which was the motto for the 1992 Earth Summit in Rio de Janeiro). For instance, if we are alarmed because since 1950 human population has jumped from 2,500 million to 6,000 million, we should be even more alarmed to learn that, in the same period, use of fresh water has increased fourfold compared to the population growth rate. No less alarming are the environmental indicators regarding impacts on soils, forests, and fisheries –including loss of biodiversity–, air –including acid rain–, atmosphere (ozone depletion and the greenhouse effect), and even in outer space, where we already have placed quite a bit of garbage. Not to mention, of course, impacts on and of non-renewable resources, like oil and other fossil fuels.

Sixth, man is a social being and here I simply quote the essay on "The Environmental Function of Property and Human Actions" which was included in my book entitled "Environmental Law.- Proposals and Essays" (1990): "By existential category we mean the simple fact that we are not social beings by our own will, but by existential determinism. We can be considered human only sharing with others. There have been many ways to refer to this category along history. For example, Cicero said that, by nature, man is used to forming groups; Voltaire said that man's instinct drives him to live in society, as it drives him to eat and drink; Aristotle states in "The Politics" that one who does not need to live in society is either a God or a beast; and twenty three centuries later, Jacques Monod, winner of the Nobel Prize for Physiology and Medicine in 1965, expressed that man is a social being by genetic transmission and cultural heritage. For the jurists' opinion, we just need to recall what Luis Recasens Siches understood by the word man. "The term man –he said– implies a reciprocal existence from one to others; a community of men, a society". Thus, the social being is implied in the word man".

Finally –and under reserve of inter alia– man is an ecosystemical being, in the sense that, quoting the above mentioned document, "the part of the ecosystem together with other biotic and non biotic elements that are in the biosphere; and whose actions are subordinated and subordinating to the ecosystem; that he is impacted by environmental factors and causes environmental impacts; that he is the last link of a number of food chains, etc.".

Therefore, there is nothing worse for a human being than refusal to recognize the existential categories to which he belongs. That is what is happening with humans who are alienated from nature and have lost their sense of belonging to and depending on nature (namely, his ecosystemical existential category), losing thus their sense of vitality, as the less intelligent expression of an intelligent being living without coexisting with life and the sources that nourish it: and where ultimately we must find the first rotten root of the loss of horizon for our social, historical, and cultural categories in the process of building human history. It is where we will end as a result of the destruction of forests; so, before we look into material losses that this destruction will certainly bring to humankind, we have to highlight the destruction that man himself implied in a process in which each new blow of the axe in the woods is equivalent to a new stab in a process of ontological suicide.

This is, in fact, the first unfortunate change in human society due to changes of forests into deserts: alienated from nature and absorbed by the landscape of human coexistence in stagnant compartments, in the cement and steel jungle of the cities, which grow at a pace that, even in developing countries such as Peru, has shifted since the 1950s from 70-30 to 30-70 as the ratio between rural and urban populations. The human soul has also been devastated, man has alienated himself from other beings and, what is even worse, from his inner self. Having lost our sense of belonging to the ecosystem, is it not strange that we give only what we have as a sense of sociability –comparing with the goods and services that are exchanged among trees in order to build the forest that makes each of them into a complete individual reality? We built social and antisocial societies where the incapability of interacting in society –certainly not for becoming Gods– is a logical consequence that in each individual member of the social body there is as much the vitality for exchanging, as the need to get in touch with life in the forests. This is the antisocial paradox of a gregarious being that forgets his links with nature! This is not the only drama: together with the urban phenomenon, during the same period, and with the technological advances in modern agriculture, also the relationship between farmers and land has changed abruptly, and now they have become hired hands of an industry that uses biological machines for converting hi-tech inputs into products.

I strongly believe that it would be impossible to build a properly humanistic society without recovering the sense of existential vitality, whose two major sources of inspiration are the seas and the forests, and where the best weapon we can use, since not many of us can be scuba divers, is to let people to have the "experience of the forest".

The fate of the forests is decided in cities where the alienation from nature is so obvious that citizens have forgotten that their entire lives depend on natural resources, yet they have no inkling of the way food is produced, fibers of the clothes they wear are made, the electricity they enjoy just at the turn of a switch is produced, or the water they can get just opening a faucet is provided, and, therefore, how these are exhausted.

Evidence of Alienation

The best evidence of this alienation is supported by these two pathetic facts:

On one hand, city based environmental movements present foresters and forestry operations as the bad guys in terms of forest destruction when we all know that the war we are really losing is against deforestation for crop lands. We all know that not even the worst forestry practices cause as much impact as the best farming practices. Here fits an anecdote on the technical validity of their discourse: I own a piece of land that is located about two hours away from Santa Cruz de la Sierra –capital of the major timber producing department in Bolivia– which I bought with the idea of establishing a Private Reserve of Natural Heritage (on which I will elaborate later) and I called it "Creator Spiritus" –in Latin the spirit of creation– and where I find that spirit or the closest thing to it. Well, every time I take this kind of environmentalists –and their "air conditioner discourse on rural issues"– to my forest and we walk into it, the same thing happens over and over: they fill their lungs with pure air that has a wild fragrance and, astonished, almost slobbering and with their eyes popped out, they enjoy and celebrate the advantages of a "pristine forest". So I tell them that this piece of land is actually as much a virgin as a prostitute retired after 60 years of uninterrupted work, but this is not noticeable since she practiced her trade only with foresters, not with farmers. As a matter of fact, that is the big difference between Creator Spiritus and the surrounding area: that my Saturday girlfriend (the woman retired from a dissolute living only with especially discreet clients, foresters) remains almost normal, with her trees standing, and, after the years, it is pretty hard to find differences between the virgin and the dissipated forest, because only under the fallen leaves you can find the rotten stumps of trees as evidence of former romances; meanwhile, in the surroundings, there are many abandoned brushy fields, some cultivated fields and pastures, and streams that have become dead puddles.

On the other hand –as further evidence of alienation from nature–, we have groups of city environmentalists demonstrating on the main square, wearing masks and asking the government to forbid slash and burn agriculture, and the renewal and disinfecting of the grasslands by fire. Well, I am the son, grandson, and great grandson of farmers and I myself own a coffee plantation –and let me tell you that it is the latest in fashion design, in terms of the lace and loops required for the agroforestry look–, so being an old hand at the trade I can quite confidently say that fire is the cheapest tool farmers can use, and the worst environmental damage is not a result of controlled burns, but of uncontrolled fires. The best way of proving this is that last year 13 million hectares were burnt in Bolivia, and of these only a hundred thousand were cleared for agricultural use and maybe a couple of million were burnt in savannas and grasslands. What I mean is that while the serious environmentalists try to implement regulations for clearing and controlled burning –obviously only in lands previously allocated for agricultural uses–, the others, those that portray loggers and foresters as the bad guys, scream for a law that stipulates zero burning. I would back their demands for passing such a law, but only with a small condition: I would challenge each one of these "zero burning" environmentalists to clear by hand, without fire, just one hectare that has been opened to expand the lands for feeding and dressing people. At that very moment I swear, by the chastity of my Saturday girlfriend –Creator Spiritus–, that I will not give up until this law becomes a reality.

Meanwhile, I will keep working with BOLFOR and supporting the Forest Service (Superintendencia Forestal) in trying to implement regulations for clearing and controlled burning; and, if we succeed, I assure you, no urban environmentalist will ever notice the smoke. I mean that if we reach the target we are aiming for, namely that the only areas burnt are those that peasants, farmers, and cattlemen really do want to burn. For us who know the value of this extraordinary environmental victory, the "zero burning" goal appears only as a distraction factor for our cause, a factor that, in the eyes of rural people, takes any credibility away from those urban green-asphalt movements.

The End of the Skin

The concept of "experiencing the forest", is a main tool for the process of social evaluation of forests and all the goods and services that make ecological viability a sine qua non condition for the planet's vital economy. The new forest legislation in Bolivia (Ley 1700 from July 12, 1996 and General Regulations approved by Presidential Decree No. 21453 on December 21, 1996) provides for the creation of Private Reserves of Natural Heritage. These allow any landowner to establish within his property, up to 5,000 hectares, for a minimum of ten years, in a voluntary and unilateral way: a public document explains the values to be protected, the initial status in order to have an objective reference for monitoring, the rules for control and vigilance to be applied, and communicates the decision to the Forest Service. In turn, the Forest Service approves the designation through a resolution conditional to annual certifications of validity, since all of these areas are exempted from taxes on rural property and have legal protection from being classified as unused lands or from seizure for such a reason.

The idea is to create a constellation of areas with standing forest –including interpretative trails, identification of trees, internal streams, etc.–, that multiply the chance of selling the "forest experience" and the smell of rotten trunks and fallen leaves, as a breath of God, for massive consumption by people who cannot afford what is offered to elite consumers who visit national parks as they would do exclusive boutiques.

The easements in private lands (such as steep slopes, riparian protection strips, wetlands, lakes and ponds, etc.), created by the above mentioned legislation, could act as branch offices of a franchise to give life to the human spirit and reconcile it with nature, as a precondition for its reconciliation with humanity. It would be nice if foresters could include eco-tourism programs in addition to their forestry activities.

From having cleared all the trees to stop hunger, to going hungry due to excessive forest clearing.

To recapitulate the concepts I presented at the beginning of this paper, the process of civilization, which started when the first tree was cut, can lead to disaster when the clearing of forests takes place in areas that are not suitable for agriculture or cattle ranching due to their tendency to different types of degradation, such as erosion. This is the seed for later tragedy in the case of environmental refugees. Haiti, for instance, is not the poorest country in the Americas by mere chance, but for having 50% of its territory turn into bedrock as a result of the clearing of its hill forests for croplands, which have lost their soil to erosion and now it lies at the bottom of the sea. I will not insist on talking about something that you already know: water supplies are dependent on forests and many countries, cities, and towns, all over the world, are now suffering the consequences of destroying watersheds and water catchments, to a point where wars might start due to water scarcity–or in other words by all the trees that were cut no matter where, when, nor how many–. On the other hand, the paradox is that clearing forestlands and protection forests, including ecological easements, exposes us to the risk of losing areas currently in agriculture. For instance –and of course this is neither the only nor the worst case, but the one I have witnessed– in the Bolivian lowlands, the Rio Grande has experienced severe siltation due to sediments originated by widespread deforestation, at such a fast rate that perhaps in less than a decade the riverbed might reach the top of one of the major bridges that cross it (1.5 Km), with all the implications for increased flooding risk and soil drainage problems in an area that supplies most of the soybean produced in Bolivia. Towns like Pailon (the Bolivian capital of soybean) and Okinawa (a Japanese colony) are now below the level of the riverbed; approximately three meters in the first case and almost six in the second. On the other hand, large rivers such as the Ichilo, Yapacaní, and Chimoré have experienced severe shifting in their riverbeds, which have extended up to 500 meters. No doubt this is a trend that can be observed throughout the Amazon basin.

As you can see, taking into account the environmental tragedy implied by the conversion of production and protection forests to croplands, to think of foresters as the bad guys is so banal as to pretend that the major problem for poor people is that they cannot have caviar and champagne. So the main priority is to oppose conversion and, then, ensure that production forests are managed in a sustainable way; these should also be a priority for the Forest Service. That is to say that, compared to the environmental disaster that unplanned land conversion might cause, even selective logging becomes a trivial subject, since at least in this case the forests remain standing and continue to provide ecological services;

not ignoring, of course, the severe damages that such poor timber harvesting practices would cause in the remnant forest in terms of genetic erosion.

Conclusion: Land Planning According to Land Use is, in This Case, the DosePrescribed by Paracelsus.

I teach my students that the best environmental management tool is land planning and that the second best is environmental assessment. The queen and the princess. And, therefore, if both were effectively implemented, we wouldn't have the severe environmental problems we are experiencing. Indeed, virtually all the forestry and agrarian laws that were passed in the last 50 years have used land planning as the axis for its normative structure. The problem is that in very few cases we have succeeded in enforcing it –or making a reality of what is written on paper and printed on maps–, organizing the country in protection lands, forestlands and agricultural lands; and doing this in the right place and the right way.

I would like to finish my presentation by recalling some of the progress that has taken place in Bolivia in terms of forestry, which I bring for you to take home, as a gift of my beloved adoptive homeland.

The new forestry law in Bolivia established Land Use Plans (Planes de Ordenamiento Predial) as a tool to bring to the farm level that which was established in a macro/planning level for departments or eco-geographic regions. So, the law stipulates that when changes in use from macro to micro level take place there should be a "principle of benignity for changes in use", meaning that it is permitted only to change to forestry or protection uses those lands allocated, at the macro level, for crops or cattle ranching, but not the other way around. Also established by the law was the principle of In dubio pro forest (if in doubt favour the forest) not only for preventive classification of forestlands and protection lands without being subject to studies for macro level classification, but also to resolve conflicts of potential uses that may arise during the process of classification (for example, the same land could be suitable for forestry uses due to the high quality of standing timber and also be apt for farming due to the good quality of soils; in that case, In dubio pro forest is the mandate of law). This land use planning (approved by the Agrarian Service –Superintendencia Agraria–) is a mandatory tool where ecological easements are defined, in order to be monitored by the Forest Service, and registered as a real state burden, being a requirement for selling rural property or to apply for farming loans. This tool is part of a group of tools that drive the National Forestry Regime, such as forest management plans; programs to control timber supply and processing (to prevent illegal trade of forest products by controlling processing centers in the cities, rather than prosecuting timber poaching activities that could be spread in vast land areas); the Forest Service itself (with an institutional design based on immunity from political pressure and vested interests); certificates of origin for timber to control timber harvesting; authorizations for land clearing and controlled burning; the character, by juridical fiction, of auxiliary agents of public authority by engineers and technicians working privately; juridical security for owners and stewards of land and forests (intruders can be thrown out in 72 hours); means of social accountability, etc.

Bolivia is undertaking an extraordinary effort to make this aircraft take off and reach cruising altitude by having all the engines working –which are the tools mentioned above–, in order to care for the essential element of natural heritage that, in the long run, would decide the destiny of the Bolivian people: its forests, including biodiversity, and lands in general. This may not be the story of Alice in Wonderland but I believe that, considering the scarcity of materials and even of qualified human resources, to have reached almost 800,000 hectares of internationally certified forests as managed in a sustainable way, to lead all tropical countries in this subject, and to have been the fifth country in the world with approved international standards for certification, means that something has been done the right way.

In the name of this combative people who struggle in the middle of the loneliness of their isolation that swims in an ocean of forgetfulness, my greetings and exhortation to build humanity, building the culture of the tree in the human soul.

People Issues in Forest Management

Robert Lewis, Jr.
Deputy Chief for Research & Development
Forest Service, U.S. Department of Agriculture
Washington, DC, USA

Introduction

It is an honor for me to speak to you today in place of Dr. Carol Colfer of CIFOR. Dr. Colfer sends her regrets and shared some of the remarks she planned to cover in her speech. The title of her speech was "Cultural Diversity in Forest Management." I have read her speech to make sure to cover the points she would have made. Amazingly, I found that although she and I may use different words and different approaches, we would be speaking about the same subject and that is, the importance of people issues in forest management and the need to consider social factors in planning for sustainability of the world's forests.

A View of the World Forests

Much of what is known about the state of the world's forests is summarized in a paper by David J. Brooks, "U.S. Forests in a Global Context," which can be found on this home page http://www.fs.fed.us/global/pub/links/global.html. The picture that is painted is a shrinking forest resource, increasing world population, much of which is poor, and loss of forest cover due to a host of reasons

Shrinking Resources. Forests cover about 4 billion hectares of the earth's surface or about 30 percent of the land area. Because the definition of forest is fairly liberal-land with trees taller than 7 meters and having a density of about 20 percent or more-we expect that the actual forest cover is less. One half of the world's forests and 80 percent of the world's population is in Asia, Latin America, and Africa. Many of the tropical forests happen to also be in developing countries, and are mostly in the tropical zone.

In the past 20 years, increasing public attention has been given to a variety of global environmental issues, including climate change, ozone depletion, and loss of biological diversity. In the United States, the attention to these issues has often surpassed the concern for the availability of timber or industrial forest products. The concern for deforestation over the last 50 years was focused mostly on the loss of tropical forests, although temperate and boreal forests have received their shares of attention.
Population. "Too many people, too little land" is a common lament in many parts of the world. The distribution and population growth rates will increase pressure on global forests in the coming decades for both industrial products and environmental services.

Poverty. More than half of the world's population and two-thirds of the population of developing countries still live in rural conditions. More than 80 percent of the world's population is relatively poor, and relies on forests for basic sustenance - principally fuel and land for growing crops. These factors explain a rapid loss of tropical forests (170 million hectares of tropical forest between 1980 and 1990).

Land Use Change. In addition to uncontrollable harvesting of timber for basic needs such as fuelwood, land use changes for agriculture, industrial, and urbanization purposes contribute significantly to the reduction of forest cover. It is also important to note that fuelwood is still the world's most important use of timber (90 percent of timber production in developing countries and about 50 percent worldwide).

Analysis of world trade on imports and exports was given in Brooks' paper. It shows that the United States is a net exporter of pulp and paper products and is a net importer of solid wood products from tropical countries. The consumption patterns of the wealthy nations and the need to sustain economic growth led by the United States will continue to be a factor in the flow of wood materials around the world.

What are the people issues?

As a research community, we are playing an important role in the sustainability of the world's forests. In the debate about sustainability, where the environment and people are intricately linked, often the focus has been on the ecological element without sufficient attention to the equally important social and economic components. Whether we are interested in cultural diversity, or the contribution of cultural diversity in forest management, 1 believe it is worthwhile for us to discuss people issues that need to be taken into account in forest management.

Some United States Issues. There are several issues in the United States that may be rather unique and may deserve attention from all government, academic, as well as private sector research perspectives. They are:-

Tribal relations. Robert Tippeconnic (1995) gave a good overview of Native American perspectives and philosophy toward nature and their relationship with the place, the land, and resources in North America. Native Americans are indigenous people of the United States, including Native Alaskans and Native Americans. Today the U.S. Government recognizes 547 Native American tribes. The largest is the Navajo Nation in the States of Arizona, New Mexico and Arizona. These tribes own about 23 million hectares. Today, they have a unique relationship with the U.S. Government. As sovereign governments, tribes have much to say about the welfare of tribal members and the management and use of tribal lands and resources. Some tribes, in ceding their lands to the U.S. Government, reserved the rights to fish, gather, hunt, and graze livestock. However, there are still many situations where certain claims by tribes are still unresolved.

Underserved communities. The population of the United States is getting increasingly diverse. There is a realization that forest management must take into account the needs and desires of all segments of society, including underserved populations and communities. Coincidentally many of the underserved happen to be ethnic minority and poor communities. Forest Service research is trying to understand ethnic participation in resource management and use. Also, there is a need to increase the use of natural resources by the underserved community. A model of such work is the social science research on cultural diversity of Los Angeles County residents using the national forests (Tierney, Dahl and Chavez, 1998).

Environmental justice. The President issued an executive order directing "Federal actions to address environmental justice in minority populations and low-income populations." According to this law, all populations should be provided the opportunity to comment on land management proposals before decisions are made. All populations are allowed to share in the benefits of, and are not affected in a disproportionately high and adverse manner by government programs and activities affecting human health or the environment. This assurance is implemented as part of the National Environmental Policy Act (NE-PA) compliance procedures (USDA Departmental Regulation, 1997).

Subsistence/dependence on natural resources. Many shifts in forest policy are possible because of the social and economic structure of highly developed industrial economics. Many forest-dependent communities of the Pacific Northwest have been able to adapt to these shifts, thanks to a reasonable prospect of re-employing labor displaced by reduction in commodity uses of the forests. The United States as a whole has been able to adapt because the consumer impacts of reductions in commodity production can be mitigated by technological developments and by the ability to import commodities. In other words, wealthy countries have more decision space in setting forest management policy. This is not true with many communities in the United States that do not have options (e.g., Appalachia and many remote areas where there are no alternative employment opportunities).

Developing World Issues

Upland development. Throughout the mountainous areas of Southeast Asia and Southwest China, poverty, population growth, environmental degradation, social marginalization, and economic dependency are now interacting to create a downward spiral that is currently reaching crisis proportions, both socially and environmentally (Neil Jamieson, Le Trong Cuc, and Terry Rambo, 1998). Interestingly, this phenomenon is not unique but is quite common to many mountain communities around the world.

Loss of indigenous knowledge. The reliance on forests for subsistence is highest in the mountainous areas, especially in the tropical forest areas. Often, the ethnic minorities are also residents of mountainous zones. As a case in point, 51 ethnic groups live in the uplands and mountainous regions of Vietnam. As population increases in the lowlands, and the need for land increases, there is an upward migration of lowland people to higher elevations looking for land to grow crops such as tea and coffee. The tribal and ethic minorities are being forced to move higher up, or be totally marginalized. Coupled with the degradation of watersheds and loss of biodiversity, the loss of indigenous cultures and the richness of their knowledge is a major concern.

Involvement of local people to solve environmental problems. Realizing that centralized decision making does not promote sustainable forest management, the governments in the Asia-Pacific region are experimenting with decentralization and devolution of forest management responsibility to local government (Philippines), to local units in China, Laos, and Vietnam. There are different approaches and also debates about what degree of decentralization (of administrative functions) and devolution (of power) is desirable (Enters et al., 2000). However, it has been shown in many areas that the best way to create jobs, prevent illegal logging and poaching, reduce shifting cultivation, and invest in long-term management of forests is the practice of community forestry. Incentives to manage for both forest cover and economic well being will be the driving forces for sustainable forest management. In many cases, the communities already have the infrastructure, such as women and youth unions, that can be mobilized to accomplish goals that cannot otherwise be attained.

Fair and equitable distribution of resources. A look at distribution of land and resources reveals that the axiom "too many people, not enough land" may not be totally correct. The real issue is in the distribution of land and resources. Besides land, the other significant resource is water. Many population centers are built around waterways or depend on availability of water at the expense of poorer and rural communities. Environmental justice still has a long way to go worldwide.

Agroforestry. At the interface of farming and forest management, the combination of crops and trees has to be part of the landscape. Agroforestry is extremely important for the management of buffer zones between farming communities and natural forest reserves. Although the science and knowledge base of agroforestry is improving with experience in general, much experimentation and learning is needed to be adaptable to local conditions.

Managing ecotourism. Ecotourism is an important opportunity to improve economic conditions for communities near centers of high and fragile biodiversity such as the buffer zones around biological reserves. Successful ecotourism schemes require partnerships between many levels of government and local people, non-government organizations and people skilled in networking. Unfortunately, human weaknesses such as greed and unreasonable control lead to lack of the trust needed for successful partnerships.

What Forests Services Research & Developement is Doing to Respond

The Forest Service International Programs staff has a strategy of several focus countries where several programs are managed. To name a few, the programs are fire management, forest monitoring/remote sensing, forest health/invasive species, migratory species/habitat management, watershed management protected area/ecotourism, sustainable forestry practices, policy analysis and development, and disaster assistance. The various countries where the Forest Service has programs include Brazil, Mexico, Venezuela, Indonesia, India, China, Vietnam, Russia, and more.

Forest Service scientists have been involved in international work, and several FS representatives at this IUFRO Congress have been leaders in their field of expertise. The role that FSR&D plays is to provide technical assistance with many areas of expertise such as fire management, insects and disease, silviculture, wildlife management, forest products technology, inventory and monitoring, etc. There are many more areas that we would wish to be engaged in but still lack the capacity to respond.

Challenges to IUFRO

In the words of Neil Jamieson (East-West Center) who has spent a lifetime in international work, the ground is littered with failed projects. What can we, as a science community, do that adds value to what is most needed? 1 suggest more attention on a few research areas that seem most appropriate:

Preservation and Restoration of Indigenous Knowledge. Together with biodiversity and forest cover, indigenous knowledge of land management is disappearing everyday as the fragile mountain ecosystems are degraded. The need to capture the knowledge base of the environment and how to sustain it is more urgent than ever before.

Community Forestry. Engaging people's participation is a noble goal that requires a great deal of effort. However, without research to understand what people want and their ideas for co-management of the land, the projects will not be a success.

From the economic development point of view, more research is needed in the areas of agroforestry and special forest products that provide options to local people, regardless of country or region of the world. The values of non-timber forest products will expand options to manage for timber species and for larger trees.

Although plantations are a small fraction (3-5 percent) of all forests, they are managed intensively to meet the needs for timber, and non-timber forest products. Use of indigenous species plantation should be encouraged to avoid drastic landscape change and non-native species invasive problems.

Special research attention should be given to sustainable forestry in the highlands where the ecosystems are at highest risks. Special skills and social science to resolve conflicts are badly needed to deal with various interests from different groups and governments

Finally, research can help develop opportunities to enhance environmental and economic sustainability with well-designed ecotourism schemes.

Closing Statements

I began this speech with a fairly bleak picture of the state of the world's forests. I am, however, going to end with a note of optimism. I believe that research and development will play a larger role in sustaining the world's forests. I believe that our contributions go beyond technological and ecological fields. There is a whole realm of social and people research that we will bring to bear on policy and management. Dr. Colfer would agree with me in her prepared speech: "...we have to move on from forestry culture that excludes people. The world's forests as they exist today are the product of millennia of interactions between people and their environment."

I would suggest that we work together to develop a deeper understanding of the cultural diversity that is inextricably linked to our environment. We also need to be more engaged with local communities to develop the solutions that are adaptable and relevant to the long-term sustainability of their culture and environment.

Thank you and have an exciting discussion on this topic.

Cultural Diversity in Forest Management

Carol J. Pierce Colfer
CIFOR, P.O. Box 6596 JKPWB, Jakarta 10065, Indonesia

Introduction

As an anthropologist, I feel particularly honored to have been invited to make this address to IUFRO's Congress 2000. I have spent much of my life among people who have sophisticated and productive ways of managing forests and I have been frustrated at the fact that foresters have often failed to recognize the knowledge of these communities and the role they can play in modern sustainable forest management. The cultural diversity that impinges on forestry through the variety of traditional management strategies extant in the world's forests is extraordinary. Local communities' forest management practices have been the subject of anthropological investigation for a number of years (Conklin 1957, and numerous anthropological pre-cursors). But only recently have there been serious attempts to bring the knowledge of foresters and that gathered from local people by anthropologists and other social scientists together in a productive and synergistic way.

Just as we have come to recognize the significance of biodiversity in recent years, it is now incumbent upon us, in my view, to acknowledge the potential of cultural diversity. In this presentation, I begin with two examples of local forest management systems. I then discuss the ethical and practical reasons for attention to such systems, particularly pragmatic ways by which this kind of knowledge can benefit foresters and the forestry profession. I conclude with some suggestions relating to ways we might improve our ability to tap local knowledge, organization and creativity in solving today's pressing forestry and environmental problems.

Cultural Diversity

If we look at the remaining forests of the world, we can find a huge variety of human patterns of behaviour, belief, and preference in these forests. From my perspective, these differences represent a true treasure trove of knowledge and potential that we are not using at our peril.

My communities leads me to think we can make better use of this human resource. I give two illustrative examples that I know well, below; but these are replicated in myriad combinations and forms, many times over if we consider the world at large. I selected these two examples because they represent two purported extremes, from a group considered by some to be "under-developed" (from Indonesia) to a community in the "developed" world (the United States)—yet they share significant problems that relate to issues of cultural diversity.

I first went to the Indonesian community of Long Segar, East Kalimantan, in 1979, and have maintained contact with that community ever since. I began working in the American Quilcene (in the State of Washington) in 1972, and have made periodic visits back, with the most recent being in 1997. Neither the forests nor the people have fared particularly well in either location. I should stress at this point that I am pointing no fingers—the reasons for what is happening in forests and among people of diverse cultures around the world are complex, without simple villains.

Long Segar, East Kalimantan, Indonesia

Long Segar is a village of Dayak swidden cultivators who reside along the Telen River in the middle of the Indonesian province of East Kalimantan (for a fuller description, see Colfer with Dudley 1993; Colfer et al. 1997).[2] In 1979, when I first moved to Long Segar for a year of research, the village was surrounded by tropical rainforest deemed valuable by foresters and loggers primarily for its abundant, uniform, light hardwoods—the dipterocarps that fed the world's plywood mills.

The Uma' Jalan Dayaks who lived there depended on that forest for a much wider variety of goods and services. Their swidden system involved the cutting of 1-2 ha plots each year, for rice cultivation, supplemented by a variety of other secondary food and medicinal crops (peppers, cucumbers, corn, etc.). Soon after the harvest of the rice crop, the people could begin to look forward to the maturation of some longer term crops like cassava, banana, papaya, which kept bearing for a year or more. Gradually the field would be "invaded" by the natural regrowth, in which medicinal plants thrived, along with a number of edible ferns, palm hearts, and so forth. As the forest began to take shape again, fruit trees, domestic, semi-domestic, and wild, began to mature. After a few years, the fruits could be harvested. Along with such fruits, rattans, bamboos and other fibres grew to harvestable size, while the forest evolved into a suitable habitat for mammals, large and small. Eventually the trees grew large enough to harvest as timber and the forest took on the characteristics of old growth (cf. also Mackie 1986; Chin 1985, for more ecological studies of this system in nearby communities).

[2] The Long Segar example is particularly relevant in the Malaysian context, since many Long Segar patterns are similar to longstanding Malaysian, particularly Bornean, examples (cf. Brookfield et al.1995; Chin 1985; Freeman 1970; Geddes 1961; Kedit 1993; Langub 1993; Metcalf 1974; Morris 1976; Padoch 1982; Roseman 1991, to name a few).

This agroforestry system created a patchwork or mosaic of forest stands at different ages surrounding the village, allowing for a diverse range of plants and habitats appropriate for a variety of animals. Each family had access to land in several stages of regrowth, allowing diversity of diet. These different micro-habitats, available to each family, were typically not equally affected by any particular natural disaster, forming a safety net when disaster struck (whether drought, floods, fires, or pests and diseases of various kinds).

The system, in a context of low population density, also maintained ecological functions, protecting the soils and river quality by keeping the soil covered most of the time, and contributing to aesthetic values like clear water, shade, diverse animal life, and natural beauty.

The traditional management system involved rules of use. Individual families had rights to particular plots (initially obtained by cutting a rice field), transferred to their offspring of both sexes. Yet the village retained a voice in decisions about land and resource use in the village territory. Decisions to make rice fields in a particular place involved discussion among the families owning adjacent plots and there were mechanisms for resolving related disputes within the village. There were regulations to preclude the wanton destruction of valuable trees; and rules that allowed individuals to claim particular trees for which they had an intended use (partially detailed in Colfer et al. 1997).

Knowledge about ecological matters—plant and animal identification, patterns of behavior among animals, seasonal variation in availability of forest products, appropriate habitats and growth requirements for different species, etc.—among the general populace was substantial. Particular sub-groups within the community tended to have more knowledge about particular topics: Women knew more about medicinal plants (cf. Leaman et al. 1991); men, about hunting (cf. Puri 1997; or among the Iban, Wadley et al. 1997).

Now, in the year 2000, much of this forested habitat has disappeared. First it was commercially logged under the direction of the Indonesian government and Georgia Pacific (later P. T. Kiani Lestari). Then one part was allocated for a several thousand ha transmigration area; another area was handed over to the timber company for plantation development (cf. Colfer with Dudley 1993); local people were urged to shift to permanent tree crops; and in 1997-98, the whole area burned, leaving grasslands, vines, and disheartened, hopeless people (cf. Colfer 1999)

Quilcene, Washington State, USA [3]

In the mid 1970s, Quilcene was a small but thriving logging community on the Olympic Peninsula of Washington State (see Colfer 1977; or Colfer with Colfer 1978). The area was forested (hemlock, Douglas-fir, spruce, cedar), owned and managed by a complex mix of individual and industrial land owners, the US National Park Service, the US Forest Service, and the State of Washington.

The community was composed of, and divided by, two "camps": "Locals" and "Public Employees", marked by different values and ways of life. The "locals" were stereotypically born and raised in the area (though some in-migrants adopted the "local" lifeway and "passed" as locals), with logging being the symbolic heartland of the local "subsistence system" (see also Colfer et al. 1999, for a brief overview of Quilcene stakeholders and their characteristics).

"Locals" had an interest in and knowledge about the local environment, including a whole host of experience with local natural resources. They knew when and where to find huckleberries and the prolific blackberries, various kinds of mushrooms, and other forest foods—often canned or frozen by the women. Some harvested wild salal and other forest plants for sale in the cities to florists. Hunting was a popular sport among the men (deer, elk, mountain goats were favorite prey) and fishing was a passion for others (salmon, rock cod). Gathering oysters, crabs, gooeyducks and other clams from the exposed tidal areas were regular activities for young and old.

"Public employees' were those families whose primary wage earner was employed by one government agency or another (including local school teachers). They were reputed to be better educated than the locals; but they were also labeled disrespectfully as "paper pushers" by local community members. US Forest Service employees were the symbols for this category. Knowledgeable about technical forestry, their job descriptions did not really allow them to recognize the myriad functions to which local forests were put. The emphasis was on logging and managing the forests for sustainable timber production. Other functions were substantially lower in USFS priorities.

By the late 1990's, much of the Olympic Peninsula's old growth forest had been logged, and environmentalist pressures put a stop to logging there. Young local families had moved out; the once thriving community of loggers had

[3] There are a number of useful books that discuss some of these issues: White (1980), Van Syckle (1980), Lien (1991); Satterlee (1992). Dietrich (1992) provides the best summary of the issues.

become a self-described "sick community" of retired people and public employees (Dietrich 1992 notes the same process in nearby Forks). Like in Long Segar, the cultural integrity of the community has been attacked at its core; and the old growth forest has also been decimated.

I cannot trace the exact links between the attack on the integrity of these cultures and forest loss; nor can I identify any one group of people solely at fault. I suspect there are other factors, like global power and wealth inequities, high population growth, corrupt governance, that are affecting both people and forests. But these two cases represent a more widespread and depressing pattern that contains important warnings for all of us interested in the fate of people and forests.

Ethical Issues in Which Foresters Play a Part

Prabhu et al (1998) have argued that the whole idea of sustainable forest management is intimately connected with our value systems—meaning that we cannot reasonably ignore cultural diversity (one important source of differing values). Addressing these values head-on makes a certain amount of sense. Besides the probable fact that most foresters do not want to play a continuing, though often unknowing, role in the kinds of human and ecological problems outlined in the previous section, there are a couple of issues that should strengthen our interest in integrating cultural diversity issues in forest management in a more meaningful way.

The first issue is one that has been used routinely when defending our concerns over biodiversity. Just as we do not yet know which aspects of biological systems and which particular plants may prove useful, even vital, to humans in the future, so we do not know which aspects of human systems may prove important for our future viability as a species. The fact that many communities, and the integrity of their ways of life, are directly dependent on maintenance of forest ecosystems is the central link between this issue and the forestry profession.[4] I do not argue for protecting cultures in some pristine state, as one might collect zoo specimens. Rather I suggest that recognition of the complexity and dynamism of human systems is a necessary first step for foresters of this millenium. Such recognition can foster respect for local human systems and help us make effective use of the global cultural and intellectual wealth represented by forest-based cultural diversity.

A second ethical issue relates to what many consider a human right: for forest people to have a say in the direction and speed of change to which they are subjected. This issue is also often phrased in terms of global concerns about democracy. In many forests, the inhabitants are marginalized within their own societies—by poverty, low educational standards, lack of infrastructure, ethnic discrimination, etc.—and do not have the means to make their views and preferences felt.

The scale of these ethical issues ranges widely, from concerns pertaining to the whole human species, to concerns pertaining to individuals in communities. In the next section, I turn to a scale we are usually more comfortable with—that of individual forests and individual communities. This scale is perhaps the one at which we have the most potential to effect benign changes.

The Utility of Cultural Diversity for Foresters and Forestry

Whether your interest is in enriching the future of humanity by maintaining cultural diversity or protecting a particular forest by using cultural diversity, I argue that it makes sense for foresters to work with local communities.

I turn now to the pragmatic reasons foresters may be interested in what cultural diversity has to offer. Many foresters have become increasingly interested in looking at forestry from a more holistic perspective, recognizing and better managing the multiplicity of products that forests produce—beyond timber (cf. Jerry Franklin's "New Forestry"). However, such a goal requires new methods, new approaches that are a bit alien to conventional forestry. I believe that local communities can provide important hints about these issues, with their long experience of multiple uses of their forests.[5] And—for those who are interested—making use of such experience and knowledge can contribute substantially to protecting cultural diversity.

I propose three principle ways that local communities, in all their diversity, can contribute significantly to formal forest management—whether primarily for timber production, for conservation purposes, or for multiple use forestry. These suggestions simply build on existing, usually informal, management of the world's forests.

[4] To put this issue in a contemporary and controversial light, the Malaysian Government has often publicly criticized the negative aspects of human systems in America (e.g., governance, economics, morality). Supporting and encouraging cultural diversity represents one practical mechanism for countering potential adverse impacts of globalization and possibly western-dominated cultural homogenization.

[5] Other fields are ahead of forestry in taking advantage of this expertise. In agriculture, for instance, there is a vast literature on collaboration between scientists and farmers (farming systems research and development); in gender and diversity studies, the relevant and often neglected knowledge of women and other marginalized groups has been demonstrated repeatedly; in health and family planning, the use of and cooperation with traditional practitioners has blossomed in recent years.

Knowledge

First, many local communities have a vast store of knowledge, based on generations of day-to-day experience with their environment. This knowledge is typically unavailable in any immediate sense to newcomers (such as forestry professionals and other formal forest managers). This knowledge can be holistic, such as practical understanding of how local ecology functions.[6] Kenyah and other Bornean Dayaks have agroforestry systems that make use of natural processes of regeneration after forest clearing for environmental and economic services; that they have a holistic understanding of their own systems has been demonstrated in numerous ethnographies.

Leach and Mearns (1996) have compiled a series of analyses of large scale and long term development efforts built on inaccurate understanding by outsiders of African ecological contexts—contexts that are in many cases understood and manipulated by local people to their advantage. Such major misunderstandings are common when managers, politicians, and researchers do not listen to local people.[7]

Fairhead and Leach (1996), for instance, have done exhaustive historical studies showing that rather than an invasion of savannahs from the north, in northern Guinée, as is commonly assumed, local people have in fact been central actors in extending forest islands into that savannah. This is a West African example of the kind of overall understanding of ecological processed mentioned above.

Box 1 (excerpted from Fairhead and Leach 1996:109)

"People value forest islands around their villages for numerous reasons, whether for the protection they provide " convenient sources of forest products or for suitable microclimatic conditions for tree crops. Historically, forests reinforced fortification, and parts of them continue to house men's and women's initiation and ritual activities. Inhabitants therefore encourage forest island development more or less deliberately, principally by altering fire and soil conditions so as to favour forest regeneration (Leach and Fairhead 1993; 1994). Collecting thatch and tethering cattle on the village margins remove flammable grasses and help create a firebreak. When necessary, this can be supplemented by a targeted burn in vegetation on the settlement margins early in the dry season to reduce the effects of later, more damaging fires. Gardening, villagers assert, tends to create soil structure and water relations favourable for tree establishment. Sometimes settlements are founded on old garden sites, or their margins are deliberately gardened for a limited period to help forest establishment. The village-edge soils are also fertilized by the excreta of domestic animals and people, and by hearth ash and other wastes scattered there. For all these reasons, savannas on settlement margins tend gradually to develop dense semi-deciduous moist forest vegetation. Initial fire-resistant tree species gradually cede to more fire-intolerant ones, pioneer forest species cede to those typical of later forest successional stages, and biodiversity increases over time.

At times, villagers have accelerated the formation and establishment of forest islands by planting trees. Before the twentieth century, for instance, silk cotton (Ceiba pentandra) and other fast-growing tree species were commonly planted as part of settlement fortifications. Islands have also been modified and expanded to create tree crop plantations, whether for the kola anciently valued and traded in this region, for coffee which became an important cash crop from the 1940s, or for the fruit trees and bananas currently favoured by villagers. Villagers also enrich forest islands with useful food, medicinal or construction species, by transplanting wildlings or encouraging their growth from suckers or cuttings.

For inhabitants, then, forest islands are far from the relics of a disappearing 'nature'; instead they are strongly associated with settlement, existing because of it and its everyday activities."

Box 2: (excerpted from Cline-Cole 1996:129)

"Environmental protection and fuelwood production, the two pillars of introduced forestry, rate much less highly as goals in indigenous forestry. The latter places a much greater premium on fruit and food production and shade provision, with environmental protection and fuelwood production being considered of only subsidiary importance. Similarly, although introduced forestry favours a few "dedicated or single-use exotic, species, local inhabitants perceive that, overall, with the exception of the (naturalized) exotics neem (for shade) and mango (for fruit), indigenous multi-purpose species are much better suited to the dominant goals of insider forestry. Such species make up 18 of the 20 species reported as the most frequently occurring farm trees in the drylands (Silviconsult 1991). And, while the Kano State forestry establishment, for instance, speaks of "a total lack of [seedlings and tree] care

[6] As with formal scientific knowledge, local knowledge is incomplete, partial, sometime wrong.

[7] It is important to stress here that listening to local people is different from doing whatever local people want. What I propose involves listening to them, and then working together to develop cooperative and adaptive management that builds on what is good from both local and formal management perspectives, striving to solve problems.

and protection…and [a] general ignorance of the importance of the uses of trees on the part of collectors" (KSAC 1987:6), there is increasing evidence that forestry management practices like the protection of naturally regenerating seedlings, transplanting of wildlings and farm-tree planting continue to be widespread in the drylands (Lockwood 1991; Silviconsult 1991)."

In Box 1, Fairhead and Leach summarize the view local people have of their forest-savannah mosaic in the northern margins of Guinée's forest zone, and how and why they contribute to its expansion:

Cline-Cole (1996) reports similar differences in perception of ecological problems and their solutions, in a Nigerian example, see Box 2.

Ethnographic descriptions of traditional systems abound (cf. for example, the collection by Croll and Parkin 1992, for Africa; Clay 1988, or the Redford and Padoch 1992 collection for South America).

Another kind of knowledge is what has come to be phrased "indigenous knowledge" by many. See for instance, the journal, Indigenous Knowledge and Development Monitor, published in the Netherlands. There is also a worldwide network of Indigenous Knowledge (IK) Centres, listed in this journal. IK usually refers to specific, technical kinds of knowledge, such as forest products in the area and their uses that may be unknown to outsiders, behaviour of local animals, growth habits of local plants, and interactions among local species.

Almost any ethnography that addresses natural resource concerns of the people studied includes some aspects of indigenous knowledge. However, foresters and other natural scientists may be reluctant to confront the jargon and sometimes dense prose of social scientists.

Local knowledge has been approached more directly by anthropologists in the sub-discipline of ethnoscience since the 1950s (Conklin 1957). This research has included local taxonomic classification, keys, componential analyses to determine how local people differentiate among classes. It has drawn from psychology, linguistics, and ethnobotany; and more recently has shared conceptual approaches with the field of artificial intelligence. The results of these studies form an excellent starting point for foresters interested in gaining access to some of the benefits of cultural diversity directly.

The University of Wales in Bangor has an Ecological Knowledge Research Group that publishes studies on agroforestry-related, knowledge-based systems. They strive to integrate local people's knowledge more effectively into interdisciplinary and development contexts. Their computer-based approach, which strives to tap the underlying logic and rules of indigenous knowledge systems by integrating the methods of ethnographers and knowledge engineers (e.g., Southern 1994; Joshi 1997; Walker et al. 1997), also holds promise for application in forestry contexts.

Institutions and Organizations

The second way in which cultural diversity can contribute directly to forest management derives from the existence of indigenous or local institutions and organizations (cf. Ostrom 1990, 1994; Blunt and Warren 1996). All cultures have institutions, whether we mean by that term, organizations or rules and regulations. Local organizations are natural entry points into communities; they represent patterns of interaction that can serve as communication and mobilization channels; and they can serve as sources of information and inputs by local people into the planning, implementation and evaluation processes necessary for effective management.

In many forested contexts, local people's traditional rules and regulations—which functioned in the past to regulate and monitor access to resources—have been weakened by ineffective state efforts to establish control (cf. Peluso 1994; Dove 19??; Cline-Cole 1996; Colfer et al. 2000). However, in many areas, sufficient strength remains on which to build, if external managers were to support local efforts in this regard.

Human Resources

The third way in which cultural diversity and forestry come together pertains to the human resources local people represent. In the broadest terms, their creativity is currently unavailable in most forest management contexts. Although local people are there, their input is not sought, their views and potential solutions not heard.

However, to get more specific, one particular role they could, but normally do not, play involves monitoring. Problems of both local communities' and other external actors' (like loggers, plantation companies, conservation projects) failing to comply with regulations are commonplace.

In West Kalimantan, where I worked with local communities to co-manage a wildlife reserve in the early 1990s, we found that logging companies were not complying with the governmental regulations stipulated in their contracts. The government did not have the funds, personnel, or even expertise, to monitor such contracts; the result was that the timber companies had a free rein. This example was by no means unique.

Involving local communities in the monitoring activity—assuming they could also be involved in setting the regulations to be followed by all parties—could ensure routine availability of monitoring personnel, with a motivation to monitor effectively.[8] Simply letting local people know the existing regulations would be a first step in many areas, like West Kalimantan. Going beyond that, to joint regulation setting, could result in progress toward a more equitable division of benefits from forest use than is currently the case in many forests.

Conclusions and Actions

So what does all this imply? When I think of forest management I carry with me a number of assumptions. I assume, for instance, that we want to maintain the environment, ensure continued production of forest products, and maintain and hopefully improve the quality of human life in and around forests. I also have concluded that in both forested and human contexts, the normal state of affairs is dynamic and changing, that complexity is and will continue to be the order of the day. Finally, I assume that sustainability of all these things involves serious value judgments—on the part of all stakeholders.

If we are interested in all these things, I think there are some implications for the training of future scientists and managers (both social and biophysical). We all need to learn more about each other's disciplines, and learn more open-minded attitudes that can enhance our abilities to work together. Foresters would benefit from more exposure to what we already know about cultural diversity, particularly as it relates to forestry issues; and social scientists could do a better job of contributing their expertise if we understood more about biophysical sciences. Both would benefit from reductions in jargon. These are long term goals….and the truth is, the forests and the cultures they have spawned are being degraded and disappearing at frightening rates.

We have concluded at CIFOR that we must orient some of our research to improving forest management by trying to integrate the culturally diverse knowledge and institutional systems, and local human resources with other extant systems of management—now. We are hypothesizing that more collaboration among stakeholders and more institutional learning (adaptiveness) will result in better management. To test this, we have selected a range of forested sites in forests in Asia, Africa and Latin America (varying by forest quality, stakeholders, management goals, devolution status, and other dimensions); and we have developed or identified a set of tools, methods, and approaches that we are making available to research partners, including local people. We are using "fuzzy", qualitative methods (like participant observation, participatory action research, and future scenarios analysis), quantitative methods (like Multi-Criteria Analysis, multi-dimensional scaling, surveys), and computer assisted methods (Multi-Agent Systems (CORMAS), Criteria and Indicators Modification and Adaptation tool (CIMAT), and Analytic Hierarchy Process (AHP)) to bring about more adaptive and collaborative management in our research sites. We are monitoring and comparing these processes.

We are taking a two pronged approach—trying to make changes, while observing what we are doing—knowing that our ability to remain objective will be questioned. However, we have concluded that the complexity and dynamism of social and forest contexts, combined with the urgency of finding solutions to the world's forest management problems, require drastic measures. Our approach is novel and throws up many challenges, but presents rich opportunities for learning about how people transform new information into knowledge and action. We think it is essential that we begin to have a better understanding of how to strengthen the adaptive capacity of human societies. Ultimately, these sorts of approaches embodying collaborative learning and adaptation must succeed.

Greater attention needs to be paid to the link between research and its impacts. As noted above, the forests are disappearing quickly and the diverse cultures within them are under attack. More creative means must be found to make research findings—whether indigenous knowledge, effective institutional arrangements, locally adapted monitoring systems, or specific silvicultural techniques—available quickly to those who can use them. If we do not create or identify innovative strategies for increasing our impact, we are in danger of serving only to document the loss of two kinds of global heritage: our forests and our cultures.

Most fundamentally, we have to move on from a forestry culture that excludes people. The world's forests as they exist today are the product of millenia of interactions between people and their environment. The more we study

[8]Cf. some of the Joint Forest Management experience in India (e.g., Poffenberger and McGean 1996), Nepal's organization of user groups to manage forests (e.g., Hobley 1996), Philippine experience with Ancestral Domains and the work of the Department of the Environment and Natural Resources (e.g., Cornista and Escueta 1990) represent good Asian examples, reported in the Asian Forestry Network series coordinated by Poffenberger (see also Carter 1996). The best known African example of course is Zimbabwe's CAMPFIRE, where communities have been involved in wildlife protection for some time now (Child and Peterson 1991). In Latin America, McGrath et al. 1999 discuss similar issues in relation to fisheries management.

even the most remote and pristine forests, the more we realize that the

hand of humanity is everywhere. The present biodiversity of our forests is a product of the co-evolution of forests and people. More importantly, in all societies, rich and poor, there are people who value forests. Many people, myself included, feel better and safer and more fulfilled when diverse forests occupy a significant place in our landscape.

I suspect that, on that note at least, I will find unanimity among those gathered here today.

IUFRO Awards and Honours

IUFRO Scientific Achievement Awards (SAA)

The IUFRO Scientific Achievements Award Winners

Dr. Angelstam, Per Krister, Sweden
University of Agricultural Sciences, Grimsö Wildlife Research Station
- For scientific achievements in the field of ecological structure and processes in natural taiga-landscapes.

Dr. Bhat, K. M., India
Kerala Forest Research Institute, Division of Wood Sciences
- For his fundamental and applied research in the fields of forest products, wood sciences and technology.

Dr. Dancik, Bruce, Canada
University of Alberta, Department of Renewable Resources
- For his outstanding contributions to forest genetic research, sustainable forest management practice and leadership in forest policy development.

Dr. Kangas, Jyrki Juhani, Finland
Finnish Forest Research Institute, Kannus Research Station
- For research achievements and world-wide recognition in the areas of optimization methods, modelling expertise and participatory and interactive planning of multi-functional forestry.

Dr. Lee, Su See, Malaysia
Forest Research Institute Malaysia, Kepong, Kuala Lumpur
- For scientific contributions to forest pathology as applied to diseases of fast-growing plantation trees and to dipterocarp ectomycorrhiza research.

Dr. Price, Colin, U.K.
University of Wales, Bangor, School of Agriculture and Forest Sciences
- For contributions to science and distinguished research achievements in the field of theory and application of forest and environmental economics.

Dr. Reed, David D., USA
Michigan Technological University, School of Forestry and Wood Products
- For his research on forest biometrics as applied to the quantitative assessment of impacts of stress on forest trees and stands.

Dr. Vertessy, Robert Alexander, Australia
CSIRO Land and Water Canberra; Cooperative Research Center for Catchment Hydrology (CRCCH)
- For scientific contributions in the field of deterministic modelling of forest catchment hydrologic processes and in the area of hydrologic field measurement techniques.

Dr. Wingfield, Michael J., South Africa
University of Pretoria, Forestry and Agricultural Biotechnology Institute
- For research achievements in the field of plant pathology and the establishment of the Tree Pathology Cooperative Programme.

Dr. Yeh, Francis Cho-Hao, Canada
University of Alberta, Department of Renewable Resources
- For pioneering achievements in the field of molecular, population and quantitative genetics of forest trees.

Prof. Dr. Gensiruk, Stepan Antonovych, Ukraine
Ukrainian State University of Forestry and Wood Technology, Department of Forestry
- For his research achievements in dynamics of forest changes in mountainous areas and formulation of ecological system for managing nature reserves.

Outstanding Doctoral Research Award (ODRA)

Dr. Hui, Gangying, China
Chinese Academy of Forestry Beijing, Research Institute of Forestry
- Dissertation in 1998, at the University of Göttingen on Integrated Growth and Yield Model System for the Tree Species Cunninghamia lanceolata.

Dr. Kropil, Rudolf, Slovakia
Technical University Zvolen, Department of Forest Protection and Wildlife Management
- Dissertation in 1994, at the Technical University Zvolen, on Structure and Production of Breeding Bird Communities in Selected Natural Forests in Slovakia.

Dr. Muschler, Reinhold G., Costa Rica
Tropical Agricultural Research and Higher Education Centre
- Dissertation in 1998 at the University of Florida, on Tree-Crop Compatibility in Agroforestry: Production and Quality of Coffee Grown Under Managed Tree Shade in Costa Rica

Dr. Skovsgaard, Jens Peter, Denmark
Danish Forest and Landscape Research Institute, Hørsholm
- Dissertation in 1997, at the Royal Veterinary and Agricultural University,
on Management of Sitka Spruce without Thinnings.

Dr. Sudin, Rahim, Malaysia
Forest Research Institute Malaysia, Kepong
- Dissertation in 1996, at the University of Sheffield, on Development, Properties and Durability of Oil Palm Fibre Cement Composites.

Dr. Wei, Rung Peng, Canada
University of Alberta
- Dissertation in 1995, at the Swedish University of Agricultural Sciences, on
Prediction of Genetic Diversity and Optimizing Selection in Breeding Programs.

Dr. Radeloff, Volker Christian, USA
University of Wisconsin-Madison, Department of Forest Ecology and Management
- Disturbance regimes and landscape scale management in the northwestern Wisconsin Pine Barrens, USA.

Honorary Membership

Honorary Membership is IUFRO's highest award; it acknowledges persons who have rendered particularly important services to the Union. The award consists of a certificate, in Latin, commending the individual for excellent work carried out for IUFRO.

Prof. Dr. Franz Schmithüsen
The Swiss Federal Institute of Technology The ETH, Zurich, Switzerland

Dato' Dr. Salleh Mohd Nor
Tropbio Research Sdn. Bhd., Malaysia

IUFRO International Council

The International Council IUFRO

The International Council (IC) is the supreme authority regulating the affairs of the Union and guiding its Executive Board. According to the IUFRO Statutes, each country, in which IUFRO has a Member Organization, has one delegate and an alternate member in the IC, irrespective of the number of the member institutions. The IC meets in practice only when a World Congress is in Session and acts as a General Assembly of the Union.

The IC traditionally has two meetings at the World Congress. This arrangement allows the delegates to re-discuss Agenda items, e.g. change of Statutes, after elaboration in country delegations or, in the case of Congress Resolutions and Recommendations, gives the IUFRO Secretariat time for translation into the four IUFRO languages. The meetings were held on 8 and 11 August, 2000, at the Legend Hotel, Ballroom 1, Kuala Lumpur, Malaysia.

The President of IUFRO officiates as the Chairman and the Secretary of IUFRO as the Secretary of the Meeting. 50 plus one per cent of all the countries represented in IUFRO (at the time of the XXI IUFRO Congress, 55 authorized representatives) are required for a quorum. The voting procedure of the International Council is as follows: Any modification of the Statutes of the Union must be adopted by a majority of two thirds of the valid votes cast. (At this Congress the figure was 37 votes in favour.) Decisions not affecting a change of Statutes must be supported by a simple majority of the IC Members present. Each country represented in the IC has one vote.

The President's report covered all major achievements and highlights of the last inter-Congress period. A brief summary reads as follows:

- The Executive Board took account of the Resolutions of the XX IUFRO World Congress in Tampere, Finland.
- It drew up a Strategic Plan for the Union.
- It issued Bidding Rules for IUFRO Congresses.
- It established the Terminology Project based at the IUFRO Secretariat.
- It developed and expanded an incomparable web site.
- It increased the number of IUFRO publications, including creating a new series published jointly with CAB International (CABI), the IUFRO Research Series.
- It established the Global Forest Information Service, an Internet-based meta-data service to coordinate world-wide access to forest information.
- It strengthened and enhanced the work of the Special Programme for Developing Countries and the IUFRO Secretariat.
- The Executive Board commissioned an external Review of the IUFRO Secretariat, SPDC and Terminology Project.
- A common format for Agenda papers submitted to the IC was developed.
- Three Honorary Memberships were proposed to and later agreed by the IC by ballot vote. Honorary Membership was conferred on:
  Howard Kriebel, USA (handed over at the Division 2 Meeting in Beijing, China, in 1998)
  M N Salleh, Malaysia (1999, but handed over formally at the IUFRO Congress)
  Franz Schmithüsen, Switzerland (2000, and handed over at the Congress)
- It prepared amended IUFRO Statutes for decision by the International Council.

The IC Meeting approved the Resolutions of the XXI IUFRO World Congress, addressed to all Member Organizations and governmental authorities responsible for forest affairs in IUFRO countries. The Resolutions addressed six topics: Role of Forests and Trees in Human Welfare; Attention by Policy-Makers; Role in Intergovernmental Processes; Research and the Input of Forestry Activities; Information; and Research Capacity. The Resolutions were translated into the four official IUFRO languages and distributed to Congress participants at the Closing Ceremony.

The IC Meeting decided on the venue of the XXII IUFRO Congress. According to the newly adopted Bidding Rules the offer to the IUFRO members of Australia, to hold the Congress in Brisbane, in August 2005, was accepted.

The IC decided on and approved new IUFRO Statutes. Important points were:

- Change in IUFRO's English title – from "Forestry" to "Forest". It reads now "International Union of Forest Research Organizations".
- Introduction of the post of "Executive Secretary".
- Clarification of the roles of President and Executive Secretary, to maximize transparency and minimize overlap while enhancing management of the Union's business.
- Change of focus for the International Council to provide advice to the President and Board and to facilitate its work in guiding IUFROs policy.
- Meetings of the International Council outside the Congress may be called by the President. He may call

such meetings for decision-making purposes, physically or electronically or by mail.
- Introduction of voting by proxy in International Council business to maintain international equity, recognizing that some members are unable to attend all meetings and to obtain a quorum of voters for major issues.
- Removal of gender-specific text.
- Creation of new categories of awards to enhance the recognition of high-quality scientific research.
- Addition of the category of "Sustaining Member" for organizations or individuals providing substantial financial support to the Union.
- Cessation of Board membership for members from Regions and increase in the number of General Members of the Board in order to achieve a more equitable representation of geography, gender, nationality and scientific discipline.
- New names for the Vice Presidents:

  Vice-President Science for the former Vice-President Programme and
  Vice-President Policy for the former Vice-President Administration.

After the second IC Meeting the traditional IUFRO President's Reception took place. On Saturday, 12 August, a Tree Planting Ceremony at the "Taman Tasik Permaisuri", "Queen's Lake Gardens" at Cheras was attended by the IC Members. Five species of Malaysian native tree species had been selected for tree planting.

The IC Meeting was attended by 55 IC Country Representatives at the first part on Tuesday, 8 August, and by 57 IC Country Representatives at the second part on Friday, 11 August, 2000. 109 countries were entitled to representation, see the list below.

IUFRO Five-Year Report

Five-Year Report of IUFRO

Report by Professor Jeffery Burley

President of IUFRO

In my period as President I have reported annually in detail to IUFRO's Policy and Planning Committee and to the Executive Board on my Presidential activities; these reports are available in the minutes of the meetings of these bodies. In addition, after each Executive Board meeting, I have written to members of the International Council and to Directors of Member Organisations to inform them of the major outcomes of the Executive Board meetings and of other significant activities in which IUFRO has been involved. The reports of the two Vice-Presidents and Treasurer will cover the programme, administrative and financial activities of the past five years.

Therefore, for this meeting of the International Council, I will highlight activities leading up to items on this agenda that require IC approval; for these and other agenda items, IC members should have received the background papers.

As it began its work in 1996, the Executive Board took account of the resolutions of the 20th IUFRO World Congress in 1995 and the changes that were then occurring in forest policy, management and research; it drew up a strategic plan for the Union. In addition to planning the 21st Congress and a large number of meetings of research units and Task Forces, the Executive Board considered the structure, aims and activities of our Union to carry out this strategic plan. It noted that environmental stresses and increased human demands on natural resources require knowledge and decisions that address social, economic and environmental needs; the scope of these requires more interdisciplinary science and stronger linkages among all stakeholders. These in turn require stronger links between policy and science, more widespread dissemination of research results and a wider membership of the Union itself from institutions and individuals concerned with research in forests but not necessarily in forestry per se.

The Executive Board therefore:- (i) expanded the number of cross-disciplinary Task Forces to eight; (ii) obtained official observer status in a number of international fora and agencies; (iii) enhanced the work of the Special Programme for Developing Countries; (iv) strengthened the Secretariat (with great support from the Government of Austria and the Federal Forest Research Centre in Vienna) to support the scientific work of the Divisions and the policy work of the EB; (v) developed and expanded an incomparable Web site; (vi) increased the number of IUFRO publications, including creating a new series published jointly with CABI (the IUFRO Research Series), and (vii) established the Global Forest Information Service, an Internet-based metadata service to coordinate world-wide access to forest information.

In addition, IUFRO comprised nearly 700 Member Organisations with 13,000 scientists; these contributed to 268 research units, 8 Task Forces, 1 Special Programme and 1 Project that organised 334 meetings in 65 countries of which 41 were developing and emerging economies. These resulted in, inter alia, 91 sets of proceedings. In addition, 9 Occasional Papers, 6 IUFRO World Series books and 4 IUFRO Research Series books were published. The IUFRO News appeared quarterly in English and four-monthly in Spanish while, of course, an annual report was published each year.

The Executive Board commissioned an external review of the Secretariat, Special Programme and Project; this was chaired by Honorary Member and former Vice-President Administration, Jim Cayford, and comprised eminent members including the late Abdou-Salam Ouedraogo of IPGRI who tragically died in an air accident while on official IPGRI duty. The report of this exhaustive and intensive review, coupled with the EB's view of external and internal developments, led to the proposals for the new EB structure and committee structure shown in the attached four figures; in order to allow a prolonged and substantive discussion of future strategies and structures, this will be considered as agenda item 12 at the second IC meeting although discussion of the revised Statutes and Internal Regulations that resulted from these proposals will be considered in both meetings (as items 7 and 8).

Figure 1 shows the functional needs of IUFRO and highlights the need for the scientific, disciplinary activities of Divisions to associate more closely with those of other international professional societies, while at the same time seeking interdisciplinary activities stimulated by Task Forces to support intergovernmental and national policy requirements.

For ease of comparison, Figure 2 and Figure 3 show the current and proposed Board structure. Although these do not have to be approved per se by the IC, they illustrate the thinking that led to the proposed revised Statutes and Internal Regulations. Figure 3 in particular contains four salient features:-

(i) IUFRO should develop clear strategies and programmes for science and policy, each under the leadership of a Vice-President;

(ii) in order to involve the IC ever more closely in the policy guidance of the Board, the current Members from Regions and Presidential Appointees are replaced by up to 10 General Members to be approved by the IC. These would seek to balance the geographic, scientific and gender composition of the Divisional Coordinators and Deputies;

(iii) while the Treasurer will continue to be located in Switzerland and the Secretariat in Vienna, it is clear that collectively they provide the administrative and financial support for the Union; it is proposed to rename the Secretary post as Executive Secretary to reflect the vast amount of daily work in managing theUnion;

(iv) together all these changes will free the President for more strategic thinking and for even greater representation of the Union externally.

The Executive Board established an Ad Hoc Committee to revise the Statutes and Internal Regulations in the light of these planned developments. This Committee was chaired by Karel Vancura, met several times, corresponded frequently and produced draft versions that were discussed by the Policy and Planning Committee and by the full Executive Board at several meetings. Before approving the Statutes, the IC should pay particular attention to those dealing with categories of membership, the replacement of Members from Regions with General Members; the scope of Divisions; the nature of Task Forces, Special Programmes, Special Projects and Chapters; the nature and location of the Secretariat and Treasury; and the change of title from Secretary to Executive Secretary. The Internal Regulations do not require formal IC approval but they are included on the agenda for information and discussion.

It is notoriously difficult to prepare Congress Resolutions that are innovative, stimulating, relevant to those they seek to address, and acceptable to those who attended a congress. The draft submitted to the IC was prepared by the President and the Resolutions Committee and in addition it has already been considered by the PPC and EEB. The IC must approve their style and content so that they can be prepared and translated for announcement and distribution at the closing ceremony.

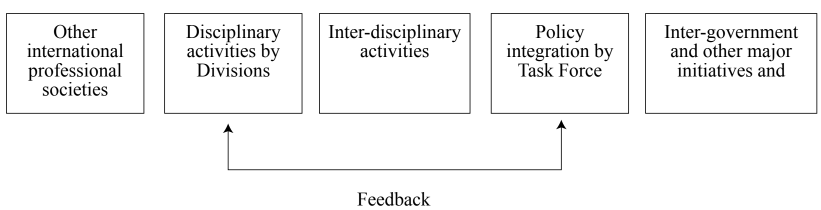

Figure 2. Current EB structure

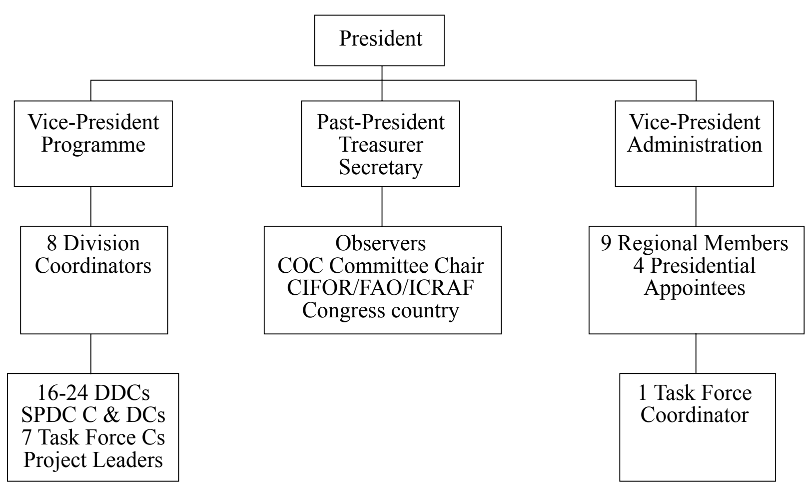

Figure 3. EB Structure proposed

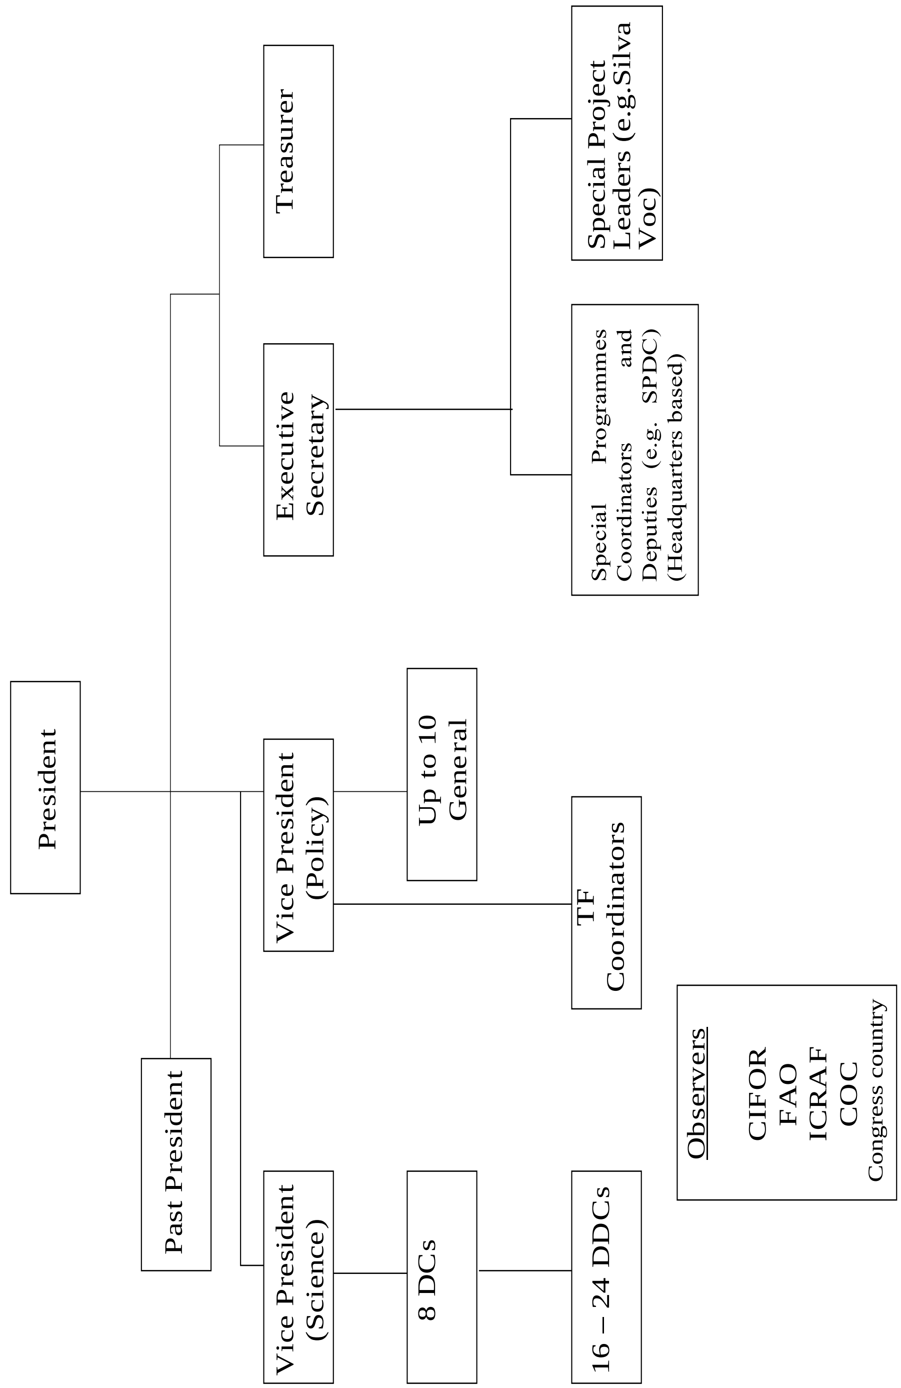

Report by Dr. Risto Seppälä

The Vice President (Programme)

The Vice President Programme (VPP) is responsible for chairing the Programme Committee (PC) and supervising the Special Programme for Developing Countries (SPDC). The PC includes Division Coordinators and their Deputies as well as the Coordinators of research-oriented Task Forces (TF). It approves the terms of reference for new Research Groups and reviews periodically the programmes of the Groups. The PC also develops ideas for new Task Forces.

Two new Divisions were created at the beginning of the 1999-2000 period, and Divisions have also made changes in their internal structure. No new Divisions will be proposed for the next period.

The number of Task Forces has increased considerably during the current term. In all, nine TFs have been established, seven of them reporting to the PC. Four of the existing TFs will continue in the next period.

The SPDC continued to assist in the development of human resource capacity in developing countries and countries with emerging economies. After a successful four-year period, the SPDC Coordinator Robert Szaro returned to his home country, the U.S., and a new Coordinator will hopefully start at the beginning of 2001. During the current term the SPDC has had two Deputy Coordinators, one in Africa and one at the IUFRO headquarters in Vienna.

The most important single task of the PC is to plan the structure and contents of the scientific programme of IUFRO World Congresses. For the Kuala Lumpur Congress the PC established a Congress Scientific Committee (CSC) led by Eric Teissier du Cros whose contribution has been crucial to the success of the Congress. This is the first time in IUFRO's history that a special CSC has been in- charge of the scientific programme.

The structure of the Kuala Lumpur Congress is different from that of the previous IUFRO Congresses: the majority of contributions are scientific posters whereas in earlier congresses oral presentations dominated. Another new feature is that most of the programme is based on an open call for papers instead of invitations which have only been applied to Plenary and Sub-Plenary Sessions this time .

In principle, all accepted scientific contributions to the Congress have been reviewed with the aim to raise the quality of presentations. However, as the review system has not yet been fully operational, this aim will be only partially achieved.

In order to emphasize the importance of a synthesis approach, the IUFRO Executive Board requested that every IUFRO research unit should prepare a State-of-Knowledge Report (SKR) indicating what we know and what we do not know. At the Kuala Lumpur Congress many units will deliver their SKRs.

During the current period most Divisions have had Interdivisional or All-Division-Meetings, while the Task Forces held their meetings, too. The first Latin American Regional Congress took place in 1998. Although the importance of these major mid-term congresses is increasing, most IUFRO meetings are at the level of divisional units. Over 300 meetings have been held this term by the Research Groups and Working Parties.

A considerable amount of proceedings and other publications have been generated from these IUFRO meetings. Sales of IUFRO's Occasional Papers and World Series publications have been good. In addition, a new IUFRO Research Series publication was launched in 1999.

Some Task Forces have actively contributed to international processes. In fact, two most recently established IUFRO TFs originated from the intersessional activities in support of the Intergovernmental Forum on Forests (IFF). In addition to the impact of IUFRO on international processes, the individual scientists of the Union have made major contributions to international meetings, such as the World Forestry Congress.

This report tries to be short and therefore it can describe only a few highlights of the IUFRO programme activities. Most of the work, including the most important ones, has been done in the respective Divisions and in their corresponding units, as well as in the Task Forces. IUFRO's more than 700 office-holders are the core of the Union, and its future will depend on the success of their activities.

The work of the VPP and the PC would not have been possible without the support of the IUFRO Secretariat. The whole Vienna staff has shown extraordinary dedication to the Union, but we owe our special gratitude to the IUFRO Secretary, Heinrich Schmutzenhofer, whose capacity remains unmatched also in difficult times.

Report by Dr. Jacob L. Whitmore

Vice President (Administration)

Background

In accordance with the Internal Regulations of the Union, the Vice President (Administration) (VPA) is responsible for chairing the Administration Committee (AC) which also includes the Treasurer and at least four other members of the Executive Board (EB). During the 1996 – 2000 period, the AC included the Treasurer, the Secretary, all Members from Regions, the four Presidential Appointees, with the VPA as Chair.

The main functions of the AC are to:-

- Review periodically the financial status of the Union,
- Recommend to the EB an annual budget setting forth major fund commitments,
- Recommend to the EB investment policies appropriate for the Union,
- Propose new or improved administrative procedures and operational guidelines for the Secretariat or any one of the Union's administrative or technical bodies.
- Provide leadership in developing strategic guidance for the Union, in the form of strategies and new ways of doing business; and
- Assist the EB in communications that enhance membership and general public awareness of the Union

In addition to Chairing the AC, the VPA also served as Deputy Chair of the Nominating Committee (NC), Member of the Policy and Planning Committee (PPC), the Statutes and Internal Regulations (S&IR) Ad Hoc Committee, the Resolutions Committee and the Finance Committee, and Chair of the Ad Hoc Congress 2005 Committee. The Public Relations Committee, also Chaired by the VPA, was rather inactive during this term, but many of its functions were covered by sub-committees within the AC.

Administration Committee

At the XX IUFRO Congress in Tampere, Jerry Sesco was elected as VPA by the International Council (IC). However, at the beginning of 1997 he was given a new, non-research position in his agency and resigned the VPA post. Jacob L. Whitmore was then elected as VPA to fill the remainder of the term. Most activities of the AC, summarized in the sections below, were not greatly affected by this transition, largely because Dr. Sesco had reached the 'final draft' stage for, or at least had set in motion, many of the AC activities planned for this term.

IUFRO Strategy

In December 1995, the new VPA-elect was requested to draft an IUFRO Strategy, with input from EB members. This was a continuation of efforts which begun prior to April 1993. A revised draft was presented to the 1996 EB by Dr. Sheila Andrus, Assistant to Vice President Sesco, with a final version presented at the 1997 EB. A summary was included in the IUFRO Brochure, presented at the World Forestry Congress at Antalya.

Congress Bidding Rules

The AC initiated guidelines for the procedure of bidding for future Congress venues. A draft of these was presented at the 1996 EB by Sheila Andrus, and further modified at the 1997 EB. The Secretary distributed the final version to all member organisations (except Malaysia), in anticipation of Congress 2005.

Increase / Vitalize Membership

The membership of this ad hoc committee was established at the 1996 EB, to be chaired by Prof. Prem Khosla. Primary focus was on regional or national levels; costs/benefits of IUFRO membership; financing member subscriptions; and donors' roles in support of member institutions. A strategic plan was developed, aimed at increasing membership.

Improvement of Cooperation with the IC

The 1996 EB set up an Ad Hoc Committee on Informing the IC, as well as looking at the role of the IC. It was agreed that the EB should depend more on the IC for advice, public relations and membership. With the help of Dr. David Flinn, guidelines were spelled out on how to better inform the IC on issues to be raised at the IC meeting in Kuala Lumpur. Feedback from the IC on how well informed they were prior to this meeting would help guide the next EB.

International Relations Task Force

This TF was created by the 1996 EB. Its purpose was to a) inform the EB of current issues and initiatives dealing with forestry and their implications in research, b) identify IUFRO's expertise in relevant forestry topics, important in association with mega-tendencies, so that it may get involved through its various working parties and research groups, c) prepare state of the art reports and a shopping list of research needs, and d) assist in improving IUFRO's image and in establishing collaboration with international agencies and initiatives. Led by Ruben Guevara, a report was presented, which may serve as guidance for the next EB.

Honors and Awards Committee

Members of this Committee included J. Burley, D. Flinn, A. Furuberg, R. Guevara, J. Prado, C. Sales, M. N. Salleh, H. Schmutzenhofer, L. Sennerby-Forsse, and A. Winkler, with J. Youngquist as acting chair. The selected members represented both the Programme and Administration Committees and reported to the Executive Board through the Administration Committee. In summary, there were 3 persons nominated for Honorary Membership, 11 selected for the Scientific Achievement Award, and 27 selected for the Distinguished Service Award. There were two new awards created, and 7 people were selected to receive the Outstanding Doctoral Research Award, and 9 people will be selected at the Congress for Best Poster Awards. The IUFRO Honors and Awards booklet will be updated to include these additional forms of recognition.

IUFRO Net, Internet Networking

Near the end of 1995, a paper was developed entitled "IUFRO-Net: an electronic network to enhance and facilitate communication within IUFRO". It spelled out homepages, mailing lists, newsletters, meetings and proceedings or other publications as components of that communications goal, and proposed a IUFRO-Net Task Force. The members of this new Task Force were identified at the 1996 PPC meeting, and the Task Force, led by Dr. Lauri Valsta, presented a report at the 1997 EB. The members of the Task Force have been extremely dedicated and productive during their tenure, and have contributed greatly to the Union's improved communications abilities.

Increasing Visibility

This ad hoc committee agreed to produce an IUFRO Brochure, in time for the World Forestry Congress, and thanks to the efforts of David Flinn, Prof. Ladislav Paule, and others, this was accomplished. Several inserts were also prepared, including one per Division, a summarized IUFRO Strategy, and an application for membership form. The Brochure was prepared in English, French and Spanish.

Agreement with WSL Re: Treasury

Early in the term, our Treasurer Dr. Schlaepfer left WSL, and it became apparent we would need to concern ourselves with the future location of the IUFRO Treasury offices. Contact was made with Dr. Mario Broggi, new Director of the WSL in Birmensdorf, who agreed that WSL would continue to provide Treasurer/Treasury services to IUFRO.

Fund Raising

An ad hoc Fund Raising Committee was established at the 1997 EB, with Dr. Ruben Guevara as Chair. Fund raising strategies were presented in a report at the 1998 EB. Such strategies included the need for IUFRO to tackle certain world problems, with its membership, in a systematic manner, and in the process to raise some funds for IUFRO Programs. The report also included strategies for IUFRO to work with the private sector, in partnership, seeking mutual benefits through sponsorship of seminars, conferences, workshops, publications and projects. It was concluded that these strategies must be implemented by the Secretariat, and the Board, with participation of key, well-connected individuals in key member organisations.

Finance Committee

At the suggestion of the Vice President (Programme), the AC was requested to consider "the need for a Finance Committee for fund-raising under the aegis of the Administration Committee", at the 1996 EB. Such a committee was established at the 1998 EB, with Dr. John Youngquist as Chair. Terms of reference, an investment policy framework and reporting relationships were developed and approved at the 1999 EB meeting. This information can be found in the minutes (appendix 16) of the 38th EB meeting. The result so far has been better definition of IUFRO's investment strategies, as well as investment in September 1999 of a sizeable portion of IUFRO funds in an investment account with Credit Suisse.

Financial Operations

The AC reviewed annual budgets and financial statements prepared by the Treasurer and the Secretary as well as annual audits. It also reviewed proposals concerning subcription rates, and applications for membership. In all instances, recommendations were made to the Executive Board concerning these, and other financial issues. The AC has noted repeatedly the financial soundness and health of the Union.

Statutes and Internal Regulations

The AC oversaw the Ad Hoc Committee for Revision of the Statutes and Internal Regulations (S&IR), led by Dr. Karel Vancura. Having begun in mid-1997, Dr. Vancura's task was especially difficult due to recommendations by a Review Panel (see below) which required much of the pre-1999 S&IR work to be re-done. The revised S&IR, as recommended by the EB, were sent out to the IC in May, 2000. The International Council will need to vote on these S&IR, the week of the congress.

Review Panel

President Burley established a Review Panel at the 1998 PPC, led by previous VPA James Cayford, to visit the Secretariat and make recommendations regarding the Secretariat and the SPDC. The VPP and VPA drafted TOR for the Review Panel, and with the President, participated in the Review. The AC examined each of the Panel's recommendations and made its own observations to the EB on each. As mentioned above, the S&IR had to be re-revised based on EB approval of individual Panel recommendations. One of the Panel's recommendations changes the role of the VPA to a Vice President (Policy), and re-names the VP (Programme) as Vice President (Science).

Nominating Committee

A Nominating Committee was proposed at the 1997 PPC meeting, with the mandate to consider a "person's initiative and input, his/her ability to attend meetings, as well as the international distributions of the candidates". Membership of this committee was approved at the 1997 EB meeting, with the Immediate Past President, Dr. Salleh, as Chair. All EB members were requested to recommend nominees for the new EB/EEB, and over 80 names were submitted. Most of these agreed to serve, if elected. Nominations from the Divisions regarding Division leadership were given special attention. The revised S&IR call for up to ten General Members to replace the current Presidential Appointees and Members from Regions, and the slate of nominees reflects this. The slate of nominees, as recommended by the EB, was sent out to the IC in June, 2000. The International Council will need to vote on these nominees, the week of the congress.

Congress 2005

Bids to host Congress 2005, based on the new Congress Bidding Rules, were received by May 1998. It quickly became obvious that of these, Australia was the more serious contender, and the 1999 EB recommended Brisbane, Australia as the venue for the IUFRO World Congress, to be held 8—14 August, 2005. The IC will need to vote on this matter, the week of the congress.

Concluding Remarks

As is true with most organisations, certain IUFRO officers tend to take on a much larger than average share of the workload. These are the extraordinary people who ensure the success of an organisation, who are usually ready to apply themselves even more to the tasks at hand for the benefit of all, in spite of being already overloaded with work. As is often the case, these people are often not recognised publicly for their accomplishments. The EB members know them all too well; indeed some of them are EB or EEB members. Their contribution is a major reason for the health and well-being of IUFRO since 1995.

One of these must be mentioned here, as he served as back-up to the VPA for AC and other VPA duties. David Flinn energised the AC, the PPC and the EB with his insight and can-do attitude. Many of us assumed and hoped he would move up within the EB for next term, but must respect his reasons for not doing so.

In addition to the above, the Austrian Staff specifically, and the contribution of the Austrian Government in general, must here be recognised. The professionalism and dedication of those at the Secretariat is another major reason for the success of IUFRO during this current term.

To all of these fine people, and especially to Rita Z'berg of Birmensdorf for her superlative work on the IUFRO Treasury, we owe our gratitude.

Report by Dr. Lisa Sennerby Forsse

Division 1 Coordinator
Silviculture

Coordinator	:	Lisa Sennerby Forsse,
Deputy Coordinators	:	John Parrotta
		Menachem Sachs,
		Rodolpho Salazar,
Web master	:	Jerry Vanclay

Introduction

In Division 1 Research and Development is focussed on studies of forest and ecosystem management in natural and artificial silvicultural systems in the boreal, temperate and

tropical zones. The use and communication of results from R&D are based on a common appreciation that the use of silvicultural methods when tailored to a given site makes it possible to achieve environmentally and economically sound sustainable management.
The activities are organised in nine Research Groups, (RG):-

- Stand Establishment, Treatment and Amelioration
- Improvement and Silviculture of Oaks
- Tropical Silviculture
- Short Rotation Forestry for Biomass Production
- Improvement and Silviculture of Beech
- Forest Vegetation Management;
- Unevenaged Silviculture
- Agroforestry and
- Restoration of Degraded Sites.

Under the main theme of each RG there are Working Parties (WP) dealing with different topics. Under the present 9 RG's there are 30 WP's which adds up to a total of 39 units within Division 1. Division officers total about 100 representing more than 40 nations.

Changes in Division Leadership During the 5-year Period

In 1997 Dr. Les Whitmore was appointed new Vice-President for Administration of IUFRO and Deputy Coordinator Professor Lisa Sennerby Forsse was elected new Division 1 Coordinator. She was at that time research manager for Silviculture and Environment at the Swedish Forestry Research Institute, SkogForsk, in Uppsala, Sweden, and adjunct professor in Silviculture and Short Rotation Forestry at the Swedish University of Agricultural Sciences. Dr. John Parrotta from the International Institute of Tropical Forestry in Rio Piedras, Puerto Rico, was elected to replace Sennerby Forsse as Deputy Coordinator of Division 1.

Web Pages

During this period the Divisions web pages have been completed and each unit has its own homepage. The Coordinators of each unit are supposed to submit a short statement about their unit and give information about already achieved as well as planned activities. It is important that the information on the homepage is regularly updated.

Events 1996-2000

During the period, Division 1 and its Research Groups and Working Parties sponsored 57 symposia, workshops, conferences and study tours with an even distribution of meetings over the five years. Out of the 57 meetings, 21 meetings were held in developing countries and 3 meetings were held in countries with economies in transition. The number of publications recorded by the Secretariat is 12 and the probable number of publications is about the double.

Interdivisional Meetings

1997

Divisions 1 and 8: Managing Productivity in Plantation Forestry. Concepcion, Chile. May 5-9, 1997.
Divisions 1 and 8: Conference on Tropical Secondary Forests: Science, People and Policy. Turrialba, Costa Rica, 10-12 November 1997.

1998

Divisions 1, 4, 6 and 8: Forest Ecosystem and Land Use in Mountain areas" in Seoul, Korea, October 12-17.
Divisions 1, 3, 6 and 8: "Conference on New Approaches to Integrated Management of Primary and Secondary Forests for the 21st Century". Belem, Para, Brazil. 1998. Co-sponsored by EMBRAPA-CPATU/CATIE/WWF/ CIFOR.
Divisions 1 and 8: "Conference on Tropical Secondary Forests: Science, People and Policy". In Turrialba, Costa Rica, 10-12 November 1998.

1999

Divisions 1 and 8: "Silvicultural problems in mountain regions". In Davos Switzerland September 6-10.
Division 1 and 2: "Silviculture in Latin America". In Santo Domingo, October 18-22.

2000

The XXI IUFRO World Congress: In Kuala Lumpur, Malaysia, 7-12 August.
11 meetings were held by different Division units at the Congress in K.L

Other Events

Establishment of new Working Parties:
WP 1.15.04: Adaptive and social research in agroforestry. Coordinator: Christine Holding, Kenya.

WP 1.07.19: Forest dynamics and yield regulation systems for tropical/subtropical moist forest.
Coordinator: Armin Seydack, Dept of Water Affairs and Forestry, South Africa

Report by Dr. Eric Teissier Du Cros

Division 2 Coordinator
Physiology and Genetics

Between January 1996 and August 2000, Division 2 held 36 scientific meetings and published 10 proceedings. Some of these have been transformed into peer-reviewed books. During the Congress 2000, Division 2 held 10 Group Sessions. It was involved in one Plenary Session ("Matching research to Society Needs", by Christine Dean, a geneticist) and one Subplenary Session ("Management and Conservation of Forest Gene Resources", organised under the umbrella of the corresponding Task Force, by Veikko Koski and Francis Yeh, both Division 2 office holders).

Division 2 kept strong ties with its Siamese brother, the newly created Division 7, Forest Health, after a refined surgical separation in 1995 by Howard Kriebel, past Division 2 Coordinator. Many geneticists and breeders have participated in meetings organised by Division 7, particularly those where genetics and resistance are involved, for instance Research Group 7.01.00 “Physiology and Genetics of Tree/Phytophage interactions”.

Several Important Events Occurring During the 1996-2000 Term Should be Highlighted:

The whole Division 2 Conference was held in Beijing, China, in August 1998 and chaired by Csaba Matyas from Hungary. The local organisation was coordinated by Professor Hong Jusheng from the Academy of Forestry, Beijing, China. The event was called “Third IUFRO Consultation on Forest Genetics and Tree Improvement” and held with the technical collaboration of FAO. More than 100 scientists from 33 countries participated. They were geneticists, breeders, pathologists, entomologists and biotechnologists. A selected set of oral presentations was peer-reviewed and published as a book in early 2000 by Csaba Matyas, entitled Forest genetics and sustainability. Third IUFRO-FAO Consultation on Forest Genetics and Tree Improvement. August 22-28, 1998, Beijing, China. Kluwer Academic Publishing House at Dordrecht, The Netherlands. 287p. Conclusions and recommendations from the conference were published by Teissier du Cros, E., Matyas C., and Paule, L. in: 1999. Contribution of genetics to the sustained management of global forest resources. Third IUFRO-FAO Consultation on Forest Genetics and Tree Improvement. Conclusions and recommendations. August 22-28, 1998, Beijing, China. Forest Genetics, 6(3) 61-64.

China follow-up Congress Sessions. Two sessions were organised by Csaba Matyas for the Congress 2000 as a follow-up of the 1998 Beijing Conference. Their theme was "Future of Breeding and Plantations in a Sustainably-oriented World".

A Honorary Membership. Howard Kriebel has become a Honorary Member of IUFRO. His award was conferred on him by Professor Jeff Burley, IUFRO President, during the Division 2 conference. Howard is still very active in IUFRO as:-

- WD 2.02.15 "Five needle pines".
- Representative of Division 2 on the IUFRO Task Force on the Internet.
- Division 2 web moderator.
- Member of the Ad Hoc Committee for Revision of the Statutes and Internal Regulations.

Congratulations to the Former Division 2 Coordinator!

A Task Force. IUFRO was invited as an observer to the 10th Session of the FAO Panel of Expert on Forest Gene Resources (FGRs), in Rome, in September 1997. It was suggested that IUFRO could provide its expertise in two areas: (1) by creating a Task Force on forest gene resources and (2) by working on the terminology related to this topic (see SilvaVoc report). The principle of a Task Force has been accepted by the IUFRO Executive Board later in September 1997. The Task Force was established in January 1998. Its terms of reference were to:

- • Synthesize scientific information on :
- scientific knowledge necessary for the conservation of FGRs: management of base and breeding populations, maintenance of representative diversity, including rare populations,
- case studies on in and ex situ conservation,
- interactions between human activity and integrity of FRGs, including silviculture, forest operations, agro forestry, forest and landscape management, and others,
- effect of environmental factors on the integrity of FGRs: insect pests, diseases, air pollution, climate change,
- • Organise sessions, particularly during the IUFRO Congress 2000,
- • Prepare publications on all these items.

The Task Force was chaired by Veikko Koski (Deputy of Research Group 2.04.00) until August 2000 and includes representatives of all IUFRO Divisions. Some of these are links with other interested organisations, including FAO, IPGRI (International Plant Genetic Resources Institute) and CIFOR. It is now chaired by Per Ståhl. The Task Force held a Subplenary Session during the Congress 2000 and is currently preparing a State of Knowledge Report.

Coordination. During the 1996-2000 term, the Coordinator and his two deputies have shared responsibilities, as follows:

- Research Groups 2.01.00 (Physiology) and 2.09.00 (Seed

physiology and Technology): Bob Luxmoore, Deputy Coordinator for Physiology.
- Research Groups 2.02.00 (Conifer Breeding and Genetic Resources) and 2.08.00 (Hardwood Improvement, Culture and Genetic Resources): Ladislav Paule, Deputy Coordinator for Genetics.
- Research Groups 2.04.00 (Genetics) and 2.10.00 (Legislation on Forest Reproductive Material): Eric Teissier du Cros, Coordinator.

Additionally, since Eric Teissier du Cros was asked to chair the Congress 2000 Scientific Committee, Bob Luxmoore, with the help of Ladislav Paule, was in charge of the Division 2 scientific programme for the Congress 2000.

The new coordinating team for the 2001-2005 term will be:

- Ladislav Paule, Coordinator
- Bob Luxmoore, Deputy Coordinator for Physiology
- Zohra Bennadji, Deputy Coordinator for Genetic improvement
- Csaba Matyas, Deputy Coordinator for Genetics and Biotechnology

New Working Parties. Two Working Parties have been created:

- 2.08.06: Genetics of Nothofagus, Roberto Ipinza, Chile, Coordinator
- 2.04.10: Genomics, David Neale, USA, Coordinator

Report by Dr. Dennis P. Dykstra

Division 3 Coordinator,
Forest Operations and Techniques

Overall summary	
Total meetings held	61
Meetings held in developing countries	35
Meetings held in countries with economies in transition	5
Publications produced	14

List of meetings by year, 1996-2000

1996

Co-sponsored the “Seminar on Harvesting and Wood Transport” at the University of Paraná in Curitiba, Brazil, 19-23 May 1996.

“International Mountain Logging and Pacific Northwest Skyline Symposium”, [organised in collaboration with FERIC, the Forest Research Institute of Canada, and the University of British Columbia], Campbell River, BC, Canada, May 1996

“Seminar on Environmentally Sound Forest Roads and Wood Transport” [organised together with the FAO/ECE/ILO Joint Committee on Forest Technology, Management and Training], at Sinaia, Romania, 17-22 June 1996.

Co-sponsored the 1996 annual meeting of the Council on Forest Engineering (COFE). Marquette, Michigan, USA. July 1996.

“Mechanisation and Workforce Research Methods”, coordinated by 3.07.00 and 3.07.05, at Garpenberg, Sweden, 18-23 Aug 1996.

“Harvesting, Wood Delivery and Utilization” co-organised with the Canadian Woodlands Forum of the Canadian Pulp and Paper Association a conference on “Certification: Environmental Implications for Forestry Operations” at Quebec City, Canada, 9-11 Sep 1996.

“Safety and Health in Forestry”, organised by the FAO/ILO/ECE Joint Committee, Hueningen, Switzerland, 5-12 Oct 1996.

Nursery Establishment Operations for Difficult Sites. Co-sponsored by 3.02.01 and 3.02.03. Himachal Pradesh, India, 6-12 Oct 1996.

1997

“Planning and Control of Forest Operations for Sustainable Forest Management” in Madrid and at the Valsain Forest in Spain, 16-19 June 1997.

“Natural Substances for Health and Beauty” held in Riga, Latvia, 19-21 June 1997.

“Effects of Timber Production and Harvesting on Product Quality”. With the Forest Products Society. Vancouver, BC, Canada, 22-26 June 1997.

“Simposio Internacional sobre Posibilidades de Manejo Forestal Sostenible en América Tropical”; interdivisional meeting organised jointly by Divisions 1 and 3 together with the BOLFOR Project and CIFOR, Santa Cruz, Bolivia, 15-20 July 1997.

“Sustainable Management of Small-Scale Forestry”. 3.08.00, 6.11.02 and co-sponsors, including Kyoto University, the Japanese Forest Economic Society, the City of Kyoto, Kyoto Prefectural Government, Shiga Prefectural Government, IUFRO-Japan, the Japanese National Afforestation Promotion Organisation, Japan Forestry Association, Japan Forest Technical Association, Forest Policy Research Institute, Japan Wood Products Information and Research Centre, and the European Forest Institute. Kyoto, Japan, from 8-13 Sep 1997.

“Forest Operations in Himalayan Forest, Consideration of Ergonomic and Socio-Economic Problems,” joint seminar 3.06.00, 3.07.00, and 3.11.00 in Thimpu, Bhutan, at 20-23 Oct 1997.

"Timber Harvesting and Forest Transportation" co-sponsored by the Federal University of Viçosa at Vitoria (Espirito Santo), Brazil, from 8-12 Dec 1997.

1998

"Human Factors in Forestry" with the Human Factors Group of Liro Limited at Rotorua, New Zealand, on 17 Feb 1998.
"Harvesting with Quality" joint seminar with the Federal University of Paraná at Curitiba, Brazil, 24-29 May 1998.
Division 3 Officers' Midterm Meeting, Zurich, Switzerland, 12-15 July 1998
"Integrating Environmental Values into Small-Scale Forestry" in Vancouver, B.C., Canada, from 16-20 Aug 1998.
"Third International Conference on Forest Vegetation Management", 3.11.00 and 3.11.03 in Canada 24-25 Aug 1998.
"International Conference on Indicators for Sustainable Forest Management" organised in cooperation with the IUFRO Sustainable Forest Management Task Force. Melbourne, Australia, 24-28 Aug 1998.
"Improving Working Conditions and Increasing Productivity in Forestry". Joint FAO/ECE/ILO Committee on Forest Technology, Management and Training. Zvolen, Slovakia, 9-12 Sep 1998.
"Forests and Forestry Research for the Third Millennium," Zvolen, Slovakia, 11-14 Oct 1998.
"Environmental Aspects in Forest Transportation Infrastructure" ad-hoc session on forest operations in the Division 8 conference "Environmental Forest Science". 3.04.00, 3.06.00. Kyoto, Japan, 19-23 Oct 1998

1999

"International Mountain Logging and 10th Pacific Northwest Skyline Symposium" co-sponsored by 3.06.00, 3.07.00, 3.10.00 and the Oregon State University Forest Engineering Department in Corvallis, Oregon, 28 Mar – 1 Apr 1999.
"Management Alternatives for Thinning Stands from Harvesting and Economical Points of View" was held in Ennis, Western Ireland, 5-7 May 1999.
"Timber Harvesting and Transportation Technologies for Forestry in the New Millennium" with Forest Engineering Southern Africa (FESA), Pietermaritzburg, South Africa, 10-11 June 1999.
Forestry Engineering for Tomorrow (with the Institute of Agricultural Engineers UK and the American Society of Agricultural Engineers), Edinburgh, Scotland, 28-30 June 1999
Forest Operations of the Future (with the Joint FAO/ECE/ILO Committee on Forest Technology, Management, and Training), Pessac, Bordeaux, France, 20-24 Sep 1999
"Interactions between nursery management and silvicultural operations" held 28-30 Sep 1999 at Auburn University, Alabama, USA
"Emerging Harvesting Issues and Technology at the End of the Century" 3.04.00, 3.06.00, 3.07.00, together with the University of Zagreb's Faculty of Forestry, the Croatian Forest Research Institute (Jastrebarsko), and "Hrvatske _ume" Inc. (Zagreb). Sponsored by the Ministry of Science and Technology, the Ministry of Agriculture and Forestry, the University of Zagreb, and the Academy of Forest Sciences in Opatija, Croatia, 27 Sep – 1 Oct 1999.

2000

"Developing policies to encourage small-scale forestry" (3.08.00 together with James Cook University), Cairns, Queensland, Australia, 9-13 Jan 2000.
"Logistics in the Forest Sector" (3.04.00, 3.06.00, 3.10.00 hosted by the University of Helsinki and the Industrial Insurance Company), Helsinki, Finland, 15-16 May 2000.
"New Approaches for the Management of Neotropical Primary Rainforests by Industries and Communities (1.00.00 and 3.00.00 together with EMBRAPA, CIFOR, CATIE, and CIRAD-Forêt), Belém, Pará, Brazil, 4-8 Dec 2000.
XXI World Congress
6-12 Aug 2000 Satellite meeting on "Forest Operations in the Tropics", 6 Aug
Research Group Sessions and Business Meetings organised by 3.02.00, 3.04.00, 3.05.00, 3.06.00, 3.07.00 (2 sessions), 3.08.00, 3.09.00, 3.10.00 (2 sessions), 3.11.00; Divisional Business Meeting (21 meetings)
Co-organised Subplenary Session A6, "Criteria and Indicators for Sustainable Forest Management: A Perspective at the Level of the Forest Management Unit", 7 Aug
Co-organised Subplenary Session C1, "Environmental Change and Forestry", 7 Aug
Co-organised Subplenary Session C2, "Societal Change and Forests", 8 Aug
Organised Subplenary Session B4, "Evaluation of Technologies for Society's Needs", 9 Aug
Co-organised Research Session TF3, "Criteria and Indicators: A Tropical Perspective at Stand Level", 12 Aug

Report by Dr. Klaus v. Gadow

Division 4 Coordinator
Inventory, Growth, Yield, Quantitative and Management Sciences

The Inter-Congress period was characterized by numerous meetings organised by different IUFRO units, including many interdivisional and inter-unit events. The official count of the total number of meetings, the number of meetings conducted in developing countries and meetings in countries with economies in transition is shown in table 1. The average number of meetings per Division IV unit for the 5-year inter-congress period is almost 3 (dividing 77 meetings by 26 IUFRO units) which means that on average each unit conducted a meeting every 1.7 years. There was also an increase of activities in developing countries and in countries with economies in transition.

Table 1. Division IV Meetings and Publications 1996 – 2000.

Year	Number of meetings			Number of Publications
	Total	in developing countries	in countries with economies in transition	
1996	18	5	2	8
1997	12	2	1	4
1998	11	1	0	1
1999	13	2	5	1
2000	8	2	0	8
XXI Congress	15			
Total	**77**	**12**	**8**	**22**

The very high level of activities imediately following the last World Congress is striking. Many people meet during the big events and this appears to spawn smaller professional ones. Division 4 officers made excellent contributions to the scientific program of the XXI World Congress in Kuala Lumpur and conducted important Business Meetings to elect new officers, to refresh and strengthen scientific networks and to plan future events.

Some Conference Highlights

1996

The Second international symposium on spatial accuracy assessment in Fort Collins, USA (Dr. H. Todd Mowrer)
The conference on Modelling regeneration success and early growth of forest stands in Copenhagen, Denmark (Dr. J.P. Skovsgaard)
The Monte Verita conference on Assessment of Biodiversity for Improved Forest Planning, October 1996, Ascona, Switzerland (Dr. Michael Köhl, Dr. Peter Bachmann and Dr Risto Päivinen)
The Non-market benefits of forestry conference in Edinburgh, Scotland (Dr. Hans A. Joebstl, Dr. Maurizio Merlo, Dr. C. Roper and Dr. A. Park).
The Conference on Effects of Environmental Factors on tree and stand growth in Dresden, Germany (Dr. G. Wenk)

1997

The conference on modelling growth of fast-grown tree species in Valdivia, Chile (Dr. Gonzalo Paredes)
The conference on Recent developments in accounting and managerial economics in Versailles, France (Dr. Hans A. Joebstl, Dr. Maurizio Merlo and Dr. G. Buttoud).

1998

The conference on Data management and modelling using remote sensing and GIS for tropical forest land inventory in Jakarta Indonesia (Dr. Keith Rennolls and Dr. Bapak Ir. Sumahadi)
The conference on Institutional Aspects of Managerial Economics and Accounting in Forestry in Ostia, Italy (Dr. Hans A. Joebstl, Dr. Maurizio Merlo, Dr. L. Venzi).

1999

The Remote sensing and forest monitoring conference in Rogow, Poland, organised by Dr. Tomasz Zawila-Niedzwiecki.
The Faustmann conference in Darmstadt, Germany organised by Dr. Sun Joseph Chang.
The conference on Long-term observations and experiments in forestry - focus on tropical forests in Turrialba, Costa Rica, organised by: Dr. Christoph Kleinn and Dr. Michael Köhl.
The Forest Scenario Modelling in Risk Analysis and Management conference in Joensuu, Finland, organised by Dr. Tuula Nuutinen.
The conference on Gaps and solutions in managerial economics and accounting in Forestry in Prague, Czech Republic organised by Dr. Hans A. Joebstl, Dr. Maurizio Merlo, Dr. L. Sizak.
The Forest Assets Valuation conference in Salzburg, Austria organised by Dr. Hans A. Joebstl, Dr. Maurizio Merlo

2000

The Forest Ecosystem Restoration conference in Vienna, Austria; organised by Dr. Hubert Hasenauer
The Information management conference in Munich, Germany; organised by Dr. Hans A. Joebstl, Dr. Maurizio Merlo and Dr. Martin Moog

FRA 2000 and GFIS

During the period 1996 until 2000 Risto Päivinen, Michael Köhl and Gyde Lund compiled various reports and background documents prepared for international expert panels covering remote sensing support for the global forest resource assessment (FRA 2000), estimating global forest change, and cooperation to implement FRA 2000. They represented IUFRO at 5 expert meetings and helped to organise 3 events in connection with FRA 2000.

Awards

For their contribution to IUFRO, which has substantially furthered the aims of the Union, Dr. Hans Jöbstl, Dr. Maurizio Merlo and Dr. Risto Päivinen each received the Distinguished Service Award.

Outstanding Doctoral Thesis Awards were presented to Dr. GangYing Hui from Beijing, China, and to Dr. Jens Peter Skovsgaard from Hoersholm, Denmark.

IUFRO 4.02, 4.11, 4.12 Newsletters - published in April and October each year since 1995.

Report by Mr. John A. Youngquist

IUFRO Division 5 Coordinator
Forest Products

The five-year time span from 1996 to 2000 has produced even more evidence that forests are being squeezed between the growing needs of people and a shrinking resource base. The pressure being placed on the resource also pushes technological developments to help divert those pressures. The trend to more efficiently use resources has accelerated to meet today's challenges. Key areas for utilisation research and development for Division 5 have included learning how to use the changing resource of materials in the forest, extending the resource, and implementing environmentally and socially friendly technologies wherever possible. IUFRO's Division 5 on Forest Products, which consists of 12 Research Groups and 25 Working Parties, has held a total of 51 topic specific research meetings during this 5 year time span, with 6 of them held in developing countries, and 2 of them held in countries with economies in transition. A total of 10 publications resulted from these meetings. The All-Division 5 Conference, held in mid-1997, focused on Forests Products for Sustainable Forestry, and was attended by 222 delegates from 42 countries. Discussions were held on research progress, research needs and concerns to improve 'agreements were developed to further collaborative action to carry forward key ideas and themes which were identified at the meeting. The XXI IUFRO World Congress carried 'meetings held between 1995 and 2000. A total of 97 oral papers and 271 posters were presented, and plans for collaborative research team efforts for developing leading-edge technological developments were put in place. Specific challenges that were highlighted at the Congress included: 1) determining efficient and environmentally friendly ways to extract, reduce, and convert virgin raw materials to products, 2) developing technologies to allow the re-use of materials and products, and 3) insuring that new technologies are transferred to users as quickly as possible.

Report by Dr. Niels Elers Koch

Division 6 Coordinator
Social, Economic, Information and Policy Sciences

Challenges to IUFRO Division VI for the Period 1996-2000

1) Social, economic, information and policy sciences from Division VI should be involved and integrated with the natural and technological sciences' activities in the other Divisions of IUFRO.
2) Criteria and indicators of socio-economic sustainability should be of major focus in our work in accordance with the different international resolutions on forestry.
3) Countries in transition should be better integrated in Division VI membership and programming.
4) Developing countries should be better integrated in Division VI, and we should help them obtain funding so that they can participate more fully in the work of IUFRO.
5) The new information technologies (e-mail, WWW, etc.) will be used to improve information exchange, and Division VI will play a leading role in that adventure, being responsible for information sciences (Research Group 6.03).
6) Division VI, also being responsible for nature conservation (Research Group 6.01), will work to emphasise nature conservation so that IUFRO plays an important role in the scientific work forming the basis for nature conservation.

Changes in Leadership and Organisation
Changes in Leadership

D6.00-00: Coordinator Niels Elers Koch, Danish Forest and Landscape Research Institute, has replaced Harold F. Kaiser, USA.
Deputy coordinators Max Krott, Institut für Forstpolitik und Naturschutz, Universität Göttingen, and Perry Brown, School of Forestry, University of Montana, have replaced Egon Gundermann, Germany, Niels Elers Koch, Denmark, and George Stankey, USA.
For more detailed information on changes in the leadership of the Research Groups and Working Parties, please see the Annual Reports.

Changes in Organisation
New Research Groups:

S6.15-00 New Research Group "Improving Education and Further Education in Forestry".
S6.16-00 New Research Group "Forest Sector Analysis".
S6.17-00 New Research Group "Ecological Economics in Forestry".
S6.18-00 New Research Group "Gender in Forestry".
S6.19-00 New Research Group "Ethnoforestry".

New Working Parties:

S6.03-01 New Working Party "Libraries and Information Services".
S6.03-02 New Working Party "Trends in Forest Terminology".
S6.03-03 New Working Party "Forest Decimal Classification".
S6.03-04 New Working Party "Latin American and Caribbean Information Systems Network".
S6.07-02 New Working Party "Social end Economic History".
S6.07-05 New Working Party "History of Hunting".
S6.11-06 New Working Party "Economic and Social Aspects of Forestry in Countries in Transition".
S6.11-07 New Working Party "Integration of Sociological Research with Forest Management".

Main Activities 1996-2000

All 11 Research Groups have been active during the period. Based on information from IUFRO´s www-server and information from the different Research Groups and Working Parties, a total of 71 meetings were held (including 6 meetings in developing countries and 7 meetings in countries with economies in transition) resulting in more than 17 publications. For more detailed information please see the Annual Reports.

The first ever all-Division VI conference was held in Pretoria and North-eastern South Africa from January 7-15, 1999. The conference focused on the timely topic of the contributions of science to the development of forest policies. Approximately 80 delegates from 19 countries attended with a particularly engaging group of delegates from eight African countries. In addition to the keynote, case study, and plenary presentations numerous research presentation and round table discussion sessions were held. These sessions offered the opportunity for researchers to present their work on the topic and for them to share ideas about research needs, research approaches, and policy developments.

During the period, a strong effort has been made to achieve a comprehensive presentation on the IUFRO net of the Division's units, their mandate and activities. Most Research Groups and Working Parties are now present.

Report by Dr. David F. Karnosky

Division 7 Coordinator
Forest Health

Division 7 was created in 1996 with four Research Groups: 7.01.00 (Physiology and Genetics of Tree/Phytophage Interactions), 7.02.00 (Pathology), 7.03.00 (Entomology), and 7.04.00 (Impacts of Air Pollution on Forest Ecosystems). The leadership of Division 7 included David Karnosky (Coordinator) and Deputy Coordinator Kazuo Suzuki (Japan), Bo Langstrom (Sweden), and Manfred Tesche (Germany). Within the Division there are a total of 31 Working Parties. These Working Parties held a total of 41 meetings in the past 5 years and produced some 12 major published proceedings.

Among the most significant activities of the past 5 years were the following events:

1. An All-Division 7 meeting entitled "Symposium on Sustainability of Pine Forests in Relation to Pine Wilt and Decline" was held in Tokyo, Japan, in 1998. The meeting included an open symposium for the lay public, a two-day scientific session, and a field trip to see the pine wilt problem. All through the meeting, the press and other media people were invited to attend and the meeting received a great deal of attention in the Japanese press. A major scientific proceeding resulted from the meeting.

2. The Research Group 7.04.00 continued to be very productive and active with major meetings including the 17th, 18th and 19th meetings of the "Specialists in Air Pollution Effects on Forest Ecosystems" were held in Florence, Italy (1996), Edinburgh, Scotland (1998) and Houghton, Michigan (2000). These meetings averaged over 150 participants and resulted in special issues in Chemosphere, Journal of Water, Air and Soil Pollution, and Environmental Pollution as three bound books. Kevin Percy (Canada), as well, has led the 7.04.00 Research Group.

3. Research Group 7.01.00, led by William Mattson (USA), held major conferences in France (Physiology and Genetics of Phytophage Interactions) and Hungary (Biology of Gall Inducing Arthropods) in 1997. Both conferences resulted in major proceedings. In addition, this Research Group convened in Brazil and Malaysia in 2000.

4. Research Group 7.02.00 and 7.03.00, led by Christian Tomiczek and Rene Alfaro, remained very active in our division, convening some 15 Working Parties and joint multiple Working Party meetings in the past 5 years. Among the most important publications from the Research Group was the "World Directory of Forest Pathologists and Entomologists", which was organised by D.D. Skilling and H.O. Batzer.

Report by Dr. Kyoji Sassa

Division 8 Coordinator
Forest Environment

It was decided to establish Division 8 at the Tampere Congress in 1995 and the new Division started its activities in 1996. The Coordinators (Kyoji Sassa, Kamis Awang, Timothy Boyle, Alain Franc) discussed the management of this new Division. It was decided to organise an all-Division Congress in order to understand the present structure and content of research and to consider what Division 8 should be like at the beginning of the 21st century. At first, Division 8 decided to organise its first all-Division meeting on "Forest Environment in a Changing World" in Yogyakarta, Indonesia, under the leadership of Dr. Timothy Boyle of the Center for International Forestry Research (CIFOR) in August 11-15, 1997. However, due to the surprisingly small number of registrations, these plans were dismissed.

1. All-Division 8 Conference on "Environmental Forest Science"

Then, a second attempt was made to organise it from 19 to 23 October, in Kyoto, Japan. The Coordinator applied successfully for a grant from the Japanese Ministry of Education, Science, Culture and Sports to organise the IUFRO Division 8 Conference on "Environmental Forest Science". The conference was very successfully organised. It aimed at integrating all fields of forest science and other related sciences dealing with the environment into an Environmental Forest Science and searched for promising research fields and topics in the 21st century. The number of participants was 139, including 61 foreign participants from 29 countries. The conference and the one-week field trip were very successful. The extended abstracts volume with the conference programme (262 pages) was published, and the full text volume (658 pages) was published by Kluwer Academic Publisher as "Environmental Forest Science", Forest Science Series, Volume 54 (ISBN 0-7923-5280-7). It is available from Kluwer Academic Publisher (Tel: +31-78-639-2392, Fax:+31-78-639-2254, E-mail: services@wkap.nl) and turned out to be a well sold book for Kluwer.

2. 1998 IUFRO Kyoto Appeal "Environmental Forest Science for Sustainable Development"

As a result of the panel discussion, participants, including IUFRO Vice President Risto Seppälä, Heinz Schmutzenhofer, Lisa Sennerby-Forsse, and representatives from UNESCO, FAO and the Science Council of Japan, concluded to release an appeal for cooperation and funding to related parties in the world: the ENVIRONMENTAL FOREST SCIENCE FOR SUSTAINABLE DEVELOPMENT - Appeal from the 1998 IUFRO Kyoto Conference. This appeal can be the basis for a new development of Environmental Forest Science and may attract the interest of related funding agencies. The text of the appeal was published in IUFRO News Vol. 28/issue 2, in 1999 and also in the IUFRO Annual Report 1998.

3.Cooperation with UNESCO on Landslide Research and Forest Hydrology

Division 8 cooperated with UNESCO in the organisation of the Kyoto Conference in 1998. At the same time, the landslide Research Group (8.04.03) was invited to apply for a UNESCO and IUGS (International Union of Geological Sciences) joint project: "International Geological Cooperation Programme (IGCP)" and IGCP-425 "Landslide Hazard Assessment at Cultural Heritage Sites and Other Locations of High Societal Value". The project group organised a symposium in Tokyo, 1998, a conference at UNESCO Headquarters in 1999 with support from D8; a UNESCO/DPRI-Kyoto University research cooperation agreement was exchanged at the end of 1999 based on IGCP-425.

The forest hydrology Research Group (8.03.02) organised a symposium on "Forests – Water – People in the Humid Tropics: Past, Present and Future Hydrological Research for Integrated Land and Water Management" as a satellite meeting of XXI IUFRO World Congress in cooperation with the UNESCO Project "International Hydrological Programme (IHP). Director-General Koichiro Matsuura of UNESCO attended the symposium and addressed the participants in the closing session.

4. Organisation of Division 8 Sessions in XXI IUFRO World Congress

During the Congress, Division 8 organised 2 Sub-Plenary sessions (A1: Water and Forests / 8.03 Forest Hydrology, and A2: Fire and Forests / 8.05 Forest Fire Research), 18 Group Sessions, 1 Panel Discussion, 5 Satellite Meetings (evenings), and a one-week Satellite Conference & Workshop before the Congress. There were 85 oral presentations and 118 poster presentations. A Division 8 Panel Discussion on "Environmental Forest Science and Division 8 in the 21st Century" and a Division 8 Business Meeting on "Review and Perspective of Research Group" were organised. As the result of discussions in these two Division 8 Plenary sessions, two new Working Parties were set up; two Working Parties were decided to be terminated; and it was decided to change the names and research aims of one Research Group and four Working Parties.

5.Organisation of the Interdivisional Meeting on "Forest Ecosystems and Land Use in the Mountain Areas"

This meeting was organised by Prof. Don Lee on 12-17 October, 1998, in cooperation with other Divisions.

IUFRO Officers 2001 - 2005

The IUFRO Officers for the period 2001 – 2005 as listed were approved by the International Council on proposal of the Executive Board at the General Assembly of IUFRO at the XXI Congress in Kuala Lumpur, Malaysia, August 8, 2000.

Board Members

President	Risto Seppala	Finland
Vice President	Eric Teissier du Cros	France
Vice President	Don Koo Lee	Korea

Division Coordinators

1	John Parrotta	US
2	Ladislav Paule	Slovakia
3	Dennis Dykstra	US
4	Klaus von Gadow	Germany
5	Cathy Wang	China – Taipei
6	Niels Elers Koch	Denmark
7	Kazuo Suzuki	Japan
8	Alain Franc	France

Members from Regions - General Members (according to new Statutes Valid in 2001)

		Region
Susan Conard	US	5
Ruben Guevara	Honduras/ Peru	6
Vitor Afonso Hoeflich	Brazil	6
John Innes	UK/Canada	1
Iba Kone	Kenya	7
Gordon Miller	Canada	5
Abdul Razak	Malaysia	9
Victor Teplyakov	Russia	3
Karel Vancura	Czech Republic	2
Yaoguo Xiong	China	8

Ex officio Board Members

Jeffery Burley, Immediate Past President	UK
Heinrich Schmutzenhofer, Executive Secretary	Austria
Mario Broggi, Treasurer	Switzerland
Russell Haines, COC Chair	Australia

Observers

FAO-representative – Hosny El Lakany

Members of the Enlarged Board

Division Deputy Coordinators

D1	Jerry Vanclay	Australia
	Björn Hånell	Sweden
	Florencia Montagnini	Argentina/ Costa Rica
D2	Csaba Matyas	Hungary
	Robert Luxmoore	US
	Zohra Bennadji	Uruguay
D3	Hans Heinimann	Switzerland
	Amaury De Souza	Brazil
	Mike Menzies	New Zealand
D4	Lauri Valsta	Finland
	Steen Magnussen	Canada
	Margarida Tomé	Portugal
D5	Howard Rosen	US
	Mahabala Bhat	India
	Paul Fung	Australia
D6	Perry Brown	US
	Susanna Benedetti	Chile
	Lucrecio Rebugio	Philippines
D7	Kevin Percy	Canada
	Jean-Claude Gregoire	Belgium
	David Karnosky	US
D8	Rahim Nik	Malaysia
	Albert Goettle	Germany
	James Boyle	US

The Coordinator of the Special Programme for Developing Countries

Position vacant

The Coordinators of Projects

Terminology Project SilvaVoc, Renate Prueller, Austria
Global Forest Information Service, (vacant)

The Coordinators of Task Forces

Environmental Change, John Innes, UK/ Canada
Forests in Sustainable Mountain Development, Martin Grosjean, Switzerland
Management and Conservation of Forest Gene Resources, Per Ståhl, Sweden
Water and Forests,. Rob Vertessy, Australia
Task Force on Science/Policy Interface, Richard Guldin, USA
Task Force on Public Relations in Forest Science, Max Krott, Germany

Congress Organisers

LIST OF IUFRO 2000 COMMITTEES

I. CONGRESS STEERING COMMITTEE

	Name	Agency	Category
1.	Abdul Razak Mohd. Ali	Forest Research Institute Malaysia	Chairman
2.	Aziah Mohd. Yusoff	Forest Research Institute Malaysia	Secretary
3.	Abdul Rahim Ismail	Immigration Department Malaysia	Member
4.	Abdul Rahim Nik	Forest Research Institute Malaysia	Member
5.	Abdul Razak b. Yaacob	Royal Customs & Excise Department Malaysia	Member
6.	Azmi Zainuddin	Ministry of Foreign Affairs Malaysia	Member
7.	Chew Yee Seng	Prime Minister's Department Malaysia	Member
8.	Habibah Hj. Abdul Manaf	Royal Malaysian Police	Member
9.	Haron b. Hj. Abu Hassan	Institute of Foresters Malaysia	Member
10.	Herman Anjin	Forestry Department Sabah	Member
11.	Lee Hua Seng	Forestry Department Sarawak	Member
12.	Micheal Rajoo	Malaysian Timber Council	Member
13.	Nik Adnan Nik Abdullah	Ministry of Primary Industries Malaysia	Member
14.	Mohd Rusli	University Putra Malaysia	Member
15.	Shaharuddin b. Mohammad Ismail	Forestry Department Peninsular Malaysia	Member
16.	S. Rajan	Malaysian Timber Industry Board	Member
17.	Wong Kam Wai	Malaysian Furniture Industry Council	Member
18.	Zailin Alwee	Malaysia Tourism Promotion Board	Member

II. CONGRESS ORGANIZING COMMITTEE (COC)

	Name	Category
1.	Abdul Rahim Nik	Chairman
2.	Salleh Mohd. Nor	Advisor
3.	Wan Razali Wan Mohd.	Advisor
4.	Mohd. Zamshari Abdul Rahman	Treasurer
5.	Lim Hin Fui	Secretary
6.	Azizol Abd. Kadir	Chairperson Exhibitions
7.	Abdul Rashid Ab. Malek	Chairperson Logistics & Security
8.	Baskaran K.	Chairperson Scientific Prog. & Poster
9.	Hoi Why Kong	Chairperson Finance
10.	Marzalina Mansor	Chairperson APP
11.	Mohd. Dahlan Jantan	Chairperson Post-Congress Excursion
12.	Lee Su See	Chairperson SAP
13.	Shamsudin Ibrahim	Chairperson In-Congress Tour
14.	Wan Rahmah Wan A. Raof	Chairperson PR & Publicity
15.	Lucy Chong	Member
16.	Kamis Awang	Member
17.	Mohd. Hamami Sahri	Member
