Abstract: Maintaining and restoring tropical forest cover is widely regarded as essential for biodiversity conservation and climate-change mitigation. At the same time, significant populations in these regions depend on agriculture and other non-forest land uses for their livelihoods. Convincing land users to reduce their activities that convert forests or prevent reforestation requires a mix of policy tools, like payments for environmental services or more conventional interventions such as forest-cover requirements with fines for not meeting them. However, which tools are most effective is far from a settled question, and is complicated to answer because of the cost and scale of testing them. In this presentation, we will share results of an ongoing study in São Paulo state, Brazil, that tests the relative effectiveness of four different intervention forms. These are either incentive payments vs. fines, conditioned on either individual-level vs. community-level land-use limitations, for four possible combinations. We test these interventions in the microcosm of an experimental game played by groups of eight small farmers from rural communities. The players are farmers in a watershed, and individually decide how much land to cultivate, but their harvest per unit of land increases with the ecosystem services provided by the intact forest in the landscape, which in turn depends on aggregate choices of all the players. This sets up a collective-action dilemma where payoffs increase with increasing individual land use, but decline with increasing group land use. To incentivize their decisions, players are paid an amount in local currency proportional to their in-game harvest. The game is divided into three stages, with one of the four possible intervention types implemented only during the second stage. This gives us both baseline and post-intervention stages, allowing assessment of both immediate (i.e. during intervention) and lasting (i.e. post-intervention) impacts of the interventions. All four intervention types are being tested in each of eight rural agricultural communities, along with collection of post-game interview data to help understand players' decisions. We will present results on which intervention types worked the best, and look at various lines of evidence as to why those interventions were effective.

Does protected area establishment result in pre-emptive forest clearing? Insights from Madagascar's protected area system expansion

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Jorge C. Llopis[1, 2, 3]
Julia P.G. Jones[1]
[1] School of Natural Sciences, Bangor University, UK
[2] Interdisciplinary Centre for Conservation Science, University of Oxford, UK
[3] Centre for Development and Environment, University of Bern, Switzerland

Abstract: Slowing tropical deforestation is a major global policy objective given its role in tackling the combined challenges of climate change and biodiversity loss. Establishment of protected areas (PAs) is a commonly used tool. However, PA establishment might potentially result in unintended consequences; specifically pre-emptive forest clearing as people anticipate the upcoming policy restrictions, which has been anecdotally identified in other policy contexts. This is the first study to systematically investigate the phenomenon, and to explore whether it undermines benefits from PA establishment. We focus on Madagascar, whose PA network expanded by more than 400% between 2003 and 2017, using the synthetic control method to assess deforestation outcomes in some 300 administrative units overlapping with 25 PAs established as part of this expansion. Results suggest that pre-emptive forest clearing did occur in a large number of units. In most units, PA appears to have brought net gains in avoided deforestation, but worryingly, in many other units, pre-emptive forest clearing completely negated the intervention's gains. These findings raise concerns about the prevalence of this phenomenon in Madagascar, and potentially elsewhere, and highlight the need to revisit the assumptions underpinning the theories of change informing area-based forest conservation interventions.

Dynamics Driven by New Player: Exploring Chinese Engagement in the Forest Sector of the Democratic Republic of the Congo

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Chenmei Li[1]
[1] University of Helsinki

Abstract: This conference abstract sheds light on the persistent issue of tropical deforestation and its complex underlying dynamics in the Congo Basin region. Despite having multiple policies around the globe to tackle tropical deforestation, the exploitation of forests continues to be driven and justified by the promise of development and increased societal welfare. Historically, European colonial powers such as Belgium, France, and Germany have played significant roles in forest exploitation and land conversion, leading to economic gains for their nations. In recent times, China has emerged as a new influential player in the region, further contributing to the intricate web of interests, narratives, and power dynamics. Yet there remains a limited understanding of their narratives, operations and interaction with local dynamics.

This research contributes to understanding Chinese actors in tropical forests of Congo Basin in a particularly less understood case country, Democratic Republic of the Congo (DRC). We employ mixed method approach by using bilateral trade data between China and DRC from 2015 to 2022 obtained from both customs, and qualitative data from fieldwork in DRC and China including archives and interviews.

This study increases the understanding of the main trends in China-DRC trade and investment in forest sector, and understanding of the Chinese companies associated in the forestry economic activities. The main findings include who are the operators, their operational preferences, strategics, as well as their engagement with other main stakeholders, particularly those in deforestation policy domain such as local community, Chinese and DRC's government, Civil Society Organizations, international communicates, among others. It highlights how the growing presence of Chinese actors interacts with the existing dynamics of interest, narratives and power, and draws insights on to what extent the new player affects the policy agenda towards effective, efficient, and equitable policy change in global forest policies.

This study addresses a critical knowledge gap by unravelling the dynamics instigated by this new player in the DRC's tropical forest. It contributes to a deeper understanding of the complexities faced by forest policies in the Congo Basin region and provides valuable insights to inform future policy decisions in this domain.

Environmental Sustainability and Economic Complexity: Implications for the Brazilian Forest Sector in a New Developmentalism Strategy

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Daniel Moura Da Costa Teixeira[1]
Maria Luiza Almeida Luz[2], José Luis da Costa Oreiro[1]
[1] Department of Economics of the University of Brasília, Brazil
[2] Laboratory of Built Environment, Inclusion, and Sustainability of the University of Brasília, Brazil

Abstract: The relationship between economic scale and its impacts on the environment is neither linear nor stable across economies and over time. It depends on the production structure and technologies adopted. Consequently, it is imperative to expand the share of segments that adopt "clean" technologies compared to those reliant on non-renewable natural resources and carbon-intensive methods. This can only be achieved through ecological structural change. This necessitates a continuous process of production sophistication in terms of economic complexity, which does not occur spontaneously due to market failures and the risks associated with investments in cleaner technologies and innovations. Due to the great diversity of aspects involved in this process, the developmental literature recommends a policy mix that combines fiscal, industrial, trade, and regulatory policies in a national eco-developmental strategy. This strategy should consider the accumulated knowledge on structural change and natural resource management. Specifically concerning the forest sector, public policies should unlock investments in sustainable forest management to increase its contribution to the supply of food, fibers, and forest raw materials with the potential to replace fossil resources, as well as to capture and store carbon and provide other significant environmental services. Additionally, there is potential for developing new products with a high level of technological content through advancements in forest research with native species, such as biofuels and biomaterials for the construction, cosmetic, pharmaceutical, chemical, textile, and other sectors. Therefore, this study aims to discuss the relationship between environmental sustainability, ecological structural change, and forests, and the implications for an eco-developmental strategy. This discussion takes place in the Brazilian context, where a variety of policy instruments exist to combine forest protection and sustainable use while simultaneously achieving carbon emission reduction goals. Furthermore, forest policy management is decentralized among federal, state, and municipal governments, affirming the literature's recommendation that the state's role in a national eco-developmental strategy involves policy coordination, providing information during policy management, harmonizing policy instruments, and supporting all actors in identifying opportunities for economic diversification that contribute to environmental sustainability. Consequently, it is suggested that the national eco-developmental strategy must have a high priority on the governmental agenda.

Forest Certification and Environment, Social, and Governance: The Case of Malaysian Timber Certification Scheme

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

M Murughan Manikam[1]
Mohamad Roslan Mohamad Kasim[1], Seca Gandaseca[2], Johar Mohamed[1], Zubaidah Harun[1], Pakhriazad Hassan Zaki[1]
[1] Faculty of Forestry and Environment, Universiti Putra Malaysia, 43400 UPM, Serdang, Selangor, Malaysia
[2] Faculty of Applied Sciences, Universiti Teknologi Mara, 40450 Shah Alam, Selangor, Malaysia

Abstract: The term Environment, Social, and Governance or ESG, which was mooted by the United Nations in 2004, has gained attention among investors and related stakeholders, globally. Recently, there has been increasing demand for ESG commitments in the forest-related sectors, where investors and related stakeholders require forest-related businesses to demonstrate their ESG commitments. The forest certification standards have emerged as the potential tool to meet ESG commitments. In this context, the Malaysian Timber Certification Scheme or MTCS is a forest certification standard that assures that forest and forest products are managed in a sustainable and legal manner in Malaysia. Thus, this study will explore how the MTCS-forest certification standard supports ESG commitments. The FTSE Russell's ESG data model, a model that allows investors to understand how businesses manage ESG commitments, was used in this study. The MTCS-forest certification standard supports ESG commitments, such as the protection and conservation of biological diversity, ecosystem services, and water resources, indigenous peoples' rights, workers' rights, forest management planning, monitoring and assessment, and legal compliance, among others. This shows that the MTCS-forest certification standard provides a positive impact on a broad range of ESG commitments. Thus, the MTCS-forest certification standard is a potential selection tool to fulfil ESG commitments and to provide investors and related stakeholders with an understanding of ESG practice in the forest-related sectors.

From awareness to knowledge and action: a case-study on challenges and outcomes of forest governance in the subtropics

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Alexander Christian Vibrans[1]
[1] Universidade Regional de Blumenau, Santa Catarina, Brazil

Abstract: In face of deforestation and forest degradation in fragmentated landscapes, forest governance needs action plans based on reliable and updated data of key variables. These are commonly provided by regional/national forest inventories. Here, we report the 30-year journey pursued since the raising of society's awareness about the extent of damages caused by land use changes, towards the creation of effective forest policy instruments, in the Brazilian state of Santa Catarina. First, the increasing pressure of the public opinion for protection of the Atlantic Forest lead to a federal law enforcement during the 1990ies; however, this was poorly communicated and often misunderstood as an authoritarian top-down approach. Disregarding concerns of the rural population, it resulted in resistance at local level. Later, the state government adopted actions to align land use and regularization of rural properties, thus ceasing deforestation and increasing conservation efforts. The environmental agency and police were reinforced through 18 well equipped regional offices. A continuous state forest inventory, in the molds of the brazilian NFI, was designed in 2006 to provide reliable and updated data on forest extent, composition, biomass stock/dynamic and conservation status. This assessment is now performing the third measurement cycle. A working group of stakeholders, from private/public sectors, scientists and NGOs, was created in 2012 to design a policy framework on forest and land use governance. The new policy, ratified in 2013, aims the maintenance of smallholders' livelihood, biodiversity conservation, valorization of forest lands and payment of ecosystem services. Priority programs were proposed to 1) promote silviculture of native tree species, for rehabilitation of degraded forests and commercial plantations; 2) manage secondary forests, based on traditional forms of land use rotation, as on selective cutting; 3) integrate territorial planning, licensing, inspection and environmental regularization of rural properties; 5) establish a forestry extension service to advise forest owners in good forest management. As an example of endogenous development, with own financial means, the state inventory filled a knowledge gap about state's forests, enabled full public access to collected data, now allowing society to claim the deployment of the new forest policy, truly geared to collective interests.

Impact of Indonesia's general-purpose ecological fiscal transfer on forest cover: a comprehensive evaluation approach and early results

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Colas Chervier[1]
Sonny Mumbunan[2]
[1] CIRAD
[2] University of Indonesia

Abstract: Indonesia has initiated significant reforms in order to reduce GHG in the land-based sector. Among the country’s most ambitious and recent reforms is the introduction of forest cover of subnational jurisdictions as an indicator to allocate general-purpose fiscal transfers (DAU), Indonesia’s largest and most significant fiscal transfers, from central to subnational governments. With an explicit link to forest cover, this new fiscal transfer policy is expected to change the incentive structure for reducing deforestation in Indonesia. Scientific evidence on the impact of Ecological Fiscal Transfers (EFT) is scarce, and existing studies in the early-moving countries of Brazil and India are not directly comparable to the Indonesian case of general-purpose fiscal transfers. In this research, we first adopt a political economy framework and use the Transformational Change literature to analyze the underlying policy processes leading up to this ambitious policy reform. Secondly, we present a detailed research protocol, aimed at providing evidence of the impact, and impact pathways, of Indonesia’s EFT policy for general-purpose transfer and related fiscal transfers, as well as the early results of this research. This protocol is based on a mix of robust qualitative and quantitative methods for causal inference using quasi-experimental methods and process tracing, and which share common prerequisites, to produce a sound theory of change. We further emphasize three scientifically-sound and policy-relevant questions: (1) To what extent and under what conditions do EFTs create an incentive effect that is strong enough to change the behaviors of local policy makers and to overcome the effect of business-as-usual incentives promoting deforestation (e.g. the general elections that will occur in 2024 in Indonesia)?; (2) Using quasi-experimental approaches, how do we measure the additional impact of a policy that is implemented nation-wide and whose implementation is not staggered?; (3) Through which mechanisms do such collective incentives influence the individual decisions of land users and contribute to overcoming the typical challenges faced in collective action settings, such as free-riding and elite capture?

It takes two to trade: who shapes flows of wood trade in Congo basin and how?

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Alizée Ville[1]
Maria Brockhaus[1], Grace Wong[2], Symphorien Ongolo[3]
[1] University of Helsinki (Finland)
[2] Research Institute for Humanity and Nature (Japan), Stockholm Resilience Centre (Sweden)
[3] Research Institute for Development (Institut de Recherche pour le Développement, France)

Abstract: Demand for timber in, and exports (referred to here as flows of timber) to wealthy nations have led to extensive deforestation in the countries of origin over the past decades (Rudel, 2005). Though seemingly modest on the global scale (only 1% of global traded wood volumes in 2021), Congo Basin exports volumes are rapidly increasing – by 173% in Cameroon between 2004 and 2012 (Mahonghol et al, 2016) – with irreversible effects on forest cover. Simultaneously, Congo Basin countries have enacted policies that restrict or prohibit the export of specific forest products, to slow the decline of forest cover and increase value-added. Addressing deforestation in the Congo Basin must therefore include a better understanding of how these flows are shaped. We ask: how do global forest agreements and national policies affect timber flows? And because it takes two to trade, how do national and international actors facilitate or hinder the flows of timber commodities in Cameroon and DRC?

We draw from Ecologically Unequal Exchange, allowing us to critically appraise the mechanisms which sanction asymmetrical transfer of natural resources through trade, and their effects on monetary and socio-ecological aspects. Through critical discourse analysis of the policies that act as these mechanisms, namely the Log Export Ban in Cameroon, and Moratorium on logging concessions in the DRC, we investigate underlying problematizations and assumptions embedded in policy formulation. Through interviews (n = 82), we explore how different actors perceive the role of domestic forest policies in shaping forest governance, and the strategies that they adopt in abiding or bypassing them, by inquiring about preferences in traded wood species, and tactics of resistances.

We show that ecologically unequal exchange remains the guiding principle of international timber trade, where historical trade partners retain a strong influence on policymaking. However, the apparent change in flow trajectory (China and Vietnam being the main destinations) and of preference in wood species, seem to show that Cameroon and the DRC are forming new patterns of trade with different trade partners, thereby bypassing existing policies. This work hopes to provide a more nuanced picture of the mechanisms underlying the unequal flows of timber.

Land Registry Program's Impacts on Land Use Knowledge and Conversion

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Suhyun Jung[1]
[1] Oregon State University

Abstract: Land registration can contribute to sustainable forest use and increase the livelihoods of people who depend on natural resources by establishing and strengthening land titles and property rights. The formalization of access to and rights to use forests through land registration has occurred globally through initiatives such as state-initiated land reforms and programs. While the evidence on the environmental and development impacts of land certification, registration, or titling programs abounds in the literature, less is known about (1) how land registration programs might create perverse incentives to deforest, (2) market formalization channels through which land registration programs might change smallholders' land use, and (3) how those changes might affect smallholders' welfare.

In this paper, we fill these gaps by studying the impacts of one of the most extensive land registration programs, Cadastro Ambiental Rural (CAR), on smallholders' land use change and livelihoods in Bahia and Piauí in Brazil. Using unique primary panel data collected from 1,177 smallholders and by applying various impact evaluation strategies for causal identification, we find that smallholders who complied with the Forest Code by having more than 20-30% of their land as native vegetation at the time of CAR registration have increased conversion of forests/grasslands into agriculture or pasture area by 0.5-0.8 ha more after CAR registration compared with those who were not in compliance with the Forest Code. Our investigation of mechanisms shows that rather than the land use rights shown through CAR, the knowledge about their land area might have driven the increased conversion to agriculture or pasture area. We also find that the production of subsistence crops has increased, which could have contributed to improving smallholders' livelihoods.

These findings contribute to the literature by showing how land certification or registration programs might facilitate a market formalization process that can change smallholders' land use and livelihoods. Our results have policy implications for similar land registration programs for forest conservation, suggesting that land registration programs need to consider factors associated with perverse incentives to increase cultivation area to avoid unintended consequences.

Mixing policies under the umbrella: the case of REDD+

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Sven Hans Wunder[1, 2]
Erin Sills[3], **Amy. E. Duchelle**[4]

[2] CIFOR-ICRAF
[3] North Carolina State University
[4] Food & Agriculture Organization

Abstract: Many on-the-ground interventions in tropical forests, aiming to address combined, implicitly or explicitly weighted goals of forest conservation and livelihood improvements or other co-benefits, prefer to combine different instruments simultaneously in their applied strategies. Reduced emissions from deforestation, forest degradation, sustainable management and enhancement of forest carbon stocks (REDD+) constitutes one such example of intervention/ policy mix. In a way, REDD+ has been to forest-based carbon mitigation what integrated conservation and development programmes (ICDP) have been to biodiversity conservation: an umbrella concept covering a heterogeneous mix of on-the-ground interventions. Our purpose here is to employ a bigger sample to systematically characterize the composition of REDD+ interventions, including incentives (e.g., payments for environmental services (PES)), disincentives (e.g., forest-law enforcement, protected areas), enabling actions (e.g., land reform, decentralization), and their respective subcategories. We will do so by drawing on quasi-experimental data from 16 local REDD+ sites in Brazil, Peru, Cameroon, Tanzania, Indonesia, and Vietnam, as part of CIFOR's Global Comparative Study on REDD+ (GCS-REDD+), combining data from a comprehensive implementer survey with remote-sensing data and surveys applied in nearly 130 villages to 4,000+ households, in 2010-2011 (pre-intervention) and 2013-2014 (post-intervention I). In 2018, a new round of GCS data was collected, in a subset of the 23 initiatives (post-intervention II). We will characterize the distributive patterns of action, and try to juxtapose our findings to what we know regarding the effectiveness of these forest interventions, trying to respond to the research question: were some combinations or sequences of mixed policy/ intervention instruments apparently more effective in reaching conservation and livelihood objectives? Our results will feed into tentative policy recommendations, and suggestions for the emphasis of future research.

Keywords: tropical deforestation, conservation strategies, climate change, global-comparative study

Role of National Conservation Instruments in Improved Provisioning of Ecosystem Services in the Tropical Andean Forest

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Pablo Cuenca[1]
[1] Tropical Ecosystems and Global Change Research Group. Universidad Regional Amazónica Ikiam, Parroquia Muyuna km 7 vía Alto Tena, Tena-Napo, Ecuador.

Abstract: After the pandemic, the scientific community and decision-makers have recognized with greater emphasis the crucial role of natural capital in generating well-being for the population. Whose binding element between both (natural capital and well-being) are ecosystem services.

To contribute to constructing a more resilient society to disturbances, governments have created national conservation instruments to provide more goods and services from forests, avoid deforestation of forest ecosystems, to increase carbon reserves and sequestration.

The Socio Bosque Program (SBP) is a national conservation instrument of the Ecuadorian government that seeks to generate well-being for communities through the increase and fixation of carbon. The impact assessment method under the theory of change was used to estimate the impact of (PSB) between 2008 to 2014 and 2014 to 2020 on improving a provisioning ecosystem service, such as forest carbon.

The study estimated that the amount of carbon and CO2-eq that the SBP prevented from being released into the atmosphere was 11 and 41 (ton/ha), respectively, between 2008 and 2014; the results for 2014 to 2020 are still under construction. Other research data shows that the protected area in the collective SBP was 39.121 ha, and if the SBP had not been implemented, an area of 1.077 ha would have been lost in 2014. For individual SBP contracts, the protected area was 8.675 ha, and the presence of the SBP prevented the loss of 238 ha by 2014.

These results are critical within the policy of the Government of Ecuador that pursues that ecosystem services can be negotiated within a voluntary or formal market (Art. 74 of the Constitution of Ecuador limits access to a carbon market). Based on the results, it is expected to contribute to the sustainability of the SBP, and both community and private partners have better information to negotiate the sale of carbon credits. Our conclusions are robust, even considering potential hidden biases. Therefore, the present study demonstrated that the SBP mitigates climate change's effects.

Science to support the European Union Deforestation-Free Regulation

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Manuela Hirschmugl[1, 2]
Koimé Kouacou[3], Anh Nguyen[3], Sebastian Vogler[3], Natalia Kobliu Kobliuk[3], Christian Garaus[4], Janik Deutscher[2], **Nik Cepirlo**[1, 2]
[1] University of Graz
[2] Joannneum Research
[3] Beetle4Tech
[4] University of Natural Resources and Life Sciences (BOKU)

Abstract: According to the United Nations Food and Agriculture Organization, the world has lost 420 million hectares of forest through deforestation over the past 30 years. This is significantly affecting vital forest functions such as carbon sequestration to slow climate change, provision of raw materials, serving as biodiversity hotspot. Agricultural expansion accounts for nearly 90% of global deforestation, with seven forest risk commodities representing the largest share of EU-driven deforestation. Much of the tropical forestlands lost are used to produce globally traded goods like palm oil, soy, timber, cocoa, coffee, beef and natural rubber. EU consumption of these goods is responsible for about 10% of global deforestation. To address this issue, the European Commission has introduced the European Union Deforestation-Free Regulation (EUDR) as a legal framework with mandatory due diligence requirements for companies placing forest-risk commodities and their derived products on the EU market. The regulation is ratified in June 2023.

Our project DeFREE is bringing together research institutions and an innovative start-up to develop methodologies in support of EUDR. The first component focuses on tracing: a QR-code based product tag enables consumers to trace the origin of products. The second component utilizes remote sensing to assess deforestation and degradation (D&D) in production areas and their surroundings after December 31, 2020. Previous results demonstrated that certification bodies can leverage these services to enhance the verification of reported timber harvests and identify instances of illegal and unreported logging, particularly in remote forest areas where on-site verification is logistically challenging. Based on the assessment outcomes, products will be flagged with different colors: red for D&D in the production zone, orange for D&D in surrounding areas and green for no detected D&D. Especially in the case of "orange flag" and for the assessment of degradation, in situ-data is needed. Such ground data is – especially in tropical and subtropical countries – not easy to obtain. Therefore, our third component focuses on crowdsourcing. Especially for ambiguous satellite data this additional ground data will increase information value. We will implement test cases for cocoa, rubber and coffee in Cote d'Ivoire and Uganda.

Seeking synergies in a polycentric policy mix: Brazil's priority list for deforestation control

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Jill Caviglia-Harris[1]
Erin Sills[2], **Katrina Mullan**[3]
[1] Salisbury University
[2] North Carolina State University
[3] University of Montana

Abstract: In many countries with large remaining areas of tropical forest, governance of those forests is shared across multiple levels of government with varying incentives for conservation and deforestation. In this type of polycentric system with heterogeneous objectives, central governments need ways to translate international and national priorities, such as Nationally Determined Contributions to climate action, to local governments. One mechanism widely recognized as effective was the Brazilian federal government's priority list. Launched in 2008, the priority list identified municipalities responsible for the most deforestation, and then publicized their status, targeted enforcement action to them, and restricted their access to input and output markets for agriculture. This established a collective incentive for municipal governments and local stakeholders to reduce deforestation. The priority list was layered on top of a pre-existing and complex policy landscape. We examine how previous land tenure/land use policy shaped the effectiveness of the priority list. Specifically, we establish a typology of municipalities based on the fractions of their area in protected areas and in agricultural settlements. For each type of municipality, we estimate the causal effect of being added to the priority list, using both traditional matching methods and new approaches to estimating dynamic treatment effects. The new approaches reveal that the priority list had the most impact where protected areas and agricultural settlements cover intermediate fractions of the municipalities. Those municipalities presented the greatest opportunities for synergies between the priority list and land tenure/land use policies, and thus adding a collective incentive into the policy mix was highly effective.

The struggle of conservation territories expansion in the Congo Basin: insights from the Democratic Republic of Congo

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Alexandra Rasoamanana[1]
Max Krott[1], Symphorien Ongolo[1, 2], Eliezer Majambu[3, 4], Moses Imani Musa Bin Alimasi[5]
[1] Chair of Forest and Nature Conservation Policy, University of Göttingen
[2] SENS/IRD - France
[3] Department of Geography, Le Mans University-France
[4] Department of Political Science, Official University of Mbujimayi, Democratic Republic of Congo
[5] Agronomy Science Institute of Maniema, Democratic Republic of Congo

Abstract: International actors had and continue to play key role in triggering several policy reforms in Central Africa. A significant international financial incentive to establish new conservation territories or to enlarge existing ones, either through estate-protected areas or other conservation areas (managed by private operators or by forest dependent communities). To date, up to 15% of the Central Africa is officially protected for its biodiversity, with the most imposing restriction use placed on forest dependent communities. The quest of biodiversity conservation in the Central Africa, driven by international actors, has resulted to demarcation of conservation territories in which boundaries are mostly visible on maps. Using the long-term US-funded biodiversity conservation programme in Congo Basin countries known as Central Africa Regional Programme for the Environment (CARPE) as a case study, this paper aims to assess the process in which conservation territories expansion was pursued and to what extend it has affected the power dynamics of diverse and divergent actors' interest within these mapped boundaries. Drawing on the symbolic politics as theoretical and analytical framework, we tested if the conservation territorialisation pursued under CARPE has fallen into symbolic demarcation in which the spatial claim is poorly enforced and overstated to hide inefficiency and ineffectiveness as well as injustice. We collected a mix of qualitative and quantitative data through face-to-face interviews and field observations, triangulated with a review of policy and programmatic documents. We deepened our empirical studies using one of the largest landscape conservations under CARPE which known as Kahuzi Biega-Tayna-Maiko landscape located in the Eastern of Democratic Republic of Congo. Our findings show that conservation territorialisation efforts performed in a fragile state such as DRC have fallen to a symbolic demarcation which have failed to achieve biodiversity conservation and local development objectives.

Transforming forest reserves to national parks: Political economy and governance perspectives on forest policy changes and instruments in Uganda.

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Jon Geir Petursson[1, 2]
Paul Vedeld[1, 3]
[1] Professor
[2] University of Iceland
[3] Norwegian University of Life Sciences

Abstract: Institutional arrangements to counter forest loss in Africa are rapidly evolving. Gazetting Forest reserves (FR) was a traditional governance arrangement in most countries, initially rooted in the colonial land use administration. Uganda took a bold step in 1993, reforming its forest policy and transforming many FRs to National parks (NP). With a legal notice, six FRs were converted to stronger conservation regime as NPs. In 2023, it announced again such changes, suggesting three areas be transformed. This changed overnight the conditions for forest indigenous and neighbouring communities. Following came application of multiple policy instruments, often bundled within conservation and development projects. These policy instruments, nested in the nature conservation legal and policy frameworks, included issues like collaborative agreements on resources access; revenue sharing systems; access to business, compensation for wildlife losses and different human-wildlife conflict measures.

The study is rooted in theories on natural resources governance and in particular forest governance resources systems. The objective is to examine sustainability outcomes of the transfer from FRs to NPs and how the different policy instruments implemented parallel have delivered differently to the multiple social, economic, and ecological objectives. A political economy lens analyses what priorities have become dominant from the transition. We employ mixed methods of qualitative and quantitative data analysing the governance systems, design, and outcomes from the policy instruments.

The findings show the transition having different implications for the different pillars of sustainability and the policy instruments often not effective or enduring. The outcomes for the livelihoods of neighbouring communities are generally negative. Economically they are worse off, revenues are disproportionally shared and compensation instruments weak. The ecological objectives are however improving like many wildlife populations. That has however amplified wildlife conflicts.

Countering deforestation and enhancing delivery of ecosystem services for tropical forests by transforming FRs to more strict conservation governance systems is challenging. It may have severe political economy implications, allow local neighbours significantly worse off, redirect economical gains and cause new conflicts. That has been the case in many Ugandan parks. This all comes down to identifying the effective and efficient policy instruments to deliver more just outcomes.

Understanding biological conservation governance through campaign-style enforcement in China

T4.8 Effects and effectiveness of forest policies in developing tropical statehoods

Weiye Wang[1]
[1] Renmin University of China

Abstract: Effective management of PAs has been seen as essential for biodiversity conservation and further achieving EC. However, even though the central government has set biodiversity conservation goals and passed related laws and regulations,conservation effectiveness in China has been extensively criticized. In order to improve the implementation, Green Shield Action (GSA) was conducted, which provides critical insights into the nature of environmental politics during a campaign-style inspection under an authoritarian regime. By using qualitative research method, and based on fieldwork in Fujian from 2019 to 2022, the dynamic interactions among stakeholders, the role of campaigns in environmental governance, and the logic behind policy formulation, implementation, and revision were explored. This study finds that in the campaign-style inspection, with the application of new technology and improved management, less room was left for local governments to make trade-offs and dilemmas. The high political pressure caused conflicts. These outcomes were used as a reference for the central government to adjust policy design and turn it into regular enforcement with an improved environmental governance system. The campaign-style enforcement is not the opposite of regular enforcement, but these two are closely connected in the case of GSA.

Abstract: The provision of one ecosystem service from nature often comes at the expense of another, resulting in trade-offs. There is evidence from the literature that trade-offs between provisioning and regulating or cultural ecosystem services are hard to avoid when managing forests. However, synergies between ecosystem services are also seen.

This study presents a conceptual framework for the analysis of synergies and trade-offs between ecosystem services in the forest-based circular economy. The framework facilitates a dynamic modelling quantification of environmental footprints to evaluate goals towards forest multifunctionality formulated in e.g., the European Green Deal and the New EU Forest Strategy for 2030. Furthermore, the framework allows us to assess the implementation of circularity and cascade utilisation.

Our scope includes changes to the marketed ecosystem service of timber provision and the partially or non-marketed ecosystem services of carbon sequestration and biodiversity conservation. The key question is how to preserve forest biodiversity and ensure carbon sequestration for climate benefits, while maintaining resource extraction sufficient for supplying downstream processing industries and consumers in a growing global bioeconomy.

The framework adopts a holistic systems approach for mapping economic flows and associated flows of resources, energy, greenhouse gas emissions and other relevant environmental impacts from the forest and through industries to final consumption. Our conceptual framework builds on well-established economic and environmental accounting frameworks for national accounting, material flow analysis and life cycle assessment.

Our main contribution to the literature is the design of an operationalisable framework allowing for sustainability assessment of pathways towards regenerative practices in a forest-based circular economy at the macroeconomic level, which includes the identification of modelling requirements, data needs, and knowledge gaps. We apply the framework to model the relationship between forest-based economic activities and the selected ecosystem services from the forest to the end-of-life of wood-based products at a system level. The framework can be applied for an individual country, a region, or the world as a whole.

Analyzing possible reconciliation for policy support – A case study on wood production vs. biodiversity

T4.9 Evaluating policy outcomes in complex land-use systems

Minna Räty[1]
Artti Juutinen[1], Kari T. Korhonen[1], Kimmo Syrjänen[2], Leena Kärkkäinen[1]
[1] Natural Resources Institute Finland (Luke)
[2] Finnish Environment Institute (Syke)

Abstract: Our case study investigates impacts and feasibility of implementing protection targets of EU Biodiversity Strategy 2030 in Finland. According to the protection targets, 30% of EU's land and sea area should be legally protected by 2030. The strategy aims to increase protection by setting aside forests and extending closer-to-nature forest management practices. Hence, the implementation of the strategy would impact the supply of wood and the forest management practices.

To investigate impacts, we used the European Forestry Dynamics Model (EFDM) to simulate the development of Finland's forest resources considering the protection targets. The EFDM components were estimated from National Forest Inventory (NFI) data and MOTTI forest simulator results. The impacts were analyzed via economic (standing total growing stock, net present value) and ecological (dead wood volume, bilberry and cowberry yields and coverages) indicators.

According to our simulations, the total growing stock and net present value will be lower with the additional protection than by carrying on the business-as-usual management. The additional protection resulted in intensified harvesting in the remaining forest area available for wood supply with the current harvest level. This may weaken the positive ecological impacts of protection. Reducing the harvest level from the current level is not a likely alternative either, because the demand for biomass is predicted to increase in the future, while the supply is insufficient, and EU policies aim to avoid shifting the negative impacts of resource extraction outside the EU.

The analyses were conducted while the actual targets and even terms were still to be define. Still, the strategy's possible impacts can be simulated for policy support purposes, and then reformulated and rerun once the definitions are fixed. Our approach could be used for other countries and further developed to cover more aspects, such as climate change, timber markets and forest owner's behavior.

Beyond Twenty years of Nordic Forest Governance: Key Informants perspectives on Policy changes, Trends, and Future Implications

T4.9 Evaluating policy outcomes in complex land-use systems

Ayonghe Akonwi Nebasifu[1]

[1] Ayonghe Akonwi N., Ph.D., Postdoc Researcher, GreenPole 2022-2024, Helsinki Institute of Sustainability Science (HELSUS), Department of Forest Sciences, Unit for Forest Bioeconomy, Business & Sustainability, Affiliate International Forest Policy Research Group, University of Helsinki.

Abstract: There are increasing demands for robust, legitimate, and evidence-based policy making to tackle present and future sustainability challenges, including the management and governance of Nordic forest systems. This study uses interviews with key informants to evaluate recent forest policy implimented in Sweden, Norway, Finland, and Demark. We identify and assess policies and their outcomes related to forest products, biodiversity, carbon budget, and other socio-ecological consequences. We contribute to the literature by an expert-based assessment of adaptive changes in governance approaches from a comparative perspective in the Nordics. Here, we provide in-depth insights into what factors determine successful policy making. An overarching governance paradigm that has emerged in the Nordics since last century is "freedom with responsibility". In this context, preliminary resuts indicate that there are overall shifts towards i) an increasing consideration of multifunctionality under a continuously strong focus on biomass and harvest production, and ii) a growing use of economic instruments that do not infringe on the principle of freedom of choice. What remains, a somewhat unresolved question is how to integrate responsibility for effective climate change mitigation and biodiversity conservation. We collect and present the most promising developments for present and future policy mixes that facilitate inclusive, multifunctional, and multi-level forest governance.

Keywords: Nordic forest governance; Policy evaluation; Comparative policy analysis; Adaptive governance; Sustainable forest management

Climate targets in European timber-producing countries conflict with goals on forest ecosystem services and biodiversity

Abstract: The European Union (EU) set clear climate change mitigation targets to reach climate neutrality, accounting for forests and their woody biomass resources. Increased forest resource demands might lead to increased timber harvests in forests escalating pressures on forest ecosystem services and biodiversity (FESB). The climate change mitigation policies may thus interact with goals from other policy domains, such as the EU Biodiversity Strategy or the EU Forest Strategy, both operationalized nationally reflecting the countries' priorities placed on forests.

Using three Nordic countries (Finland, Sweden and Norway) and Germany as study regions, we investigated the consequences of increased harvest demands resulting from EU climate targets. Further, we analyzed the impacts on national policy objectives for FESB through forest simulation and multi-objective optimization methods. We first used empirical models to simulated forest dynamics and management under climate change and to gain information on the future provision of FESB. Second, we modelled the future harvest demands related to EU mitigation targets using the global forest sector model GLOBIOM. Third, we elaborated the demands for FESB of three national policy domains. Fourth, we resolved the optimal forest management programs for national policy targets (bottom-up) and for EU mitigation targets (top-down) by using the method of multi-objective optimization. Finally, we analysed the cross-scale policy coherence between national- and EU-level policies by comparing the outcomes of the two optimization approaches

We show that key European timber-producing countries (Finland, Sweden, Germany) may not be able to cover the increased timber demands for material and bioenergy usage arsing under the

ambitious 1.5°C target. Focusing on EU mitigation targets further conflicts with national sectoral policies and cause adverse effects on multiple forest ecosystem services and biodiversity. We argue that the role of forests and its timber resources for achieving targets on climate change mitigation and societal decarbonization should not be overstated. Our study provides a comprehensive analysis on the potential consequences of future harvest demands required for achieving EU climate change mitigation targets. For the first time, forests are assessed to determine if multifunctional benefits can be provided while transitioning to a climate-neutral economy.

Could the Sloping Land Conversion Program Promote Farmers' Income in Rocky Desertification Areas?—Evidence from China

T4.9 Evaluating policy outcomes in complex land-use systems

Rong Zhao[1]
Tianyu Jia[1], He Li[1]
[1] Research Institute of Forestry Policy and Information, Chinese Academy of Forestry, Beijing 100091, China

Abstract: The Sloping Land Conversion Program (SLCP) is a significant measure to achieve the Sustainable Development Goals (SDGs) proposed by the United Nations in 2015. SLCP plays an important
role in poverty alleviation and income increase for farmers in poor areas. The purpose of this study is to analyze whether the income of farmers has increased after participating in SLCP, and whether SLCP has released the agricultural labor force to obtain non-agricultural income by participating in non-agricultural work. Based on the field investigation in Luocheng County and Longsheng County of Guangxi, Libo County, and Dushan county of Guizhou, this paper uses the method of propensity score matching (PSM) to explore the impact of SLCP on the income of farmers in rocky desertification
areas. According to our research, it is found that: (1) SLCP has a positive effect of 5.2% on the average annual net income of farmers, a positive effect of 43.2% on agricultural income, and a negative effect of 9.8% on non-agricultural income, but all of the effects are insignificant. Selective deviation will overestimate the impact of SLCP on farmers' total income and agricultural income and underestimatethe impact on non-agricultural income. SLCP failed to promote the transformation of farmers into secondary and tertiary industries. The mechanism of SLCP to increase farmers' income is complex. (2) Farmers' participation in SLCP is influenced by work experience and education level in human capital, participation in skills training in social capital, and owning durable consumer goods in physical capital. Although SLCP will promote economic development under the condition of improving the ecological environment in the future, it is not advisable to exchange farmers' livelihood for ecological construction at present. The implementation of SLCP should consider not only the overall ecological benefits, but also the short-term social and economic benefits.

Evaluating the impact of 20 years of forest policy for endangered fish habitat in the Pacific Northwest, USA. Using multiple methods to inform policy.

T4.9 Evaluating policy outcomes in complex land-use systems

Brian Danley[1]
Sergey Rabotyagov[2], Luke Rogers[2], Alec Solemslie[2]
[1] Uppsala University
[2] University of Washington

Abstract: The legislature in the State of Washington commissioned the University of Washington to conduct a policy impact assessment after 20 years of the "forests and fish" policies intended to protect endangered salmon habitat. This paper situates the resulting policy report in the broader context of policy impact assessments in a forest governance context. We identify a common goal among all stakeholders of protecting small forest lands from development pressures and maintaining the environmental services they provide. The central trade-off the report analyzes is the net outcome of regulations and policies intended to secure riparian function against the complaint of forest owners that the same regulations are an incentive to divest from forest stewardship thereby driving the conversion of forest lands to non-resource uses and reducing riparian functions. Evaluating the impact of forest policy in the State of Washington was facilitated using the Forestland Database to account for the relatively dynamic land use change patterns in the state, including: lands that go in and out of forest land use, conversions between different kinds of resource land use categories, changes between family forest ownership and industrial ownership status, parcelization and agglomeration, and changes to riparian zones themselves.

In addition to social-ecological complexities, the policy environment includes a mix of regulations, an easement program for partial compensation of foregone timber revenues in riparian zones, an alternative management program, and a landowner assistance office. We outline how a combination of stakeholder interviews, policy document and budgetary reviews, two new forest owner surveys, a previous forest owner survey, and causal inference techniques using parcel data were employed to analyze the impact of the policy mix and derive policy recommendations. The report identifies policy leverage points to help sustain forestry in a complex land use environment and support riparian functions, yet after 20 years of policy implementation and ongoing conflicts most policy suggestions were not novel to policymakers. We close by discussing the challenges of distilling a 400+ page policy report into recommendations for practitioners as well as the outcomes the report has had on state policy, such as increased funding for public stewardship foresters.

Forests in systemic transition (ForTran): Bringing solutions to balancing efficiency with fairness and resilience in the forest system

T4.9 Evaluating policy outcomes in complex land-use systems

Daniel Burgas[1, 2]

Abstract: Global changes in the forest sector accentuate the conflicts among views on how to use forests. Forests are an important source of intangible and material well-being , but their resilience is being challenged by climate change and biodiversity loss. In response to these challenges, policies at EU and national levels are being designed to facilitate a green and just transition in how we perceive and use forests. To promote effectiveness and coherence among forest-related policies and actions, we need a system-level approach. To explore the importance of utilizing a system-level approach we focus on the Finnish forest system, which is affected by global phenomena such as climate change, and the increasingly polarized and politicized debates on national and international policies. Through this approach, we address the challenges faced by private sector enterprises and society in finding increasingly resilient and sustainable ways to use the forest. We combine participant observations, semi-structured interviews and facilitated workshops with forest stakeholders and governance actors to produce qualitative information to maps the rich diversity of views, values and practices regarding forests and plausible future paths towards resilient forests (JUST). To define how much forest resources can be used without compromising the natural capital of forest ecosystems (GREEN), we combine those views and needs with ecological knowledge and state-of-the-art forest simulation and optimization methods interactively with stakeholders. Simultaneously, we find solutions for business, forest management and governance to enable systemic change (TRANSITION). These findings are summarized into a new and flexible coupled human–environment systems method to bring together the social and ecological solutions for resilient forests and just green transition. The knowledge created will enrich our understanding of the interconnectedness of the social, economic and ecological dimensions of the coupled human-environment forest system and will allow for better mixes of policies and other mechanisms to unlock novel opportunities that strengthen the resilience of forest use.

How to improve the evaluation of forest outcomes under complexity – insights from large-scale deforestation assessments in the Neotropics

T4.9 Evaluating policy outcomes in complex land-use systems

Daniel Schoenig[1]
Jérôme Dupras[2], Christian Messier[1, 2]
[1] Université du Québec à Montréal
[2] Université du Québec en Outaouais

Abstract: To support decision-making, robust assessments are needed that determine how forest outcomes are affected by environmental policies and management interventions, and by the properties of the social-ecological systems in which they are embedded. The inherent complexity of forest systems makes it particularly challenging to disentangle, attribute, and quantify effects on forest change. Based on complex adaptive systems theory, we developed an approach to causal inference that allows assessing the effects of policies, interventions, and system attributes in a spatially explicit way, while addressing issues of confounding and non-linear relationships. Given that ongoing deforestation in the Neotropics continues to fuel biodiversity loss and climate change, we provide two examples of how a complex adaptive systems view can enhance our understanding of forest outcomes. The first example addresses the effect of different (and overlapping) types of protected areas governance and indigenous tenure regimes on deforestation patterns. To this end we formulated spatially explicit models based on 20 million point observations in the Amazon region and Central America. Our method allowed us to separate the effects of governance and tenure regimes both from each other and from confounding variables that are known to affect deforestation (such as distance to roads, topography, population density, and others). Our results indicate that, overall, indigenous tenure and protected areas are equally effective at reducing deforestation, but also that the effectiveness shows pronounced variation at the country scale and below. As a second example, we assessed the affect of the COVID-19 pandemic on deforestation rates in the Neotropics, again controlling for known deforestation drivers. We observed that there is a pronounced spatio-temporal variation of this effect, which suggests that the pandemic has affected deforestation through multiple pathways. Based on these examples we explain how the approach can be used to assess other forest outcomes (such as ecosystem services and biodiversity indicators) and how the results can be used to support decision-making and adaptive management.

Implementation of Public Policies in High-Risk Fire Areas: The Case of Mação, in central Portugal

T4.9 Evaluating policy outcomes in complex land-use systems

Rafael Anjos[1]
Paula Soares[1], Pedro Ochôa Carvalho[1]
[1] Forest Research Center, School of Agriculture, University of Lisbon

Abstract: Rural fires in Portugal annually devastate thousands of hectares of forest areas. High-risk fire areas experience more frequent occurrences compared to other regions of the country. Public policies are intended to play an important role in preventing these occurrences, acting at the level of forest and landscape management. This study examines the implementation of public policies in areas with high-risk fire, focusing on the case of Mação, in central Portugal. Semi-structured interviews were conducted with key institutions and political actors involved in the implementation process. This research aimed to understand the factors that determine the success and failure of public forest policies implementation. The findings revealed that coordination between institutions and stakeholders is crucial for policy implementation, highlighting the role of local political actors in carrying out political measures. The results allow us to understand the need for inter-institutional coordination strategies and mechanisms are important to mitigate these frequent fire occurrences.

Integrative governance, multi-actors, and power relationships to human-elephant conflict: The case of elephants in Xishuangbanna, China

T4.9 Evaluating policy outcomes in complex land-use systems

Feng Ba[1]
Yao Zhang[1]
[1] China Agricultural University

Abstract: The conservation of nature is critical for the preservation of biodiversity. However, it can also lead to conflicts and challenges for communities who rely on natural resources. This paper focuses on the Human-Elephant conflict (HEC) in Xishuangbanna National Nature Reserve, China, and examines the causal linkages between governance systems and HEC. Drawing on integrated governance (IG) theory and actor-centered power (ACP), we analyze the influence and interaction of three policy systems, namely Asian elephant conservation policy, agricultural development policy, and forestry policy, on the governance of HECs. We also explore the power dynamics among multiple actors involved in policy formulation and those affected by policies to identify the drivers that influence the performance of governance. Our findings suggest that the interaction within policy systems significantly impacts the transition of land use and human-elephant relationship at different governance stages, with farmers playing a crucial role in shaping conflict management. Specifically, we document a 30-year evolution of human-elephant relationship in a tropical rainforest community and provide recommendations for future conflict management from the perspective of integrated governance. Overall, our research contributes to a better understanding of the complex dynamics of wildlife conservation and its impacts on local communities, emphasizing the importance of adopting an integrated governance approach in managing conflicts.

Research on the Profit Contribution of Forest Ecological Benefits—Based on Policy and Market-Tools Compensation Projects in Nanping

T4.9 Evaluating policy outcomes in complex land-use systems

Yingli Huang[1]
Jiabin Yao[1]
[1] Northeast Forestry University, China

Abstract: Abstract: Measuring the profit contribution of ecological benefits is an important prerequisite for the operation of the value-realization mechanism of ecological products. Based on the theory of ecological benefits and ecosystem services, combined with system dynamics and the project cost benefit method, a forest-ecosystem-service capitalization of the resources and assets value and the realization of an ecological product-benefit system is constructed. The value-realization project of the national reserve-forest ecological products in Nan-ping City, Fujian Province, the National Ecological Civilization Pilot Zone, was selected to calculate the cost and income during the 30-year operational period of the project, and to calculate the profitability of the forest-ecosystem ecological benefits in the project, using different scenarios. Scenario 1: The project income will only be enough to cover the costs of the project operation, and the cost will be recovered at the end of the project operation. Scenario 2: With policy-based ecological compensation, compared with scenario 1, the total project-input line-of-revenue breakthrough and total project-cost line were advanced by 3 years and 2.5 years, respectively. Scenario 3: With the additive effect of the ecological benefit of the ecosystem, compared with scenario 2, the total project-input line-of-revenue breakthrough and total project-cost line were advanced by 3.5 years and 6 years, respectively. It is suggested that the guiding role should be that of policy-based ecological compensation, expanding the scope of ecological-market access, and attracting social investors to participate in the development of ecological products by means of diversified ecological compensation such as market-oriented tools, so as to fully realize the profit contribution of ecological benefits to the project through the realization of the value of ecological products.

Structural Leverage Points for Sustainability Transitions in Polycentric Forest Governance: The Case of Forest Genetic Resources Policies in Europe

Abstract: To tackle deforestation, biodiversity loss, and climate change, Europe is taking a lead role by adopting numerous policies (e.g., the Green Deal) related to access, management, and use of natural resources, aiming at transitions towards a sustainable, green, and just society. Thus, we are facing significantly increasing policy complexity that implies high possibilities of incoherence within domain-specific policies and among policy domains and policy levels. Multiple effects, as substantial trade-offs and spillovers can be further observed in further transposing of the EU policies to regional, national, sub-national, and consequently local levels. While on the decision-making level transition efforts might result in uncoordinated policies and ill-designed policy instruments, on the implementation level, this might manifest in inefficient and poor implementation that reflects in the unsatisfactory state of forests and other natural resources. Starting from the premise that forest genetic resources (FGR) are a basic constitutive unit of forest trees and ecosystems underpinning biodiversity, adaptation, and resilience, our contribution illustrates the complexity of polycentric forest governance by identifying social/system-level leverage points and potential strategic policy interventions, based on the case of FGR in Europe. Building on the literature review, expert

interviews, and policy gap analysis within Horizon Europe project OptFORESTS (101081774), we analyzed policy gaps pertaining to FGR. We explored policy domains that both directly and indirectly relate to FGR in Europe, mapped current and forthcoming European policies, and identified types of policy instruments. Our results indicate that there are at least four policy domains to consider based on their *sensu* relation, as the manner by which they address FGR *(sensu eminenti, stricto, lato, and amplo*). By focusing on *sensu* relationships of policies at the intersection of different policy domains, we identified synergies and tradeoffs between policy instruments and pointed leverage points in policy areas that will be the key for future actions in facilitating sustainability transitions. To guide future policy reforms and adjustments for unlocking the potential of FGR for a more resilient environment and sustainable society, we provide a better understanding of policy (in)coherence among and within policy domains such as agriculture, environment, health, and technology.

Synergistic Approaches to Sectoral Policy Coordination: A Case Study of North Korea

T4.9 Evaluating policy outcomes in complex land-use systems

Suyeon Min[1]
Mi Sun Park[1, 2]
[1] Graduate School of International Agricultural Technology, Seoul National University, Pyeongchang, Gangwon 25354, Republic of Korea
[2] Center for International Agricultural Development, Institutes of Green Bio Science and Technology, Seoul National University, Pyeongchang, Gangwon 25354, Republic of Korea

Abstract: This research delves into the intricacies of forest governance and policy coordination with a focus on promoting sustainable forest management in North Korea. The study investigates the complex land-use systems that involve conflicts over forest resources and competing interests in rural development, economic growth, agriculture, landscape management, and environmental protection. By conducting a meticulous analysis of 56 forest-related laws and their provisions, this research sheds light on the synergistic contributions of diverse sectors to the dynamics of forest management. An analytical framework is employed to categorize forest-related articles based on their respective ecosystem services, allowing for a comprehensive assessment of sectoral coordination and the diverse functions fulfilled by forests.

The findings of this study underscore the significance of provisioning services in fostering coordination between the forest and agricultural sectors, highlight the role of cultural services in facilitating coordination between the forest and urban sectors, and emphasize the foundational importance of supporting and regulating services in achieving coordination across the forest, environmental, and energy sectors. This enhanced understanding of sectoral coordination emphasizes the distinct functions fulfilled by each ecosystem service, paving the way for effective forest management strategies.

This study provides a comprehensive overview of the complexities inherent in decision-making processes, trade-offs, and the multifaceted policies required to effectively combat deforestation and promote sustainable forest management. Considering diverse interests and the varied utilization of forest resources, the result offers insights into transforming trade-offs and conflicts into opportunities for synergistic cooperation. Moreover, the research identifies crucial leverage points within ecosystem services to facilitate sectoral coordination of forest and non-forest sectors. The findings of this study propose a constructive option, highlighting the benefits of shared management through coordinated efforts among sectors, as informed by the comprehensive legal analysis conducted. This research contributes to the body of knowledge on forest governance, providing valuable insights for policymakers, practitioners, and scholars working towards sustainable forest management and the conservation of forest resources.

Synthesizing the evidence of anticipatory forest use behaviours under policy introduction

T4.9 Evaluating policy outcomes in complex land-use systems

Jorge C. Llopis[1, 2, 3]
Neal R. Haddaway[4, 5], Nurzhan Omirbek[1], Blake A. Simmons[6], Rachael Garrett[7], Julia P.G. Jones[1]
[1] School of Natural Sciences, Bangor University, UK

[5] Africa Centre for Evidence, University of Johannesburg, South Africa
[6] Tampa Bay Estuary Program, St. Petersburg, FL, USA
[7] Department of Geography and Conservation Research Institute, University of Cambridge, UK

Abstract: Sound forest conservation policy is needed to tackle the combined challenges of climate change and biodiversity decline. However, policy introduction might potentially trigger unexpected outcomes, such as displacement effects, where avoided deforestation is spatially displaced elsewhere, or rebound effects, where gains in resource use efficiency leads to increased extraction of the resource. The implications of these unintended policy outcomes are well understood and considered by policy makers. However, a set of unintended outcomes of forest conservation policy that has so far escaped detailed scrutiny is that of anticipatory behaviours, where forest edge residents or landowners change behaviour in advance of policy implementation.

Anticipatory forest use behaviours have been detected under a range of policies. A classic example are nation-wide conservation policies, like the Endangered Species Act in the United States, with several cases reported where landowners pre-emptively destroyed endangered species' forest habitat within their property. Terrestrial protected areas establishment also led to pre-emptive forest clearings by forest edge populations in Madagascar, to secure land that would be out of reach once the conservation scheme would be in place. Even if not directly aimed at forest conservation, land titling programmes may also encourage related behaviours, such increased conversion of forest to agricultural land, in the hope farmers will acquire a formal title for the land just cleared through the forthcoming programme, which was found in Cambodia and Madagascar. Such behaviours might also emerge in the case of voluntary participation to programmes, like sustainability certification of agricultural commodities production, which found with palm oil in Indonesia.

In this talk we will present results from an evidence synthesis we are conducting to compile and describe the evidence on anticipatory forest use behaviours under the introduction of policy around the globe. The synthesis is being conducted as a systematic map, and the database resulting from this work, which contains all relevant studies and their attributes, will be freely available to interested users. The database will serve as repository of cases to help increase decision-maker's awareness of the risk of policies triggering such unintended behaviours, and hopefully, will stimulate more formal study of the phenomenon.

The burden of multifunctionality: balancing timber provisioning, carbon sequestration and biodiversity targets in Swedish forests

T4.9 Evaluating policy outcomes in complex land-use systems

Federico Lingua[1]
Sampo Soimakallio[2], Jari Niemi[2], Jenni Nordén[3], Line Nybakken[4], Tord Snäll[1]

[2] Finnish Environment Institute, Helsinki, Finland
[3] Norwegian Institute for Nature Research (NINA), Oslo, Norway
[4] Faculty of Environmental Sciences and Natural Resource Management, Norwegian University of Life Sciences, Aas, Norway

Abstract: In recent decades, public awareness regarding the vital role forests play in providing a wide range of services to human society has been steadily increasing. This is reflected in targets of EU policies such as the Biodiversity Strategy for 2030 and the New EU Forest Strategy for 2030, which recognize the multifunctional nature of forests and advocate for increasing the share of protected land area. However, concurrently, in the Fennoscandian region there are evidences of an increase in harvest levels. Hence, forests in Europe appear to be subject to divergent policy objectives, and questions arise on their ability of simultaneously fulfil all the expectations that policy-makers and stakeholders have placed on them.

In this context, it is crucial to obtain an understanding of the trade-offs and synergies among forest ecosystem services at the national scale. It is equally important to consider the potential consequences that the EU forest policies may have on the provision of ecosystem services in the short, medium, and long term and hence the feasibility of their objectives. In the present work, we conduct such analysis of the Swedish forests.

The backbone of our work is a comprehensive century-long nationwide forest simulation that incorporates over 100 management alternatives, utilizing data from national forest inventory plots. For each of these alternatives, we estimated the expected harvest levels, functional biodiversity and climate benefits provided based on a life-cycle analysis assessment. Lastly, by employing multi-objective optimization we select the optimal set of management alternatives to achieve the different goals set by EU policies and investigate the consequences that these could have on the future of Swedish forests.

Our analysis suggest that while forests certainly do play a central role in reaching the ambitious Green Deal targets they cannot simultaneously meet all of them targets posed by EU policies. Therefore, to avoid suboptimal forest use and management, realistic quantitative targets of forest biodiversity and ecosystem services should be urgently proposed and implemented.

“Which strategies should we use?” - Modelling actors’ decision-making to forest policy interventions

T4.9 Evaluating policy outcomes in complex land-use systems

Hanna Ekström[1, 2]
[1] Department of Political Science, Lund University
[2] Centre for Environmental and Climate Science, Lund University

Abstract: Recent forest policy debates have highlighted an increased recognition of the diverse values that different actors see in forest ecosystems. In combination with evidence of the importance that resilient forest ecosystems have in relation to climate change mitigation, livelihoods and biodiversity, there is an urgent need for methods that take broader perspectives into account to understand the complexity of governing forest systems.

In this study, we combine a social-ecological system understanding of forests with policy feedback theory for seeing how policy interventions are received by forest actors, and how their interactions and decisions in turn affect forest use. A mixed methods approach is applied, using the spatially explicit agent-based modelling framework CRAFTY. Agents’ decision-making is informed by historical land use data and interviews with Swedish forest actors. The case is focused on Swedish forest policy interventions, with the purpose to explore the mechanisms between forest actors and the environment, and whether and how these interactions are driving changes in the forest landscape.

The results indicate that while objectives and beliefs are important dimensions for distinguishing forest actors’ decision-making, actors’ time, and resources for seeking advice and accessing new practices have a major impact on how policy interventions play out. The study shows promising results for using agent-based model as a tool for capturing trade-offs in complex governance problems, by integrating qualitative data from participatory processes in combination with social simulations and a dynamic vegetation model. In this way, the study contributes to methodological development on how integration of quantitative and qualitative data representing different types of knowledge production can broaden our understanding of complexity within forest governance.

T4.10 Finding paths in everyday forest negotiations – towards sustainability and justice in climate transitions

Climate vulnerability and the politics of forest restoration in India

T4.10 Finding paths in everyday forest negotiations – towards sustainability and justice in climate transitions

Kanchi Kohli[1]
Manju Menon[1]
[1] Independent Researcher

Abstract: Global climate agreements have required national government to pledge contributions for emissions reduction and commit to net zero emissions targets. India's NDCs present a threefold strategy to reduce emissions, offset the emissions reduction gap and increase climate finance to achieve these outcomes. In this paper we examine policy and legal apparatus adopted by national and sub national governments in India to achieve "additional carbon sink of 2.5 to 3 billion tonnes of CO2 equivalent through additional forest and tree cover by 2030." The paper will use the recently proposed amendments to India's forest conservation legislation to understand the national government's persuasion to legally recognise the role of forests in achieving emissions mitigation targets. Does this proposed amendment reorganise the federal structure of India forest restoration practices? Does it facilitate title holding indigenous and forest dwelling communities in being partners in climate mitigation? The paper will draw upon an historical understanding of forest restoration practices in India and examine their role in India's climate policy discourse.

Everyday struggles to transform tree rights: The decentralization and recentralization of state and corporate power through community-based management

T4.10 Finding paths in everyday forest negotiations – towards sustainability and justice in climate transitions

Eric Kumeh[1]
Mark Hirons[1], **Constance McDermott**[1]
[1] University of Oxford

Abstract: Community Resource Management Areas (CREMAs) have come to play a central role in Ghana's climate mitigation and adaptation strategies in the cocoa growing regions of southern Ghana. Initially formed as institutions to facilitate community-based wildlife management and habitat protection in a manner that is 'socially just' – i.e., locally empowering and beneficial – they have more recently been elevated to a central role in Ghana's Reducing Emissions from Deforestation and Degradation (REDD+) strategy. This paper draws on case studies in two different cocoa forest landscapes, with different histories of external interventions, to unpack how this 'climatization' of CREMAs as mechanisms for social justice has generated everyday struggles across multiple scales, from local actors to the Ghanaian Wildlife and Forestry Departments, Non-Governmental Organizations (NGOs) and cocoa companies.

Based on 44 key informant interviews, participant observation and 32 focus group discussions, we find evidence of both decentralization and recentralization of decision-making power in REDD+ processes among communities and higher levels of state and corporate actors. Evidence of decentralization is strongest in CREMAs that receive relatively strong and sustained local and NGO support, though in all cases farmers' lack of tree tenure rights favors state control over tree resources. Meanwhile, power struggles between government agencies and/or between cocoa companies sourcing in the same area have led to competing social justice claims, with destabilizing and variable effects on power across scales. These findings highlight the importance of everyday forest relations across all scales and how the social justice claims of community-based management may be variably harnessed to decentralize or recentralize forest and climate governance.

Geopolitics and everyday forest conservation in North Karelia and Finnmark: the case of the Greenbelt of Fennoscandia Initiative

T4.10 Finding paths in everyday forest negotiations – towards sustainability and justice in climate transitions

Ian Florin[1]
[1] University of Geneva

Abstract: This presentation aims to communicate to practitioners and researchers the results of a research conducted in Scandinavia and published in 2023 in the journal Sociologia Ruralis.

It investigates how the framing of forest conservation in terms of sustainable development both enables and constrains participation in conservation initiatives. The Green Belt of Fennoscandia, an initiative to develop a transnational ecological network of old forests between Finland, Russia and Norway, is used as a case study.

A desk study and 40 interviews with participants of two regional working groups from this initiative show how the mobilisation of the concept of sustainability encourages actors living in and near high conservation value areas to become leaders of projects in favour of both nature conservation and economic development. This research also describes how the lack of state engagement and potential conflicts between regional and national levels can discourage these actors to commit to the initiative.

This research refines previous work on the reduction of the role of the state in conservation, illustrating the scalar dynamics of sustainable development implementation in a European rural context. It provides material to inform the governance of conservation projects, by highlighting how an approach that aims to boost local participation can in fact discourage it, if the reduction of the role of the state is not accompanied by resources, formal rights to democratic representation or/and an acknowledgement of past work.

Green transition vs local realities in forestry: Finland and Sweden

T4.10 Finding paths in everyday forest negotiations – towards sustainability and justice in climate transitions

Isidora Dabic[1, 2]
Jerbelle Elomina[1, 2], Ivana Zivojinovic[1, 2, 3], Gun Lidestav[4]

[4] University of Agricultural Sciences, Umeå, Sweden

Abstract: For more than a century, forest industry has been an integral part of the regional economy in Northern Finland and Northern Sweden as well as the main contributor to the net export value. Consequently, national forest strategies have promoted the use of forest for industrial expansion and economic growth. However, sustainability concerns and more recently expectations on green transition, highlights the competing land use interest in the region. As the latter brings about an extensive increase in the mining industry and wind power production and distribution, it becomes essential to examine, at multiple levels, how green transition is understood in relation to forest use and what are the trade-offs and synergies realized in the localities. Through the analysis of national and regional strategies, and semi structures interviews with local experts in two forest industry dependent municipality Kemi in northern Finland and Malå in northern Sweden. Ensuing, we problematize the complexity of long-term competing land use interests amplified by the green transition movement. Results show that for both municipalities, there is an expansion of the forest industry's wood procurement area brought about by the increase in demand of wood within and outside the municipality. Such expansion means encroachment to the existing land use which is reindeer husbandry, tourism, hunting and gathering of natural products as every man's right in both countries. Reconciliation is needed between the actors to sustainably manage the forests and have a better understanding of the different actors' perspectives.

Guiding principles for Romanian Forest Strategy: stakeholders perceptions

T4.10 Finding paths in everyday forest negotiations – towards sustainability and justice in climate transitions

Nicolae Talpă[1]
Aureliu-Florin Hălălișan[1], Liviu Nichiforel[2], Bogdan Popa[1]
[1] Department of Forest Engineering, Faculty of Silviculture and Forest Engineering, Transilvania University of Brașov, Șirul Beethoven No. 1, 500123 Brașov, Romania.
[2] Faculty of Forestry, Ștefan cel Mare University, Universității No. 13, 720229 Suceava, Romania.

Abstract: An important step in promoting a strategic direction to ensure a sustainable way of managing forests in Romania was the elaboration of the National Forest Strategy for 2030. This strategy contributes to the desired integration of European level objectives into national strategic plans by referring to the objectives contained in the New European Forest Strategy for 2030. The strategic options for the development of forest policies proposed in the strategy were formulated based on several guiding principles of forest management, reiterated from the perspective of validating the strategic assumptions at the European level. The guiding principles that should guide public policy in the forestry field and the main recommendations for their operationalization were subjected to a public consultation process with the stakeholders in the forestry sector. This research presents and qualitatively analyzes the opinions expressed by the participants regarding the proposed guiding principles for forest policy. The analysis is based on 146 responses received from those enrolled in the process (response rate 68%). The results showed that different degrees of consensus were highlighted during the consultation. Principles with a high consensus, reflected in firm strategic desires, and principles that create controversy among respondents, reflected in contradictory strategic options, were identified. Also, 74 responses corresponding to the formulation of new principles were recorded within the consultative process, their relevance being analyzed within this research. The guiding principles, as emerged from the opinions expressed by stakeholders, are: a) related to forest management: the principle of ensuring the continuity of ecosystem services, the principle of ensuring the stability of forest ecosystems, the principle of representativeness in biodiversity conservation, the principle of economic viability and competitiveness; b) principles of good governance: the principle of scientific substantiation, the principle of legislative coherence, the principle of administrative efficiency, the principle of respect for property, the principle of intersectoral integration, the principle of participatory politics and the principle of transparency. The importance of analyzing these principles results from the fact that they must provide the basis for the creation of a forest governance framework adapted to the structural changes of the national forestry sector.

Inclusive multi-use forestry adoption in Sweden through social learning networks

T4.10 Finding paths in everyday forest negotiations – towards sustainability and justice in climate transitions

Jenny Friman[1]
Jayne Glass[1], Therese Bjärstig[2]
[1] Uppsala university
[2] Umeå university

Abstract: Forest management practices in Sweden are embedded in an established industrial structure in which forests are managed for industrial timber supply, yet this structure has been criticized for hindering the adoption of sustainable forest management practices. Multi-use of forests holds the potential to leverage alternative and more sustainable forest management methods. Adopting alternative forest stewardship methods can contribute to diversifying primary production and provide a wider variety of income opportunities in rural regions while also improving a wide range of environmental benefits and social inclusion. The aim of the study is to explore how social learning for adopting multi-use forestry can be facilitated and negotiated by social networks and build an inclusive forest management. These relations were investigated by following family forest owners who already are adopting multi-use forestry and alternative forest management practices, and their micro-level social networks in three geographic regions in Sweden. This was done by using qualitative methods such as semi-structured interviews, structured observations and group discussions. The study investigates how institutional structures and intersectional social dynamics impact the adoption of multi-use forestry by family forest owners. The study pays attention to the power dynamics and social relations between forest owners and the social networks and other actors within the forestry sector and how these dynamics impact the adoption of multi-use practices. The insights from this study have the potential to improve policy interventions that enable and accelerate the processes of inclusive and just social learning and forest innovation between key actors to accelerate the implementation of more sustainable forest use and management.

Struggles and limits for territorial sovereignty in the context of forest extractivism: cases in Galicia, Spain and Araucania Region in Southern Chile

T4.10 Finding paths in everyday forest negotiations – towards sustainability and justice in climate transitions

Marien González-Hidalgo[1]
Diego Andreucci[2], Sandra López[3], Rita Calvario[4]
[1] Swedish University of Agricultural Sciences
[2] Universidad de Barcelona, Barcelona, Spain
[3] Universidad de la Frontera, Temuco, Chile
[4] University of Coimbra, Coimbra, Portugal

Abstract: In recent years, the concept of sovereignty has been key to centering the power of communities and peoples who are unequally affected by environmental changes, conflicts and disasters. Concepts such as "Food Sovereignty" and "Energy Sovereignty" are currently key in the work of social movements (such as La Vía Campesina) to put the rights of peoples at the center above the economic interests of the agro-industry, and related to the generation, distribution and consumption of energy, respectively. However, and despite being highly contested spaces, a specific debate of the term "sovereignty" in forest contexts has not yet been discussed in detail, or beyond its connections with territorial sovereignty. In this communication, we first present the concept of forest sovereignty as a term where environmental justice and decolonial ambitions meet in defining the future of forested areas for the people living in the territories. Further on, we analyse preliminary interviews with local communities, urban and rural activists who live in forest territories in conflict in North-West Spain and Southern Chile in order to discuss the struggles and limits of forest sovereignty in such contexts.

Sustainability and justice in Northern forests? Exploring intersecting and cumulative land-use conflicts in Swedish Sápmi

T4.10 Finding paths in everyday forest negotiations – towards sustainability and justice in climate transitions

Karin Beland Lindahl[1]
Tom Mels[2]
[1] Unit of Political Science, Department of Economy, Technology, Art and Society, Luleå University of Technology
[2] Department of Human Geography, Uppsala University, Campus Gotland

Abstract: It is often claimed that climate mitigation and, more broadly, a transition to a sustainable future, is heavily reliant on renewable and non-renewable resources. Forests are expected to contribute to climate mitigation, while being managed and subject to different kinds of resource exploitation. Massive investments are currently directed towards northern Sweden to increase fossil free production of electricity (including batteries) and steel. This transition towards green technologies involves increased demands for biomass, timber, minerals and wind for power production. These resources are available in the forests of Sápmi, the traditional territory of the Indigenous Swedish Sámi. However, the cumulative land use implications of ongoing and planned industrial activities and investments are substantial and contentious. Resource extraction has not least far-reaching impacts on rural environments and local and indigenous communities. Indigenous Sámi reindeer herding communities (RHCs) depend on access to forests while encountering increasingly intensified forestry practices. Deeply concerned about the cumulative effects of forestry, mineral exploitation, and energy production, they call for alternative visions of a transition to a fossil-free and just society.

This paper explores the prospects of new collaborative planning solutions to intersecting forest- and mineral-related land use conflicts in Swedish Sápmi. Based on interviews with Sámi RHCs, other key actors and an analysis of relevant policies, it explores the intersection of different knowledge systems and understandings of justice in the context of forests and collaborative land use planning. The paper specifically addresses the importance of landscapes and institutions conditioning the collaborative system, trade-offs and claims to justice. Two questions are addressed: how do rights- and stakeholders make claims to justice and connect these to forest landscapes and institutions; and how can collaborative planning, claims to justice, and supporting institutions be coordinated to facilitate trade-offs that are perceived as fair and legitimate? While the empirical focus of this project is on forest management and mining in northern Sweden, the conceptual approach and planning solutions may be applied to other contexts and support transition to a sustainable future.

Traditional Sámi knowledge, Árbbediehto in collaborative land use planning

T4.10 Finding paths in everyday forest negotiations – towards sustainability and justice in climate transitions

Kajsa Kuoljok[1]
[1] Swedish University of Agricultural Sciences, Uppsala

Abstract: The Sámi culture and economic activities have revolved around the forest for thousands of years. Reindeer husbandry has been a central Sámi livelihood and is conducted on almost 50 % of the land area in Sweden. Reindeer husbandry depends on having a large grazing area and a range of forest in different ages. As reindeer primarily graze lichen under the snow during winter and terrestrial lichens growing in old pine forest, a varied landscape is an important factor for husbandry. In Sápmi fragmentation and competition in the reindeer grazing areas from infrastructure, mining, wind power, forestry and effects of climate change causes stress upon reindeer herders. Sámi critical voices highlight the unquestioned rush to support renewable energy production without taking the Sámi rights into recognition.

By looking how Sámi reindeer herders understand and conceptualise land use conflict in reindeer grazing land, ways to adapt to these challenges are discussed. Reindeer herder´s close relationship with the forest and their traditional Sámi knowledge, *árbbediehto* are some key factors in their adaption strategies. *Árbbediehto* has evolved over long period of time and is transferred from generation to generation. However, unpredictably changing environment and climate poses new circumstances for husbandry and challenges the value and the usefulness of *árbbediehto*. The adaptive capacity of reindeer herders today is also hampered by lack of political power and lack of supporting legislation. This restrains reindeer herders' opportunities to practice their livelihood as preferred.

From an ethnological perspective, this case study has through interviews with experienced reindeer herders from different Sámi reindeer herding communities in Norrbotten and Västerbotten County explored herders' strategies to meet land use conflicts and climate transition. The interviews have focused on the role of *árbbediehto* in adaptation and its possible use in collaborative land use planning to handle land use conflicts. Further, the intersection of different knowledge systems in planning has been explored. For future, better appreciation for and understanding of reindeer husbandry and use of *árbbediehto* in ways that are fair and ethical appropriate in the society would improve life for reindeer herders. Also regulations that strengthen Sámi rights in land use conflicts.

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

Biocultural Treescapes: Exploring the Feedback between Values of and Care for Trees

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

Jacqueline Hamilton[1]
Elena Bennett[1], Murray Humphries[1]
[1] Department of Natural Resource Sciences, McGill University

Abstract: The ways that people value trees influences how they act toward the trees in their care in complex and nuanced ways. Our study investigates the reciprocal relationship between people and trees in the Mont Saint Hilaire Biosphere Reserve, near Montreal, Canada. This study provides valuable insights into the feedback between trees and tree managers. Our findings highlight the importance of people's values, in addition to ecology, in shaping forests.

Using a mixed method approach, we illustrate that specific values, particularly values relating to the provisioning and cultural contributions of trees, shape the care work of land managers and ultimately the biophysical structure of trees in the Mont Saint Hilaire Biosphere Reserve in ways that are often not captured in models of ecosystem services or similar concepts. We identify ways in which these values influence forest management practices like promoting the growth of certain species or pruning to promote or reduce fruit production.

We used a combination of random ecological plots to assess the biophysical attributes of trees and forests within the mixed land uses of the Mont Saint Hilaire Biosphere Reserve, followed by semi-structured interviews to understand the ways in which land managers value and manage those specific randomly selected trees. Our results show that people are shaping trees and forests based on their values in addition to other factors like resources and knowledge.

Our results also emphasize the intrinsic value of care work for trees. Land managers expressed the act of managing trees (planting, pruning, cutting) as a mutual benefit to trees and themselves. By probing the feedbacks between value and management, our understanding of the role of land managers in nature's contributions to people through management or care work can be enhanced, contributing to a more complete understanding of how people shape forests. We hope our results will be of interest to those seeking to understand the governance of trees, promoting a holistic approach that recognizes the diversity of values associated with trees and fostering a sense of responsibility for their care and our mutual wellbeing.

Building community and individual RESilience thrOugh NATurE based therapies (RESONATE)

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

[13] Natuurvoormensen

Abstract: We present an overview of an ongoing Horizon Europe funded project (RESONATE, 2023-2027) which is exploring the impact of nature-based therapies on human health and well-being. The talk will begin with an overview of a new theoretical framework developed especially for the project which argues that many of the positive associations between contact with the natural world, especially forests, and health and well-being can be explained via nature's ability to build and maintain biological, psychological and social (i.e. biopsychosocial) resources that make people more resilient to everyday and chronic stressors. We call this new approach Nature-based Biopsychosocial Resilience Theory (NBRT). Building on this novel theoretical approach we will explain how the RESONATE project is exploring nature's role in building biopsychosocial resilience through: 1) a systematic mapping review of existing nature-based therapies globally; and 2) nine original Case Studies each of which are evaluating health, environmental, economic and social outcomes. In addition to discussing how we are measuring the effectiveness of the interventions, we will explain how we are paying particular attention to the mechanisms underpinning successful project implementation and expansion by integrating Social Innovation Action approaches with Process Evaluation methodologies developed to assess complex interventions in public health. Our aim is to provide a clear set of What Works Guidelines tailored to different stakeholders' needs (e.g. health practitioners, land owners, forestry organisations, local planners, resident bodies etc.) which can be used to develop and sustain wider uptake of nature-based therapies to promote health and prevent disease in populations across Europe and beyond.

Creation of socially sustainable conditions for nature stays of preschool children in public care

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

Elisabeth Quendler[1, 2]
Dominik Mühlberger[2], **Alina Branco**[1]
[1] University of Natrual Resources and Life Sciences, Insitute of Agricultural Engineering, Peter Jordan Straße 82, 1190 Wien
[2] Bundesforschungszentrum für Wald, Seckendorff-Gudent-Weg 8, 1131 Wien

Abstract: In the past decades, numerous nature children's groups have been founded in Austria, which hereby make an essential contribution to more nature knowledge transfer to preschool children.

Due to the physical underload and psychological overload (lack of exercise, digitalization, ...), to which preschool children are now exposed, the urgency of nature education in the context of public care at preschool age increases.

Furthermore, there is the circumstance that preschool children before the mandatory kindergarten year cannot spend several times per year, legally insured against accidents in the natural environment. In order to obtain insurance coverage, the public insurance carriers consider the fulfillment of minimum requirements for the natural area similar to existing in the public sector.

The first necessary step is the survey of the current situation in nature children groups, in order to be able to derive minimum requirements for the natural space as well as existing built infrastructure.

Cycling in different environments: mental well-being in South American and European contexts - preliminary results

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

Emerson Soldado[1, 2]
Adilson Marques[3], Nuno Loureiro[4], Teresa Magro-Lindenkamp[1]
[1] University of São Paulo, Brazil
[2] Federal Institute of São Paulo, Brazil
[3] University of Lisbon, Portugal
[4] Polytechnic Institute of Beja, Portugal

Abstract: The connection between well-being, physical activity, and contact with nature is an emerging topic in academic research, particularly given its pertinence to planetary health. This study investigates potential correlations between the frequency of bicycle use in different environments and mental well-being, employing a comparative approach between Brazil and Portugal. Using an online questionnaire, established psychometric scales were applied, including the Perceived Stress Scale-4 (PSS-4), the 5-item World Health Organization Well-Being Scale (WHO-5), and the Positive and Negative Affect Schedule (PANAS). Additionally, questions about bicycle use and sociodemographic information were included. The Brazilian sample (n=405, average age 46.94, 28.7% female, 71.3% male) showed significant differences with higher levels of negative affect and lower well-being on the WHO-5 scale compared to the Portuguese sample (n=95, average age 43.41, 9.5% female, 90.5% male). Preliminary analyses using Spearman's correlation showed, in the Brazilian sample, bicycle use in rural areas negatively correlated ($p < 0.05$) with perceived stress ($r=-0.247$) and negative affect ($r=-0.263$) and positively with WHO well-being ($r= 0.264$) and positive affect ($r=0.309$). Similarly, trail use showed a correlation with perceived stress ($r=-0.232$), negative affect ($r=-0.202$), well-being ($r=0.257$), and positive affect ($r=0.342$). However, no significant correlations were found on the parameter evaluated in urban contexts and highways. In Portugal, leisure park usage presented the sole significant correlation, positively aligning with positive affect ($r= 0.404$). Though not significant, rural and trail environments correlated positively with positive affect and well-being and negatively with negative affect and PSS. Similar to Brazil, urban contexts and highways showed no significant correlations. Despite these correlations being less intense than those in Brazil, they pointed in the same direction, indicating similar patterns between the two countries. In summary, while this study is ongoing and the results are preliminary, data suggest that cycling in environments with more natural elements in Brazil and Portugal may be associated with improved mental well-being. However, it is crucial to underline that correlation does not imply causality. Further research is necessary to deepen these findings and explore potential causal mechanisms.

Economic Valuation of Cultural Ecosystem Services: A Review of the Methods with a Focus on Green Care

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

Aisling R. Sealy Phelan[1]
Elena Pisani[1], Mauro Masiero[1], Laura Secco[1]
[1] Dept. of Land, Environment, Agriculture and Forestry (TESAF) - University of Padova, Italy

Abstract: Green Care (GC) is a catch-all term summarising initiatives that primarily address human physical and psychological health, wellbeing, and social inclusion with human-nature interactions at its core. To date, most studies have focused on the therapeutic effectiveness of GC interventions, while systematic research evaluating the economic value of GC benefits is still limited. Such intangible benefits from nature can be conceptualised within the ecosystem services framework as cultural ecosystem services (CES). Although methods are available for the monetary valuation of CES, they are complex and results are often context-specific; hence CES, in general, are undervalued and understudied, and the total economic value of GC still largely unexplored. The aim of this study, is to undertake a comprehensive analysis of the literature on the monetary valuation of CES with the intention of identifying and evaluating suitable methods for a subsequent valuation of the health and wellbeing benefits delivered by GC. Using a systematic approach, this study conducts a global literature review of peer-reviewed studies identified by applying a pre-determined search protocol in the Scopus database. Search keywords were selected based on a rigorous testing and refining process by the authors. Inclusion/exclusion criteria were defined to select relevant papers for further detailed analysis. The selected studies are categorised and analysed for commonalities, methods employed, and evaluated considering our overall focus on the economic value of GC.
Our results show a variety of different methods are applied to the valuation of CES, such as the travel cost method (TCM) and choice experiments. Most of the studies focus on use values by employing the TCM and/or valuing recreational services while less studies address non-use values. Many studies combined several methods, frequently integrating non-market valuation with qualitative methods. Few studies address the benefits of GC, however those identified employed direct market valuation approaches, such as the avoided cost method. In light of our research objective, and our results indicating a lack of studies focusing on the valuation of the benefits of GC, we identify several relevant methods for this task such as cost-based approaches and choice experiments and critically evaluate their suitability.

Exploring the factors related to eco-tour guides toward sustainable ecotourism in Amami-Oshima Island, Japan

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

Soshi Aiba[1]
Sayed Abdullah Waez Zada[1], Kazuhiro Harada[1]
[1] Nagoya University

Abstract: Ecotourism is a sustainable form of tourism that aims to balance environmental protection and tourism use, and ecotour guides are increasingly attracting the attention of stakeholders as key coordinators of this effort. We conducted a case study focusing on eco tour guides on Amami Oshima Island, Japan, to determine the factors for environmental exploitation and protection in a sustainable manner. The findings indicated, through a chronological analysis of local attitudes that prior to the 1990s, that there was a conflict between environmental protection and use in the wake of large-scale development projects. However, since the 2000s, there was increased momentum for the designation of national parks and world heritage sites, and an increased focus on stage-wise changes in protection and use, rather than opposition to them.

A system employing eco-tour guides was established, along with the designation of national parks and world heritage sites. These guides led the creation of the system, and a consensus on environmental use was obtained through engagement with residents and the government. The increased number of guides contributed to a certain level of success in these attempts at effective ecotourism.

However, the recognition of ecotour guides by tourists and compliance with voluntarily established rules were cited as problems. Thus, we found that developing a system is insufficient, and acknowledgement of how the environment has been accepted and interpreted locally is essential to balance nature conservation and tourism.

Green Care Innovation System Framework. An analytical tool to understand leverages for advancing nature-based health and well-being in Europe

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

Aynur Mammadova[1]
Catie Burlando[2], Colm O'Driscoll[3], Ilaria Doimo[3], Davide Pettenella[1]
[1] University of Padova
[2] Impact Hub Ticino
[3] Etifor

Abstract: In the Anthropocene, the climate crisis, biodiversity loss, and urbanization have profound effects on health and well-being. Decoupling humans from nature in the current economic system also leads to the loss of stewardship, cultural identity, and sense of place. It manifests as rural outmigration, weakened social ties, reduced value-generating activities, exacerbated social inequalities, and increased socioeconomic instabilities. Green Care has emerged searching for solutions that focus on the interconnectedness between nature and human resilience. In this research, we take Green Care as an umbrella concept that recognises the nature-human interdependence and focuses on designing opportunities for contact and connection with natural environments to address individual and societal needs, with special attention to reduced impact on nature. In this definition, Green Care spans across diverse knowledge and value systems, disciplines, sectors, land tenure, and management practices. It also offers a unique social field for experimentation, innovation, and entrepreneurial activities. It is a field where technological, sectoral, organizational, institutional, and social innovation become intertwined, creating new and sustainable attitudes and relationships with natural environments. Taking the innovation systems approach, we developed a conceptual and analytical tool for understanding the complexity of the Green Care innovation system in Europe to formulate potential policy responses as levers for advancing nature-based health and well-being. Using a stepwise and iterative approach, we developed a preliminary conceptual framework of the Green Care Innovation System that guided us in the data collection through surveys and in-depth interviews with 20 selected case studies. We revised the framework after the data analysis and as a result, identified the actors, system functions, and blocking mechanisms in the form of challenges and adequate policy responses as levers in Green Care innovation processes. To focus multi-sectoral attention on the health, well-being, and social inclusion benefits of nature, we formulated potential policy responses for the decision-makers and key action points for practitioners.

Integrating Green Care Initiatives into Traditional Health System: a literature review focused on governance dimensions

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

Alessandra Rigo[1]
Elena Pisani[1], Laura Secco[1]
[1] Dept. of Land, Environment, Agriculture and Forestry (TESAF) - University of Padova, Italy

Abstract: The umbrella term Green Care (GC) includes a spectrum of interventions supporting health promotion, disease prevention, and rehabilitation. GC can potentially improve public healthcare provision, responding to modern increases in demand for healthcare in the general population and the specific needs of vulnerable groups. Actions aimed at expanding care provision are often undertaken by the government justified on public economic grounds to reduce the impact of market and information failures that undermine people's ability to maximize their welfare. Despite this, public health organizations and institutions have not yet recognized GC's potential in supporting innovative health practices. Green Care Initiatives (GCIs) are organized interventions involving professionals of different legal entities (e.g., private, public) and various fields (e.g., forestry, healthcare, agriculture) representing diverse environmental, economic, social, and health-related stakes. Therefore, the issue is strictly connected to the partnership composition, decision-making processes, and rules implemented by GC actors and, thus, embedded in a governance framework. Given this, our aim is to comprehend which conditions could enable GCIs to be recognized within the public health system by adopting an analytical understanding of governance. Therefore, we conducted a systematic literature review of international studies on integrating GCIs into healthcare systems by exploring the conditions observed for this to happen and through which specific governance arrangements. By following the PRISMA guidelines, search strings of keywords were combined concerning the themes of "Green Care," "Healthcare," and "Governance" in Scopus and Web of Science databases. Then, pre-defined criteria were applied to refine the selection of relevant documents. Finally, findings were categorized under the main dimensions to facilitate qualitative analysis. Results from our research indicate that the discourses around governance are more developed in Social Farming, while contrastingly, Forest-based initiatives remain little explored. Our governance analytical framework could facilitate institutional awareness and evidence-based decision-making to support the integration of GCIs into healthcare practices. Furthermore, it could help determine relevant aspects for the success of GCIs by paving the way for developing an evaluation framework based on different health and environmental governance dimensions.

Relationship between Visitors Motivations in Canadian and Brazilian's Parks

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

Louise Queiroz[1]
Teresa Magro-Lindekamp[1]
[1] Department of Forest Sciences, Luiz de Queiroz College of Agriculture, University of São Paulo, Piracicaba, São Paulo, Brazil

Abstract: Several studies indicate benefits promoted to human well-being after having frequent contact with nature. Understanding the motivations that lead people to leave the comfort of their homes and visit natural areas more frequently can help to establish public policies that enhance the benefits already known in the medical field. The study by Lemieux et al. (2012) addressed the perceived importance of well-being related to motivations for visiting two parks in the autumn of 2011 in Canada (n=166).Using the same methodology, we addressed the perceived well-being indicators that motivated the visit to an urban park in the autumn of 2023 in Brazil (n=150).

The well-being indicators evaluated include physical, psychological, social, intellectual, spiritual, ecological, environmental, cultural, occupational and economic. Of these indicators, the Brazilians who participated in the survey considered psychological well-being (71.33%), physical well-being (66.66%), environmental well-being (64.00%) and social well-being (63.33%) as "very important", with all indicators considered "very important" by at least 45% of the Brazilian participants. As "not important", only psychological, spiritual and occupational well-being were scored by Brazilians, with a minimal portion (0.66%).

Comparing the results obtained in Brazil and Canada, it was observed that Brazilians tend to consider well-being indicators related to motivations for visiting parks more important than Canadians. When averaging the indicators identified as "very important", we obtained 59.20% for Brazilians and 27.32% for Canadians. A difference of more than 30%. While Canadians consider such perceptions as "not important", on average 5% more than Brazilians.

The data obtained show that the motivations for visiting parks are related to human well-being, being an important value for people. However, it is observed that there is a difference in the two contexts, which indicates that there are other factors that can collaborate in motivating the promotion of well-being, in addition to contact with nature. This study is still in progress and in the near future we will obtain results from the same indicators in other Brazilian protected areas.

The case for a relational turn in forestry

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

Austin Himes[1]
Kyle Dues[1]
[1] Department of Forestry, Forest and Wildlife Research Center, Mississippi State University

Abstract: Forests are central to some of today's greatest ecological challenges, including climate change, biodiversity loss and many environmental justice issues. The discipline of forestry can make key contributions to helping address those problems, but it has also contributed to them. We suggest that the institution of forestry must transform to be more relational and inclusive for it to consistently be part of the solutions and not a contribution to the great ecological and societal challenges we face. In this presentation, we identify and articulate four core principles of forestry drawing from textbooks, university curriculum, the Society of American Foresters code of ethics, policy documents, peer reviewed literature, and the writings of prominent foresters who influenced the codification of the discipline. These principles are: 1) Forests should be managed; 2) Forests should be owned; 3) Decisions about forests should be based on western science; 4) Forest should sustainably provision goods and services for human ends. We explore how these institutionalized principles limit the inclusivity of the field of forestry and keep it from being compatible with diverse worldviews and values. Further, we suggest such limitations hamstring the discipline's utility in combatting climate change, biodiversity loss, and environmental injustice. To overcome these limitations and make forestry a more diverse and inviting field capable of addressing 21st century challenges, we propose revising these four principles so that they reflect relational values and relational worldviews. The new relational principles of forestry we propose are: 1) Care for and respect the forest; 2) Timber can be owned, but other aspects of forests cannot; 3) Traditional Ecological Knowledge and other ways of knowing can complement western science in determining forest practices; 4) Forests should sustainably support people's diverse values of and about forests. Revising these principles in print is easy but revising them in practices requires an institutional transformation of the discipline including shifts in the way forestry is taught and expanding what approaches to forest management and policy are acceptable.

The Role of Community Faith Based Organization in Enhancing Forest Governance: Comparative Study of Gwasii and Kibiri Forest, Kenya

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

Bernard Odit[1]
Samson Okoth Ojunga[1], John Otuoma[1], Edward Mbuvi[2], Stella Gatama[1]
[1] Kenya Forestry Research Institute (KEFRI), Lake Victoria Eco-region Research Programme P.O Box 5199-40108 Kisumu, Kenya
[2] Kenya Forestry Research Institute, Forestry Research Support Services, P.O. Box 20412-00200 Nairobi, Kenya

Abstract: Globally, regionally, and locally, most forests are managed by the state with minimal community involvement resulting in high levels of degradation. In Kenya, the forestry sector has experienced poor governance in the past and still faces challenges in ensuring sustainable conservation and management of forest ecosystems. Effective forest governance requires empirical evidence on how different forest governance structures and systems contribute to improved forest conditions and management. The study conducted a comparative analysis of forests managed under different faith-based institutions including traditional, church and government-managed forests and among the Tiriki and Abasuba Tribes of Kenya. The study sites engaged 40 participants from Kibiri forest and Gwasii forest in Kenya. The approaches applied in the study included an ecological approach and social assessment of governance in the management of forests under different management regimes such as state, faith-managed and community-managed forests. Focus group discussions, and scoring of governance system using the 3 pillars of forest governance frameworks developed and applied widely by FAO. Community shrines and church-managed forests appeared to be in a much better condition than the gazetted (state-managed) forests which were in the worst condition. The stem density of woody plants in community shrines (450 stems ha^{-1}) and church-managed forests (675 stems ha^{-1}) was within the expected range for well-managed natural forests of 300 to 1,000 stems ha^{-1}. The scores on governanace showed notable differences with strong scores for concordance of sector level policies having a higher score in Kibiri gazetted forest (2.4) and Gwasii gazetted forest (2.3), legal framework and forest related policies within gazetted forests in Gwasii was 1.3) while in Kibiri the gazetted forest (1.0). There are weak community forest governance systems leading to the high degradation of government forests. The culture and local belief systems of the local communities have also contributed greatly to the conservation of the forest. We recommend that traditional and faith-based forest management practices be integrated into forests managed by the state and that such practices be piloted in sections of the forest before wider application in other forests in the country.

Towards mainstreaming the use of forests for health through multi-actor collaboration

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

Liisa Tyrväinen[1]
[1] Natural Resources Institute Finland, Bioeconomy and the Society Unit, Helsinki, Finland

Abstract: Frequent contact with and exposure to forest environments are shown to have positive effects through different pathways on human health and wellbeing. During the past 20 years the research in Finland has primarily focused on urban and peri-urban forests looking at the associations between self-reported and clinical manifestations of health and the accessibility and use of nature spaces, key patways of health outcomes in various local contexts and, how different users may response to forest exposure. More recently there is increasing number of studies looking at how nature contact can boost human immune function and decrease the risks for non-communicable diseases.

The forest-based care research has been conducted in interdisciplinary collaboration across outdoor recreation, sports, health sciences, psychology, ecology, environmental health and medical scientist involving wide range of universities and research institutes to contribute to the current knowledge base. Natural Resources Institute Finland has been a leading national institute to initiate studies and research collaboration focusing on the health benefits of forests. During the past years the cumulated scientific knowledge has been increasingly acklowledged in forest and environmental policies such as the first Finnish Outdoor Recreation Strategy 2030, in urban planning as well as social and public health services. The improved knowledge has also supported the expansion of Green Care practices in Finland, offering nature-based activities targeting well-being, social inclusion, pedagogy, recreation and tourism. More recently, medical sector has been more actively initiating scientific studies and promoting preventive health care practises and long term health promotion programs such as The Finnish allergy & asthma -programme (2008-2018) and the Nature step towards health -program (2022-2032) in Päijät-Häme health care district grounding its key actions on the Planetary Health -concept and initiative.

This presentation describes briefly the current status and scientific development of forests for health -research in Finland and its future prospects. Moreover, already established or most promising forest-based care practices will be presented and analysed how they can support transformative change toward sustainable, responsible, and just societies. Finally, the potential and key challeges of mainstreaming forest-based care practises will be discussed.

Which trends and socio-economic opportunities of forest-based care initiatives?

T4.11 Forest-based care as an innovative pathway to shifting values, uses and governance of forests

Ilaria Doimo[1]
Colm O'Driscoll[1], Laura Secco[2], Anna Biasin[2], Giulia Amato[1], Rik De Vreese[3]
[1] ETIFOR | Valuing Nature (Italy)
[2] LEAF Department, University of Padova (Italy)
[3] European Forest Institute, Resilience Programme

Abstract: We are witnessing a growing number and typologies of forest-based care initiatives (FBC), from forest bathing and healing forests in Asia, these initiatives are expanding throughout Europe providing a wide set of cultural ecosystem services. While this diversity provides a lot of potential business opportunities, the market is relatively young and not always fully recognized. Further the research on the economic impact of this emerging sector is still lacking. Nevertheless, market is relatively young and not always fully recognize and the lack of a clear overview of these two aspects, may result in gaps regarding the full understanding of potentials and benefits and widespread implementation of FBC.

To contribute to fill these gaps, our research group developed a first FBC market outlook, within the framework of the Erasmus + GREEN4C project founded by European Union. We used an online survey (n=40), to obtain an overview of the FBC sector in Europe, and through focus group discussion and interviews with six experts in the field we explored success factors, challenges, and next steps. What emerged is a widespread need to increase the acceptance of FBC, together with the need to be recognized by health sector and insurance and the need to diversify the sources of funding. Being able to demonstrate the economic effectiveness and positive impacts of FBC along with the effectiveness for health purposes, might unlock future opportunities for wider adoption of such practices. Building also on these results, within the Horizon Europe funded project (RESONATE, 2023-2027), using 9 EU case studies we will assess the saving potential for health and social-related costs, the cost-effectiveness, and the quantification of hypothetical impact of a generalized adoption of nature-based therapies, and particularly FBC.

In this talk we will start by framing the main trends in FBC initiatives to have a general overview of what's happening in Europe, then building on the results of the GREEN4C market outlook on FBC, we will have the opportunity to share the first results towards the economic impact assessment of nature-based therapies (RESONATE).

T4.12 Forests in Cities: Ecology, management, and silviculture.

A cross-continent study on the relationship between microhabitats and organismic diversity between native and exotic species in city trees

T4.12 Forests in Cities: Ecology, management, and silviculture.

Anastasia Rubio[1]
Somidh Saha[2]
[1] Yale University, Yale School of the Environment, New Haven, Connecticut, USA
[2] Karlsruhe Institute of Technology, Institute for Technological Assessment and Systems Analysis, Karlsruhe, Germany

Abstract: Urban forests play a critical role in the healthy functioning of cities and those who occupy them through various ecosystem services, such as supporting biodiversity and creating habitats. Solitary trees are a vital component of urban forests. As cities worldwide undertake greening initiatives, we must understand the relationships that utilize these services to their fullest potential. This study aims to understand how the difference in the native status of two tree species between two continents influences their ability to support biodiversity in the urban environment. Additionally, this study attempts to understand the role of the enemy release hypothesis in the microhabitat production between native and non-native trees. This was achieved through a survey of microhabitats and tree health of *Acer platanoides*, a tree species native to central Europe, and *Quercus rubra*, native to the northeast United States, in Karlsruhe, Germany and New Haven, USA. 160 trees equally comprised of both species with a DBH greater than 20 cm in parks and along streets were selected in both cities for a total of 320 surveyed trees. Variables relating to tree and site conditions, such as tree height, DBH, crown dimensions, crown light exposure, crown transparency, competition, and distance to buildings and streets, were collected in conjunction with tree health and microhabitat surveys. An environmental DNA analysis using the meta barcoding technique on leaf, bark swabs, and soil samples has been conducted to detect fungi, invertebrates, and vertebrates diversity on sub-sample of selected trees in Germany and USA. Currently, data collection and laboratory analyses are going on, and we will present the findings of our study at the IUFRO world congress. We expect to get our first results by spring of 2024. Our findings from the surveys and eDNA analysis will illuminate the relationships between native status, tree heath and biodiversity in cities. Our cross-continent approach and focus on microhabitats, organismic diversity, and pathogens will contribute to our understanding of urban ecological processes and the native vs. exotic species debate in tree species selection for planting inside cities.

Biodiversity indicators in urban and peri-urban forests in central Italy

T4.12 Forests in Cities: Ecology, management, and silviculture.

Francesco Parisi[1, 2]

[5] Fondazione per il Futuro delle Città, Firenze, Italy

Abstract: Invertebrates are central to structuring and maintaining the functioning of urban forests, which provide critical ecosystem services. Identifying the role of invertebrates in urban forests help reveal their importance to practitioners and the public, not only to preserve biodiversity but also to make the public aware of their functional importance in maintaining healthy greenspaces. In urban environments, intense land management, pollution, and the removal of dead or decaying wood often pose threats to numerous species and ecosystem functioning.

The aim of this work was to examine interrelated biodiversity indicators (forest structure, tree-related microhabitat, beetles, and birds) in urban environments in three Italian cities, differing in spatial, environmental, and social dimensions (Campobasso, Florence, and Rome).

In each city, four forest sites were selected were selected along an urban-to-rural gradient. In each area, field works were carried out into 15 circular plots with a radius of 13 m. In each plot, we collected data to derive biodiversity indicators related to stand structure, deadwood, tree-related microhabitats, beetles, and birds. Two types of traps were used for monitoring the beetles, window flight traps and pitfall traps, to capture both flying and ground beetles. The traps were checked approximately every 30 days for a total of 4 samplings, from June to October.

We analyzed the stand structural indicators, the amount and types of deadwood components, and the microhabitat occurrence, evaluating their impact on the abundance, distribution, and diversification of saproxylic and non-saproxylic beetles, and the bird fauna.

Results were discussed to compare the three city types in relation to the complexity features of the examined sites and the different levels of biodiversity present in the studied plots.

The study was carried out within the Project "National Biodiversity Future Center - NBFC".

Designing legible forests for an urban silviculture

T4.12 Forests in Cities: Ecology, management, and silviculture.

Nicholas Pevzner[1]

[1] University of Pennsylvania, Department of Landscape Architecture, United States

Abstract: Silviculture is the art and science of growing trees. Although commonly associated with non-urban forest landscapes, the principles of silviculture may help guide the design and management of urban forests as well, whether those forests represent remnant forests, spontaneous urban woodlands, large forest parks, or designed natural areas. But the application of silviculture to these kinds of forests in cities, at least in the U.S., in uncommon, and has long been met with resistance—as far back as Frederick Law Olmsted's Central Park experiments with “planting thick and thinning quick,” public sentiment has been protective of trees, even when forest health would have benefitted from such treatments. As complex social-ecological assemblages, forests in cities need to respond to the expectations and desires of people and communities, and their institutions and cultural systems.

Landscape architecture, meanwhile, is the art and science of designing cultural landscapes, but rarely stays engaged with the long-term management of designed spaces after initial planting, nor typically participates in the design of sites for ecological experiments. Yet landscape architects help to shape cultural attitudes about nature in cities, and their design skills could be used to improve the public literacy of urban forest ecological dynamics and forest management. How might urban silviculture, drawing on techniques of both landscape architecture as well as forestry and urban ecological science, increase the public literacy of beneficial forest management? Existing spatial prototypes and design interventions offer promising ways forward towards increasing the public legibility of forests, and could be leveraged to increase the public acceptance of the emerging principles and techniques of urban silviculture for forests in cities. Examples of such spatial principles, drawn from precedents of successful designed landscapes, demonstration forests, and ecological experiments will be shown, in order to suggest ways that such techniques can be deployed in for advancing the legibility of urban silviculture. The design of legible forest landscapes and demonstration forests in cities can utilize techniques from both landscape design and ecological science—in line with the interdisciplinary framework of urban silviculture; we will explore what the design of more legible forests in cities could look like.

Development of silvicultural concepts for forests around urban areas to mitigate the urban heat island

T4.12 Forests in Cities: Ecology, management, and silviculture.

Marco Diers[1]
Linda Gruber[2], Johannes Weidig[1], Jörg Bendix[2]
[1] Department of Silviculture, Climate Protection and Adaptation, Biological Production, HessenForst, Germany
[2] Laboratory for Climatology and Remote Sensing (LCRS), Geography, University of Marburg, Germany

Abstract: Particularly in urban areas, global warming is leading to an increasing heat load on the residents living there. The urban heat island effect causes cities to cool down less at night than their surrounding areas. The positive cooling properties of trees and parks in urban areas are widely known. To date hardly known, however, are the effects of peri-urban forests on the urban climate. Silvicultural factors in their interaction with landscape structure have not yet been sufficiently investigated to guide forest management in practice towards the goal of mitigating urban heat.

In a sensitivity study, forestry factors are investigated with regard to their influence on the cooling effect of an urban area using the micro-scale urban climate model MUKLIMO_3 TD of the German Weather Service. In different scenarios, the factors tree species, stand density and forest structure, as well as the forest-open land ratio are systematically changed and resulting cooling effects are evaluated. Based on the results of the sensitivity study, silvicultural measures for peri-urban forests to mitigate urban warming will be developed.

The study is part of the project "Optimized forest management around urban areas for improved cooling and air exchange" which is kindly funded by the Hessian Climate Plan. The project is a cooperation of the LCRS (Laboratory for Climatology and Remote Sensing) of the University of Marburg and HessenForst.

Ecology and Management of Forests ---- in Cities

T4.12 Forests in Cities: Ecology, management, and silviculture.

Richard Hallett[1]
Max Piana[2], Tara Trammell[3], Nancy Sonti[4], Clara Pregitzer[5], Sophie Plitt[5]
[1] USDA Forest Service, NYC Urban Field Station
[2] USDA Forest Service, Amherst, MA
[3] University of Delaware, Department of Plant and Soil Sciences
[4] USDA Forest Service, Baltimore Field Station
[5] Natural Areas Conservancy

Abstract: Forests in cities, which are sometimes referred to as urban forested natural areas or woodlands, are an important component of the total urban forest and tree canopy. Although forests in cities are like rural forests in structure, composition, and function, these habitats are threatened by multiple, co-occurring, and often exacerbated urban and climate stressors. Furthermore, forests in cities often lack a formal silvicultural framework and there is a need for evidence-based forest management strategies. At the most basic level, we suggest that cities can benefit from the existing body of knowledge established for nonurban forested ecosystems; put more simply, forestry has a place in the management of urban forests. However, given the complex set of drivers that are either unique to or exacerbated in urban systems, we take this argument a step further and suggest that managing forests in the city demands innovative strategies be added to the silviculturists' toolbox. By rigorously applying silviculture science within cities, we advance applied ecological knowledge that may extend beyond cities and inform forest management across the urban–rural continuum. From climate change to invasion of exotic species, urban ecosystems provide a window into conditions that nonurban ecosystems will face in the future. Advancing an urban silviculture may therefore not only help to conserve ecologically and culturally valuable habitats in cities, but may also serve as a proactive step in advancing nonurban forest conservation practices in an increasingly human-impacted and uncertain future.

In the United States, networks of municipal forest managers, community groups, university and federal scientists have been formed. The Forests in Cities (FIC) network was formed in 2019 and includes 17 cities from across the United States. The FIC is a national network dedicated to promoting, and advancing health forested natural areas across America through science, management, partnerships, and communications. The Northeast Urban Silviculture Network was formed in 2020 and is focused on cities in the northeastern U.S. (Baltimore, MD to Springfield, MA). This network is focused on knowledge co-production and has implemented multi-city applied management studies leveraging local and scientific knowledge to explore climate-adapted forest management strategies.

FLORAL COMPOSITION AND STRUCTURE OF REMNANT SEMI-DECIDUOUS FOREST IN URBAN LANDSCAPE: A CASE STUDY OF NAIROBI CITY PARK IN KENYA

T4.12 Forests in Cities: Ecology, management, and silviculture.

James Maua[1]
John Ngugi[1], Paul Kirika[2], Magrate Kaigongi[1], Jane Njuguna[1]
[1] Kenya Forestry Research Institute
[2] National Museums of Kenya

Abstract: Nairobi City Park Forest (NCP) is a semi-deciduous forest within an urban landscape in Kenya. Due to the growing urban population, there is increasing pressure on the available green space, which may negatively impact the forest ecosystem and its ecological integrity. Therefore, monitoring the forest is essential. This study aimed to achieve three objectives: (1) determine the diversity and composition of plant species, (2) assess the structure of woody plant species, and (3) evaluate the regeneration status of the dominant woody plant species in NCP. Twenty four nested-plots of size 625 m2 (25 m X 25 m) were used to collect vegetation data. The plants were categorized into three groups; seedlings, saplings, and mature based on DBH classes then the floral composition, population structure and status of natural regeneration determined. A total of 58 plant species belonging to 48 genera and 28 families were documented. The dominant mature tree species were *Craibia brownii* (17%), *Drypetes gerrardii* (8%) and *Strychnos mitis* (7%) while the saplings were dominated by *Craibia brownii* (15%), *Rawsonia lucida* (10%), *Vepris simplicifolia* (10%) and *Rothmania urcelliformis* (8%). The mean density for trees with dbh ≥10 cm was 584±431.1 stems/ha whereas the basal area was 12.9±9.6 m^2/ha. Shannon-Wiener index had a range of 2.3 - 2.9 implying high diversity in NCP. There was a significant difference in the storeys in the vertical structure ($F_{(2,437)} = 456.756$, $p=0.0001$); species in the storeys ($F_{(47,355)} = 1.537$, $p=0.017$). There was a significant difference in height between the upper and lower storey whereas there was no significant difference in height between the upper and middle storey and also between the middle and lower storeys. The top ten dominant species comprised 54.6% of the total Importance Value Index (IVI). The woody plants with poor and no regeneration comprised of 40% of all species. It is recommended that species with a low Importance Value Index and poor regeneration status should urgently be prioritized for conservation. The results of this study provide valuable information for the development of sustainable management strategies for the NCP, with a focus on urban green space and biodiversity conservation.

[3] The Davey Institute

Abstract: The temperate deciduous forest biome has been subject to more anthropogenic development than any other on earth. It covers less than 5% of the Earth's habitable land area, yet holds approximately 25% of the human population. Destruction and fragmentation of temperate deciduous forest is accelerating as more people move to cities and urban and peri-urban areas expand. Our focal study area of the Boston-Washington (BosWash) Megalopolis of eastern North America is an excellent region in which to study this phenomenon and what it means for modern forest function and biodiversity: most development and alteration has occurred here within the past 400 years, unlike Europe and Asia.

Our analyses show that there are approximately 250,000 deciduous forests in the BosWash Megalopolis of 1 ha or greater size, 92% of which are less than 50 ha and are surrounded by human development. Those surrounded by the densest human populations are also among the smallest, so that the daily "forest experience" of most people is that of a relatively small woodland. We will present a summary of the various trophic levels and abiotic conditions across a latitudinal and urbanization gradient in the form of an "average and idealized" Megalopolitan forest. We will also present synthesis providing an understanding of the current and future ecosystem services that these forests may, or may not, provide. Finally, the authors will outline possible paths toward improvement and protection of forest in the Anthropocene.

Heritage urban trees in public spaces. Case Aburra Valley-Antioquia-Colombia

T4.12 Forests in Cities: Ecology, management, and silviculture.

Ana Maria Monsalve Cuartas[1]
Diana Marcela Ruiz[2], Paola Andrea Morales Ramirez.[2], **Ana Valentina Masso Ardila**[3]
[1] Lisbon University. Agronomic Superior Institute. Portugal
[2] Humboldt Institute. Colombia
[3] Algarve University. Science and Technology Faculty.

Abstract: Urban Forest and trees have evolved to adapt to the local urban environment in which they grow. Such local adaptations lead to genetically differentiated populations, with traits that enable them to adapt to local biotic and abiotic stress factors in urban space. Many tree species can't stand up with rapidly changing climate, resulting in maladapted forests with reduced capacity to provide multiple ecosystem services. Some human-facilitated into the urban environment is necessary to match or realign the populations to the environment to which they are best adapted. An example of these are old and tall trees that in the urban context of Aburra Valley (Antioquia - Colombia) are identified most of them as Heritage trees.

With a local efforts, investigation, visibilitation, new policies ,economic resources and forest inventories for 2006, ten urban areas in Aburra Valley (Colombia) reported 420,750 trees in their public space (trees, palms or shrubs more than one (1) meter tall), these trees inventoried belonging to 367 species. By the year of 2022, 543,135 trees were reported belonging to 794 species

Into these community of urban trees almost 100 heritage urban trees were identified in 12 species in 2006. After that, other trees are incorporated in the list of the heritage trees until 2022. The list in 2023 of heritage trees is incremented with new species and trees with almost 900 trees in 170 species. That means a forest community into urban areas hath need an urban contemporary silviculture towards ecologically-based practices and natural regeneration. These metropolitan valley actions towards ecologically-based silviculture is going on mainly in conservation of these heritage trees.

The objective is show and to discuss close-to-nature silviculture as a tool for climate change mitigation in urban forestry areas. Following a comparation in 2 moments (2006-2022) of urban heritage trees ecologically-based management and their actual state in 10 urban territories (Metropolitan Aburra valley) will showcase current trends and developments in forestry practice and research for management and care.

Managing urban woodlands conservation for a better balance of their socio-ecological roles

T4.12 Forests in Cities: Ecology, management, and silviculture.

Charlotte Langlois[1]
Stéphanie Pellerin[2], Alexandre Bergeron[2], Françoise Cardou[3], Alain Paquette[1]
[1] Université du Québec à Montréal, Département des sciences biologiques, Canada
[2] Université de Montréal, Institut de recherche en biologie végétale, Canada
[3] University of Toronto, Department of Biological Sciences, Canada

Abstract: Conservation efforts regarding natural woodlands in cities are increasing more than ever due to the rising awareness of the benefits they provide. They are valuable biodiversity hotspots and participate in the connectedness of surrounding natural areas and migration corridors, but they also participate in numerous human-oriented services, such as the mitigation of heat islands, general well-being and recreational opportunities. However, up until now, the conservation prioritization of urban woodlands has for the most part solely been driven by the ecological roles they fulfill. Practitioners usually consider their ecological integrity or connectivity as an indicator of their value and to select where conservation actions should be conducted. By doing so, we might be contributing to separating woodlands ecological and social roles and overlooking environmental inequities, compromising long term city resilience.

The aim of this study is thus to compare the outcome of different methods of prioritizing the conservation of urban woodlands in order to highlight the existence of spatial intersections or trade-offs between them. We will evaluate the (i) ecological integrity, (ii) connectivity, (iii) multifunctionality of ecosystem services, and (iv) population vulnerability of a network of 50 woodlands located in Montreal. Soil water retention, temperature regulation and carbon sequestration will be used to compute a single metric of multifunctionality. Different prioritizing scenarios considering the four above-mentioned methods taken separately and combined will be generated and compared to each other to highlight if they point to similar or different conservation priorities. Data treatment and analysis are presently being conducted and results are yet to come. The outcome of this research is expected to help practitioners build management plans that will ensure a sustainable balance of the complex socio-ecological systems that cities are.

Operationalizing silviculture in the city: novel approaches to forest assessment and management in Philadelphia, PA

T4.12 Forests in Cities: Ecology, management, and silviculture.

Max Piana[1]
Richard Hallett[1], Tara Trammell[2], Jarlath O'Neil-Dunne[3], Maximilian Blaustein[4], Aelin Compton[4], Dhan Parker[4]

[2] University of Delaware
[3] University of Vermont
[4] Philadelphia Parks & Recreation

Abstract: Forests in cities are an important greenspace for urban dwellers and regional biodiversity. Urban silviculture is a systematic framework for developing knowledge-based management approaches for forests in cities. Urban silviculture is based on an understanding that the social and ecological context of forests in cities alters these ecosystems, and as such, traditional management approaches, including forest mapping, inventory, and operational activities may need to be modified and in some cases, novel strategies developed.

In this presentation, we examine how the city of Philadelphia, PA, USA is leading the way to develop, test, and integrate urban silviculture approaches in order to conserve, sustain, and grow forests. Within Philadelphia, there are ~10,000 acres of city-owned parkland, of which, more than 6,000 acres are natural land and primarily forested. We present case studies that include novel methods in forest mapping, an urban-adapted inventory that defines urban management units (e.g. canopy gaps, edge), and planting and management strategies for these different stand conditions. The latter includes long-term studies designed to test pre-planting treatments (e.g. mechanical removal vs. herbicide) and planting techniques designed to re-establish native canopy species (e.g. appropriate tree density; nurse tree methods). In doing so we discuss how these management approaches may be scaled up and/or replicated elsewhere. Finally, we present the need for research, and in particular long-term studies, to build and expand an urban silviculture toolbox for forest managers in cities.

RESTORING FUTURE FORESTS: DRIVERS OF URBAN TREE RECRUITMENT DIFFER BY SPECIES' SUCCESSIONAL STATUS AND JUVENILE GROWTH STAGE

T4.12 Forests in Cities: Ecology, management, and silviculture.

Kiri Joy Wallace[1]
Sarah Busbridge[1], Katherine de Silva[2], Stephen Hartley[2], Bruce D. Clarkson[1]
[1] University of Waikato, Environmental Research Institute
[2] Victoria University of Wellington

Abstract: Projects restoring forests from scratch in cities using native species are increasing in frequency throughout Aotearoa New Zealand. While early-successional tree species establishment and formation of a canopy is often successful, the long-term existence of forests depends on their capacity to regenerate and persist. This entails germination and recruitment of seedlings into the sapling growth stage, especially for middle and late successional species. Here we investigated drivers promoting recruitment of species in two successional categories (early vs. mid-late) in 79 restored urban forests spanning 4 to 58 years since planting across nine cities. Negative binomial generalised linear models were used to determine relationships between abundance of early and mid-late successional native woody juveniles across three growth stages as related to the predictors forest age, patch size, herbaceous ground cover, canopy openness, and site microclimate (air and soil temperatures). We found as forests age, canopy openness decreases and the understory microclimate cools and stabilises. This cooler microclimate promotes increased abundance of only the mid-late juvenile trees, even though canopy closure promotes an increase of both early and mid-late native tree seedling germination and recruitment. This effect's strength decreases as seedlings grow taller, and is not important for juveniles of either successional status once in the sapling stage. These findings indicate that seedlings and saplings have different light requirements. Herbaceous cover plays an early role as it is inversely related to short seedling abundance, but once seedlings reach sapling height there is no relationship. Increased restored forest age is the most important predictor of greater seedling abundance, although larger forest patch size is similarly important for just the mid-late successional woody species. These results indicate that to promote restored urban forest succession (juvenile tree recruitment), management should vary depending on forest age, site conditions, and developmental stage of the restored forest.

Silviculture in the City: Urban and Climate Adaptation Management

T4.12 Forests in Cities: Ecology, management, and silviculture.

[3] University of Kentucky, Forestry and Natural Resources, USA

Abstract: Forests in cities are dynamic, living structures vital for local-to-global biodiversity conservation and climate change adaptation. Assisted forest migration studies enhance forest resilience to current and future changing climate regimes. In 2020, we established the USA Northeast Urban Silviculture Network, along with urban forest practitioners and city land managers, to co-produce urban- and climate-adaptation management strategies. Our primary goal is to build resilience in urban forests in response to myriad environmental challenges, such as invasive plants and pests, deer herbivory, and climate change. The Urban Silviculture Network co-produced an assisted population migration study in five cities along the USA Atlantic coast to study climate adaptation management strategies in urban forests.

In fall 2021, we collected over 100,000 acorns across six provenances (seed zones) of the USA Atlantic coast and southern states (KY, TN). In spring 2023, we planted 6000 chestnut and white oak seedlings in forest canopy gaps across four cities (Springfield, MA, New Haven, CT, Philadelphia, PA, Baltimore, MD). In addition, we planted over 2000 oak seedlings across three common garden experiments in Springfield, MA, Katonah, NY, and Baltimore, MD. In each forest canopy gap and common garden, we planted seedlings from six provenances in a full transplant experiment. Our research design will provide insight on how: 1) oak seedlings from northern provenances withstand warmer climatic conditions in southern latitudes predicting whether local resilience to future climate scenarios is possible, and 2) oak seedlings from southern provenances withstand northern latitude stresses, such as late frost, predicting whether assisted migration can provide resilience to climate change. In addition, our research informs how above- and below-ground (e.g., apical dominance, root:shoot biomass, root architecture) oak traits relate to tree survival and growth. In our southern most city, we observed foliar green-up in 98% of our oak seedlings in the early growing season. At the end of the 2023 growing season, above- and below-ground traits will be related to seedling survival and growth. Our findings will identify fundamental traits and provenance that determine oak seedling resilience to changing climate regimes, further informing management strategies for climate adaptation in urban forests.

Structure, composition, and tree health of the urban forest in Kumasi, Ghana: Implications for climate change adaptation and urban forest management

T4.12 Forests in Cities: Ecology, management, and silviculture.

Angela Beckmann-Wübbelt[1]
Shalom Daniel Addo-Danso[2], Sebastian Schmidtlein[3], Fabian Fassnacht[4], Armin Grunwald[1], Somidh Saha[1, 3]
[1] Institute for Technology Assessment and Systems Analysis, Karlsruhe Institute of Technology (KIT), Karlstr. 11, 76133 Karlsruhe, Germany
[2] CSIR-Forestry Research Institute of Ghana, P. O. Box UP 63 KNUST, Kumasi, Ghana
[3] Institute for Geography and Geoecology (IfGG), Karlsruhe Institute of Technology (KIT), Kaiserstr. 12, 76131 Karlsruhe, Germany
[4] Institute of Geographical Sciences, Freie Universittät Berlin (FU-Berlin), Malteserstraße 74-100, 12249 Berlin, Germany

Abstract: Past and ongoing rapid urbanization led to an immense degradation of the urban forest in Kumasi, Ghana. Additionally, increasing heat waves, droughts, and extreme weather events pose challenges to the urban forest in the more than 3-million-inhabitants city in West Africa. A prerequisite for the sustainable management of urban forests is a comprehensive knowledge of the composition of the vegetation and its spatial distribution in urban and peri-urban areas. However, such knowledge of the natural and anthropogenic factors affecting the current state of urban forests needs to be improved in Ghana and other West African countries.

A tree inventory was conducted in 238 plots distributed all over the Greater Kumasi area between August and December 2022. We found and measured 647 trees in our plots and evaluated numerous liana, shrub, banana trees, and palms. We systematically observed and documented tree health indicators. The plots were installed following the guideline of *i-Tree-Eco* from the US Forest Service. The Simpson Index provided information about the diversity of the urban forest. In addition, statistical analyses were used to study patterns and limitations of natural succession in the urban forest in Kumasi. We analyzed the age structure of the urban forest in different land use classes to distinguish the natural and man-made recruitment and mortality patterns. Using non-metric multidimensional scaling (NMDS), we investigated the similarity of urban forest composition in different land uses.

We found that anthropogenic and management activities in Kumasi heavily impacted the urban forest. Those impacts increased with an increasing degree of densification, leading to increased degradation. We are still analyzing our field data, and we will present the first results of the study regarding the structure, composition, and health of urban forests in Kumasi, Ghana in the conference. We will discuss the impact of the findings on the sustainability of Ghana's urban forests and their ecosystem services provision. Further, we will discuss implications for climate change adaptation and urban forest management in West African cities such as Kumasi in Ghana.

Tree cover increases bird predation on insects and enhances biotic resistance of urban trees

T4.12 Forests in Cities: Ecology, management, and silviculture.

Marco Basile[1]
Eckehard Brockerhoff[1]
[1] Swiss Federal Research Institute WSL, Birmensdorf, Switzerland

Abstract: Bird predation on insects can improve growth conditions for plants and help control invasive insect populations. This ecosystem service can be enhanced by environmental conditions that promote bird diversity and abundance and, consequently, their predation rate on insects. We investigated bird diversity and abundance along a gradient of urban tree cover to understand how much tree cover promotes insectivorous birds. We also investigated predation rates of birds on artificial caterpillars to understand how much tree cover contributes to predator control of insects. Birds were surveyed in the cities of Zurich, Basel, and Lugano (Switzerland) using point counts along replicated transects placed in city areas with different tree cover: < 20%, 20-40%, 40-60%, and in the peri-urban forests. To measure insect predation rates, artificial caterpillars were deployed at the same locations. Attack rates of birds were counted from the artificial caterpillars and related to bird diversity and abundance at each site. To refine the predation rate assessment, we also considered the predation rate experienced by larvae of the horse chestnut leaf miner (*Cameraria ohridella*), a widespread invasive moth commonly found on horse chestnuts (*Aesculus hippocastanum*). For this, 10 leaves of horse chestnut trees were collected at several study sites, and caterpillar mines on leaves inspected under a stereomicroscope to identify mines opened by birds to feed on the larvae. We found that tree cover had a positive effect on bird diversity and increased the share of insectivorous birds in the local bird assemblage. Similarly, predation rate on artificial caterpillars was higher at sites with higher tree cover. This finding was also confirmed by the predation rates experienced by the horse chestnut leaf miner. However, high tree cover areas were rather rare in the studied cities, leaving most of the urban trees exposed to potentially high herbivory and with low biotic resistance. In addition, bird predation on insects could be enhanced by increasing diversity of native trees in the urban tree assemblages.

Tree Ring Analysis of Dominant Species from Variable Urban Forests in the Mid-Atlantic United States

T4.12 Forests in Cities: Ecology, management, and silviculture.

Kendall McCoach[1]
Tara Trammell[1], Vince D'Amico[1, 2]
[1] University of Delaware
[2] United States Forest Service

Abstract: The majority of temperate forest in the eastern U.S. exists as a patchwork of small, isolated, urban forests. Often these forests have a history of deforestation followed by regrowth under surrounding urbanization. Due to their history and location, urban forests experience altered environmental conditions which mimic global change, such as increased temperatures. These urban effects could be beneficial or detrimental to tree growth, and may vary between forests due to variable city structure and urban heat island (UHI) intensity. Because urban forests exist in highly populated areas, humans rely on them to provide physical and mental health benefits. Additionally, we increasingly rely on the carbon (C) storage potential of forests as nature-based solutions for climate change. If tree growth declines in a forest it may not be able to provide all of the necessary ecosystem services.

Here, I present an analysis of tree cores from 15 mid-Atlantic forests, spanning an urban intensity gradient in Newark DE, Baltimore MD, and Philadelphia PA. I collected tree cores from 4 dominant species; *Acer rubrum, Liriodendron tulipifera, Fagus grandifolia, and Quercus spp*., and from multiple plots within each forest. The trees were selected based on their distance to the forest edge and their size, so as to include a range of sizes and therefore a range of ages. The cores were measured and chronologies were constructed using software programs CooRecorder and CDendro. The resulting chronologies reveal the growth rate throughout time for each species, across multiple cities and varying degrees of urban intensity. Smaller and therefore younger trees show a different growth rate than older trees due to differences in their life stage. This observation could have implications for managing forest growth in the typically mixed-age forests of this region. Future research will investigate whether these patterns in tree growth rate are reflective of temperature variations across different cities and urban intensities.

Urban forest seed bank composition and invasion varies across the developed east coast of the United States

T4.12 Forests in Cities: Ecology, management, and silviculture.

Jack Levy-Diedrich
Tara Trammell[1], **Vincent D'Amico**[2]
[1] University of Delaware
[2] United States Forest Service

Abstract: Urban forests are increasingly receiving attention for their potential to both provide ecosystem service benefits to human population centers and habitat for non-human populations within an otherwise developed and urban landscape. However, in contrast to rural forests within the same ecoregions, urban forests typically contain higher richness and abundance of non-native plants, which may pose a threat to the existing native plant community. While the dynamics of soil seed banks have long been studied within temperate deciduous forests, we know relatively little about how seed bank composition varies within and across urban forests in the same areas.

Invaded seed banks may compromise biodiversity in these forests by replacing the native canopy with quick-growing non-native trees following large disturbances. Furthermore, recruitment from the seedbank by non-native understory species may prevent the growth and establishment of any canopy individuals, fundamentally altering the structure of these ecosystems. Consequently, a better understanding of which landscape and patch variables correlate with highly invaded seed banks can help practitioners and cities more strategically intervene to secure the future biodiversity of urban ecosystems.

In order to discern how urban forest seed bank composition changes across the developed landscape, we sampled soil seed banks from 25 forest patches across five cities along the urban east coast of the United States. Soil samples were collected from multiple locations in each forest, allowing us to assess how seed bank composition varies within forests, between forests, and across cities. Seedling emergence trials were then conducted in greenhouses to characterize the community composition of seed banks. While our findings suggest that the non-native composition of urban seed banks varies greatly from forest to forest, urban forest seed banks within our largest cities, Philadelphia and Baltimore, were much more invaded overall. While upwards of 60% of emergents from some of these forests were from non-native species, other forests within the same cities had a much stronger native character. Our results suggest that urban forest seed bank composition varies greatly across the urban landscape and provides a potential roadmap for practitioners on how best to restore and maintain urban forests.

T4.13 Gender sensitive leadership in research

Addressing Sexual Harassment in the Lab & Field

T4.13 Gender sensitive leadership in research

Shannon Rawski[1]
[1] Ivey Business School, Western University

Abstract: Sexual harassment is a persistent problem in academia, including the biosciences. The field of forestry poses unique challenges to the management of sexual harassment. Contextual factors, such as remote isolated work locations in the field and small spaces in laboratories, and social factors, such as masculinity contesting norms (e.g., competing to be the most masculine/dominate) in STEM fields, pose the risk of sexual harassment opportunities, especially for those with intersecting marginalized identities (e.g., women, people of color, LGBTQ folks). Even when unrealized, these risks can still affect women and marginalized people in the workplace, who may engage in career-damaging "trajectory guarding" behaviors (e.g., avoiding certain coworkers or work spaces) to protect themselves from potential sexual harassment. This presentation will review what is known about sexual harassment from the social science literature (e.g., psychology, sociology, management), focusing on specific evidence from STEM fields and academia. Multiple forms of sexual harassment (e.g., "come on" harassment, or unwanted sexual attention, and the far more common "push out" harassment, or gender harassment) will be defined and clarified for the audience. Common myths about sexual harassment will be dispelled with research evidence (e.g., the myth that only women are targets, the myth that sexual harassment is primarily motivated by sexual desire, the myth that false allegations are common). The harms of sexual harassment for targets, bystanders, and organizations will also be reviewed. Finally, the presentation will focus on potential actions to both prevent and respond to sexual harassment based on the three levels of allyship behavior (i.e., self, interpersonal, and organizational) and prior research on bystander intervention (i.e., types of interpersonal responses, barriers to intervention). The presentation will conclude with resources for the audience to continue learning more about sexual harassment and how to address it in forestry contexts.

Breaking barriers: Promoting gender equality in forestry research through supportive student environments in developing countries

T4.13 Gender sensitive leadership in research

Ginna Marcela Granados Benavides[1]

[1] Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria (UP), Pretoria 0002, South Africa

Abstract: The forestry sector in developing countries, especially in the Southern Hemisphere, experienced significant growth and development during the 1970s. However, during the same period, women were advocating for education and equal rights. The progress of women's inclusion and participation in this sector has been notably slow, with many countries still monopolizing the industry and decision-making only for males. The main focus is on highlighting the importance of creating a student environment that fosters support for women in developing countries, specifically the significance of gender-sensitive leadership in research. By creating an inclusive and supportive environment, it becomes possible to empower and encourage women to actively participate in the forestry sector and enhance women's participation and representation. By employing gender-sensitive approaches, such as ensuring equal opportunities, providing mentorship, and fostering a supportive network, barriers can be overcome, and the potential of women in the sector can be fully realized. There are many challenges faced by women in developing countries and the need for collaborative efforts involving academia, industry, and policymakers to create a conducive environment that supports women's development and success in the forestry sector. Ultimately, to contribute to the wider conversation surrounding gender equality and women’s empowerment in environments where voices are heard.

Death by a thousand cuts: Gender microaggressions, their impact and the way forward

T4.13 Gender sensitive leadership in research

Josephine Queffelec[1]
[1] Natural Resources Canada, Canadian Forest Service, Canada

Abstract: Scholars propose that sexism, just like other forms of discrimination, is not as blatant as it used to be a few decades ago. Rather, sexism is expressed more subtly through what they call microaggressions. The term is defined as intentional or unintentional verbal, behavioural and environmental indignities exhibited by people, groups of people or organisations that communicate a biased or prejudiced view of a marginalised group. Men cutting me off, not paying attention when I speak, telling me to smile more, looking at and speaking to me as if I were physically or emotionally fragile, or not respecting my authority as a team leader are only a few examples of the many microaggressions I have experienced as a woman in science. These daily slights threaten women's identity because they create a lack of alignment between how they see themselves (i.e., capable, and qualified leaders and scientists) and the way their coworkers see them. Additionally, they burden women with the task of decoding the microaggression, and emotionally regulating to respond to the situation in a way that is socially acceptable. While this more modern form of discrimination might be less conspicuous, studies have shown that it is as capable as its predecessors to cause burn out, depression, anxiety, or trauma, and as such, impact women's mental and physical health. The talk will review the concept of microaggression by giving examples encountered by women in the field of forest research. The talk will also cover the impact that gender microaggressions have on women. It will provide a concrete guide to responding to microaggression either as a victim, bystander, or team leader, and to responding to accusations of microaggression if the audience were to become perpetrators. Finally, the presentation will provide advice for team leaders to reduce the potential for microaggression within their team by actively cultivating a culture that promotes safe communication and reflection.

Fostering inclusive development to maintain a stable work-life balance for female forestry researchers

T4.13 Gender sensitive leadership in research

AMINA MAALIM[1]
MERCY GICHORA[2], JANE NJUGUNA[3], JOSEPHINE MUSYOKI[4]
[1] KENYA FORESTRY RESEARCH INSTITUTE, AGROFORESTRY, KENYA
[2] KENYA FORESTRY RESEARCH INSTITUTE, ENTOMOLOGY, KENYA
[3] KENYA FORESTRY RESEARCH INSTITUTE, PATHOLOGY, KENYA
[4] KENYA FORESTRY RESEARCH INSTITUTE, DRYLAND FORESTRY, KENYA

Abstract: Professional female researchers often face unique challenges when it comes to balancing work and personal life. Some of these challenges include; long and extra working hours resulting from demanding fieldwork (data collection, analysis, and writing. Secondly, juggling family commitments and work responsibilities often create conflicts; gender bias, and discrimination in terms of decision-making and practice. Thirdly, they encounter a limited support system in accessing resources that are tailored to their needs and demands for career growth and psychological well-being. This leads to increased stress, burnout, implicit expectations, self-imposed pressure, and feelings of overwhelm while struggling to maintain a balanced healthy work-life.

Forestry research organizations and institutions should strive to create inclusive and supportive environments that address these challenges and promote a healthy work-life balance for all researchers. This is crucial for reducing gender inequality and ensuring the active participation and empowerment of female forestry researchers globally.

Through a participatory virtual group discussion with 15 fellow female forestry researchers from various expertise, age groups, and regions of Kenya, it has been suggested that crucial strategies should be enforced to improve work-life balance for female researchers in order to support their overall well-being and productivity. Majority indicated the need for setting clear boundaries between work and personal life in order to organize and manage the two differently and at their designated time. The need to utilize technology and remote working, teleconferencing, or having flexible working hours can offer more flexibility and control over work schedules. Prioritizing self-care through engagement in activities that promote physical and mental well-being such as exercises, hobbies, spending time with loved ones, and having more breaks and vacations to help maintain energy levels and reduce stress. The need to delegate tasks to junior researchers in a sense of mentorship and focusing on more collaborative research and networks with low, mid, and high-level career researchers whilst practicing open communication to meet individual objectives and expectations set.

In conclusion, achieving a work-life balance requires regular evaluation and adjustments for self and work prioritization and advocacy for workplace policies for promoting flexible work hours, family-friendly environments, and support programs for caregivers.

Lead with your heart: A case study of women leaders in the only forestry state-owned enterprise in Indonesia

T4.13 Gender sensitive leadership in research

Pipiet Larasatie[1]
Chorirotun Nur Ulifah[2]
[1] University of Arkansas at Monticello, USA
[2] Perhutani, Indonesia

Abstract: With respect to gender diversity, forestry is generally regarded as a men dominated sector. This viewpoint is corroborated by global forestry workforce statistics. As a workplace, forestry has traditionally been associated with a macho-masculinity culture. The masculine image and the notion of manual work and physical strength have resulted in more men workers in forestry. This gender imbalance has influenced its leadership environment. Although there is considerable research about women in forestry, to the best of our knowledge, there are few comprehensive gender and leadership studies in forestry in less developed countries. Studies specifically researching gender and leadership in the forestry sector are mostly conducted in North America and Nordic countries. This study aims to investigate women's leadership dynamics in *Perhutani*, the only state-owned enterprise who is responsible for managing the forest resources in Indonesia, one of countries with the largest forest area in the world. For years, *Perhutani* workers' gender composition is relatively static with 93% of men employees, compared to only 7% of women employees. Eleven women leaders from middle to top management level were interviewed with four themes questions: (1) gender and forestry industry, (2) career path of the women leaders, (3) impacts and benefits of women leadership, and (4) future of forestry sector. Utilizing inductive thematic analysis, we found that our respondents showcase heart and mother leadership. The styles are resulted from being raised in patriarchy culture with theological narrative. The heart-led leaders draw on the qualities of empathy, love, and vulnerability while mother leadership means not only leading with the heart of mother, but also with the mission, vision, and actions of mother. Future research can be directed to investigate the recently established women's network in *Perhutani*, as a result of the top-down approach from the Government of Indonesia. Can this network provide an inclusive environment for *Perhutani*'s women employees as well as potential mentorship for advancing their careers?

Scientific Masculinization of Community Forestry

T4.13 Gender sensitive leadership in research

Radha Wagle[1]
[1] Ministry of Forests and Environment, Government of Nepal

Abstract: Community forestry is widely recognized as a decentralized forestry program empowering women to participate in decision making in their forestry actions. Establishing women in vital leadership positions in community forestry institutions is not only a process or means, but also an outcome toward creating gender-equal society at large. Overlooking gender inequality for higher productivity of goods and services from forest ecosystems cannot be justified if sustainable forest management is considered a vehicle for community forestry to prosper. This study examines Nepal's scientific forest management program particularly in community forestry within the framework of feminist institutionalism. Key informants' interviews were carried out to collect primary information. Formal and informal institutions, structure-agency, power relations and continuation and change in community forestry institutions were analyzed. Excessive emphasis on timber production, introduction of silviculture without rolling out it to community people, trivialization of social and gender issues by highlighting higher production of goods and services, paying low attention to forest benefits that were valued by women and sidelining women in timber sale and financial activities were found to further marginalization of women in community forestry. The community forestry that is considered a model for women empowerment and gender-responsive forestry regime seemed to more masculinized due to scientific forest management. Although scientific forest management sensitized forestry stakeholders toward actualizing the full potential of forest goods and services through silviculture intervention, it failed to continue and strengthen women leadership and decision making by putting men back in *de facto* decision-making roles. Scientific forestry contributed to masculinizing community forestry and continuing unequal power relations between men and women in forestry sector institutions. Some recommendations are made to enhance

Who is your supervisor? Dealing with unconscious bias in forestry academic leadership

T4.13 Gender sensitive leadership in research

Estrella Luna-Diez[1]
[1] Birmingham Institute of Forest Research, University of Birmingham

Abstract: “Who is your supervisor?” This is a question I get all the time. Similarly to being ID’d in the supermarket when you want to purchase an 18+ item, this question could be welcomed by some people as temporarily, it makes you think “I must look young”. However, in an academic context, is a poisoned question as it is completely linked to the assumption that for one reason or another, I do not fit the characteristics of an Associate Professor but I “look” like a student. This question may be asked specifically to me due to different factors such as gender, nationality, age or physical characteristics, which all have been associated to unconscious bias. Other characteristics linked to unconscious bias are race, ethnicity, religion, sexual orientation, economic background, political affiliation and disability. Unconscious bias can impact our decisions, perceptions, set baselines and expectations of someone or something. Whereas there is nothing wrong about being a student (we have all been one at some point!), at a professorial level, unconscious bias resulting in that perception can affect the careers of researchers in those specific groups. It has been shown that unconscious bias is one of the factors to hinder gender balance representation at research institutions, research impact or race/gender balance on grant funding success, resulting in fewer women professors, fewer citations on women-led publications and more research funding allocated to white male researchers, respectively. There is therefore a need to enhance awareness on inequalities and bias within research institutions. However, a study demonstrated that perception of bias in research institutions differs between men and women, with women perceiving greater degree of inequality. Considering the male-dominated representation in professorial positions in forestry, it is of vital importance to improve awareness and training on inequality and unconscious bias to minimise their consequences. In my presentation, I will cover from a personal perspective, different strategies that women (and men) researchers could implement to increase awareness and reduce unconscious bias in their research institutions. Moreover, I will briefly provide some examples of institutional strategies which are being developed at the Birmingham Institute of Forest Research.

T4.14 Governing EU's forests: policy narratives, perception and power

Transposing EUTR Requirements in the Western Balkans: multiple case study of Slovenia, Croatia, Serbia, Bosnia and Herzegovina, and Montenegro

T4.14 Governing EU's forests: policy narratives, perception and power

Maja Radosavljevic[1]
Mauro Masiero[1], Todora Rogelja[1], Branko Glavonjic[2], Dragan Comic[3], Davide Pettenella[1]
[1] Department of Land, Environment, Agriculture, and Forestry (TESAF), University of Padova, Viale dell' Università 16, 35020 Legnaro (PD) - Italy
[2] Faculty of Forestry, University of Belgrade, Kneza Viseslava 1, 11030 Belgrade, Serbia
[3] Faculty of Forestry, University of Banja Luka, Vojvode Stepe Stepanovica 75a, 78000 Banja Luka, Republic of Srpska, Bosnia and Herzegovina

Abstract: Although between 2015 and 2020 the deforestation rate had a 40% global decrease compared to 1990s values, deforestation and forest degradation remain major concerns. The size, trends and impacts of these processes are emphasized by illegal practices. To halt them, the European Union (EU) is taking a lead regulatory role through flagship policies, e.g., the Forest Law Enforcement Governance and Trade (FLEGT) program, including the EU Timber Regulation (EUTR), and the newly adopted European Regulation on Deforestation-free Products (EUDR). While the EUDR is not yet implemented, evaluation reports of EUTR and FLEGT implementation present inconclusive results, highly dependent on the national context of EU member states or exporting countries. Among high-risk exporting countries are also some Balkan countries, considered as a corridor of illegal timber and timber products from Eastern to Western Europe. Although some scholars focused on forest and timber trade legality in the Balkans, existing studies are patchy and there is limited research on how Balkan countries are adapting national forest policies to the EUTR. This study aims to contribute to filling this gap by identifying the main actors involved in the adaptation of national forest policies to the EUTR and EUDR within selected Balkan countries (Slovenia, Croatia, Serbia, Montenegro and the Republic of Srpska - BH), as well as investigating their roles and relations. Using multiple embedded case study designs, we conducted a qualitative content analysis of policy documents and 30 key stakeholder interviews in selected countries. We used network analysis to map the actors involved and influenced by the adaptation of national policies, as well as to examine the resource and information flows between them. Our results indicate that in all targeted countries state actors are the key stakeholders: they form small elite communities representing policy networks characterized by rather formal patterns of information exchange and resource dependency. This indicates the persistence of strong state authority and weak shifts towards innovative 'soft' forest governance. Our research contributes to a better understanding of forest policy adaptation and highlights power relations paving the way for improving measures in combating deforestation and promoting sustainable forest management in the Balkans.

Dismiss, ignore or integrate – the Swedish parliamentary parties' arguments on the new EU forest strategy for 2030

T4.14 Governing EU's forests: policy narratives, perception and power

Johanna Johansson[1]

[1] School of Natural Sciences, Technology and Environmental Studies, Södertörn University, Sweden

Abstract: To address the critical consequences of climate change, and achieve the environmental goals in Agenda 2030, the European Commission has drawn up an agreement for the member states, the Green Deal. The focus of our study was the EU commission's flagship initiative – the new EU forest strategy for 2030 – which addresses the role of forests to mitigate climate change and halt biodiversity loss across Europe. Sweden is one of Europe's most extensively forested countries and the forest strategy will create avenues for enhancing the sustainable use of Sweden's forests. In this paper, we examine how the Swedish parliamentary parties represented in the national parliament argue regarding this strategy and upcoming regulations, with a particular focus on the themes 'supporting the socio-economic functions of forests' and 'protecting and restoring EU forests and large forest areas'. The arguments are analysed using an argumentative analysis targeting three main strategies that are frequently used by political parties in general, including the adversarial strategy, the dismissive strategy, and the accommodative strategy, showing that a political party either ignore, dismiss, or integrate the political issue into their political agenda. The results show that a clear majority of Sweden's parliamentary parties express explicit negative concerns towards the forest strategy and the Commission's involvement in Swedish forest policy. Most of the parties argue that there is too much focus on biodiversity protection in the strategy, and that it poses threats to national sovereignty and current Swedish forest management practices. Current management and harvesting are generally considered key actions in Sweden's ambitions to achieve climate neutrality by 2045. It turned out that all parliamentary parties used one or more of the three main strategies in their argumentation, implying that some ignored the political issue, dismissed it, or integrated it into their political agenda. These results have implications for current and upcoming regulatory discussions, in which the Swedish government may choose to delay the progress of EU polices.

EU policy effects on Finnish non-industrial private forest owners

T4.14 Governing EU's forests: policy narratives, perception and power

Matti Valonen[1]
Maurizio Sajeva[1], Jani Laturi[1], Paula Horne[1], Sanna Inkilä[1]
[1] Pellervo Economic Research, Forest and Environmental Economics Research Group, Finland

Abstract: Multiple pieces of legislation that affect forestry have been proposed during the tenure of the current European Commission. When introduced this legislation will change the operational environment of the forest sector. Most of the legislation is still in preparation, so the overall effect on the forest sector is still unknown.

The project aims at improving the non-industrial forest owners' understanding of the overall effect the EU legislation will have on them and their forest management. This will be achieved by providing a concise and descriptive synthesis based on the information available in autumn 2023 on the content and effects of the legislation. The EU legislation under closer assessment includes most notably the nature restoration act, the LULUCF revision, the EU Taxonomy act and its' technical criteria, and the revision of the renewable energy directive.

The synthesis will be formed in the autumn of 2023 with the cooperation of Finnish stakeholders, both in the public and private sector, that follow closely the legislative process of the EU. Aided by their insights, an overview can be formed on how the various pieces of legislation may affect non-industrial private forestry and forest owners. The project will produce a policy brief presenting the synthesis of the effects of the new or revised EU legislation. To conclude the project, a public workshop or panel discussion will be organized on how the EU forest related legislation should be influenced in their opinion. This will be organized in November or December 2023.

Fighting for Forests and Watching the Woods: Conflicting Use Interests and Sustainability Regulations in Europe's Forest Policy

T4.14 Governing EU's forests: policy narratives, perception and power

Michael Boecher[1]
Katrin Beer[1]
[1] Otto von Guericke University Magdeburg, Chair of Political Science and Sustainable Development

Abstract: In recent years, the European Union introduced numerous new forest-related policies and targets. In these policies and the accompanying political and scientific debates, conflicting use interests become clear: Forests play a central role for biodiversity protection, as they provide a habitat for many kinds of species. Furthermore, they serve as a space for recreation for humans. In recent debates, forests are also understood as important carbon sinks in climate policy, and they are important for the regional climate and water management.

In addition to these rather nature and climate protection oriented and recreational use interests, forests can be used commercially in many ways. Forest biomass is a material that has been used as a building material, for the production of goods and the generation of energy for centuries and it is seen as a central resource in the bioeconomy, which aims at a shift from fossil resources to bio-based resources. Within this economic dimension of forest use, conflicting use interest come up between material and energetic use routes of wood and concepts of efficient and sustainable circular systems are currently debated.

Forests are part of the global, regional and local carbon cycles and there are European policies that regulate different parts of the forest carbon cycle. This contribution analyzes European regulations that relate to different kinds of forest use, climate policy and sustainability regulations. A focus lies on the role of forests and woody biomass for the energy transition in the heat sector and corresponding regulations. The contribution is based on a qualitative interview study on European bioeconomy and bioenergy policy, on the results of a quantitative survey (N = 1,427 participants) and a literature and document analysis. It identifies important political conflicts arising from different forest-related use interests, points out critical points in recent political debates and discusses implications for the regulation of forest use and sustainable wood use in Europe's multilevel governance system.

Forest Governance in the Baltic Region - Sustainability Pathways for Adaptive and Inclusive Forest Governance.

T4.14 Governing EU's forests: policy narratives, perception and power

Alessandra Giolo
Johanna Johansson[1]
[1] Södertörn University, Department of Environment, Development and Sustainability Studies

Abstract: The Baltic region, with its central role in international trade, the diverse forest functions and variety of actors involved, is the ideal location to test a new nexus approach. The proposed WEFF nexus (Water-Energy-Food-Forest) highlights the interdependence of resource security and sectors that underpin these securities. Combined with adaptive management, the newly developed nexus could enable new pathways for sustainability. The aim of the project is to map, analyse and propose a governance system where water, food, energy and forest synergies are highlighted and enhance each other through strategies that build on the scientific evidence of the involved actors and groups, and aims for long term cooperation and sustainability. Adaptive management and participatory governance are going to be used aiming effective stakeholder engagement at different scale leading to informed decision-making processes. Forest governance increasingly require combinations of different methodologies, as implications of production and protection of forest resources and management impact all aspects of society: a combination of qualitative and quantitative methods ranging from interviews to experts to statistical analysis are required to reach the aims of the research. Practices and polices related to water, food and energy security are scrutinised to identify synergies and trade offs, and results would guide towards potential solutions and set conditions of emergence for cooperation between security division for long term sustainable development. As global pressures such as climate change, rising global population and consequent demand for resources, forest are increasingly considered a viable and sustainable way to meet those demands. Setting up an efficient and collaborative agenda for governance is then necessary to avoid additional thresholds and define a safe operational space for human activities in the long term. The conceptualisation of this sustainable governance combining water, energy, food and forest sector is the overall aim of this proposed project.

From sectoral policy change to cross-sectoral (dis)integration? A longitudinal analysis of the EU's Forest and Rural Development Policy

T4.14 Governing EU's forests: policy narratives, perception and power

Simon Fleckenstein[1, 2]
Metodi Sotirov[1]
[1] Chair of Forest and Environmental Policy, Institute of Environmental Social Sciences and Geography, University of Freiburg, Germany
[2] University of Helsinki, Faculty of Agriculture and Forestry, Department of Forest Sciences, Helsinki, Finland

Abstract: Policy integration (PI) is critical to address cross-cutting challenges like climate change and biodiversity loss holistically. In the European Union, forests are confronting increasingly adverse climatic conditions and numerous stressors that impact their vitality and biodiversity. Political efforts to counteract these trends are mainly channeled through funding from the Rural Development Policy (RDP) as a pivotal part of the Common Agricultural Policy (CAP). In contrast, forest policy is hardly institutionalized at EU level. This study employs longitudinal qualitative content analysis and examines the development of sectoral policy change and its implication for the cross-sectoral integration of forest policy into agricultural policy at the EU level. Results suggest that adopting the new Forest Strategy (EU-FS) for 2030 in 2021 represented a provisional paradigm shift in EU forest policy. This shift is characterized by a substantial reprioritization of policy objectives, transitioning from an emphasis on economic aspects to a more climate- and biodiversity-centric approach, alterations in supported policy instrument types and the introduction of various new (legislative) instruments. This development was facilitated by changes in government leadership along with political reorientations introduced under the EU Green Deal and an intensification of forest damages in many parts of Europe in recent years. On the other hand, the CAP and its RDP, remain largely characterized by an ideational and policy path dependence, and the latest reforms hardly reflect ambitious forest policy objectives both from budgetary and content perspectives. Findings imply that the latest seemingly decoupled developments within both policy areas resulted in a resurgence of policy silos and an increase in forest policy fragmentation at the EU level.

Governing EU's forests on the route to Paris: an examination of how EU's policy goals translate to the national context of the member states

T4.14 Governing EU's forests: policy narratives, perception and power

Auvikki de Boon[1]
Johanna Johansson[2], Andreas Eriksson[3], Camilla Sandström[1]
[1] Umeå University, Department of Political Science, Sweden
[2] Södertorn University, School of Natural Sciences, Technology and Environmental Studies, Sweden
[3] Swedish University of Agricultural Sciences, Department of Forest Resource Management, Sweden

Abstract: Following the Paris Agreement and the European Parliament's declaration of a climate emergency, the EU has developed multiple directives and strategies, including the European Green Deal, the EU Biodiversity Strategy, and the fit for 55 package, which describe EU's forests as a key contributing sector to the aimed for sustainability transition and agreed climate goals. In addition, the EU has made commitments that these transition processes are conducted in a just manner. We examine how the EU's ideas around forests' role in reaching the climate goals translate to the national contexts of the member states. We aim to gain deeper understanding of potential differences in framings of the forest at different levels, potential synergies and trade-offs between different prescribed roles to forests at different levels, what policy instruments are proposed to motivate forest owners to manage their forests so as to contribute to the fulfilment of these roles, and in what way just transition considerations are incorporated in these policy instruments. We conduct a case study in which we analyse and compare the Paris Agreement, EU climate and biodiversity directives and strategies, and Swedish government bills, strategies, and action plans for the forest sector. We find that, whilst there are many roles and goals ascribed to EU's forests, there is no clarity in governance on how to fulfil these both at the EU and nationally in Sweden. The current setup provides opportunities for synergies in the short-term, but risks goal conflicts and trade-offs in the long-term. In addition, there is a divergence in focus of policy instruments, where EU climate policy builds on rules and regulations and economic instruments, whilst the Swedish forestry policy focusses on social and information-based instruments. Neither include rights-based instruments and the EU's commitment to create just transitions has no prominence in the proposed policy instruments and national level policy documents. We conclude that the current translation of EU goals to the national level in Sweden provides insufficient clarity and incentives for forest owners to engage with the sustainability transition and risks a lack of perceived legitimacy through its limited attention to considerations of justice.

Legitimacy of EU forest-related policies in digital media discussions: linking theories and empirical findings

T4.14 Governing EU's forests: policy narratives, perception and power

Tapio Rantala[1]
[1] Department of Forest Sciences, University of Helsinki

Abstract: The new strategic EU guidelines and legal regulations that partially override the competence of member states will increasingly affect the legitimacy of forest-related policies, also at the national levels. The implementation of new policies requires reasonable public support and willingness to cooperate, especially in countries like Finland, where more than 10% of the population are private forest owners and many others engage in forest-related recreational activities.

The research series examined the perceived legitimacy of the EU forest policy, social values used in the evaluations, identification with political communities, and the support of politicians in public discussions on social media platforms and discussion forums of news media. Theoretical basis and methods for the analysis of textual data were employed from political science and social psychology.

Most evaluations regarding the legitimacy of the EU forest policies and the exercise of power by the EU were negative across all data sets. In this context, trust in the competence of the EU concerning forest issues was predominantly low and self-identification as European was also weak. The evaluations of politicians involved in EU-induced forest policy decision-making were also mostly very unfavorable.

The fair distribution of benefits and burdens among both European nations and domestic citizen groups was the most common social value used to assess forest policies. Legitimate policy was also deemed to require fair compensation for both one´s own nation and private forest owners for their conservation measures. Following concerns about distributive justice, the preservation of national sovereignty and the right to autonomous decision-making emerged as the second most frequently mentioned social values. The next highest emphasis was placed on economic objectives and private ownership. The values related to nature protection and climate protection were brought up much less frequently than in the previous studies on national level policies and the same applies to values related to democracy, good governance, and fair markets.

The comprehensive theoretical framework developed in this study is useful for the analyses of various public policy discussions; however, the text-analytical methodology is not only limited to fixed categories and therefore it can be flexibly applied in different contexts and countries.

Meeting the European Unions' Forest strategy goals: a comparative European Assessment

T4.14 Governing EU's forests: policy narratives, perception and power

[11] University di Padua

Abstract: The new Forest Strategy for the 2023 for the European Union was adopted in July 2021, creating a new policy drive for policymaking. While the implementation of the EU Forest Strategy is accompanied by debates around the principle of subsidiarity and competencies for forest policy, until now no systematic scientific assessment has been conducted which looks at to what extent countries meet these goals. This study aims at: i) assess to what extent the national and sub-national forest policies of European countries align with the EU's goals; and ii) identify opportunities and challenges for enhanced implementation.

This study refers to 15 countries and 3 regional cases ensuring a variety of socio-economic contexts and forest related conditions. We applied mixed methods based on comparative content analysis. Specifically, a total of 221 policy documents were analyzed through a content analysis, and a vast number of semi-structured expert interviews (69) conducted based on a common interview guideline that was translated into national languages were conducted.

The results of this comparative assessment show that the level of alignment of national implementation with the new EU forest Strategy depends on each country implementation trajectories. In most of the countries significant policy efforts are devoted to defining sustainable limits and practices for forestry whist advancing at the same time new measures on protecting, restoring, and enlarging EU forests. Climate change and their impacts are acting as trigger for putting forest higher in the policy agenda and getting more attention of public opinion and media. However, there is a general lack of mechanisms and participatory planning addressing different ecosystem trade-offs and involving concerned societal groups and scientists systematically in goal formulation. Moreover, there is an increased polarization between conservation and forestry, which results in multiple level and regional governance structures that are not well coordinated. A lack of human and economic resources constrains, in some cases, the ability of public administrations to conduct public management of forest goods and services, and to achieve ambitious goals - embedded

in more complex policy frameworks. We conclude with 9 policy recommendations to overcome these challenges and strenghen EU forest governance.

Overlaps and tensions within actor networks and EU policies towards the implementation of the Biodiversity Strategy and the Nature Restoration Law

T4.14 Governing EU's forests: policy narratives, perception and power

Kaisa Korhonen-Kurki[1]
Dalia D'Amato[1], Mihai Adamescu[2], Salla Rantala[1]
[1] Finnish Environment Institute
[2] UNIVERSITY of BUCHAREST

Abstract: The Earth systems are faced with multiple crises, of which the biodiversity crisis is recognised as perhaps the most severe and complex, in combination with the climate and pollution crisis. The 2019 EU Green Deal (EGD) represents an ambitious plan for a more radical response to such challenges towards transforming the EU into a more sustainable and yet prosperous society, in a just and inclusive way. In the context of the Green Deal, the new EU Biodiversity Strategy for 2030 (BDS2030) aims at protecting, conserving and enhancing European biodiversity and associated ecosystem services, as central elements to transformative change.

The effective implementation of the BDS2030 is challenged, among other things, by the heterogenous landscape of actors involved in the co-creation of knowledge and in decision-making processes related to biodiversity, as well as by horizontal policy incoherence, which involves policies beyond biodiversity, such as agriculture and forestry.

In this study we further explore such challenges by examining the biodiversity science-policy arena at the EU level, and look at overlaps and tensions in roles and responsibilities within actor networks, as well as within existing policies, relevant to biodiversity, including in relation to forest. We base our analysis on social network analysis of key organizations operating in the EU science-policy interface (n=100) as well as a document analysis of EU policy documents (such as EU forest strategy) from key sectors relating to biodiversity and forests. We particularly focus on the Nature Restoration Law as an example of cross-cutting policy process that provokes different knowledge needs within the science-policy arena. The preliminary findings show that the EU science-policy interface hosts several actors with overlapping and conflicting positions and interests, and such diversity is similarly reflected in the policies analysed.

Policy change and learning related to forests and climate change in Germany between 2000-2022

T4.14 Governing EU's forests: policy narratives, perception and power

Pascal Renaud[1]
Metodi Sotirov[1]
[1] University of Freiburg, Chair of Forest and Environmental Policy

Abstract: Policy process research has shown that both power and learning matter for explaining policy change or stasis over time. However, we still do not have sufficient knowledge about how learning contributes to policy change, through which mechanisms it works and how it interacts with power related factors. Learning is particularly relevant for forest related policy, which deals with highly complex ecosystems and wicked problems concerning the supply of wood, climate change adaptation and mitigation, and biodiversity conservation. The use of scientific and other types of information are thus an essential part of forest related policy processes.

Forest related policy in Germany represents a relevant case study in this regard. Within the EU, Germany has the fourth largest forest area as well as the biggest population, greenhouse gas emissions and GDP. Linked to an increase in the average air temperature by 1.6°C between 1881 and 2021, extreme weather events have become more common since the 1990s. Recent heat waves and droughts, storms and bark beetle outbreaks have led to significant forest damages and increased public attention.

The research paper deals with the question to what extent and why forest related policy in Germany has changed or remained stable between 2000 and 2022 and how policy learning has contributed to it. The paper focuses on a longitudinal analysis of forest and climate policy at federal level and in two selected states with particular attention to regulation and public funding for forest related climate change mitigation and adaptation.

The Advocacy Coalition Framework serves as analytical framework, which assumes four pathways to policy change, including external and internal events, negotiated agreements and policy learning. Theory on policy learning helps to shed light on the updating of policy related beliefs by multiple actors such as in parliaments, ministries, business associations, environmental organisations, and scientific advisory boards. Methodologically, the paper draws from qualitative content analysis of policy documents and statements by actors with a process tracing approach. It thereby contributes to empirical and theoretical research on policy learning as independent variable and policy change as dependent variable with a focus on forests and climate change.

Politicization of the EU Forest Strategy at the Member State Level: Implications for forest management

T4.14 Governing EU's forests: policy narratives, perception and power

Oliver Truffer[1]
Costanza Chimisso[2], Tim Rowe[2], Kato Van Ruymbeke[2], Tamaki Ohmura[1], **David Ellison**[1], Eva Lieberherr[1], Liesbet Vranken[2]
[1] Natural Resource Policy Group, ETH Zürich
[2] Society-Environment Interactions Group, KU Leuven

Abstract: The forest can take a central role in the efforts to mitigate climate change. Several factors, however, inhibit a clear delineation as to what this role entails. One set of factors includes the large variation of interests, legal frameworks and forest policy paradigms with related forest management practices of EU Member States. Another set of factors relates to the potentially conflicting goals of sequestering carbon in wood products and sequestering carbon in standing forests (sinks), all while providing other forest ecosystem services. This latter potential antagonism is also reflected in the EU Forest Strategy which aims to enhance the multifunctionality of forests, promote long-lived wood-based products as well as non-wood based products such as ecotourism and other aspects linked to multifunctionality. Depending on Member States' interests, priorities and forest policy paradigms, these potential goal conflicts or trade-offs within the EU Forest Strategy may lead to politicization at the national level and to very different forest management strategies. In a systematic literature review, we zoom in on the forest management practices across Europe, map them and analyze them according to their contribution to mitigate climate change, be it in wood sinks or wood products.

Promoting effective forest Payments for Ecosystem Services through the EU financial and state-aid programs: the ProForPES project

T4.14 Governing EU's forests: policy narratives, perception and power

Paola Gatto[1]

[5] Department of Forest and Soil Sciences, University of Natural Resources and Life Sciences, Vienna, Austria

Abstract: In the context of European and national legislation and financial programs, Payments for Ecosystem Services (PES) are gaining momentum as innovative solutions for meeting societal demand for ecosystem services from forests in Europe. In particular, the EU Forest Strategy 2030 encourages Member States to develop payment schemes for ecosystem services to compensate additional costs met by forest owners and managers in the provision of several regulation and cultural services, such as forest biodiversity, carbon storage, recreation. This calls for increased coordination and coherence amongst the existing EU policies, financial instruments, and state-aid programs towards the common goal of designing payment schemes, as well as for understanding potentialities and limitations of such innovative tools with respect to more traditional environmental policy instruments. The paper will present the first results of the ongoing LIFE21-ProForPES project, which aims to investigate the readiness, possibilities, and barriers to mainstreaming PES and PES-like schemes within the EU policy framework currently under development. The existing gaps and potentialities for PES and the synergies across different EU policy tools are assessed through an in-depth institutional analysis of existing programmes undertaken with the help of policymakers and experts in PES design and policy integration. This is followed by a scenario-based policy assessment achieved through a robust stakeholder consultation process, involving national public administrations and agencies, policy makers, protected area managers, forest owners and their associations, research institutions, private companies, investors. The project will provide recommendations for future funding programmes targeting appropriate forest ecosystem services (or their bundles), actors, institutional and financial models, temporal and spatial scales.

So Many Principles, So Much Policy Confusion

T4.14 Governing EU's forests: policy narratives, perception and power

Alma Galicia Cruz[1]
David Ellison[1], Tamaki Ohmura[1], Oliver Truffer[1], Eva Lieberherr[1]
[1] ETH Zürich

Abstract: Striving for policy coherence aims at the careful harmonization of diverse goals. The governance literature suggests "policy coherence" is an important strategy for addressing potential conflicts between divergent goals, and for mitigating policy tradeoffs and unintended consequences. Indeed, regarding forest policy goals, the Member States of the EU have very different interests.

The forest-related policy terrain and potential policy pathways are rapidly proliferating into ever newer areas. For some time, *multifunctional* and *multi-purpose* forestry described forest policy frameworks with both pluralistic objectives and largely unified (congruent) goals. However, as the principal top-down objective, "*climate change mitigation*" has rapidly replaced multifunctional/multi-purpose forestry as the organizing principle around which policy coherence has been promoted. Thus, for example, "*climate smart forestry*", and the promotion of the renewable circular bioeconomy have become one of the principal goals of future forest management strategies. In turn, in addition to climate change mitigation, goals such as biodiversity protection and increased nature conservation are quickly becoming the principal topics and policy orientations of the day.

Alone, concepts such as climate change mitigation, sustainable land resource use, or biodiversity protection provide organizing principles around which cohesive policy objectives can be coherently organized. Organizing principles lend a much-needed degree of coherence to the practice of policymaking, and, as such, may well contribute to more successful policy outcomes. However, the proliferation of climate change mitigation strategies, bioeconomy interests, biodiversity goals and conservation objectives have increasingly rendered the policy arena more complex, creating powerful interest divisions both within and across states and actors. In particular, the *EU Green Deal* and the *Biodiversity Strategy for 2030* exemplify this shift in policy orientations and the proliferation of policy pathways. And, to some extent, biodiversity and conservation goals have eclipsed policy orientations such as the bioeconomy strategy, though perhaps less so with respect to climate change mitigation.

Taking this development of EU policy into account, this paper analyzes EU forest policy by means of a policy document analysis. It assesses whether and how the prioritization of new and potentially divergent policy goals affects policy coherence, and in doing so favors some interests over others.

Taxomania! Shaping EU forest policy through financial regulation?

T4.14 Governing EU's forests: policy narratives, perception and power

Anna Begemann[1, 2]
Camilla Dolriis[1], Alex Onatunji[1], Costanza Chimisso[1], **Georg Winkel**[2]
[1] European Forest Institute, Governance Programme, Bonn Office, Platz der Vereinten Nationen 7, 53113 Bonn, Germany
[2] Wageningen University & Research, Forest and Nature Conservation Policy Group, P.O. Box 47, 6700 AA Wageningen, the Netherlands

Abstract: The EU taxonomy has made headlines in recent years due to major concerns mainly from member states and their prime ministers but also of environmental groups over the question of what should be considered a sustainable investment including in forests and forestry. While supposedly "science based", this new classification system has raised fears of resetting existing EU and member state sectoral policies through the "back door" of financial regulation and/or greenwashing unsustainable activities. Building on 46 expert interviews conducted in three interview rounds in 2019, 2021 and 2022 as well as process tracing, we investigate the evolution of advocacy coalitions and strategies used to influence the development of the forestry criteria for the taxonomy regulation and its climate and environmental delegated acts. Our findings illustrate a very complex process that is connected to a diversity of sectoral policies including EU forest and nature policies and that translates into cross-sectoral alliances, highlighting strikingly different worldviews and economic and bureaucratic/political interests connected to it. Due to the rich set of strategies and deals made at different levels as well the overall lack of transparency, "science-based" decision-making is challenged to the impossible. While the forestry criteria have been excluded for the time being for parts of the regulation, fossil gas is included, pointing towards a disbalance in favour of certain economic and political interests and despite the EU Commission's goal to enhance private finance for achieving its climate commitments and the Green Deal. The taxonomies ambiguity as well as the political struggle including for the development of the forestry criteria, question its potential as a gold standard to be copied by other countries overall.

The EU de facto Forest Policy: Insights from Finland, Slovakia and Slovenia

T4.14 Governing EU's forests: policy narratives, perception and power

Lenka Haluskova[1]
Daniela Nousiainen[2], Spela Pezdevsek Malovrh[3]
[1] Technical University in Zvolen, Department of Forest Economics and Management, Slovakia
[2] University of Eastern Finland, School of Forest Sciences, Finland
[3] University of Ljubljana, Department of Forestry and Renewable Forest Resources, Slovenia

Abstract: The European Union (EU) founding treaties do not establish a common forest policy. However, several bodies within the EU implicitly, and some of them explicitly, deal with the issue of forests. The latest major strategic document focused on forests is the EU Forest Strategy to 2030. Despite the fact that the document aims to integrate different objectives related to forests, it is perceived as controversial on several points. Member States argue for insufficient involvement during the adoption process, conflicting goals and vague definitions. The poster aims to point out the perceptions on uploading as well as downloading the EU de facto forest policy, with a focus on the New EU Forest Strategy in Finland, Slovakia, and Slovenia. A total of thirty interviews were conducted in three countries to explore the perceptions of key domestic forest policy actors from forestry and environmental administrations as well as non-governmental policy arena, e.g. forest owners, industry, research, and environmental NGOs. Finland is the most active in uploading its policy to the EU within selected countries. It forms a national joint position that includes the positions of various domestic actors. Slovakia and Slovenia are represented by governmental forest experts and create interest coalitions with strong forestry-like-minded countries. In addition, Slovenia is active in informal groupings with fewer members. All three countries have been active in commenting on the New EU Forest Strategy, but they believed that their positions were not sufficiently taken into account. These three countries perceive a strong influence of the EU forest policy despite the fact, it is formally the exclusive competence of the Member States. A turn towards an ecological orientation of the EU in relation to forest policy, confirmed by the New Strategy, may have further consequences for domestic policy-making and financing of the forestry sector.

Understanding forest related conflicts and solutions based on local realities: the case of Gällivare Sweden

T4.14 Governing EU's forests: policy narratives, perception and power

Jerbelle Elomina[1, 2]
Ivana Zivojinovic[1, 2, 3], Helga Pülzl[1, 2]
[1] University of Natural Resources and Life Sciences, Vienna
[2] European Forest Institute – Forest Policy Research Network
[3] Centre for Bioeconomy

Abstract: With the EU's green transition, bioeconomy and sustainability goals being pursued, coupled with the impacts of the war in Ukraine, the demand for forest land and resources is increasing which causes conflicts with mining, energy and traditional activities like reindeer husbandry and hunting. Our study aims at understanding the landuse conflicts using a constructivist lens and conducting a holistic analysis by including multiple sectors. Constructivism offers insights for conflict analysis and conflict resolution because it directs our attention on the historically contingent and constitutive nature of the social structures, agents of conflicts, the social construction of identity, history, culture and the reproduction of conflict. We apply this approach in Gällivare, Northern Sweden which is a small Arctic town undergoing social transformation to accommodate varying demands from multiple sectors. In line with our approach, we therefore ask: How do local stakeholders perceive the conflicting demands from various sectors and what are the conditions wherein these sectors can exist side by side? Using discursive analyses, and looking at the three main elements of conflict: actors, discourses and identity, we analyzed national policy documents and semi-structured interviews with local experts from different sectors including indigenous people. Initial results show that alliances between sectors are created and sectors adapt a 'solution-oriented' thinking that reformulates the conflict into a positive situation where solutions are preferably discussed instead of causes, ignoring the root cause of the conflict and applying Band-Aid solutions. We also found that sectors are aware of the 'cumulative effects' of their operations in addition to the effects of other sectors on the environment, which promotes collective action and inaction. Lastly, green transition is used as a discursive weapon to marginalize and delegitimize traditional livelihoods such as reindeer husbandry and hunting, thereby facilitating industrial exploitation of indigenous lands including forests. On the one hand, solutions are hard to come by as stakeholders are skeptical and can only depend on negotiations and active representation as a way to move forward.

“We need to give up something” - Readiness of Finland to adopt and accept the New EU Forest Strategy for 2030

T4.14 Governing EU’s forests: policy narratives, perception and power

Niina Pietarinen[1]
[1] University of Helsinki

Abstract: Environmental policymaking has shifted from largely state-dominated, to a multi-level, shared responsibility of national and transnational actors alike (Arts & Leroy, 2006). Finland, with comparatively high forest cover and contribution of forest industry to national GDP, faces the challenge of ongoing biodiversity loss despite a long history of national forest legislation and programmes. When the European Commission published “the New EU Forest Strategy for 2030” in 2021, emphasizing environmental outcomes, it was welcomed by the Member States with varying reactions; the traditionally timber-oriented countries, including Finland, resisting the strategy.

This study analyzes Finland’s readiness to *adopt* and *accept* the EUFS by assessing primary and secondary data through a critical institutional policy analysis lens and policy integration framework (Nilsson & Persson, 2010; Di Gregorio, 2016). Readiness to adopt EUFS is assessed by analyzing objectives of national forest-related policies, action plans, and legislation in relation to the objectives set out in EUFS. To capture a full understanding of the readiness, the study considers policy documents from fields of forest, biodiversity, climate change (adaptation and mitigation), energy, bioeconomy, and rural development. The readiness to accept the EUFS is examined through semi-structured expert interviews that aim to increase understanding on actors’ views on national forest-related priorities and factors affecting those.

The initial findings indicate that the existing policy documents seem to primarily align with the EUFS through goals supporting the economic functions of forests. However, a lack of coherence and communication amongst actors in Finland suggests the absence of a unified forest vision. Other gaps are related to lacking political will for adopting and accepting the EUFS, partly legitimized by concerns that Nordic forestry expertise and needs are ignored in the EU. Among most forestry actors, “the productivity reflex” – more production and extraction as a solution - is a dominating response to climate, energy, and biodiversity crises. Meanwhile, environmentally oriented forest actors suggest strengthening forest carbon sink and socio-cultural uses of forests. These findings imply several challenges for the implementation of the EUFS. Meanwhile, opportunities might arise due to changing preferences of private forest owners, and national climate and biodiversity ambitions.

T4.15 Healing Power of Nature: Forest Therapy in Action

Trees, Nature & Health Economics: Putting a Value on What Counts

T4.15 Healing Power of Nature: Forest Therapy in Action

Kathleen Wolf[1]
Jennifer Egan[2]
[1] University of Washington (Seattle), Nature and Health Alliance
[2] University of Maryland, Environmental Finance Center

Abstract: Extensive and rigorous research indicates that urban natural systems, including urban forestry, contribute to residents' health and wellness. Thousands of studies link public health outcomes with green space experiences, including therapeutic effects for cardiovascular diseases and mental health disorders, positive immune system response, stress reduction, improved gestational and infant health, and reduced mortality rates. Natural experiments during the COVID-19 pandemic further document the importance of green space access and wellness. Evidence of nature and health effects range in scale from small groups of treatment patients to entire nations. These outcomes represent significant potential economic value, as most nations face high, and ever-increasing healthcare costs. Yet few natural resource or public health economic analyses have included nature-influenced human health outcomes in comprehensive valuation approaches. This absence is impactful as economic analysis helps support policy development and solidifies consistent budgets. However, political and civic support, including budgeting and funding to sustain resilient urban nature and urban forest systems, falls far short of what is necessary to maintain ecosystem health, and associated human health benefits. Public health policies, plans, and insurance incentives rarely acknowledge health and green experience outcomes, which include improvement in quality of life and ubiquitous morbidities. The evidence indicates that green experience can mitigate health disparities and cost-effectively decrease the burden of disease and improve health equity. Our presentation will offer a conceptual framework for nature and health benefits economics. We first make the case for nature and health as critical to issues of global concern. Then we summarize the links between nature integration within built landscapes and resulting biophysical services and salutogenic benefits. We outline how both the health and environmental disciplines use similar decision-making tools based on economic analysis of costs and benefits. Emphasizing cost-effectiveness analysis, the conceptual framework explores potential community-based urban greening and urban forestry interventions that promote human health. Studies of nature and health economics are sparse. Our examples of potential applications will demonstrate nature and health valuations and provide suggestions for future analysis that can promote community-level wellness and support green space and forest therapy investment.

A Multi-Country Study Assessing the Mechanisms of Natural Elements and Sociodemographics behind the Impact of Forest Bathing on Well-Being

T4.15 Healing Power of Nature: Forest Therapy in Action

Alex Gesse
Montse Subirana-Malaret[1], Alexandre Miró[2], Aracely Camacho[3], Kirsten McEwan[4]
[1] Universitat de Barcelona
[2] Highland Amphibian and Reptile Project
[3] Universidad Autónoma del Estado de México
[4] University of Derby

Abstract: Iterventions such as forest bathing (slow, mindful nature walks) have been shown to increase our connection to nature and be an effective intervention for improving health and well-being.
However, there is variation in the activities delivered during forest bathing and the guidance given. Few researchers have evaluated which activities, elements of nature, and senses are responsible for improvements in well-being. The current evaluation addresses this gap and also monitors the emotional state and nature connection following guided forest bathing walks. Participants (N = 1142) across 35 countries completed post-walk evaluation surveys online. Results suggest that well-being and nature connection were rated very highly following forest bathing activities. Experiencing happy feelings and trusting emotions were especially highly rated. The natural elements perceived as contributing the most to well-being were sound-related elements. In terms of sociodemographics, women had higher well-being and nature connection ratings than men; ratings were higher in specialised nature resort areas, with little difference between natural and urban park areas; higher scores were seen in the southern hemisphere and during hot or long-day seasons. This has implications for forest bathing, forest therapy, and nature-based training organisations and their guides who want to improve their method of intervention delivery, maximise well-being, and enhance nature connection

Co therapist forest: the IWSI method brings forest therapy into health care and rehabilitation

T4.15 Healing Power of Nature: Forest Therapy in Action

Melanie Dr. Adamek[1]
[1] IM-WALD-SEIN Institute for Forest Medicine and Forest Therapy (IWSI), Munich, Germany

Abstract: Climate crisis, heat stress, water scarcity, pest plagues, pandemics, increasing life-style related diseases, demographic change, rising health care costs, digitalization, flood of information, ever accelerating everyday work, stress and excessive demands - keywords showing that forests and humans face similar existential challenges.

But while the forest might be even better off without humans, human existence is hardly conceivable without forests. So, for a good reason, societies around the world are seeking new concepts to integrate the forest into the value chain in innovative ways.

Forest therapy offers excellent opportunities for this in health care contexts. The bond between humans and the forest and the multifactorial effects that the forest as a natural space exerts on body, mind and soul of humans are now so well researched that they can form the basis for an experimental model of forest therapy.

In the field of individual preventative health care, this model must admittedly meet different standards than in the field of medical rehabilitation of (chronic) diseases.

The presentation highlights two projects with which the Im-Wald-Sein Institute intends to bring more forest and nature into people's everyday life and medical care and how it is contributing to the further development of a target group specific, living world-related and effectiveness proven model of forest therapy and forest medicine.

Comparison of the Mindfulness Therapy Interventions on University Students' Emotions and Attention in Different Environments

T4.15 Healing Power of Nature: Forest Therapy in Action

Yu-Jun Yang[1]
Guang-Yu Wang[2], Xiang-Fei Gong[1], Shi-Qi Wang[1], Wei-Yin Chang*[1, 3]
[1] College of Forestry, Fujian Agriculture and Forestry University, Fuzhou 350002, China
[2] Faculty of Forestry, University of British Columbia, Vancouver, BC V6T 1Z4, Canada
[3] Forest Therapy Committee, Chinese Society of Forestry, Beijing 100091, China

Abstract: After COVID-19, university students experienced stress-related health conditions due to restrictive measures that limited face-to-face communication. These measures have led to feelings of isolation and stress among students. Additionally, the transformation from in-person teaching classes to online classes had adverse effects on academic quality, happiness, and overall life satisfaction. Mindfulness therapy has been proven by scholars to improve people's health and manage stress and negative thoughts. However, traditional therapy meditation is typically conducted indoors. The primary purpose of this study was to identify: 1) whether mindfulness therapy intervention in forest and indoor environments can affect the health of university students; 2) whether the forest therapeutic effect differs depending on the environment.

We recruited 109 university students to participate in a two-week long study and divided them into three groups: the forest group, the indoor group, and the control group. The forest and indoor groups received one hour of mindfulness therapy intervention every day in the corresponding environment, while the control group received no intervention. Physiological and psychological indicators were used in this study. Physiological indicators included heart rate variability (HRV), heart rate (HR), and blood pressure (BP), while psychological indicators included the Profile of Mood States (POMS) and the Five Facet Mindfulness Questionnaire (FFMQ).

The results indicated that participants who received mindfulness therapy in both forest and indoor environments experienced positive effects on their emotions and self-attention compared to those in the control group. However, concentration of self-attention was more significant in the indoor environment than in the forest, possibly due to the absence of noise and distractions in an indoor room. On the other hand, participants in forest environments exhibited greater reductions in stress, depression, and anxiety symptoms, as well as an increase in positive emotions compared to those who were in indoor.

Finally, this study showed that in the post-COVID-19 era, a two-week mindfulness therapy intervention can benefit contemporary people with limited time. Further studies are needed to examine the long-term effects of mindfulness interventions in different environments and their potential applications in promoting mental health.

Keywords: Mindfulness intervention, Physiological and psychological indicators, Stress reduction, post-COVID-19 era.

Developing an Islamic-Inspired Forest Therapy Module for Senior Citizens: A Pilot Study

T4.15 Healing Power of Nature: Forest Therapy in Action

Nur Najwa Dina Abong[1]
Abdul Wahab Deraman[1], Keeren Sundara Rajoo[2, 3], Daljit Singh Karam[4], Arifin Abdu[5], Mohd Hakeem Bin Mohd Ibrahim[4], Muhd. Amin Abdullah Bin Azhar[2]
[1] Kelantan State Forestry Department, Malaysia
[2] Department of Forestry Science, Faculty of Agricultural & Forestry Sciences, Universiti Putra Malaysia, Sarawak Campus
[3] Institute of Ecosystem Science Borneo, Universiti Putra Malaysia, Sarawak Campus
[4] Department of Land Management, Faculty of Agriculture, Universiti Putra Malaysia
[5] Department of Forestry Science & Biodiversity, Faculty of Forestry and Environment, Universiti Putra Malaysia

Abstract: This pilot study aims to develop an Islamic-inspired forest therapy module specifically designed for senior citizens. The research will be conducted in August 2023 at Bukit Bakar Forest Eco Park, Machang, Kelantan. A total of 20 senior citizens will participate in a three-day, two-night forest therapy program, which will incorporate various activities including Ancient Malay Exercise and Religious Lectures.

The primary objective of this study is to investigate the effects of the Islamic-inspired forest therapy module on the mental and physical well-being of senior citizens. The participants' blood pressure will be recorded, and they will complete the Positive and Negative Affect Schedule (PANAS) scale and Depression, Anxiety, and Stress Scale (DASS-21) before and after the program. These assessments will enable the measurement of changes in participants' emotional states and stress levels resulting from the forest therapy intervention.

Additionally, qualitative interviews will be conducted with the participants to gather their perspectives on the activities that had the most significant impact on them. This qualitative data will provide valuable insights into the specific elements of the program that resonated with the participants and contributed to their overall well-being.

The findings from this pilot study will serve as a foundation for further research and the development of evidence-based forest therapy programs tailored to the needs of senior citizens, particularly Muslims. By understanding the impact of forest therapy on the mental and physical health of senior citizens, healthcare professionals and practitioners can better support the well-being of this population.

This study contributes to the emerging field of nature-based interventions by exploring the integration of Islamic values into forest therapy modules for senior citizens. The results of this research have the potential to inform the development of culturally appropriate and effective interventions that promote the health and well-being of older adults in a holistic manner.

Evaluation of the restorative potential of urban forest through a forest therapy program

T4.15 Healing Power of Nature: Forest Therapy in Action

Jelena Tomićević-Dubljević[1]
Milena Trmčić[1], Ivana Bjedov[1], Marija Nešić[1], Dragana Čavlović[1], Ivana Živojinović[2], Oliver Tošković[3], Ivana Lozjanin[4], **Anna Maria Palsdottir**[5], Slavica Čepić[1]

[4] Public Enterprises "Vojvodinašume", Forest administration "Sremska Mitrovica" Sremska Mitrovica, Serbia
[5] Swedish University of Agricultural Sciences, Department of People and Society

Abstract: More proof is needed to understand the underlying restorative potential of urban and peri-urban forest and how to plan, design, and manage urban forest to optimize their restorative impact. Also, there is a great need to identify and describe specific qualities of urban forest that may support health processes guided by a professional forest therapist. Forest therapy bases have been established in many countries in the world. However, there is a lack of research on forest therapy in Serbia, especially in urban forests. The forest therapy program was designed and implemented to evaluate the perceived psychological benefits of spending structured time at two urban forests in Belgrade. The participants in this study were voluntary students from the fourth year of the Faculty of Forestry (n=18) randomly selected for the study group (n=9) and the control group (n=9). The study group had two hours walk with a forest therapist and control group had a walk without forest therapy program. Participants in both groups were assessed pre- and post intervention using the questionnaire consisting of the Profile of Mood States (POMS) and after the walk, they filled out the questionnaire regarding Perceived Sensory Dimension (PSD). This study indicates that forest therapy in urban forests has clear benefits for human health and well-being.

Exploring the potential of a guided forest bathing programme as a nature-based intervention for well-being, restoration, and nature connection

T4.15 Healing Power of Nature: Forest Therapy in Action

Jonna Sandin Larkander[1]
Petra Ellora Cau-Wetterholm[2], Annelie Vårhammar[3], Marcus Hedblom[1], Matteo Giusti[4], Anna María Pálsdóttir[1]
[1] Swedish University of Agricultural Science
[2] Scandinavian Nature and Forest Therapy Institute
[3] Stockholm Resilience Center, Stockholm University
[4] University of Surrey

Abstract: Stress-related mental illness is a growing public health challenge worldwide, and Sweden is no exception. Shinrin-yoku (forest bathing) is a nature-based intervention developed in Japan during the 1980s to curb growing incidences of stress-related illness in society. Shinrin-yoku has spread across the world since the 1980s. In Sweden, the Scandinavian Nature and Forest Therapy Institute (SNFTI) provide guided forest baths in accordance with the Eco-Forest Therapy theory, method and guiding skills. The aim of this study was to evaluate how participants experienced a guided Eco-Forest Therapy intervention programme (one a week/3 week) and if participation increased perceived well-being, restoration, and nature connection and decreased perceived fatigue. A sequential mixed methods design was adopted to strengthen the study's results. The intervention was conducted by certified SNFTI guides in a variety of forest settings from the northernmost- to the southernmost parts of Sweden. 124 participants from the general public were enrolled in the intervention programme from the start, and 75 answered all surveys in a correct manner. The results show that the intervention programme had significant positive effects on the participant's perceived well-being, fatigue, restoration, and nature connection and that feelings of well-being, restoration and nature connection seem to be mutually reinforcing. The positive effects are confirmed by the pre-and post-measurements of the whole intervention programme, by the pre-and post-measurements of each forest bathing session and by the results of the interviews. There is particularly strong evidence for the beneficial health effects perceived directly after each forest bathing session, where the standardized mean difference (effect size) is above one standard deviation for all three baths. The beneficial short-term effects are also confirmed in the interviews. The most valued experiences are; finding rest, and reminders of personal needs; the guided group sessions became a safe haven and fascinating nature experiences. The least valued experiences are; feeling pressured to share – and reflect on others´ experiences, disturbing sounds and emotional turmoil when slowing down. The results indicate that forest bathing can be important for supporting human health and well-being. Randomised controlled trials are warranted to confirm this.

Findings from a Mindfulness-based Forest Therapy Intervention for Supporting Individuals with Substance Use Disorder

T4.15 Healing Power of Nature: Forest Therapy in Action

Philip Hosmer[1]
Nicole Mattocks[2]
[1] Nature Worx, Inc.
[2] University of Maryland School of Social Work

Abstract: Forest therapy has been shown to reduce depression, anxiety and improve overall physical health. However, little is known about the potential of forest therapy for supporting recovery from substance use disorder. Non-profit organization Nature Worx, and a university researcher, measured the effects of forest therapy on individuals in addiction treatment. Our goal is to establish findings regarding the effectiveness of Nature Worx sessions for reducing anxiety, depression, and substance cravings.

Methods

We used a one-group post-test only design to measure attitudes towards nature, and perceived anxiety, depression, and substance cravings before and after a 90-minute session. Sessions were facilitated by trained guides who lead experiential activities promoting connection with nature. After each session, participants complete a survey assessing levels of anxiety, depression, and substance cravings. All participants (N=821) were enrolled in an inpatient or extended residential program, between March 2020 and April 2022. All descriptive and bivariate analyses were conducted using STATA 16.

Results

Respondents experienced a mean 1.15-point reduction in anxiety (on a 1 to 5 scale) from pre- to post-intervention. Similarly, respondents reported reductions in depression (M=.74) and substance cravings (M=.43) after one session. A comparison of average change scores by baseline cravings indicates that respondents who reported “somewhat high” to “very high” cravings before the session experienced a significantly greater reduction in cravings compared to those with “very low” to “moderate” baseline cravings ($t(786)=-11.31$, $p < .00$). For those with high cravings at baseline, the average change from pre- to post-intervention was 1.4 points (SD=.16). Additionally, 89% of participants reported feeling more connected to the natural world, and 95% learned ways that nature could support their recovery.

Conclusions and Implications

These findings indicate the average participant experienced reduced anxiety, depression, and substance cravings after participating in a session. Additionally, the greatest reductions in cravings were found among the highest risk group, suggesting Nature Worx sessions may curb strong cravings. The majority of participants understood how nature could support their recovery, demonstrating the sessions give participants tools to use. Nature Worx sessions are affordable, accessible, and could be a sustainable supplement to traditional forms of substance use treatment.

Forest Bathing in Canada: A Randomized Controlled Trial Investigating Environmental Influence on Health

T4.15 Healing Power of Nature: Forest Therapy in Action

Tara L. Brown[1]
[1] Forest Resources Management, Faculty of Forestry, The University of British Columbia

Abstract: Forest bathing, a nature-based therapeutic practice originating in Japan, has gained recognition for its significant mental and physical health benefits. However, the influence of environmental factors and the effectiveness of different forest bathing techniques on health outcomes remains understudied, particularly in North America. To address this research gap, we led a year-long randomized controlled trial in Vancouver, British Columbia, a city characterized by abundant, diverse urban green spaces and biodiversity.

While respectfully acknowledging the enduring connection of Indigenous Peoples connection to the land and their historical practices that resonate with forest bathing, our study focused on the health outcomes of two contemporary forest bathing techniques: guided and self-guided multisensory immersion. Interventions took place across four diverse urban forests in Vancouver, spanning all four seasons, and health impacts were evaluated using physiological and psychological measurements.

This study sheds light on the intricate relationship between individuals and their environment, providing insights into how it shapes health outcomes in the context of forest bathing in Canada. The findings have far-reaching implications for public health policy, urban planning, and forest management, particularly in cities rich in green spaces like Vancouver. Furthermore, our findings can inform the development of more personalized forest bathing interventions.

By highlighting the critical role of urban forests in promoting health and well-being, this study contributes to interdisciplinary research bridging forest science and health. It adds to the growing body of knowledge on forest bathing while underscoring the importance of considering environmental factors for designing effective nature-based interventions.

Forest Therapy for Women with Gynaecological Cancer—A Feasibility Study to Find New Alternatives in Cancer Rehabilitation

T4.15 Healing Power of Nature: Forest Therapy in Action

Hanna Anundi[1]
Ann Dolling[2], Anna María Pálsdóttir[3]
[1] Women's Clinic, Central Hospital Kristianstad, J. A. Hedlunds väg 5, 291 33 Kristianstad, Sweden
[2] Department of Forest Ecology and Management, Swedish University of Agricultural Sciences, 901 83 Umeå, Sweden
[3] Department of People and Society, Swedish University of Agricultural Sciences, Box 190 23422 Lomma, Sweden

Abstract: Psychosocial support during cancer rehabilitation has proven to be insufficient and nature-based treatment is one of the alternatives mentioned as the way forward. In an ongoing study we offer women suffering or recovering from gynaecological cancer participation in a ten-week forest bathing intervention, as an add-on to the standard care. Our aim is to evaluate the patient's experience of the intervention, and whether it can improve general health and well-being.

The study started in the autumn of 2022 and is planned to continue until the end of 2023. It is a prospective single-case study, including quantitative and qualitative approaches using validated self-administered instruments (pre–post measurements) and semi-structured interviews (post) on women's lived experience of the intervention. The quantitative outcome measurements will be the quality of life, fatigue and depression/anxiety. There is also a questionnaire on perceived sensory dimensions experienced in the forest environment. The study will include 24 participants, divided into four groups of 6 participants. Once a week for ten weeks, the participants will be offered a session of a 2.5-hour stay in the forest with breathing exercises, slow movement, time in silence and privacy and a social gathering to conclude each session.

Up to this date one group of participants is completed, one group is ongoing and two more groups are planned to start in the late summer and autumn of 2023. Spontaneous feed-back from the participants has been encouraging. Data will be analysed in the spring of 2024 and presented at the congress.

To our knowledge, this is the first study on forest bathing for cancer survivors in Sweden.

Healing Power of Nature: Forest Therapy in the Modern Era

T4.15 Healing Power of Nature: Forest Therapy in Action

Guangyu Wang[1]
Yawei Wei[1], Mei He[1], Gonghan Sheng[1]
[1] Multidisciplinary Institute of Natural Therapy, University of British Columbia

Abstract: In our modern, fast-paced, urbanized world, we often find ourselves overwhelmed by stress, anxiety, and various mental health challenges. The healing power of nature has long been recognized as a potent remedy for these afflictions. This talk delves into the transformative effects of immersing oneself in nature, particularly the therapeutic benefits of forest environments. The presentation will explore how forest therapy can positively impact our physical, mental, and emotional well-being: 1) the physiological effects of spending time in forests, such as reduced blood pressure, decreased stress hormone levels, and enhanced immune system functioning; and 2) the psychological benefits from forest bathing, including improved mood, increased attention span, and boosted creativity resulting from immersing oneself in a forest's calming and awe-inspiring environment. While exploring the practice of forest therapy, we delve into various techniques and mindfulness exercises that can be employed to engage with the forest environment fully. We discuss the importance of sensory awareness, deep breathing, and mindful walking for cultivating a mindful and enriching forest bathing experience. The talk also highlights how to integrate these techniques into their own lives, allowing them to harness the healing power of nature for their well-being.

How forest social prescribing can provide opportunities and benefits to participants and providers of nature based interventions

T4.15 Healing Power of Nature: Forest Therapy in Action

Liz OBrien[1]
Jack Forster[1], Katy Spencer[1]
[1] Forest Research

Abstract: Social prescribing has risen up the agenda in Britain in recent years. In England the National Health Service employed one thousand link workers to match people with a range of problems (psychological and physiological) to community-based activities that can benefit their health when medication is not needed or not the complete answer to the issues they face. Nature based interventions that consider the health needs of individuals who need support have increased in recent years as well. Forestry England and Sport England (both government bodies) developed a partnership programme called Active Forests in 2014. In 2019 as part of the programme a green social prescribing pilot project called 'Feel Good in the Forest' was developed focused on two forest sites in urban areas. A range of activities were developed as part of the pilot project from seated exercise, Nordic walking, reading ramblers, archery, to walking football. An evaluation of the pilot project involved focus group and interviews (n=52) with participants, organisation representatives and exercise providers, and surveys were completed by participants (n=103). There was a total of 6,183 visits during the pilot project by 265 people. The qualitative data revealed some significant impacts for participants particularly in terms of their mental wellbeing, social connections, self-confidence, and self-esteem. The survey results show that participants in the pilot were less happy and more anxious than the general population in England and therefore these were the type of participants that the project was aiming to engage with. Interviews with NHS referral agents and providers of activities such as Age UK highlighted the calming atmosphere of the forest as an important element of the project and as a space in which people felt more comfortable being active as they viewed the forest as a non-judgemental place. There are lessons to be learnt on the use of questionnaires that explore mental wellbeing as these can seem intrusive to participants when they first participate in the project. The findings reveal the benefits and challenges of the intervention for both participants and those involved and delivering the project, providing insights for future improvements of similar interventions.

Managing stress among middle-aged working women through forest therapy approach

T4.15 Healing Power of Nature: Forest Therapy in Action

Keeren Sundara Rajoo[1, 2]
Daljit Singh Karam Singh[3], Nur Najwa Dina Abong[4], Zahari Ibrahim[5], Arifin Abdu[6]
[1] Department of Forestry Science, Faculty of Agricultural & Forestry Sciences, Universiti Putra Malaysia, Sarawak Campus
[2] Institute of Ecosystem Science Borneo, Universiti Putra Malaysia, Sarawak Campus
[3] Department of Land Management, Faculty of Agriculture, Universiti Putra Malaysia
[4] Kelantan State Forestry Department, Malaysia
[5] Forestry Department Peninsular Malaysia
[6] Department of Forestry Science & Biodiversity, Faculty of Forestry and Environment, Universiti Putra Malaysia

Abstract: This study aims to determine the effects of forest therapy on the stress levels of middle-aged working women. Nineteen middle-aged working women (54.80 ± 0.68 years old) participated in a half-day forest therapy program conducted at Bukit Ekspo; A tree-dominated urban park located at the centre of Universiti Putra Malaysia. For the physiological indices, the systolic blood pressure (SBP), diastolic blood pressure (DBP) and pulse rate of the participants were evaluated three times a day; Before breakfast, lunch and dinner. The readings were obtained two days before, during and three days after the forest therapy program. The physiological readings obtained two days before the study served as the baseline reading, as it represented the normal, everyday physiological condition of the participants. The baseline SBP (124.16 ± 0.79mmHG) and the baseline DBP (81.89 ± 0.50 mmHg) of the participants were beyond healthy levels, falling into Stage 1 hypertension. The mean SBP of the participants significantly reduced during the forest therapy day (118.72 ± 0.67mmHG) and three days after the forest therapy day (119.51 ± 0.79mmHG). This reduction was also observed for the DBP readings, whereby the mean DBP readings for the forest therapy day (78.65 ± 0.44mmHG) and three days after (78.47 ± 0.48mmHG) were lower than the baseline values. There were no significant changes in the pulse rate. For the psychosocial perspective, the participants self-evaluated themselves to determine the effects of forest therapy on their mental wellbeing. Only 16% of the participants believed that they successfully performed self-regulation when faced with stressful situations, although 74% of the participants admitted to experiencing stress on a daily basis. After participating in forest therapy, the majority of the participants felt rejuvenated and more at ease at work. In conclusion, forest therapy is an effective stress management tool for middle-aged female employees.

Natural Forest, Cultural Forest, or Urban Landscape? Effects of Different Environment Types on Stress Recovery in Virtual Reality

T4.15 Healing Power of Nature: Forest Therapy in Action

Xin Wang[1]
Guang-Yu Wang[2], Ke-Xin Xiong[1], De-Sheng Guo[1], Mei He[2], Wei-Yin Chang*[1, 3]
[1] Fujian Agriculture and Forestry University, College of Forestry, Fuzhou 350002, China
[2] University of British Columbia, Faculty of Forestry, Vancouver, BC V6T 1Z4, Canada
[3] Taiwan Forest Therapy Society, Taipei 10617, China

Abstract: Despite a number of studies have demonstrated the benefits of forest therapy on people's health, few have focused on the potentially different effects between natural and cultural elements in forest therapy sites. Therefore, a laboratory-based study was conducted to explore whether environmental types in forest therapy sites could produce different stress recovery effects. The environmental types of Chinese national forest therapy sites were classified into two types, forest natural landscape and forest cultural landscape, based on the Chinese "National Forest Therapy Site Quality Assessment Standards (LY/T2934—2018)" and the landscape characteristics of forest therapy sites, with urban landscape as the control group.

172 university students took part in a stress induction task before being randomly assigned to view a video in virtual reality (VR) environment for 6 min: (a) forest natural landscape video; (b) forest cultural landscape video; (c) urban landscape video. Heart rate (HR) and electrodermal activity (EDA) were selected as physiological indicators while Visual Analogue Scale (VAS) and Short State Anxiety Inventory (SSAI) were selected as psychological indicators.

Results showed that all three environment videos can significantly reduce stress, with HR, EDA, VAS, and SSAI all significantly lower than before the exposure. Meanwhile, forest natural landscape and forest cultural landscape had better improvement in nature connectedness and greater perceived environmental restorativeness than urban landscape. Although there was no significant difference between the three groups on physiological indicators, forest natural landscape and forest cultural landscape had better stress recovery benefits in VAS and SSAI than urban landscape, which were mediated by increasement in nature connectedness and greater perceived environmental restorativeness.

Our findings provide evidence for the construction of forest therapy sites as well as the stress management utilizing virtual reality device.

Natural Resource Management and Livelihood Change in National Park Communities in China

T4.15 Healing Power of Nature: Forest Therapy in Action

Suyuan He[1]
[1] Renmin University of China, School of Agricultural Economics and Rural Development , China

Abstract: A national park based protected area (PA) management system has been set up in China, with a policy target of biodiversity security and providing ecological services to the public, while fully securing the conservation of natural ecosystems.In the past, the management of China's PA system focused on eliminating human impacts and achieving biodiversity security. However, China has a large number of local residents within PAs. In some regions, the disagreements between local residents and conservation management agencies were intensified into conflicts under the high-pressure environmental inspections from the central government since in 2018. How to reduce the conflicts between biodiversity conservation and economic development in and around PAs has become an important issue for the government, the local residents and the public. With the establishment of national parks, the intense conflicts between the PA management agencies and local residents have gradually been released in some areas. By using a qualitative research method, this study explores the factors for this shift with multiple national park cases in China. It is found that except the changes of conservation policy, the dramatic economic and social changes taking place in China also played a significant role.

NURTURING WELLNESS: UNVEILING THE HEALING POWER OF FORESTS ON MENTAL HEALTH AMIDST POST-PANDEMIC CHALLENGES

T4.15 Healing Power of Nature: Forest Therapy in Action

Aditi Mishra[1, 2]
[1] Sachin Uniyal, Govind Ballabh Pant National Institute of Himalayan Environment, Almora, India.
[2] Shriya Adhikari, Forest Research Institute, Dehradun, India.

Abstract: The Himalayas have long captivated individuals with their majestic peaks, lush forests, and serene natural beauty, providing solace and inspiration. As urbanized societies continue to seek refuge in these mountainous landscapes, recognizing the potential of the Himalayas to enhance human well-being becomes crucial, especially in the aftermath of the COVID-19 pandemic resulting in stress, depression, and other mental health disorders. This study investigates the transformative potential of forest therapy as a tool for post-pandemic well-being and sustainable tourism in the Kumaon Region of Uttarakhand Himalayas in India.

The study aimed to gain insights into the experiences and perceptions of tourists who participated in forest therapy programs following prolonged periods of lockdown, social distancing and isolation. By employing surveys, interviews, and psychological assessments, the research examined the effectiveness of forest therapy in mitigating the psychological burdens caused by the pandemic and subsequent stressors. Specifically, the study explored the impact of forest therapy as a key approach to reduce **pandemic-related anxieties, depression,** and **post-traumatic stress disorders (PTSD)** within the unique context of the Mystic Himalayan Woodlands.

The results indicate that forest therapy in the Himalayas emerges as a powerful intervention for post-pandemic well-being, with significant **reductions in stress levels, alleviation of depressive symptoms,** and **enhanced psychological resilience.** The picturesque landscapes and serene natural beauty of the Himalayan forests provided participants with a restorative sanctuary to reconnect with nature, facilitating a sense of tranquillity, relaxation, and rejuvenation. Bridging **forest therapy and medical tourism** can play a crucial role in providing sustainable **livelihood opportunities to the communities** by harnessing the benefits of the therapeutic qualities of nature.

As a major outcome of this study presents that by harnessing the healing power of the Himalayas and promoting forest therapy as a **transformative approach** to well-being and **sustainable tourism**; policymakers, practitioners, and tourism stakeholders can foster a harmonious relationship between nature, and well-being. Incorporating forest therapy into sustainable tourism practices and **public health frameworks** can create a balanced and resilient future, promoting the well-being of both visitors and the **Himalayan ecosystem.**

Keywords: Himalayas, forest therapy, well-being, sustainable tourism, COVID-19, post-pandemic, mental health.

Shinrinyoku (forest bathing) followed by the Japanese tea ceremony

T4.15 Healing Power of Nature: Forest Therapy in Action

Sumire Kawamoto[1]
Kate Bast[2], Mary Binkley[3], Mariko Inoue[4]
[1] APA - The Engineered Wood Association
[2] Association of Nature and Forest Therapy guide, Shinrin-yoku Madison
[3] Naturalist
[4] Tama Forest Science Garden, Forestry and Forest Products Research Institute

Abstract: This study examines the integration of shinrinyoku and the Japanese tea ceremony to promote well-being in daily life.

"Shinrinyoku" is a term coined by the Forestry Agency of the Government of Japan in 1982, aligning with existing terms such as "seawater bathing" and "sunbathing." It has become rooted in Japan due to its historical and cultural association with forests. Shinrinyoku practice has extended beyond Japan. For instance, in Wisconsin, USA, Kate Bast, an Association of Nature and Forest Therapy (ANFT) guide, initiated Shinrin-yoku Madison in early 2019, conducting private and group walks through forests. Additionally, the Natural Resources Foundation in Wisconsin, a non-profit organization, included shinrin-yoku fundraising field trips annually. The ANFT approach to forest therapy often concludes with tea brewed from wild herbs collected by the guide.

The Japanese tea ceremony originated from China and was initially employed for medicinal and ritual purposes by Buddhist monks. By the 16th century, the ceremony underwent a transition, with utensils being replaced by simpler Japanese items, including bamboo and wood. The traditional tea-making procedures, which emphasize mindfulness, have been handed down through generations and have naturally integrated into everyday life activities. In a formal tea ceremony, which includes a light meal, guests can enjoy a forest garden leading to the tea room.

In 2021, the authors initiated the combination of shinrinyoku and the Japanese tea ceremony. These practices, originating from Japan, share similarities.

1. Being present: Both practices emphasize full presence in the moment, immersing oneself in the surroundings and engaging the senses to become aware of the natural environment.
2. Increasing sensitivity: Both practices aim to enhance well-being through the connection with nature. Shinrin-yoku directly provides an opportunity for individuals to reconnect with nature.
3. Inner calm: The slow walking in shinrinyoku and the deliberate movements of the tea ceremony can induce a state of tranquility and mindfulness.

We anticipate that the integration of shinrinyoku and the Japanese tea ceremony will serve as an effective practice for fostering a deep connection to nature, allowing participants to closely observe and interact with the natural wooden items used in the tea ceremony.

The contribution of green pharmacy towards cancer management: Case study of Zanthoxylum paracanthum Kokwaro (Rutaceae) in Kenya

T4.15 Healing Power of Nature: Forest Therapy in Action

Abstract: *Zanthoxylum paracanthum* Kokwaro (Rutaceae) is an endemic Kenyan and Tanzanian plant used in folk medicine by local populations. Although other *Zanthoxylum* species have been studied, only *Z. paracanthum* stem extracts have been profiled, even though the roots are also used as herbal remedies. The dichloromethane/methanol (1:1) root bark extract was studied in this report. Eight root bark compounds were isolated and their structural identities were confirmed by mass spectrometry (MS) and nuclear magnetic resonance (NMR) (using COSY, HSQC, NOESY and HMBC) analyses. The structural identities were determined as follows: the fatty acid, myristic acid (**1**); the sterol, stigmasterol (**2**); the lignin-sesamin (**3**); two carboline alkaloids, 10-methoxycanthin-6-one (**6**) and canthin-6-one (**7**); and three phenanthridine alkaloids, 8-acetonyldihydrochelerythrine (**4**), arnottianamide (**5**) and 8-oxochelerythrine (**8**). Some of these compounds were identified in the species for the first time. These compounds and the extract were then tested in vitro for antiproliferative activity against the human breast cancer (HCC 1395), human prostate cancer (DU 145) and normal (Vero E6) cell lines. The root extract and some of the compounds had antiproliferative activity against the HCC 1395 cell line. Stigmasterol and canthin-6-one had IC_{50} values of 7.2 and 0.42 indicating the high potential present in these chemicals in cancer management. The root bark extract also showed activity, at 8.12 g/mL, against the HCC 1395 cells. Out of the chemical isolates, 10-methoxycanthin-6-one and canthin-6-one showed the strongest inhibition of the DU 145 cells. The root extract had significant antiproliferative activities, supporting the traditional use of this plant in treating cancer-related ailments.

Keywords: *Zanthoxylum paracanthum*, anticancer activity, medicinal plant, phytochemistry, traditional medicine

The Effects Of Forest Therapy On The Cognitive Performance Of University Students

T4.15 Healing Power of Nature: Forest Therapy in Action

Keeren Sundara Rajoo[1, 2]

[4] Kelantan State Forestry Department, Malaysia
[5] Forestry Department Peninsular Malaysia
[6] Department of Forestry Science & Biodiversity, Faculty of Forestry and Environment, Universiti Putra Malaysia

Abstract: This study examined whether short weekly forest therapy sessions could enhance the cognitive performance of university students. Twenty undergraduate students participated in the study, which took place at an urban forest in the University Putra Malaysia Bintulu Sarawak Campus. Participants were randomly assigned to either a forest therapy group (FTG) or a control group (CG), with ten students in each group. The FTG received 30-minute forest therapy sessions twice a week (eight sessions in total), while the CG continued with their regular daily activities during the study.

During each session, the FTG engaged in one forest therapy activity, such as sensory enjoyment, leisurely walking, or breathing exercises. The QuantifiedMind web-based cognitive test was used to measure participants' executive function, working memory, and reaction time before and after the study. Two tasks were assigned for each cognitive function, and paired T-tests were used to analyze the results. Additionally, an exit survey was conducted to gather FTG participants' feedback on their forest therapy experience.

No significant changes in cognitive performance were observed in the CG. However, after four weeks of forest therapy sessions, the FTG demonstrated significant improvements ($p \leq 0.05$) in executive function and working memory. Both executive function tasks showed significant improvement: sorting (377.94±94.89, $p = 0.022$) and coding (364.86±141.42, $p = 0.042$). Similarly, both working memory tasks improved: design copy (473.28±59.71, $p = 0.040$) and visual back digit (386.49±102.72, $p = 0.007$). However, there were no significant differences in both reaction time task.

FTG participants reported that the earlier forest therapy sessions had little impact on their mental health, but as they became more familiar with the practice, they experienced an improvement in their ability to manage everyday stress.

In conclusion, this study shows that one hour of weekly forest therapy sessions can positively impact the cognitive performance of university students. The results suggest that universities should consider incorporating forest therapy into their wellness programs to provide students with an enjoyable, low-cost, and effective method of managing stress and improving cognitive performance.

The emerging global network of forest therapy guides

T4.15 Healing Power of Nature: Forest Therapy in Action

Amos Clifford[1]
[1] Association of Nature and Forest Therapy Guides and Programs

Abstract: Over the past 12 years a global network of trained forest therapy guides has emerged. Inspired by Japanese and Korean practices, a wide range of variations on forest therapy have been developed and deployed, largely by entreprenurial companies and leaders in the field. The goals of forest therapy practitioners range from enhancing the health- and well-being of individuals affected by stressful lifestyles, to developing relationships between forests and humans for the purpose of promoting global health. This session is aimed at promoting dialogue between forest management professionals and forest therapy researchers and practitioners.

Using Campus Forest for Students' Psychological Well-being

T4.15 Healing Power of Nature: Forest Therapy in Action

Won Sop Shin[1]

[1] Department of Forest Sciences, Chungbuk National University, Cheongju-si, Chungbuk, Rep. of Korea

Abstract: University students are in a transitional period of transition from adolescence to adulthood and s face problems such as adaptation to new environments, intense interpersonal competition, academic difficulties, and uncertain future, etc. Forest therapy is considered an effective way to improve students' mental health. Many researchers have investigated the effectiveness of forest therapy programs for diversed target populations. However, very few study has been conducted forest therapy effectiveness for university students. This study performed to investigate students' psychological benefits, such as academic stress and self-esteem, from forest therapy program using campus forests.

The study employed a randomized 3 × 3 crossover study. Twenty-three university students were randomly assigned into three groups to eliminate the order effect. Twenty-three university students were randomly exposed to three conditions: a self-guided forest therapy program, a guided forest-therapy program, and routine activities. All participants participated in all interventions once a week for three weeks, and each intervention was conducted over a one-week washout period to eliminate the carryover effect of the intervention. Measures included the Positive and Negative Affect Schedule (PANAS), the Rosenberg Self-esteem Scale (RSES), and the Connectedness to Nature Scale (CNS).

As a result, forest-therapy programs significantly improved participants' negative emotions and self-esteem. This study also shows that not only guided forest therapy programs but also self-guided forest therapy programs have a positive effect on psychological health. Therefore, these findings suggest that running guided forest therapy programs and self-guided forest therapy programs as university in-campus programs will significantly help university students' mental health.

What is A Better Way to Achieve Recovery in A Forest? An Experimental Comparison of Forest Therapy Activities and Forest Walks

T4.15 Healing Power of Nature: Forest Therapy in Action

Desheng Guo[1]
Guorui Zhang[1], Qinbo Wang[1], Guangyu Wang[2], Mei He[2], Xin Wang[1], Weiyin Chang[1, 3]
[1] Fujian Agriculture and Forestry University, College of Forestry, Fuzhou 350002, China
[2] University of British Columbia, Faculty of Forestry, Vancouver, BC V6T 1Z4, Canada
[3] Forest Therapy Committee, Chinese Society of Forestry, Beijing 100091, China

Abstract: Forest therapy has been recognised as a preventive therapy with a restorative effect. In China, forest therapy activities in forests by forest therapists are now a popular form, and the profession of forest therapist has been included in the Chinese Professional Register. However, it is a question of whether the restorative effect of the forest is a result of the activity or of the environment itself. To this end, the aim of this study was to investigate the difference between the physical and psychological restorative effects of forest therapist-led activities and forest walks, and the possible causes of the restorative effects.

A pre-post field experimental design was used to assess restorative effects by measuring physiological indicators (blood pressure, heart rate variability) and psychological states (nature connectedness, perceived restorativeness, positive emotions, state anxiety) produced during different types of forest therapy programs. Mediation was also used to analyse the possible causes of the restorative effects. 247 university students were randomly assigned to spend 1.5 hours on an approximately 1.5 km long forest path in two groups: a) the activity group was led by a forest therapist with activities focusing on the five sensory experiences; b) the walking group was given a free walk.

The results showed a significant decrease in systolic blood pressure and state anxiety, and a significant increase in sympathetic nervous activity, nature connectedness and positive mood in both groups. There were no significant differences between the two groups on any of the indicators. We found that nature connectedness significantly predicts the reduction of state anxiety, and that this prediction was also mediated by perceived restorativeness and positive mood.

We suggest that the restorative effects of forest therapy are significant regardless of the type of program. It is also recommended that forest therapy activities should be designed to increase participants' sense of nature connectedness and positive mood. For those who are unable to participate in forest therapy activities led by forest therapists, walking alone in the forest may also have restorative effects.

Keywords: Forest therapy program, Nature connectedness, State anxiety, Restorativeness, Mediation analysis

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Active resource use is the basis for restoring and sustaining Broad-leaved woodlands across Africa'

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Coert J Geldenhuys[1]
Emeline S P Assede[2]
[1] University of Pretoria, Department of Plant and Soil Sciences, c/o Forestwood cc, South Africa
[2] University of Parakou, Faculty of Agronomy, Benin, and University of Pretoria, Department of Plant and Soil Sciences, South Africa

Abstract: Regeneration and growth to maturity are key elements of sustainable resource use in natural forest systems, as in plantation forestry. However, perceived needs for their protection constrain such active use from natural forest systems. Zambezian and Sudanian broad-leaved seasonal woodlands represent the most extensive natural forest systems in Africa. They are dominated by strongly light-demanding canopy tree species with vegetative regrowth from rootstocks and cut stumps as main regeneration strategy (many canopy tree species show good regeneration from seed). Sustainable use of their products, values, and services is critical to sustain the livelihood needs of millions of people across Africa.

We present information from various comparative observations and time series studies (Zambezian Region) and experimental studies (both regions). The latter assessed thinning intensity (0 to 100% stem cutting) within stand development stages (early Stage 1 to advanced Stage 3). Mature stands (Stage 4) were excluded because of limited presence. Experimental thinning showed the woodlands suffer from protection. The time-series study in Zambian Copperbelt Miombo assessed recovery of biodiversity, productivity, and diverse resource use value over 15+ years in land uses of protection, single-tree timber harvesting, slash-and-burn traditional agriculture, and charcoal production. Contrary to general perception, the best to worse land use systems were charcoal production, slash-and-burn traditional agriculture, single-tree timber harvesting, and protection! Stem diameter growth (based on growth rings) was 0.5 to 2.0 cm/year in young regrowth stands up to stage 3 of up to 15,000 stems/ha, with no silvicultural treatment. In Sudaniand woodland, 60% thinning produced highest biomass production (0.88 t/ha/year) and tree height growth (in Stage 3).

Based on the results, we advocate selective stem thinning in Stages 1 to 3 (cutting suppressed and deformed stems, with branch-pruning remaining stems), and group-felling in mature Stage 4 (generally without active regeneration of canopy tree species). The proposed gap size in group-felling is 3-5 times the height of mature woodland - to provide ample light for diverse and productive shoot growth from cut stumps. Forest landscape restoration is synonymous with active resource use. It is like managing eucalypt plantations but in much more diverse natural broad-leaved woodlands.

Adoption and the Role of Fertilizer Trees and Shrubs as a Climate Smart Agriculture Practice: The Case of Salima District in Malawi

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Judith Francesca Mangani Kamoto[1]
Frank B Musa[1], Leo C Zulu[2]
[1] Lilongwe University of Agriculture and Natural Resources
[2] Michigan State University

Abstract: Fertilizer trees and shrubs can improve degraded soil and avert the impacts of climate change on smallholder farmers in Malawi. This paper analyses the roles of fertilizer trees and shrubs and factors that determine adoption, as well as the intensity of use of fertilizer on trees and shrubs in maize-based farming systems using the Tobit model. A household survey involving 250 smallholder farmers was conducted in Salima district, Malawi. The analysis shows that adopters of fertilizer trees and shrubs considered fertility improvement, shade, source of food and erosion control as main roles of fertilizer trees and shrubs. The Tobit model shows that households with relatively more land are more likely to adopt fertilizer trees and shrubs than those with small land sizes. Adoption is higher among farmers who had been exposed to fertilizer trees and shrubs for longer periods than others had. Land tenure, education and availability of labor also influence the adoption of fertilizer trees and shrubs. Results further show that household and farm characteristics and availability of extension services explain the current adoption rates of tree-fertilizer technologies. Our findings can guide effective targeting of farmers to ensure higher adoption and sustainability of fertilizer-tree and shrub technology for climate-smart agriculture among the smallholder farmers.

Between the red lines: The effect of historical agricultural zoning policies on dry forests and rural welfare in Namibia

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Vanessa Amatotsero[1]
Javier Miranda[1], Jan Börner[1, 2]
[1] Institute of Food and Resource Economics, University of Bonn
[2] Center for Development Research, University of Bonn

Abstract: Rural livelihood strategies are highly context dependent. This makes cause-effect relationships between poverty and natural resources, such as forests, chronically hard to establish empirically. Key contextual determinants of the relationship between poverty and the environment are known to include bio-geophysical and socio-economic factors, but crucially also cultural and historical trajectories. One way to infer on the role of these factors in shaping interactions between rural poverty and forests is to study the dynamics of these outcomes under different policy regimes, while holding other factors constant. Here we exploit a unique historical policy experiment that is likely to have had a lasting effect on land cover and rural poverty in Namibia. Long before Namibian independence, ruling authorities had divided the Namibian territory into two zones that allowed for different types and modes of agricultural activity. The location of the line that separated the two zones was changed several times due to political and veterinary reasons. We use the historical spatiotemporal variation in this agricultural zoning policy in a spatial regression-discontinuity design to explore heterogeneous impacts on rural welfare and vegetation dynamics. Preliminary results suggest that changes in the red line policy are likely to have partially contributed to substantial differences in todays rural wealth distributions with implications for the integrity of dry forests in the region. We discuss research needs and policy implications with a particular emphasis on the role of agency and power as determinants of rural poverty via land as well as market access and distribution mechanisms.

Forest incomes in Tanzania, Kenya and Namibia: a pathway 'out of poverty', towards aspirations?

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Eleanor Gardner[1]
[1] Forest Research

Abstract: The tropical dry forests (TDFs) of southern and eastern Africa are critical to the livelihoods of the world's poorest households. Their timber and non-timber products provide 15-44% of household income in the region and their ecosystem services irreplaceably support the agricultural systems on which smallholder farmers depend. However, TDFs are under threat: tree cover declined 11% in Tanzania, 32% in Namibia and 14% in Kenya between 2000 and 2021.

Poverty traps, alongside population growth, are major drivers. Poor access to credit and savings prevents the accumulation of capital, preventing future access. Raising the 'effort' needed to succeed, poverty also reduces individuals' aspirations, investments and chances of success. In this context, the literature suggests poor households turn to fuelwood to consume or sell so to i) meet daily consumption needs, ii) provide a safety net in times of shocks and potentially iii) provide a 'pathway out of poverty'. The latter refers to the accumulation of capital to specialise or diversify livelihoods but empirical evidence appears inconclusive.

This paper implements a novel approach to determine whether informal forest incomes provide a 'pathway out of poverty' for 2,228 households in Tanzania (Morogoro, Iringa regions), Namibia (Zambezi region) and Kenya (Baringo County). Linear and censored regression models are applied to survey data to analyse whether asset and social status aspirations lead households to raise their share of forest income in total income as a means to increase farm investment when credit or savings may be unavailable.

Results suggest that aspirations make households more likely to invest on-farm, with farming households in Namibia increasing expenditure and their Tanzanian and Kenyan counterparts diversifying. While poor households depend more on forest incomes, higher shares of forest income only increase spending a very small amount in each country. Accordingly, aspirational households do not substantially raise their shares. The case for a substantial 'pathway out of poverty' is therefore weak. Policy implications emphasise 1) informal forest incomes are no substitute for formal investment support and 2) addressing poverty's constraints on aspirations could contribute to sustainable livelihoods with at least no direct detrimental (albeit limited positive) impact on TDFs.

Incorporating Regeneration dynamics in developing Sustainable Silvicultural systems: A pathway to towards improved livelihood in the Zambezian region

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Stephen Syampungani[1]
Annie Sikanwe[1], Malindi Mubita[1], Jules C Zekeng[1]
[1] ORTARChI Chair of Environment and Development, Copperbelt University, Box 21692, Kitwe, Zambia

Abstract: Many rural economies in Southern Africa are premised on subsistence exploitation aspects such as charcoal production and shifting cultivation. These aspects of woodland exploitation have been perceived as the major contributors of forest degradation, deforestation and biodiversity loss. Currently, many governments are putting a lot of efforts on ensuring that these aspects rather done away with. This is because specific studies on regeneration mechanisms of the Zambezian vegetation have been limited yet integrating the knowledge of these is a pre-requisite for developing appropriate silvicultural management regimes of this Southern African vegetation formation. Our study examined the different regeneration mechanisms tree species in the two vegetation formations (Biakiaea and Miombo) of the Zambezian region by excavating the around plants and assessing the aerial and basal sprouts within a number of plots along transects in different age classes of different disturbance categories: for example, among 63 species studied in the Miombo woodlands, 41 were observed to to regenerate through coppicing while others regenerated from both seed and root suckering. Significant difference in terms of the influence of regneration mechanisms on shoot collar diameter and height development were observed with coppicing ($p < 0.001$) and true seedling ($p < 0.001$). The variation in regenration mechanisms and associated influence on shoot development has a direct implication on developin sustainable silvicultural systems for the Zambezian region. The presentation disccuses how management of the Zambezian region for rural livelihood would require a strategy that incorporates regeneration mechanisms in planning such systems

Introduction to the session poverty alleviation and forest integrity in tropical dry forests

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

[1] Thünen Institute of Forestry, Hamburg, Germany
[2] Department of Forest Engineering, Eduardo Mondlane University, Maputo, Mozambique
[3] The Miombo Network
[4] Department of Forestry, Lilongwe University of Agriculture and Natural Resources, Lilongwe, Malawi

Abstract: Tropical dry forests are heavily threatened by deforestation, degradation and climate change. They are particularly affected by fuel wood extraction, exploitation of high value timber species, grazing and browsing, and conversion into agricultural land. Additionally, they are increasingly exposed to fires, as consequence of climate change and land use pressure with severe consequences for water availability, food security and livelihoods. Especially in poor countries and rural areas TDF are an essential basis for livelihoods. More than 2 billion people depend on wood fuel for their daily cooking and heating. While TDF are frequently considered as safety net for the poorest, others see TDF as a poverty trap. There is an urgent need to fill ecological and management research gaps and develop strategies towards a paradigm shifts for sustainable management. In this presentation we give an introduction to the session, highlighting the most important research question which shall be addressed: Is there evidence for management practices in TDF which foster livelihoods, maintain forest integrity and enable long term sustainable development pathways?

New knowledge for the restoration of endangered tree species in the Tropical Dry Forest in Colombia.

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Milton Rivera Rojas[1]
Jaime Andres Arias Rojas[1], Jhon Jairo Zuluaga Pelaez[1]
[1] Corporacion Colombiana de Investigación Agropecuaria

Abstract: The conservation and protection of native endangered tree species is fundamental to guarantee, not only the existence of all the components that interact in an ecosystem, but also the ecosystem services provided by the tropical dry forest (TDF). For 8 years we have evaluated the behavior of four tree species of high use value by farming communities in the Colombian Caribbean region: *Aspidosperma polyneuron* Müll.Arg (Carreto), *Caesalpinia ebano* H.Karst. (Ebano), *Peltogyne purpurea* Pittier (Tananeo) and *Bulnesia arborea* Jacq. (Guayacan). Seed germination rate (GR), survival (S) and growth in height (HT) and Normal Diameter (ND) were determined. In 2007 these species were registered in the Red Book of threatened plants in Colombia with a high degree of vulnerability, mainly based on the reduction of native populations, high demand for their wood and lack of knowledge about their behavior. In this study, the GR, S, HT and ND parameters have been quantified; In addition, a height growth curve by species was made for the observation period. When evaluating different pre-germination treatments, no statistically significant differences were found between the treatments, in any case exceeding 50% seed germination rate. On the other hand, at the age of 8 years, survival ranged between 86% and 95%. Regarding the development in height and diameter, *C Ebano* was the species with the best behavior, with a record of 11.3 meters and 13.1 cm respectively. The other species reached height records ranging between 5.2 and 7.6 meters, with diameters between 6.7 and 10.9 cm.

Based on the results obtained, we can conclude that the restoration of the species is possible, based on the knowledge of its performance, its high use value and motivated by its degree of threat. However, it is necessary to deepen in terms of knowledge about the management of species, increase the support of local institutions for reforestation programs, conservation strategies and protection of native populations located on farms dedicated to livestock and agricultura.

Policy, legal and financial environment for promoting Non-Timber Forest Products in Africa

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Doris Mutta[1]
Julius Chupezi Tieguhong[2], Godwin Kowero[1], Labode Popoola[3], Mafa Chipeta[4]
[1] African Forest Forum, Kenya
[2] African Development Bank, Cote d'Ivoire
[3] University of Ibadan, Nigeria
[4] Independent Consultant, South Africa

Abstract: Non-timber forest products (NTFPs) from forests or tree-based systems have been found to be crucial to enhancing livelihoods for millions of households in rural Africa. They help meet subsistence household needs for food, nutrition, income, and health and provide important alternative employment and sustenance opportunities during crises. NTFPs are also developed into commercial products and have contributed to development of pharmaceutical, biotechnology, cosmetics, therapeutic, and foods and beverages industries. Thus, the potential contribution of NTFPs as a basis for economic development including poverty reduction in African countries cannot be overemphasised, especially in the context of growing focus on green and inclusive growth. However, despite their potential NTFPs have both been overlooked and poorly regulated by governments. The policy and legislative frameworks and institutional arrangements in most African countries have been inadequate at facilitating optimal harnessing of the value of NTFPs. These weak links require strengthening. African Forest Forum studies and a review of literature on initiatives in some African countries on development of NTFPs reveal that many countries' accounting practices do not reflect their full economic values because they are almost exclusively in the amorphous informal sector. As a result, the economic system offers no incentive to preserve NTFPs that are not reflected in national accounts. The NTFPs are almost seen as common property, hence regulations governing access to NTFPs and intellectual property rights have not adequately addressed the needs and rights of custodians of these biodiversity resources. Further, in most cases, discussions on commercial exploitation are focused on theoretical treatment of the likely profitability of bioprospecting as an economic activity. The full potential for NTFPs is also not being realized because of factors related to insufficient research funding from governments and the private sector, and limited access to capital, technology and markets by local actors. This paper posits that functional policy, legislative and institutional frameworks are key to the sustainable development of the NTFP sub-sector of the forest economy in Africa for improved incomes to local communities and countries, thus, incentives for their conservation and management.

Public policies and social actions to prevent the loss of the Chiquitano Dry Forest

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Oswaldo Maillard[1]
Roberto Vides-Almonacid[1], Paola Pozo[2]
[1] Fundación para la Conservación del Bosque Chiquitano (FCBC), Santa Cruz, Bolivia
[2] Thünen Institute of Forestry, Hamburg, Germany

Abstract: The Chiquitano Dry Forest (CDF), with an area of around 23 Mha distributed between Brazil and Bolivia, is located in a transition zone between the Amazon rainforest and the dry forests of the Chaco and Cerrado. Biodiversity in this forest is very high and at least 70 species are of global conservation concern. The CDF is catalogued as one of the largest and best conserved Tropical Dry Forests in the Americas. Currently, this unique forest is highly vulnerable and under considerable pressure, which should generate global attention, considering its importance in terms of biodiversity, climate change and social impacts. Despite efforts made for more than two decades to prevent the loss of the CDF on the Bolivian side, the processes of deforestation and forest fragmentation caused by agricultural expansion and forest fires have continued to put its ecological integrity at high risk. Our study highlights deforestation in the CDF, outlines its socio-economic and environmental importance and provides recommendations from the local experience. We identified that until 2020, accumulated deforestation in the CDF reached a total area of 2.7 Mha. Moreover, in the last years wildfires have affected an area of around 2.4 Mha. We propose critical courses of action from the local experience with a strong integrated approach, including: (i) adjustments to public policies that encourage deforestation and strength environmental governance (ii) adequate land planning and management with focus on reaching economic targets while minimizing environmental effects, (iii) creation of protected areas and strengthening and better management of existing ones (iv) raising public awareness through environmental education and effective communication highlighting the real value of forests and the importance of intact ecosystems. The CDF faces a critical moment and requires urgent global and national coordinated actions and commitments at all levels to combat deforestation and forest degradation.

Reviewing the evidence on the roles of forests and tree-based systems in poverty dynamics

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Abstract: Many rural people experiencing poverty often rely on forests and tree-based systems, such as agroforestry, suggesting the existence of links between such systems and poverty outcomes. This paper reviews the evidence of such links across multiple dimensions of poverty and well-being, based on an expert panel convened by the International Union of Forest Research Organizations (IUFRO) and an extensive literature search. We consider whether, how, where, when, and for whom forests and trees in the wider landscape influence poverty dynamics. We organize the evidence according to four pathways through which forests and trees influence household poverty dynamics: 1) helping households move out of poverty; 2) maintaining well-being levels through subsistence, food security, health, and cultural and spiritual values; 3) preventing declines by mitigating risks and stabilizing consumption; 4) decreasing well-being by generating negative externalities that could trap or move households into poverty. We found that local context matters considerably, with the roles of forests and trees strongly varying across geographical, social, economic, and political settings. Another key finding is that evidence of forests and trees providing livelihood diversification and benefits that help households move out of poverty remains limited, based primarily on a small number of case studies. Evidence on the impact of gender gaps in relation to forest landscapes and poverty pathways is also lacking. However, our findings do suggest that ecosystem services provided by forests and trees play critical roles in maintaining well-being and food security and have the potential to contribute more to helping households move out of poverty and mitigating risks amplified by climate change. This review also highlights cautionary findings related to negative forest externalities that can maintain or move households into poverty. Together, these findings call for policy efforts to support the conservation and sustainable management of forest landscapes and agroforestry systems that are more targeted towards meeting the diverse needs of the rural poor. Our results also point to a need for greater effort to address gender disparities, which have been largely overlooked yet provide a critical opportunity to not only enhance gender equality but also advance sustainable poverty reduction goals.

Strategies towards multifunctional, biodiverse and sustainable productive dry forests in Uruguay

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Paola Pozo Inofuentes[1]
Ina Säumel[2]
[1] Thuenen Institut of Forestry, Hamburg, Germany
[2] Humboldt University, Berlin, Germany

Abstract: Shifting the scientific gaze from merely natural ecosystems to human-modified landscapes regarding biodiversity conservation is an important goal to meet global challenges. Within the South American dry forests, the so-called park forests are composed of native xerophilous trees growing in a dense herbaceous stratum in the transition between natural riverine forests and open grasslands in Uruguay. As in the majority of dry forests worldwide, park forests have been destroyed because of agricultural expansion, over- grazing and selective wood extraction for fuel. Quantitative biodiversity studies and the underlying mechanisms driving tree regeneration are scarce. Assessing these contributes to the development of strategies to design multifunctional landscapes in agri- and silvicultural landscapes and provide valuable information for the management of one of the most threatened and poorly studied dry forests of Uruguay. We studied patterns of tree regeneration and biodiversity across park forests. Scattered trees exert parental care in highly modified agricultural and silvicultural park forests and therefore they act as important refugia promoting tree recovery with paramount importance in these ecosystems. Scattered trees facilitate tree regeneration by three different mechanisms: (i) by providing shade for light sensitive species; (ii) by reducing grass competition within the dense grass matrix; and (iii) by promoting regeneration linked to the attraction of seed dispersers. The park forests analyzed are similar in species diversity and vary in species composition showing high affinity with the Chaco and Espinal forests. Our results have practical implications for the management of park forests: woody species such as *Prosopis affinis*, *Prosopis nigra* and *Vachellia caven* appeared as excellent candidates for use as nurses in the restoration and can be combined with temporal exclosures of grazing to foster regeneration and grow. This can be a strategy to maintain or restore natural park forests, especially using native species. We propose that biodiverse park forests have to be protected for conservation and restored whenever possible, without necessarily preventing them from being used for traditional silvopastoralism. An integrated view of the forest– grassland mosaic has to be included in management practices, e.g. by assisting tree establishment and survival in grasslands to create silvopastoral systems.

The fate of degraded tropical dry forests under continuous grazing and extractive utilization

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Nereoh Chelimo Leley[1, 2]
David Langat[1], Abdalla Kisiwa[1], John Otuoma[1], James Ndufa[1], Joseph Ruhiu[3], Christine Koskey[1]

[3] US forest Service, Kenya Country Office

Abstract: Tropical forests cover about 45% of the global forest area and are important in maintaining biodiversity and ecosystem services. However, more than 90% of the global forest loss occurs in the tropics through anthropogenic disturbances. Kenya lost about 6% of its forest cover in the past three decades due to unsustainable management particularly illegal logging, uncontrolled grazing and excisions. In this study, forest dependence, status of woody vegetation and soils, and livestock stocking rates were assessed in Chepalungu Forest, a tropical dry forest in Kenya characterised by about 87% forest cover loss. Comparative data on vegetation and soil were collected through stratified systematic sampling in 53 plots of 0.13 ha in the degraded and adjacent intact forest. Stocking rate expressed in Tropical Livestock Units (TLU) per unit area was estimated using plant oriented approach, while forest use was determined by interviewing 450 households adjoining the forest. Currently, the community obtains 19 different goods and services from the ecosystem; firewood (57%) being the most common (4.79 m^3 per household annually). The degradation created open swards which encouraged intensive grazing at a stocking rate of 4.1 TLU ha^{-1} against a sustainable stocking of 1.1 TLU ha^{-1}. This led to soil compaction as demonstrated by a soil bulk density of 1.38 g cm^{-3}. Only 29% of the sampled woody species were mature trees, a majority were regenerates of gap opportunistic species. The stem density and basal area were significantly low at 7 stems ha^{-1} and 0.24 $m^2 ha^{-1}$ respectively against expected values of 581 stems ha^{-1} and 14.2 $m^2 ha^{-1}$. Although the forest exhibited a reverse exponential curve with high density of seedlings and saplings and few mature trees, only 13% and 0.3 % of the seedlings and saplings respectively recruited to the next age class. The findings suggest that recurrent extensive grazing, uncontrolled extractive use and lack of restoration interventions disrupt and slow down succession dynamics and recovery processes of degraded native forests and may ultimately cause irreversible forest condition. Forest managers should ensure optimal resource offtake to promote the successful recovery of degraded forests, biodiversity and enhanced carbon sequestration at landscape level.

Towards integrated fire management in miombo woodlands: reflections from a community-based experience in northern Mozambique

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Natasha Ribeiro[1]
Romana Bandeira[1], Jone Fernando Junior[1], Vitorino Buramuge[1], Alfredo Duvane[2], Filipe Canção[2], Amina Amade[2], Semo Mogeia[2], Merlindo Manjate[2]

[2] Faculty of Agrarian Sciences, Lúrio University; Sanga District, Unango Campus, Niassa Province, Mozambique

Abstract: Miombo woodlands constitute the most important forest type in the sub-Saharan Africa with a high socio-economic and ecological value, but under increasing human pressure. Fire is one of the main ecosystem drivers. Any progress toward long-term solutions to improve the miombo resilience requires community involvement, commitment, and adaptation in fire management. Initiative to catalyze changes in the behavior of local communities to safely and effectively capitalize opportunities for sustainable use of fire were implemented in the Niassa province, northern Mozambique. The initiative entitled "The early controlled burning and community awareness of forest fire management", was conducted in 2022 and evaluated the forest fire management by early controlled burning and community awareness, involving three phases: i) Meeting with local communities to reach an agreement and discuss a training strategy; ii) Identification of the demonstration location and experimental design, followed by setting fire breaks, forest inventory, fuel load assessment, controlled burning; iii) Demonstration and assessment of late-season fire occurrence and impact on vegetation and, eventually, fauna; and monitoring. Field surveys were conducted in 20 ha, involving observations, measurements of forest and atmospheric parameters. Finally, a seminar was held, involving all districts economic activities staff, community leaders, and protect areas representative, for discussion and evaluation the effective of management tool for forest sustainability. Preliminary results revealed shift in the awareness of communities about the danger of wildfires, which is currently translating into the application of prevention techniques and opening firebreaks to lower the fuel load around their houses and agriculture fields. From the seminar, it was consensual that the initiative must be disseminated and shared with other communities. Proving to be encouraging, the results are being replicated to other parts of the province through the creation of fire management committees, with the support of district governments. Controlled burning significantly reduced fuel load in areas with a high load of combustible material. In our opinion, engaging communities for the success and consolidation of fire management programs requires the establishment of income alternative activities to ensure the projects' long-term sustainability.

ZAMBEZIAN ECOLOGY, WILDLIFE AND LAND USE/LAND COVER (LULC) IMPACT ON CARBON BIOMASS: A CASE STUDY OF THE BAIKIAEA FOREST OF WESTERN ZAMBIA.

T4.16 How to reconcile poverty alleviation with forest integrity in tropical dry forests: ecological research gaps and paradigm shifts for sustainable management.

Annie Namuuya Sikanwe[1]
Stephen Syampungani[1], Felix Kalaba[1]
[1] The Copperbelt University

Abstract: Tropical dry forests account for between 8% and 13% of all tropical forests globally (Hansen et al. 2013). They are important for provisioning of ecosystem services like climate stabilization by acting as carbon repositories, inaddition to, providing timber and non-timber forest products (Shackleton et al. 2007; Blackie et al. 2014). Forests are also a source of resilience for rural people (Gumbo et al., 2018) and also provide the rural poor with natural insurance or fulfilling a "safety net" function for mitigating risks in times of emergency such as times of crop failure due to droughts and other natural calamities.
Deforestation and degradation endanger virtually all remaining tropical dry forests, which should be given top conservation priority (Miles et al. 2006; Hansen et al. 2013). They are, nevertheless, among the under studied forest ecosystems, posing a challenge to sustainable forest management and formulation of appropriate forest policies and management strategies (Blackie et al. 2014). Human population and wildlife growth is the primary threat to Africa's tropical dry forests as it is associated with land use, land cover, and fire regimes (Miles et al. 2006; Leadley 2010; Sloan and Sayer 2015).

Carbon dynamics is an important aspect in the context of climate change mitigation. Forests store large quantities of C stocks in vegetation and soils and as such their management merits attention. Globally, C budgeting of forest ecosystem has seen an increase in scientific attention (Rotzer *et al.*, 2009) especially in the developed world. Grazing has been thoroughly researched (Steffens et al., 2008 & Lü FM, et al., 2011) and it's potential to directly affect plant output and, consequently, soil C inputs in other parts of the world. However, data on the implications of wildlife grazing on Zambezian ecosystems (Scurlock, 1998) such as the *Baikiaea* Forest is missing. Currently, the focus is on understanding the C reserves of rangeland ecosystems such as *Baikaiea* forest of Sioma Ngwezi National Park as data on these aspects is missing. As such, this study focusses on developing an understanding of how wildlife and human activities impacts on the carbon sequestration potential of *Baikiaea* forest under these disturbances.

T4.17 Human-Forest Relationship I - Ambiguity in “taking care of the forest”

Care as cultural practices and personal attachments towards forest among professional foresters in Finland

T4.17 Human-Forest Relationship I - Ambiguity in “taking care of the forest”

Tuulikki Halla[1]
[1] University of Eastern Finland

Abstract: Human care towards forests is most visible in various management and conservation actions. The diversity of these caring attitudes and practices often cause conflicts in the society when stakeholders such as civil society or forest sector attach different cultural, ecological, economic and social meanings as well as sustainability aims to the forests. These meanings may relate very intimately to the key values and thus the identities of these stakeholders, producing intractable conflicts that are difficult to resolve.

One stakeholder group, professional foresters, are often involved in these conflicts. Within their professional cultures, foresters express the economic care of forest for future human generations. Care is also interlinked to e.g. aesthetic and technologal practices prevailing in their professionalism. Besides profession, care intertwines in diverse ways with their personal attachments with the forests, their freetime being and doing in the forest as well as memories and even family identities. Additionally, the caring human-forest relationships are considered reciprocal, and foresters themselves feel in many ways taken care by forest.

In my presentation, I describe the caring attitudes and practices of the forest professionals. My research is based on the interview data that I have conducted with 37 Finnish foresters working in forest management, conservation and administration. My qualitative phenomenological analysis about their forest-related experiences and meaning making contributes understanding about the multidimensionality of their care-related emotions, values, and practices. It shows that care is deeply rooted in their cultural epistemologies and ontologies affecting both their personal and professional embodiments and identities - and consequently their professional attitudes and behavior.

Caring for oaks trees in England when faced with Acute Oak Decline: land manager perspectives and values

T4.17 Human-Forest Relationship I - Ambiguity in "taking care of the forest"

Liz OBrien[1]
Mariella Marzano[1], Mike Dunn[1], Norman Dandy[2], Seumas Bates[2], Gabriel Hemery[3], Gill Petrokofsky[3]
[1] Forest Research
[2] Bangor University
[3] Sylva Foundation

Abstract: There is an increasing number of pests and diseases that trees and woodlands are faced with in England. Oak (*Quercus robur and Quercus petrea)* is a valued species as it provides many ecosystem services, and it is culturally significant in Britain. Acute Oak Decline (AOD) is a complex disease involving a pathogenic bacteria causing damage and death to native English oaks. As part of a wider project interviews (n=21) and a survey (n= 297) were undertaken with land managers and owners in England to explore how oaks are valued, how they are perceived culturally and historically, and to what extent this might impact managers management and care for oaks and affect their decisions. We found that native oaks were highly valued particularly by land managers involved in managing oak in woodlands or in historic parklands. A distinction could be made between their professional values for oak such as biodiversity, timber, historical importance, and their personal values which highlighted more emotional connections, a love of oaks and a desire to care for them. Oak was viewed as culturally and historically very important and linked to English and British identity. Those with veteran and ancient oaks were more willing to spend resources (time and funding) conserving these specimens as symbols of strength, resilience and trees that illustrate the passage of time. Management responses to AOD need to be cognisant of different relational value systems held by a variety of stakeholders, and better understand how land managers care for their oaks. Therefore, understanding the values of a variety of land managers from private owners, non-governmental organisations and government bodies and their perspectives concerning different management options to deal with AOD is important. Difficult choices will need to be made concerning the deployment of resources and approaches to increasing the care for and the resilience of oaks.

Forest Stories: Knowledge, Affects and Care in Controversies around Forest Management in Germany

T4.17 Human-Forest Relationship I - Ambiguity in "taking care of the forest"

Manuel John[1]
Philipp Mack[2], Ronja Mikoleit[1, 3]
[1] Chair of Sustainability Governance, Faculty of Natural Resources, University of Freiburg, Germany
[2] Chair of Forest and Environmental Policy, Faculty of Natural Resources, University of Freiburg, Germany
[3] Department of Societal Change, Forest Research Institute Baden-Württemberg, Germany

Abstract: Since 2018, a wave of consecutive droughts has been hitting large parts of Germany, causing severe damages to large forested areas and triggering heated political and public debates. While traditionally, the German forestry sector held a strong position as central authority on all matters related to forests, a network of 'rogue' foresters, forest researchers and nature conservationists have openly challenged this privileged position in the wake of the crisis. Faced with the rapid transformation of the ecosystem, the opposing factions both highlight the urgency to act in order to 'save' the German forest and to make it climate resilient. Yet, there is a deeply rooted disagreement on how to reach those 'forests of the future', what they should actually look like in the first place and which 'facts' to rely on when making these decisions. Mutual accusations span from the profit orientation of the forestry sector to the romanticization of forests by those with a stronger ecological orientation.

We claim that beneath the surface of a seemingly rational and technocentric debate around the future management of German forests, a deep and complex web of competing, affectively charged narratives about the relationship between humans and forests can be uncovered. Those narratives carry with them a sense of care for the forests, unified by a fear of loss related to the massive changes in the forests of Germany which are becoming increasingly visible. Conflict thus does not arise around the question of whether or not to care about the forest, but rather around what 'caring' actually entails, and who should be or feel responsible for it. By drawing from different data sources, including newspaper articles, position papers and interviews with researchers and professional foresters, we attempt to reconstruct some of those "deep stories" (Hochschild 2016), revealing different forms of caring about the forests and ultimately opening up new avenues for better mutual understanding.

Taking care of forests in a changing climate – reactions to climate-damaged forests by the public and forestry actors

T4.17 Human-Forest Relationship I - Ambiguity in “taking care of the forest”

Carolin Maier[1]
Ronja Mikoleit[1]
[1] Forest Research Institute Baden-Wuerttemberg, Germany

Abstract: Among other things, forest is a place where human bodies are surrounded by non-human nature, a sought-after counter-world to mechanized, urbanized, or pandemic-limited daily life, a workplace and economic space, and a strongly identity-forming landscape element. Current climate-induced developments, such as drought, insect outbreaks, storm, or wild fires, are visibly altering forest landscapes. Between 2018 and 2022, large-scale forest dieback in Germany has altered entire landscapes at a rapid pace. Large areas of drought and bark-beetle damaged trees have been removed to prevent its further spreading, and in some places, forests have disappeared completely. These large-scale changes to our natural environment pose very hands-on practical challenges to natural resource professionals managing affected forest areas. Yet they also affect the intangible meanings people associate with forests and trigger sometimes fierce emotional reactions by both forestry professionals and local stakeholders.

Analyzing how people deal with and react to these developments offers insights into 1) the meanings and emotions associated with forests by forestry professionals and non-professional local stakeholders, as well as 2) the different social constructions of a caring relationship with the forest. We use qualitative data collected through go-along interviews and participatory observation with a particular focus on the metaphors used to express reactions to climate induced changes to the forest. What happens when the state of the forest becomes increasingly disconnected from established forestry concepts? What does “taking care of the forest” mean from different perspectives? And how to deal with conflicting interpretations of caring relationships?

We find that, in a forestry perspective, carrying the responsibility for a forest district represents an individualized, emotionally anchored care relationship that, traditionally, is timber and economy oriented. The climate-induced changes are, among other things, upsetting established silvicultural concepts, roles and notions of long-term intergenerational responsibility. The drastic climate-induced changes enable the analysis of particular societal relations with non-human nature, as well as problematic structures in forestry, such as the close coupling of territory and individuals, as well as the associated embodied professional practices and bodies of knowledge.

Taking care of the forest as a part of nature - conceptual thoughts and empirical insights

T4.17 Human-Forest Relationship I - Ambiguity in "taking care of the forest"
Ronja Schröder[1]
Anna Saave[2], **Jana Holz**[3]
[1] Carl von Ossietzky University Oldenburg
[2] Humboldt University Berlin
[3] Friedrich-Schiller University Jena

Abstract: With our contribution we aim for an introduction and exploration of the concept 'care' in relation to forests and the study of forest utilization, protection and destruction. Our main questions are: What conceptual and critical potential lies in the application of the care concept for the study of human-forest relationships? And further, how can one study the societal, economic, and subjective relations with nature in the context of forest utilization through the lens of care?

'To take care of the forest' is a commonly used expression that does imply very different and sometimes conflictual meanings and practices. Care taking in the context of forest utilization is always connected with social and political power structures, different forest management traditions as well as economic rationales. On a subjective level, a caring relation with forests can also be linked to family traditions as well as mental and physical health. Currently, global warming and biodiversity loss as well as potential solutions for these socio-ecological crises, such as a bioeconomy or a circular economy, transform how forests need to be and are taken care of.

In our contribution, we will firstly provide an introduction to conceptual approaches of 'care' rooted in feminist theory (cf. Tronto 1993) and the study of reproductive relations (cf. Biesecker & Hofmeister 2006). In recent years, concepts of care have been increasingly applied and developed further for the scientific study of human-nature relations. We discuss in which ways care concepts are suitable for the study of human-forest-relationships. Secondly, we provide empirical insights based on our field research in Finland, Germany and Canada. These highlight the potential for critical analysis inherent in studying forest utilization through the lens of care. Based on the three case studies we will then, thirdly, elaborate on three dimensions of human-forest-relationships: forest utilization, forest protection and forest destruction. We synthesize how these dimensions are on different levels intertwined with care and care taking. We close by elaborating on 'care taking' as a vital part of human-forest relationships and show how this can transform forest utilization, destruction and protection.

Unraveling ecological care and violence in forest conservation and management: approaches from Feminist Political Ecology

T4.17 Human-Forest Relationship I - Ambiguity in “taking care of the forest”

Violeta Gutiérrez Zamora[1]
[1] Natural Resources Institute Finland (LUKE)

Abstract: Political ecologists are increasingly focusing on the fundamental role of care practices and affections in socio-natural relationships. As the green economy and market-based forest conservation solutions advance (e.g., carbon credit markets and bioeconomy), it becomes necessary to recognize two key factors. 1) The changes and interlinks between labor and notions of nature and sustainability involved in forest conservation and management approaches; and 2) the interweaving between care and violence that such changes may entail.

Drawing upon feminist political ecology approaches to the care of life, this manuscript explores how we understand ecological care and its framework while recognizing the power and violence exercised in current forest conservation and management systems. Based on qualitative research conducted in Mexico and Laos PDR, the manuscript explores how care practices, knowledge and affections situated with(in) the forests are linked to violent processes that intertwine the Global South and North.

Theoretically, the manuscript aims to extend the discussions on the production of the means of life and the production of life (care labor) at the intersection of ecological conservation and forest management. It thus addresses questions of ecological care labor. Ecological care is generally described as those attempts to reduce harm and violence on the earth, species, or other human beings. However, many of these attempts are often immersed in oppressive relations based on historically constructed social hierarchies based on gender, ethnicity, class, and racialization. Recognizing oppressive relations also reveals the diverse relations and the labor involved between humans and non-human species across different spaces at the local level (the household, the city/village, the cultivation land, the forest). While also exposing the coloniality of decision-making spaces at the national and global levels.

”I have a need to take care of my forests” - Finnish private forest owners' experiences and perceptions of care

T4.17 Human-Forest Relationship I - Ambiguity in “taking care of the forest”

Reetta Karhunkorva[1]
[1] University of Eastern Finland; The Finnish Forest Museum Lusto

Abstract: Forest ownership is a complex institution. Besides relationship between the owner and the owned, it includes a complex set of both interpersonal relationships and other societal institutions but also human relationship with non-human nature.

In Finland, forests are largely privately owned. Thus private owners are an important group for citizens, national economy and forest. They own 60 % of forest land, 70 % of forest growth, the domestic forest industry buys 80 % of the wood it needs from them and everyman's rights give all access to private forests.

For individual owner, forest ownership is more than a societal institution. Forest ownership can be way of life and source of livelihood, part of the self, identity and leisure time, link to family and kin, relationship with a dear place and the people who have lived there.

Forest ownership is also about caring. Usually forest is taken care, managed, for the family, or humans more generally. Present forest owner takes care of the forest for the future generations, with respect for the past generations.

Experiences of responsibility and duty are common to owners. Forests cannot be left 'to their own devices', 'abandoned'. They must be looked after, cared for. Furthermore, experienced and lived forest ownership is also an interactive and embodied relationship with non-human nature. Physical forestry work and multi-sensory experiences in the forests are an important, nurturing part of lived and experienced forest ownership.

Global environmental issues have brought environmental ethics into the debate on forest owners’ rights and responsibilities. This paper explores, based on 50 interviews, forest owners' perceptions and experiences of taking care of their forests. What embodied and affective experiences do forest owners associate with caring for their forests? What cultural and societal meanings and practices arise from owners' perceptions and practices? What kinds of ecological, nature-sensitive meanings and practices emerge? What factors prevent or enable owners to take care of their forests more ecologically?

The concept of care in forest ownership is analysed within frameworks of environmental anthropology and critical heritology. Forest owners' experiences, practices and perceptions of care are scrutinized through the institution of forest ownership.

T4.18 Interactive forest management: Should silviculture and forest operations comply with governance or the opposite?

Analyzing Visitor Feedback to the Communication, Education, and Public Awareness Materials of Mount Makiling Forest Reserve ASEAN Heritage Park

T4.18 Interactive forest management: Should silviculture and forest operations comply with governance or the opposite?

MYRANEL CANCERAN[1]
ANGELA LIMPIADA[1], LEONARDO BARUA[1], JOSEPHINE GARCIA[2], AEROSMITH MASA[1], MILLES VIZCARRA[1], MAE BELEN PUTIAN[1], **ROGELIO ANDRADA**[3]
[1] Makiling Center for Mountain Ecosystems, College of Forestry and Natural Resources, University of the Philippines Los Baños
[2] Institute of Animal Science, College of Agriculture and Food Science, University of the Philippines Los Baños
[3] Institute of Renewable Natural Resources, College of Forestry and Natural Resources, University of the Philippines Los Baños

Abstract: In the Philippines, ecotourism offers both potential and hazards to the natural and social environment. Sustainable and responsible ecotourism is the key for mitigating threats. Mount Makiling Forest Reserve ASEAN Heritage Park (MMFR AHP) in the Philippines is the closest mountain to Metro Manila. It straddles portions of municipalities of Bay and Los Baños, and Calamba City in Laguna province, and Sto. Tomas City in Batangas province. The MMFR AHP continues to serve as a recreational and educational area for the public. Communication is essential to the effectiveness of visitor management strategies. The paper assessed the visitors' feedback on the communication, education, and public awareness (CEPA) materials in MMFR AHP. The Article 13 of the Convention on Biological Diversity (CDB) recognizes the role of CEPA in encouraging and engaging people to conserve biodiversity and use natural resources sustainably. Results revealed that the 242 respondents found maps (64%) to be the most helpful among the CEPA materials available followed by infoboards (60%), directional signs (58%), brochures (40%), videos (39%), and flyers (35%). These materials guide users, offer pertinent information, raise awareness, and give instructions on the proper use of the mountain. Respondents also suggested to include infographics about flora and fauna, exhibits, facts about the MMFR AHP and its resources, social media content, posters, and souvenirs. The history, biodiversity, natural resources, advantages, and role in shaping art, culture, and society are among the topics that respondents most want to learn more about. The respondents also revealed that their purpose of visit is for educational, leisure, hiking, biking, and photography. The paper provided proof of the materials' efficacy in raising visitor awareness and found that, depending on the respondent group, different methods of communication and resource promotion are required. Furthermore, it contributed to the development of the visitor management scheme for MMFR AHP as well as conveying conservation messages through an interpretation program. Thus, it will be easier for visitors to understand what MMFR AHP can offer and the significance of the natural resources if additional CEPA materials and programs are developed, highlighting the distinctiveness of various areas of interest.

Can social milieus help, to better target private forest owners and society, interested in forests, at large?

T4.18 Interactive forest management: Should silviculture and forest operations comply with governance or the opposite?

Peter Aurenhammer[1]
Maximilian Glormann[1], Patrick Strüber[1], Max Krott[1]
[1] Georg-August-University Göttingen, Germany

Abstract: The paper/contribution introduces to social milieus (e.g. Sinus-milieus) and their application in sectors other than forestry. It further shows, how recent forest related research has taken into account social milieus or has otherwise, at least partly, considered actor or owner beliefs and preferences (e.g. in social networks). It provides insights, to what extent private forest owners or society at large, differ in their forest related preferences or activities, comparing 10 social milieus (Sinus-milieus). The exemplary results discussed are based on a new analysis of existing secondary data, from a representative survey on German society and forest owners. We will conclude on factors, with strong differences between milieus and provide an outlook how such results can facilitate the targeting of e.g. private forest owners, by the example of a selected social milieu.

Elaborations on the explanatory power of social milieus versus classical socio-demographic variables, for German society and forest owner 'profiles'.

T4.18 Interactive forest management: Should silviculture and forest operations comply with governance or the opposite?

Maximilian Glormann[1]
Patrick Strüber[1], Max Krott[1], Peter Aurenhammer[1]
[1] Georg-August-University Göttingen, Germany

Abstract: The paper/contribution will contribute to a better understanding of the explanatory value of social milieus (i.e. 10 different Sinus-milieus) as compared to socio-demographic and forest structure variables, for the explanation of forest related belief and interest 'profiles' (i.e. a set of variables) of private forest owners as well as other society, in Germany. Results are based on a new analysis of existing secondary data, from a representative survey on German society and forest owners (about 2,400 respondents). We will conclude on the explanatory value of the compared factors (milieus, socio-demographic or forest structure) individually, looking at how frequently they reach comparatively strong relationships with dependent 'profile' variables. Finally, we will discuss implications for the use of social milieus in the practice of identifying or addressing e.g. private forest owner groups.

Interactive forest management, the case of FSC: Silviculture specialists and forest managers hand in hand with forest stewardship governance!

T4.18 Interactive forest management: Should silviculture and forest operations comply with governance or the opposite?

Marion Karmann[1]
[1] FSC International, Adenauerallee 134, 53113 Bonn, Germany

Abstract: Governance is the way rules, norms and actions are structured, sustained, regulated and held accountable. The Forest Stewardship Council (FSC) is regarded as the pioneer of a multi-stakeholder governance system in the forest sector. FSC strives to give equal weight to economic, environmental, and social interest groups, to ensure SFM through the active participation of all stakeholders in the forest services supply chain. At the forest level, these stakeholders include for example forest workers, managers of small and large forest operations, environmental NGOs, Indigenous Peoples. In combination with an independent accreditation programme that verifies the certification bodies, FSC is also widely regarded as a credible and effective forest management certification system, which communicates through the label, the 'social license', to the public that certified products are coming from well-managed forests. This 'social license' is used as a reputational risk management tool, and mentioned as the most important reason for getting certified, as shown by a number of independent research papers.

On the other hand, not all forest managers feel comfortable with external auditors assessing their management against FSC's long list of performance indicators. FSC's rules for documentation and for public reporting on change management are also mentioned as a burden. These rules include for example to report on Health and Safety trainings for forest workers, work related accidents, and on harvesting techniques and equipment, rationale for species selection.

Using concrete examples, we will show where, how and when silviculture scientists and practitioners can take an active role in shaping FSC's certification requirements and in contributing to meaningful, science-based indicators for 'interactive forest management'. We will also point out strengths and weaknesses and lessons learned in engaging and communicating with different groups of stakeholders in processes such as auditing, conflict management, trust building, and the wider governance of FSC.

Public-relation strategies for reaching out to forest-distant milieus and transdisciplinary case-study development.

T4.18 Interactive forest management: Should silviculture and forest operations comply with governance or the opposite?

Patrick Strüber[1]
Maximilian Glormann[1], Max Krott[1], Peter Aurenhammer[1]
[1] Georg-August-University Göttingen, Germany

Abstract: Private forest owners, today, belong to a considerably large share to social milieus, whose lifestyles are far away from classical, traditional forest-thinking, so called forest-distant milieus. These forest owners are increasingly difficult to be reached, by associations, advisors and other actors. In order to enhance the building of climate resilient forests for the future in Germany, we develop an approach, addressing private forest owners as well as other society, interested in forests, tailored to their social milieus. In this contribution, we will outline the development of public-relation strategies and provide strategy examples for selected social milieus. We will further draw on our approach and the concept to develop, implement and evaluate milieu-tailored activities in trans-disciplinary learning-labs.

Stakeholder involvement influencing forest management through the Forest Stewardship Council certification scheme

T4.18 Interactive forest management: Should silviculture and forest operations comply with governance or the opposite?

Henrik Von Stedingk[1]
Beatrice Jansson[1]
[1] FSC Sweden

Abstract: The Forest Stewardship Council (FSC) is a forest certification scheme based on stakeholder involvement. FSC members and stakeholders are part of the standard development and sets the requirements. The members set up the strategic goals for FSC as an organisation, both internationally and nationally. FSC has mechanisms for stakeholder involvement as part of the implementation and annual audits: certificate holders need to engage with affected stakeholders in planning their forest management; auditors are required to reach out to relevant stakeholders for comments on the performance of a certificate holder before the audit; and FSC has a complaints system for any stakeholder to bring up their views or dissatisfaction with certified forest management.

In Sweden the complaints system has been heavily used by stakeholders, especially the Environmental Non-Governmental Organisations. With time this has led to more professional handling complaints by the certificate holders, and an acceptance that stakeholders have opinions on the forest management that certificate holders need to be open to listen to.

However, there are many challenges for FSC with the complaints system. One is that the handling of complaints requires lots of resources for certificate holders and accredited certification bodies, but also for the complainers. Another is that no party within the system has the overall view of all FSC complaints. The FSC system is complex there may be a gap between the understanding and expectations of the stakeholders on one hand, and the certificate holders and the accredited certification bodies on the other.

Some solutions have been tested in Sweden such as reaching out directly to the complainers with information about the system and for certificate holders to invite stakeholders to have dialogue in the field, as well as finding ways to engage with certificate holders and the accredited certification bodies to get a better overview the complaints and what they lead to.

FSC's complaints system is an important link between forestry and its various stakeholders. An effective and fair complaints procedure is important for the credibility of the entire certification system.

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

A new Forest Governance Approach for Germany to cope with Global Change

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

[6] Cair of Soil Ecology, Faculty of Environment and Natural Resources, Freiburg University/Germany
[7] University of Applied Science, Bern/Switzerland

Abstract: On the occasion of the current revision of the German Forestry Act, and against the background of an enormous drought-induced forest die-back in Germany, the German Scientific Advisory Board for Forest Policy at BMEL (Federal Ministry of Food and Agriculture) developed a new forest governance approach to cope with global change. Its guiding principle is adaptability through a proper mix of policy instruments. We recommend six minimum standards mandatory to all forest owners, securing (i) forest preservation, (ii) avoidance of clear-cuts, (iii) accessibility for the public, (iv) adequate game stocks as well as (v) soil protection and (vi) water protection. Beyond these minimum standards, all societal demand shall be flexibly addressed by any of the following policy instruments: information; structural support; payments and other financial support; and regulations. Moreover, we recommend to create legal frameworks that incentivize private cooperation. In consideration of the public being the main beneficiary of most of the forest ecosystem services, we advocate for highest priority to financial instruments. The approach is rounded out by a specific example for forest adaptation to climate change.

Amplifying Social Innovation Impacts in the Forest Sector: Insights from Central and Southern Europe

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Elaine Anne Parlade[1, 2]
Gerhard Weiss[1, 2]
[1] University of Natural Resources and Life Sciences, Vienna (BOKU)
[2] European Forest Institute, Forest Policy Research Network

Abstract: In Europe, where a range of social innovations in the forest-based sector exists, many initiatives have failed to grow their impacts. As society aims to advance sustainability transformations, it becomes imperative to understand the processes concerning the expansion, spreading, and other approaches to the amplification of social innovation impacts. Recognizing the increasing relevance of social innovations in propelling the forest sector's role in the envisioned bio-based future, we explored the impact amplification strategies of three forestry-related cases in Central and Southern Europe. Using our proposed framework called the "*Ecosystem of Amplifying Social Innovation Impacts*" *(EASII)*, we analyzed data collected from semi-structured interviews and document analysis. Rooted in the innovation ecosystem approach, the EASII framework integrates identified structure (i.e., actors and interrelations) and process factors (i.e., motivation, interactions, knowledge, and financing) that regulate and shape amplification processes. Results from the analysis suggest that effective impact amplification entails: (1) adopting a combination of strategies; (2) employing constant amplification processes; and (3) driving behavioral change among innovation actors. Additionally, two key leverage points to reinforce impact amplification were identified: cultivating a strong sense of agency, and fostering robust relationships among the network of innovation actors. With this in consideration, policy support should thus be focused towards creating enabling environments and granting access to more innovation platforms that allow organizations to collaborate and exchange resources. Accounting for these leverage points further implies that innovation actors should implement support measures that are holistic and locally adapted.

An approach for the monetary valuation and remuneration of the climate protection services of forest enterprises

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Eva Elisabeth Neuhoff[1]
Andreas W. Bitter[1]
[1] TUD Dresden University of Technology; Institute of Forest Economics and Forest Management Planning

Abstract: Forests and forest enterprises are facing the climate change and its consequences: droughts, heats, storms, heavy rain events and bark beetle outbreaks. At the same time, forests play an important role in the climate change mitigation as carbon sinks and as bio-resource for substituting fossil-based materials towards a new sustainable bio-economy.

The objective of the present study is to develop a payment scheme model to reward the climate protection contribution of forests and forest enterprises. The approach is based on empirical data and it should be kept as simple as possible to avoid high administrative transaction costs and to guarantee accessibility for all forest ownership types.

The payment scheme consists of three key indicators: (i) volume increment of compact wood (i.e. > 7 cm DBH), (ii) closeness to nature of forest stands and (iii) the substitution effects of timber. Based on the volume increment of compact wood, the equivalent amount of CO_2 bound by the growing tree is estimated. The mathematical concept is a rather simple linear model.

In a case study, the remuneration value for the private and municipal forests of four different German federal states was calculated for every type of ownership. The data basis was the latest national forest inventory data.

The results are plausible with regard to comparable studies. The key factors are based on widely accepted values and methods. The main points of discussion are the timber use for energy, the applied closeness to nature approach, and the contribution of forest management to the climate protection.

The model developed in the present study follows the idea of providing economic support for the maintenance and expansion of the climate protection contribution, which is otherwise not a marketable service. The model should not be static. Instead, it should allow adaptions in accordance with potential changes of model assumptions that relate with system changes. A practicable remuneration system for forest enterprises for the provision of goods that cannot be traded on markets does not yet exist, at least not in Germany.

Co-management organizations as an innovative institutional arrangement in developing nature-based tourism in and around the Sundarbans of Bangladesh

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Shakil Ahmed[1]
Dr. Md. Wasiul Islam[1, 2], Dr. Abdus Subhan Mollick[1], Dr. Md. Nazmus Sadath[1]
[1] Forestry and Wood Technology Discipline, Khulna University, Khulna 9208, Bangladesh
[2] Deputy Chief of Party, USAID Ecotourism Activity, Bangladesh

Abstract: The Sundarbans mangrove forest in Bangladesh is the world's largest single tract of mangrove forest and provides direct and indirect support to more than 3.5 million people. The forest is experiencing various illegal activities and over-exploitation for many years. The majority of the population is fully or partially dependent on the natural resources of the Sundarbans due to the absence of alternative income opportunities at the area. The Sundarbans is one of the prime tourism destinations of Bangladesh. In order to manage the destination sustainably, this study focuses on the potential social, environmental, and economic benefits of nature-based tourism (NBT) as an alternative source of income in the region. It also examines how co-management organizations (CMOs) can contribute in developing NBT in and around the Sundarbans and facilitate the conservation of this unique mangrove forest. This study was used mixed-method following a semi-structured questionnaire survey by conducting face-to-face interviews to gather empirical data. A mixed result was found, and the data were validated through conducting Focus Group Discussions. The research evaluated that the co-management approach reduced people's reliance on the forest for their livelihood. The respondents expressed a positive attitude toward the conservation and development of NBT in and around the Sundarbans. If CMOs could contribute in developing NBT, the Sundarbans could be conserved more successfully. However, locals also mentioned several problems that hindered the development of NBT. This study showed that CMOs had greater implementation gaps to create NBT in the area and acknowledged CMOs' challenges and potential contributions to the development of NBT. A well-planned, proper training, education, and support from the national and local governments, as well as active assistance from the Bangladesh Forest Department were needed to develop NBT in and around the Sundarbans through the active support from CMOs. The findings will aid policymakers in recognizing the challenges associated with CMOs in developing, managing and marketing NBT in and around the key biodiversity area.

Collaborative governance, regional development and local politics: the outcomes of forest policy programmes across contested landscapes

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Johanna Johansson[1]
[1] School of Natural Sciences, Technology and Environmental Studies, Södertörn University, Sweden

Abstract: In 2018 the Swedish government adopted the country's first National Forest Programme targeting four priority areas: sustainable forest management with greater climate benefits, multiple uses of forest resources for more jobs and sustainable growth throughout the country, world-class innovation and processed forest products, and sustainable use and conservation of forests as a profile issue in Sweden's international cooperation. To realize these objectives, a key goal of the programme was to gain acceptance and initiate action across Sweden's 21 counties. The key tool of doing so was to adopt regional forest strategies and action plans targeting multiple use of forests primarily by the work of cross-boundary collaborative platforms. Inspired by an increasing scholarly literature on collaborative governance, this paper analyses the emergence, process and outputs of these collaboration platforms in the four northern counties of Sweden. It builds on statements from semi-structured interviews with participating regional state and non-state actors (*n*=35), meeting records as well as written comments from a public consultation. The results reveal a strong discrepancy between the goals communicated by the government in 2018 and the actual capacity for action by regional public administration and participating actors, especially since the collaborative platforms were not fully funded for the task at hand. Moreover, in most cases, collaboration outputs and actions were repeatedly constrained by unclear directives and coordination, current policy conflicts in national forest policy and diverse perceptions of, and possibilities for, sustainable countryside's, social innovation and regional labor markets. The paper concludes with key insights for research at the interface of collaboration, sustainable livelihoods and rural development and suggests ways forward with participatory action in contentious policy areas.

Community Forest Management and Local Development: Novel Institutional Arrangements in Resex Verde Para Sempre, Porto de Moz-Pará State, Brazil

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Milton Kanashiro[1]
Fabricio Ferreira[1], Maximillian Steinbrenner[2], Alison Castillo[3], Marcelo Almeida[4], Maria Margarida da Silva[5], Hwan-ok Ma[6]

[5] Fórum Florestal da Amazônia - FFA, Brasil
[6] International Timber Trade Organization –ITTO, Japan

Abstract: In the last decade, a significant increasing participation of Associations and Cooperatives of Family Producers from Traditional Communities, Settlements and Sustainable Development Projects (PDS) organized for Sustainable Forest Management happened in Brazil. This changes the involvement of various actors, including: governmental agencies responsible for licensing and control of productive activities; teaching, research, development and technological innovation institutions (CT&I); forest extension; associations of autonomous professionals and the third sector. Herein, in order to address all the challenges posed by this changing scenario, collective actions such as proposed by Community and Family Forest Management Observatory (www.observatoriomfcf.org), the Development Sustainable Committee of Porto de Moz Municipality and the Amazon Forestry Forum (www.dialogoflorestal.org.br/foruns-regionais/forum-florestal-da-amazonia/) have been crucial to support the Communities to implement and successfully carried out their Sustainable Forest Management Plans, in the Resex Verde para Sempre - Porto de Moz-PA. Collective arrangements of institutions were also very important to overcome and adapt, field activities during the long period of Covid-19 pandemic. The Bom Manejo II Project started in 2017 with a main focus on the dissemination of Software and the Training of professionals from Government Institutions, Universities, Institutes (Federal and State levels), Professional Associations, Producer Cooperatives and private companies. Specifically to the Bom Manejo 2 Project´s activities field work were interrupted, with a gradual and virtual resumption in the home office format, our strategy was to intensify Communication and Outreach work, keeping the Sustainable Forest Management issue in discussion to assure the importance of the forest sustainable production, income generation and forest conservation. A trans-disciplinarity and institutional arrangements enabling long-term collective work, in pursuit of local development and common well living, together with approach of One Health perspective, i.e. that recognizes the interconnectivity between people, animals, plants and the environment, is an important strategy to overcoming of climatic emergencies and recurrent events of possible zoonotic outbreaks (Covid-19, Influenza, etc.) in the Amazon. The integration of Sustainable Management of Natural Resources, encompassing forests, water and food security through the participation of ethnic groups and a collective political will, is essential for providing sustainable solution for current and future generations.

Exploring social learning in multi-use forestry and family forest owners as grassroots agents for alternative forest management

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Jenny Friman[1]
Jayne Glass[1], Therese Bjärstig[2], Sabrina Dressel[3], Brian Danley[1], Nils Droste[4]

[2] Umeå university
[3] Wageningen university
[4] Lund university

Abstract: Alternative forest stewardship methods have the potential to diversify primary production and provide a wider variety of income opportunities in rural regions while also improving environmental services. In this study, we focus on Swedish family forest owners and their social learning networks as representing a potential fulcrum on which the adoption of multi-use and alternative forest management practices may hinge. Forest management practices in Sweden are embedded in an established industrial structure in which forests are managed for industrial timber supply, yet some have criticized this structure for hindering the adoption of a wider variety of management practices. The aim of the study is to investigate how networks and processes of small-scale change in forest practices already underway, can facilitate social learning for forest owners and thus a transformation of management practices. Social learning theory places emphasis on the role of organizations that act as bridges in the transfer of ecological knowledge in the forestry sector. By drawing on social learning theory and linking it with social innovation and transformation theory, the study addresses the possibilities and limitations of leveraging the existing social learning processes of family forest owners engaged in multi-use forestry and the organizations supporting such processes.

From data collected in three different contexts in Sweden, the study shows how social learning through networks can form social innovation in forestry. Especially by supporting the implementation of multi-use forestry methods. We argue that such insights have the potential to improve institutional interventions that enable the processes of learning and innovation between key actors to accelerate the implementation of more sustainable forest use and management.

Fostering Village Development and Empowerment through Social Innovation: A Case Study of the Rural HUB in Serbia

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Ivana Zivojinovic[1, 2, 3]

[4] Center for Social Responsible Entrepreneurship – CDOP, Vrmdža, Sokobanja, Serbia

Abstract: Social innovations have emerged as a potential solution to address the current social-ecological and economic crises by fostering bottom-up initiatives for transformative social change. Particularly in rural areas, social innovations play a crucial role in promoting sustainable rural development and contribute to the overarching goal of building inclusive and sustainable economies. This study investigates the impact of social innovation on the development of rural communities through an in-depth empirical case study analysis of the Rural HUB, a co-working space located in the small village of Vrmdza in eastern Serbia, which operates on the concept of the entire village functioning as a hub. The research employs a triangulation approach, utilizing expert interviews, field observations, document reviews, and interviews with village residents to gather data. The development strategy of the Rural HUB is rooted in the sustainable eco-village model and is achieved through a collaborative effort between urban individuals and traditional farmers from the village, referred to as the rurban concept. The rurban concept serves as an open platform for the exchange of ideas, information, and experiences between diverse initiatives and individuals, aiming to integrate rural and urban knowledge to enhance personal and community life. The Rural HUB has had a wide-ranging impact on various aspects of the community, including economy, environment, culture, education, and personal development. Its comprehensive initiatives encompass educational programs, social business design training and application, the development of local products and services, sustainable farming practices, green job preparation, and service learning opportunities. This study demonstrates that the Rural HUB model can be successfully replicated in other rural areas within the country and the region, serving as a valuable best practice example that contributes to the design of more suitable and inclusive development policies and measures among relevant stakeholders.

Future of forest in the Ukrainian Carpathians in time of critical transition: why social innovation might be a trigger towards sustainability

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Mariana Melnykovych[1]
Simo Sarkki[2], Todora Rogelja[3], Tatiana Kluvankova[4], Albert Nijnik[5], David Miller[6], Maria Nijnik[6]

[5] Environmental Network Ltd, United Kingdom
[6] James Hutton Institute, United Kingdom

Abstract: The ongoing war in Ukraine has resulted in devastating consequences, including significant loss of life and the displacement of millions of people. Furthermore, the presence of mines and unexploded ordnance has made approximately 30% of Ukraine dangerous. This paper focuses on the Carpathian region in Ukraine (with 54% of forest cover), which has emerged as a refuge for war-displaced individuals and a vital center for providing humanitarian aid during this time of war in Ukraine. However, the Carpathian region now confronts increasing challenges, including the growing pressure on its natural resources, especially forest, and the lack of job opportunities. This study examines the critical transition occurring in the Carpathians and investigates the role of social innovations in forest-based sectors to facilitate this process. The analysis delves into the impact of the war on the Carpathian region, considering both the economic losses and the environmental damages to its forests. The findings emphasize the considerable potential of social innovations in addressing the challenges faced by the Carpathian region during this critical transition. By fostering collaboration among stakeholders, social innovations can play a vital role in promoting sustainable forest management practices, facilitating ecosystem restoration, and establishing initiatives such as green job opportunities and circular bioeconomy models. Additionally, the results suggest that social innovations offer valuable prospects for creating livelihood opportunities and implementing robust social support systems for the internally displaced populations in the region, with a particular focus on forest-related initiatives. Integrating social innovations into policies and strategies can alleviate the pressures on natural resources, mitigate conflicts arising from competing interests, and foster inclusive and sustainable development within the Carpathian region. Furthermore, by embracing sustainable practices and empowering local communities, social innovations provide a promising pathway toward building a resilient and prosperous future for the Carpathian region's forests.

Identifying and assessing conditions for successful joint innovation processes in wood and forest research

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Andy Selter[1]
Sabine Helm[2], Malte Jörn Krafft[3], Tim Kunkowski[2], Lea Ostrowski[4], Christiane Trost[3]
[1] University of Freiburg, Chair of Forest and Environmental Policy
[2] Technical University of Munich, Chair of Wood Science
[3] Johann Heinrich von Thünen Institute, Institute of Wood Research
[4] Johann Heinrich von Thünen Institute, Institute of Forest Ecosystems

Abstract: Given that producing and using the same resource, the forest sector and the wood processing sector are linked closely. Although wood research and forest research are embedded in similar political, societal and economic contexts, both scientific disciplines are rarely integrated and cooperation between the disciplines is weak. This particularly applies to the level of individual research groups as well as to individual research projects.

In this context, research funders like the European Union or federal ministries initiate inter- and transdisciplinary research programs. Accompanying cross-sectional research offers networking opportunities, improvement of communication between researchers and projects, result synthesis, trainings and more. They often aim at facilitating social, procedural and technological innovations and creating additional scientific and social value.

On the basis of qualitative interviews and quantitative surveys with scholars of European research and innovation clusters with a specific focus on German case studies, this qualitative comparative analysis (QCA) sets out to identify conditions that lead to the successful integration and cooperation of wood research and forests research. By analysing potential best practices, possible constraints as well as promotive factors, this research is geared towards generating additional innovation processes in the field of inter- and transdisciplinary research.

Identifying conditions for an enabling institutional environment for social innovation: an analysis of Scottish policies in the forest context.

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Katy Joyce[1]
Sam Poskitt[1], Simone Martino[1], Maria Nijnik[1], David Miller[1]
[1] The James Hutton Institute

Abstract: This paper proposes strengthening the institutional environment in the Scottish forest sector to enable the operationalising of approaches to more sustainable management and use of natural capital (NC) in Scottish forests and woodlands. These ecosystems form a significant part of Scotland's NC. Scotland's innovative National Performance Framework incorporates NC as a national indicator for economic success. However, Scottish forestry has not explicitly integrated NC considerations into policy design and a new impetus exists to engage local communities. Social innovation is a means through which communities could be mobilised for enabling impactful social and/or environmental change (e.g., the H2020 SIMRA project). However, whilst social innovation must be initiated from the bottom-up, the policy landscape must be supportive to ensure its development and sustainability. Through a thematic review of academic literature, Scottish policy instruments and grey literature, we identify an applicable set of conditions required to support the creation and maintenance of an enabling environment for social innovation in relation to forestry and woodlands in Scotland to allow it to emerge, be sustainable and spread. Key findings highlight necessary institutional changes, alongside access to financial support and capacity building. We observe that Scotland has already implemented policy instruments within the forest sector and beyond, which, subject to fostering institutional changes, provide unique opportunities to achieve the policy landscape necessary for social innovation to successfully spring up around the operationalisation of NC approaches. This necessitates innovative, transdisciplinary, and cross-sectoral networks to facilitate the emergence of converging, holistic narratives and solutions, reconfigured decision-making processes, strong social capital, and reciprocal knowledge sharing. The insights from this paper could be applied in future research to develop a framework built around the policy instruments already in place and those proposed, to enable social innovation and its contribution to the enhancement of sustainability in the forest context.

Acknowledgement

This project is supported by the Rural and Environment Science and Analytical Services Division of the Scottish Government through its Strategic Research Programme (2022-2027), project JHI-D5-1 in the Natural Resources Theme.

Identifying key stakeholders and driving factors in ecosystem services supply and demand matching

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Jianying XU[1]
Meiyu XIE[1], Yingnan CAI[1]
[1] College of Resource, Environment and Tourism, Capital Normal University, Beijing 100048, China

Abstract: Ecosystem services (ES) supply and demand has been research core of ES sustainable management. There are obvious differences between ES supply and demand in quantity, quality, spatial distribution and among stakeholders, which might lead to the heterogeneity of the match or mismatch between ES supply and demand. The mismatch between ES supply and demand is the potential cause of ecosystem degradation. Therefore, identifying the matching or mismatching relationship between ES supply and demand and their heterogeneity can effectively distinguish key regions, stakeholder groups and types of ES that need to be regulated to maximize the benefits of ES. Taking Wolong Natural Reserve as case study, the research evaluated ES supply and demand from perspective of local residents, and analyzed matching status of ES supply and demand and their difference among varied stakeholders. The results showed that significant differences existed in match/mismatch of ES supply and demand among different types of ES and stakeholders. Regard to ES types, local resident perceived four services including traditional crops, fresh water, soil conservation and maintain soil fertility were deficit, while perceived ES types including grazing, gathering, water source conservation were surplus. Three stakeholders were identified according to their perception to ecosystem service supply and demand. It was found that conservative stakeholders tended to demand ES related to agricultural production, while progressive stakeholders tended to demand ES related to alternative livelihood, such as fresh water, carbon sequestration, leisure tourism. Passive stakeholders had weak ability to change their livelihood style, and deemed most ES were low in both supply and demand. The study found that gender, age, education level, local knowledge, income level and its structure significantly affected local perceptions of ES supply and demand. This study identified differences existing in ES supply and demand matching from the perspective of local residents, and preliminarily revealed the underlying linkage and driving mechanism, which has certain significance for ecosystem management and biodiversity conservation. It also provides a new perspective to solve the conflict between nature reserve and local community in nature reserve management.

Moderation and mediation in collaborative governance platforms: the case of the Estonian national forest programme

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Meelis Teder[1]
Peeter Vihma[1, 2]
[1] Estonian University of Life Sciences, Chair of Forest and Land Management and Wood Processing Technologies, Estonia.
[2] University of Helsinki, Environmental Policy Research Group, Finland

Abstract: Managing contradictory expectations towards forest policy is a complicated governance task. By 2016, the tensions around Estonian forest policy had increased to such a level that the situation was dubbed "Forest War" in the media.

The process of preparing the Estonian Forestry Development Plan until 2030 was initiated in March 2018 and according to the timetable, the plan had to be submitted to the Estonian Parliament in spring 2020. The preparation of a central periodic policy document was planned as a collaborative governance platform, with a lead committee of 35 members (including 7 scientists) from 31 different organizations (ministries, universities, stakeholders' NGOs). As an innovative solution, professional moderators were hired to ensure constructive discussion. However, the policy discussion process failed badly after exceeding all deadlines. The new Minister of Environment dismissed the lead committee on December 07, 2020, and started to seek possibilities for relaunching the process. The new lead committee was formed at the end of March 2020. It consisted of 7 scientists, who were not members of the previous committee, and 2 officials. As of spring 2023, the national forestry program has not yet been approved, it now waits for discussions by politicians, the members of parliament.

We present an analysis of the design and process of this collaboration attempt that highlight the factors that helped and hindered the achievement of an agreement in the platform. Our analysis is based on collaborative governance theory (Ansell & Gash, 2008) and in-depth interviews (N=34) of the first lead committee members and analysis of documents. The results contribute to the theory of collaborative governance by differentiating between moderation and mediation and offer practical lessons for similar collaborations in the future.

Nature Based Solutions, Forest Landowners, and Professional Assistance: Practices, Opinions, Program Development, and Policy Implications

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Courtney Deviney[1]
Rajan Parajuli[1], Frederick Cubbage[1], Robert Bardon[1], Burke Lipscomb[1], Kathleen McGinley[2], Emily Romiti[1], Erin Sills[1], Meredith Hovis[3]

[2] International Institute for Tropical Forestry, USDA Forest Service, Rio Piedras, Puerto Rico
[3] Department of Environmental Sciences, University of North Carolina Wilmington, Wilmington, North Carolina USA

Abstract: Per the IUCN, nature based solutions (NBS) are "actions to protect, sustainably manage and restore natural or modified ecosystems that address societal challenges effectively and adaptively, simultaneously providing human well-being and biodiversity benefits." Rural lands offer diverse opportunities for innovation and application of NBS for a range of market and ecosystem values and benefits, such as timber production, carbon offsets, biodiversity, water quality and quantity, and amenities. We are conducting research to determine which NBS systems may be most useful for applications on forests and farms in North Carolina and the Southeastern United States and identify the factors that influence landowners participation in existing or proposed forestry and farm incentive programs. This research can help increase the application of NBS practices, including afforestation and forest stand improvement, agroforestry, stream restoration and buffers, and forest wetland banks, and common farm conservation practices.

We are conducting surveys of landowners of forests and farms, as well as technical assistance providers, to identify best practices for NBS, and desirable components and configurations of associated government interventions for achieving the diverse goals of NBS. The landowner survey focuses on existing forest incentives programs in North Carolina, and factors that affect landowners' willingness to participate in and invest in projects through to completion. A survey of technical assistance providers will collect information from forestry and natural resources professionals in the public and private sectors to assess their experiences and perspectives regarding the technical, administrative, and implementation needs for forest and farm NBS practices on rural private lands. Descriptive and statistical analyses of survey data will be conducted to explore answers to the research questions and to better understand the relationships among land ownership, NBS opportunities, technical and professional roles, and program and policy development implications.

On designing a regional innovation ecosystem to address transboundary forest and landscape challenges in Gippsland, Australia

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Gordon Hickey[1]
Elsa Berthet[2], Rod Keenan[3]
[1] McGill University, Canada
[2] National Research Institute for Agriculture, Food and Environment (INRAE), France
[3] The University of Melbourne, Australia

Abstract: This study analyzes the multi-level relationships between innovation actors in a regional innovation (eco)system to assess the potential for transitions towards sustainable landscape futures. The case study is the forest and natural resource landscape of Gippsland, Victoria, Australia, a region that is experiencing major environmental, social and economic disruption. The objective was to explore the design of the existing regional innovation system and assess the relationships between innovation actors to identify opportunities for enhancement. More specifically, we sought to understand the extent to which existing innovation communities (including government agencies, industry, communities, Indigenous and non-governmental agencies) are working together, sharing information, and fostering communicative relationships to support collective ideation and action towards desired futures. Based on key informant interviews and an anonymous survey of actors working towards sustainability transitions in the landscape, we identify a lack of collaborative architecture designed to help with managing commons – in this case the resilience and sustainability of the landscape. Importantly, there is no given common, and this needs to be collectively created through ideation, learning and exchange. The findings suggest the need for public policy to focus on rebalancing power relations among actors through a greater emphasis on niche design to overcome 'lock-in' effects; and supporting and stimulating the diversity of niches and their interactions to facilitate collaboration along complementary perimeters of action and experimentation. To this end, informal channels are identified as a potentially under-utilized opportunity to develop trust and reduce perceived risks of working together. Based on these results, we consider the extent to which innovation ecosystem thinking may help with designing novel multi-level architectures capable of supporting coherent transitions to more sustainable landscape futures in Gippsland. Future research and policy directions are then discussed. This study informs the ongoing efforts of regional and local governments and other stakeholders/ rightsholders to collectively innovate towards equitable, resilient, and efficient natural resource systems under increasing uncertainty through multi-level innovation processes.

Organizational models to associate forest sector's actors: experiences of integration of social and institutional innovation

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Francesco Loreggian[1]
Nicola Andrighetto[2], Mauro Masiero[1], Davide Matteo Pettenella[1], Laura Secco[1], Giorgia Bottaro[1]
[1] TESAF Department - University of Padova
[2] Etifor Benefit Corporation

Abstract: The forest sector is hit by the global environmental and political crisis and its consequences on the market, characterised by unstable prices and an increase in energy costs, that force forest management organisations to seek new forms of competitive advantage and business opportunities, while challenging them to meet the societal demand for environmental services. From another (convergent) perspective, forest management can be vital for socioeconomic development, especially in regions where the use of forest resources represents a relevant opportunity for local communities. Land ownership fragmentation is an important issue that hinders forest management in many countries especially in Southern Europe, and land abandonment is a critical factor, exacerbating the magnitude of impacts and risks of climate change, e.g. forest fires. Management of small parcels is not profitable, many small-holders give it up, and the abandonment of forests accelerates the loss of land value and fosters a vicious cycle that definitively depletes forest-related communities. Various types of innovation have been supported through, e.g., the EU RDP and CAP funds, to aggregate forest properties or to support forest-related supply chains, in order to encourage forest management, including organisational, institutional and social innovations. We present the results of a developed in the context of the project LIFE ClimatePositive, based on semi-structured interviews to a sample of 25 Italian cases, plus 10 from other Mediterranean countries, of organisational models where forest owners/managers are associated among them and/or with other actors. The research is designed to assess whether associative organisational models are a viable solution to increase forest management in marginalized rural areas; how they were inspired and established; which challenges and threats they face and what the successful factors are; what they need to consolidate and scale up in different contexts. Results show that such models often derive from institutional or social innovation processes, eventually overlapping or converging after an initial phase more characterised by one type, they must be tailored according to actors, their objectives and the socioeconomic context. Moreover, in general terms, integration of different models and cooperation is needed to overcome challenges and limits.

Sharing Forests: Participatory Practices in Small-scale Private Forests

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Pei Jung Wang[1]
Ming-Yuan Huang[2], An Chi Lou[1], Mei Chih Yeh[3], Wen Hsin Lu[1], Ya Ping Liu[4], Chiou-Lien Huang[5]

[4] Private forest owner
[5] Fo Guang University

Abstract: Until now, due to the lack of sufficient financial support, small-scale non-industrialized private forests (NIPFs) in Taiwan generally have the dilemma of forest degradation, lack of management and low productivity. Moreover, because of the low average income of forestry, NIPFs cannot dedicate most of their effort to this industry. Taiwan's Private Forest policy tools are often used to enforce afforestation or economic incentives, but have not improved their performance. Therefore, this study uses the concept of “sharing economy” to separate forestland rights, such as land ownership, decision-making rights, management rights, and use rights. Forest owners can retain ownership, while other rights are shared to other partners who are interested in assisting the owners in managing forests.

In 2019, we searched for a private forest in southern Taiwan, then guided the establishment of the "Jiasian Sharing Forest Group", with 17 sharing partners, who agreed by the forest landowner for using his forest land freely, and helping him with removal of invasive alien species, afforestation, paving forest trails, etc. During the cooperation, the sharing partners can enjoy themselves by relaxing in the forest land, planting and harvesting short-term crops, and building the forest according to their own wishes. Under the sharing forest mode of social participation, everyone jointly decided that the forest would be used diversified when keeping productive functions, and agreed that this forest would not be changed in land use or resold, thus the threat of deforestation could be solved.

In addition, we also observed 3 sharing cases of other private forests in Taiwan. All of them only share use rights with others, but do not share decision-making and management rights yet.

To compare above four cases, we put the degree of their rights-sharing, social participation, and diversification of forest use in three axes, then got the spectral ranges from high to low. We found out that when the degree of participation and rights-sharing are higher, the changes of forest structure tend to be more abundant. So far, this study supports that sharing forest seems to be one of the solutions to the dilemma of private forest management.

Social innovation as a response of forest-dependent communities to contemporary societal, environmental, and economic challenges

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Abstract: Keywords: stakeholder engagement, policy, forest, people, green recovery

In this paper, we advance conceptual and practical knowledge of social innovation and based on empirical examples from across Europe and beyond, suggest on using it to contribute to meeting the UN Sustainable Development Goals and those of the Green Recovery. Results of the application of qualitative social science techniques, including of participatory methods, combined with visualization tools, provided evidence that by adding to improving human wellbeing, social innovation can create new responses to pressing social demands that are not adequately addressed by markets or existing (e.g., public) institutions. Findings demonstrate that social innovation can assist in tackling societal challenges and utilising the opportunities available and newly emerging in marginalised wooded areas. We show how social innovation can enable forest-dependent communities to realise and develop further their capabilities, while reducing inequalities, and promoting social justice and inclusion. We believe that the conceptualization and operationalisation of social innovation in the context of forestry offered by the SIMRA and SHERPA projects of H2020, and our findings from case studies and living labs, including in Scotland (e.g., on attitudes of local people to sustainability challenges; their innovation actions; improved participation in decision-making and on impacts of social innovation on the ground) can help informing policy decisions and those on management of natural assets and the design of practice measures for a long-term sustainability of marginalised rural areas and their socio-ecological systems.**Acknowledgement**

This project is supported by the Rural and Environment Science and Analytical Services Division of the Scottish Government through its Strategic Research Programme (2022-2027), project JHI-D5-1 in the Natural resources Theme as well as by H2020 projects SHERPA (GA 862448) and SIMRA (GA 677622).

Social innovations in forestry: Lessons-learned from more-likely cases

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Kathrin Böhling[1]
Francesca Gianetti[2], Aída Rodríguez[3], Joachim Englert[4], María Rosa Mosquera Losada[5], Ana M. Ventura[6]

[5] University of Santiago de Compostela (USC)
[6] SOLUTOPUS

Abstract: Social innovation is defined as a process of change in social practices that is driven by collective agency at local level, aimed at well-being of multiple stakeholders, and related to institutional change (Rogelja et al. 2023, Weiss et al. 2021). It is a comprehensive concept and differs from other types of innovation incl. product, service, and technological innovations. The forestry sector has been described as slow to innovate and traditional, with a narrow focus on new technologies and process development. Social innovation in forestry might drive transformative change towards greener and more sustainable business and society. This process, however, is demanding and comparative research limited. The present contribution to the T4.19 session seeks to address this issue and enlarge scholarly research on facilitators and barriers for social innovation in forestry by focusing on more-likely cases.

Attention goes to the GAP-funded Operational Groups (OGs) as likely sites for (social) innovation in the forest-based sector. OGs are based in agriculture and/or forestry, bring multiple actors from different sectors together to advance new ideas and implement them on the ground. They receive funding for 3-4 years. In total, more than 2.500 OGs have been initiated across Europe yet at a far larger scale in agriculture than in forestry and unevenly distributed across the EU Member States. To address the question whether social innovation in forestry and agroforestry has distinct facilitators and barriers and how it rolls out in practice, evidence from survey data and desk research in the Horizon Europe project "European innovation partnership network promoting operational groups dedicated to forestry and agroforestry" is analysed (Project number: 101086216). The influencing factors covered in the collaborative research are: values and attitudes, cooperation, resources, market, society, and government and policy. The focus on OGs allows to control for some of the framework conditions, which eases the comparative analysis.

Socially Innovative Forest and Landscape Restoration in Brazil: Empowering Local Communities for Sustainable Change

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Abstract: Social innovations (SI) have emerged as transformative tools in the global effort to restore social-ecological landscapes through Forest and Landscape Restoration (FLR) initiatives. Traditional groups such as Indigenous, Kalunga, Geraizeiros, and rural and peri-urban communities actively implement Socially Innovative Forest and Landscape Restoration (SIFLR) in Brazil. This study employed mixed methods and social network analysis to examine Brazilian Networks of Native Seed Collectors (NNSCs) and their role in SIFLR. The findings highlight the significant investment of US$ 12 million received by these NNSCs from 2018 to 2021. This funding facilitated the production of 180 tons of native seeds, generating US$ 1.01 million in revenue for 997 seed collectors, with 55% of them being women. Notably, 46% of the collectors belong to traditional groups, and 23% rely solely on seed collection as their income source. The involvement of government, non-governmental, and university organizations is prominent in these NNSCs. Through partnerships, these networks enable knowledge exchange and cooperation in political action. The study further explores five cases within the SIFLR framework, revealing that local experimentation, familiarity with administrative procedures, and active participation in decision-making processes significantly influence the agency power of social-ecological innovators. These individuals play a vital role in driving change and empowering local communities. This research emphasizes the effectiveness of social innovations in promoting inclusive and sustainable FLR initiatives. It underscores the significance of scaling up and supporting SIFLR efforts, which have demonstrated their value in restoring social-ecological landscapes while empowering local communities. SIFLR provides a promising pathway towards achieving social and environmental goals in forest and landscape restoration by mobilizing capital, creating networks, and reconfiguring social structures. In conclusion, this study contributes to understanding the potential of social innovations in FLR initiatives, particularly in Brazil. The findings emphasize the need to prioritize and expand SIFLR

approaches to ensure the restoration of social-ecological landscapes while benefiting local communities.

Standards – consensus driven agreements to achieve and communicate several sustainability goals of forestry

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Karin Vestlund Ekerby[1]
Maria Gustafsson[1]
[1] Swedish Institute for Standards, Department of Standardisation, Box 45443, SE-104 31 Stockholm, Sweden

Abstract: Standardization provides a well-established method for developing common solutions to recurrent problems in an industry or within a subject area. International standardization within ISO and CEN has been ongoing for almost 100 years. Standardization has four principles for the work: consensus, voluntariness, openness and is stakeholder driven. Through collaboration and together with the business community, standards are developed for many topics, including ones regarding forestry.

The substantial advantage of working within the framework of standardization is that standards have a high credibility and respect in the market and authorities often refer to standards as a possible way to meet laws and regulations.

Bio-based products are an important piece of the puzzle to achieve the UN's SDG:s and in the transition to a fossil-free society by creating a bioeconomy. There are several standards for bio-based products that are important for forestry. Within Europe, the standard EN 16751, *Bio-based products - Sustainability criteria*, was developed in 2016. In Sweden, we also wrote a handbook for the implementation within the Strategic Innovation Programme BioInnovation during 2017-2020.

In the same standard series, EN 16760, *Bio-based products - Life Cycle Assessment* is published, and in 2024 a new standard that builds on the existing LCA methodology and sets additional requirements and guidelines for comparing the life cycles of bio-based products with their fossil-based equivalents is to be published.

Globally, there is an ISO-committee on *Sustainable processes for wood and wood-based products*. There, a series of three standards are developed regarding the climate effect of wood and wood-based products, taking a more inclusive approach than traditional LCA methodology, looking at the carbon balance of the forest, the value chain emissions, temporary carbon storage in products, and the displacement that occurs when wood-based products replace e.g. fossil-based ones.

These standards (and many more) can be utilized by industry to respond to various requirements placed on forestry and to achieve several sustainability-related goals as well as to communicate on and promote their products. They can also facilitate research and public debate by setting a common framework for calculation and evaluations, leaving less room for ambiguity and misunderstandings.

The causal dynamics of emergent social innovation in Swedish forest landscapes and its potential contribution to sustainable rural development

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Lucas Dawson[1]
Marine Elbakidze[1, 2], Grzegorz Mikusiński[1]
[1] School for Forest Management, Faculty of Forest Sciences, Swedish University of Agricultural Sciences, Sweden
[2] Ivan Franko National University of Lviv, Ukraine

Abstract: As social-ecological systems, forest landscapes face a range of interconnected demographic, socio-economic, and environmental challenges, which have focused research and policy attention on the role of social capital and networks in the delivery of rural development. At local levels, these challenges have triggered the emergence of social innovation – e.g., new networks and reconfigured social practices – amongst non-industrial forest owners to develop more diversified income streams and reduce the vulnerability of rural communities.

With a broader aim to understand the causal mechanisms linking social innovation to rural development, we explore an innovative social network that has recently emerged in rural Sweden. *Skogens mångbruk* connects non-industrial forest owners who practice multiple use forestry to better support a diverse set of income streams, including tourism and recreation opportunities, high quality wood and food production, hunting, and handicrafts.

Based on 25 semi-structured interviews with network participants and key stakeholders representing public and private sectors, we apply a complex systems approach to analyse this network as an emergent phenomenon within the wider social-ecological context that influences rural development in Sweden. Using qualitive systems modelling and network analysis, we identify the core underlying causal dynamics (e.g., drivers, triggers, feedbacks, etc) by which this social innovation has emerged, and by which it contributes to rural development. We show how the network emerges in response to, and continues to be shaped by, a series of path-dependent constraints and opportunities relating to institutional, economic, technological and socio-cultural factors. We compare core causal dynamics with those of a recent social innovation in small-scale agriculture as well as with other recent studies concerning multifunctional forest landscape collaborations. Our findings make a key contribution towards the development of a robust causal model for the emergence of social innovation in rural development settings, and better enable identification of suitable strategies for scaling up social innovation initiatives in support of sustainable rural development policies in Sweden.

The Potential for New Collaboration in Trail Maintenance in National Parks: A Case Study of Chubu-Sangaku National Park, Japan

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Akiho Hori[1]
Seiji Iwanaga[1], Kazuhiro Harada[1]
[1] Graduate School of Bioagricultural Sciences, Nagoya University

Abstract: Many national parks in Japan are maintained by the private sector because of lack of management by the government. In recent years, extraordinary weather conditions have caused the deterioration of mountain trails. One of the reasons for the lack of progress in administrative management is the lack of staff and budget for maintenance. Moreover, there have been reports of cases in which the spread of COVID-19 has made it difficult for the private sector, which is the main actor, maintain the mountains. The collapse of mountain trails leads to soil runoff and the decline of mountaineering culture. Therefore, a new approach to trail management in national parks in Japan needs to be considered.

This study examines collaboration and cooperation in trail management based on a case study of volunteer trail management in Chubu-Sangaku National Park in Japan. The research methods are based on observation and participation in trail maintenance by climbers, in order to analyze the techniques and methods required for them. In addition, questionnaires and interviews were conducted with climbers and volunteers in order to promote trail maintenance.

The results indicate that maintenance by climbers has the potential to become a new leader in trail maintenance. This study also revealed that although there are many climbers who desire to maintain the trails, they do not have many opportunities to do so, and the lack of information about maintenance activities does not promote their participation. Therefore, it is necessary to actively engage climbers as maintenance leaders and provide them with the appropriate information and support.

The social and institutional innovations in forest management and nature conservation in Nepal: Are they transformative?

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Ram Pandit[1]
Yoko Saito[2]
[1] Centre for Environmental Economics and Policy, Department of Agricultural and Resource Economics, UWA School of Agriculture and Environment, The University of Western Australia, Perth WA 6009, Australia
[2] Research Faculty of Agriculture, Hokkaido University, Kita 9, Nishi 10, Kita-ku, Sapporo, Hokkaido 060-8589, Japan

Abstract: Transforming the way we manage forests and conserve nature is alarmingly essential to fulfill emerging societal objectives of sustaining forests and nature while improving human well-being. In doing so it is important to change our views, values, and practices that degrade forests and nature from both individual and societal levels. It also requires a close look at the processes followed and outcomes achieved in forest management and nature governance. However, there is a strong dependency of households or society on forests and nature for livelihoods, thus requiring social and institutional innovations that could halt degradation of forests or nature in one hand while fulfilling households or societal needs on the other. In this context, we examine community forestry approach to manage forests and park-people approach to manage protected areas in Nepal. We highlight the salient features of these approaches, progress made, challenges encountered and outline some possible ways forward for sustainability. In addition, emerging societal objectives on forest management and wildlife conservation are becoming more and more complex as they need to balance nature's capacity and human needs, requiring transformation in our current practices. In this later context, we further examine existing social and institutional innovations with reference to community forestry and buffer zone policy in Nepal from a transformative change perspective. We argue that social and institutional innovations were able to bend the curve from continuing degradation to towards more sustainable paths, but the transformative change required to address the challenges to fulfill forest, nature and human objectives are yet to be materialized.

Transformational Change in the Canadian Forest Sector: Shifting from Timber Production to Ecosystem Health

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Sen Wang[1]
[1] University of Toronto, Canada

Abstract: Canada's forest sector has been experiencing a transformational change in the past two decades. Changing societal demands, intensification of competition at the global forest products market, and increasing climate change impacts have altered the way in which timber is harvested and forests are managed. Unique to the Canadian context, calls for recognition of Indigenous peoples' rights with respect to the forests and creating the conditions for greater participation by forest-dependent communities in forest governance have become new driving forces in policy considerations.

This paper provides an overview of the major trends in Canada's forest sector, in terms of the significant contributions of forests to the Canadian economy, society and the environment. The main factors at play are examined, using examples and developments in the context of British Columbia's forest sector. The paper argues that Canada's forest sector has entered a new era where forest practices are expected to facilitate a shift from the traditional dominance of timber production towards the protection of ecosystem health and resilience. The transition from woodland management to forest stewardship calls for a broader spectrum of partnerships involving industry, non-government organizations, government agencies, as well as Indigenous peoples and forest-dependent communities. To succeed in realizing the new vision will require forest professionals to change their mindset from viewing forests as a source of wood fibre to embracing forests as the places where people live, work and play.

Unlocking the Transformative Potential of Forest-Based Social Innovation for Sustainable Rural Communities in Europe

T4.19 Institutional and Social Innovations in the Forest-based Sector as a Response to Contemporary Challenges

Todora Rogelja[1]

Abstract: In the last ten years, social innovation (SI) received increased attention from policymakers and academia, due to its potential to revive marginalized rural areas, contribute to the sustainability of natural resources, and improve the well-being of local, forest-dependent communities. In general, European research on forest-based SI is based on case studies related to ecotourism, health/well-being, traditional forestry practices, participatory decision-making, gender initiatives, and others. Although those cases address various dimensions of SI processes (e.g., institutional frameworks, actors, trade-offs, benefit sharing, and impacts), to a lesser extent, they comprehensively deal with the mechanisms leading to the institutionalization of SI in the forest-based sector, as well as the long-term effects of such institutionalization on forest governance. Institutionalization is crucial for understanding the transformative capacity of SI, e.g., its' capacity to influence the system change, as formal institutionalization is the structuration process in which new formal rules are established or existing ones are reaffirmed. Our contribution aims to better understand the transformative capacity of forest-based SI by building on research on SI in rural areas and forestry (e.g., H2020 SIMRA project), and meta-analysis of several European case studies. Using constructivist institutionalism, we identified the moments of "institutional disequilibrium", as points of "contact" of informal and formal rules during the development of selected SI initiatives. Our results indicate that in the SI process informal, cross-level institutionalization precedes formal institutionalization. In the moments of formal institutionalization, local-level initiatives might get disempowered by top-down, command, and control regulation. Although a SI initiative might already achieve positive effects, the change in formal rules and thus forest governance might remain largely unlikely (at least within the policy-making arena). To scale and influence the modes of forest governance, forest-based SI needs to be coupled with institutional innovations (and changes) and supported by public actors on the national level. Forest-based SI initiatives need periods of "exceptional'' policy-making, which is deliberative, adaptive, and innovative, to fulfill the transformative potential and substantially affect forest governance. Our study offers insights into the institutional dynamics of SI pointing out that systemic changes are needed to transition to a more sustainable, green, and just society.

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

Adaptation of forest management system under the armed conflict in Ukraine

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

Pavlo Kravets[1, 2]
Oksana Pavlishchuk[1, 2], Yevhenii Khan[1, 2]
[1] National University of Life and Environmental Sciences of Ukraine
[2] FSC Ukraine

Abstract: Armed conflict as no predictable factor of the external environment, necessitated the adaptation of the management system and forestry practices in Ukraine. This adaptation required updating the tools for achieving the goals of responsible forest management. One of the measures for elimination of risk to the health and life of people is excision the areas contaminated by explosive objects (CEO) from the FSC certification scope. Certificate holders shall make relevant changes in forest management and practices in Ukraine if there are CEO areas (which should be reflected in the Annex of the FSC National Forest Stewardship Standard of Ukraine):

- take into account the applicable legislation of Ukraine in terms of hazards associated with explosive hazardous areas;

- outline approaches to the identification of CEO areas, their demarcation, mapping, take into account the best available information and be based on the application of the documented procedure;

- provide for appropriate adaptation of a management plan in terms of all its components (policies, objectives, targets etc.) and adaptation of monitoring system;

- assess, document and monitor impacts related to the CEO areas and ensure an appropriate response to such impacts through adaptive management;

- define the requirements for systematic protection of the CEO areas from unauthorized or illegal resource use and other illegal activities;

- support the legal rights of the affected stakeholders by the presence of CEO areas within a management unit;

- ensure strengthening of management strategies and actions to maintain and/or enhance of High Conservation Values on the territories that are not contaminated with explosive objects;

- prevent forest products from CEO areas from entering FSC supply chains, in particular by implementing appropriate procedures for tracking and tracing of all forest products, as well as procedures for use of FSC name and trademarks.

Incorporating these provisions in the national criteria, indicators and verifiers for excision of CEO areas from the scope of FSC certification will help to preserve the integrity of FSC certification and appropriate adaptation of forest management to the conditions of martial law and post-war situation.

Armed Conflicts, Climate Change, Wildfires and Human Security in the Cultural Landscapes of Temperate-Boreal Eurasia

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

Johann Georg Goldammer[1]
Sergiy Zibtsev[2, 3], Nikola Nikolov[4]
[1] Global Fire Monitoring Center (GFMC), Freiburg, Germany
[2] Regional Eastern Europe Fire Monitoring Center (REEFMC), Kyiv, Ukraine
[3] National University of Life and Environmental Sciences of Ukraine (NUBiP), Kyiv, Ukraine
[4] Regional Fire Monitoring Center (RFMC) for Southeast Europe and Caucasus, Skopje, North Macedonia

Abstract: Cultural landscapes of temperate-boreal Eurasia, which were formed by traditional agrarian societies over centuries, are undergoing rapid changes. Rural exodus and the accelerating trend of urbanization in some regions are associated with abandonment of land cultivation and thus directly or indirectly affecting fire regimes in some regions. Climate change is contributing to aggravation of wildfire risk and wildfire severity. This contribution looks at the specific issues linked to the heritages of civilization including industrial and nuclear accidents and armed conflicts in temperate-boreal Eurasia.

In Europe, armed conflicts have resulted in collateral damages, including wildfires, and left behind significant areas contaminated by unexploded ordnance (UXO). In regions affected by military operations, UXO and land mines constitute a major problem for post-conflict forest management and fire management. Over more than a Century, large territories have been affected by collateral wildfire damages during wars. Wildfires occurring on lands contaminated by UXO and land mines as consequences of armed conflicts are posing high risk to human security. Examples are provided from the Western Balkans (World War I and military conflicts related to the dissolution of Yugoslavia 1991-2001), Central and Eastern Europe (World War II and military activities during the Cold War), South Caucasus (dissolution of the Soviet Union and recent armed conflicts) and Ukraine (since 2022).

In the early 2000s, the Global Fire Monitoring Center (GFMC), which was established in1998 to serve the science-policy interface towards developing informed fire management policies, governance and practices, started addressing fire management solutions in conflict and post-conflict areas. Besides developing technological and managerial solutions, the GFMC is facilitating cross-boundary cooperation in fire management for confidence-building and peacekeeping in regions of political and military tensions. In the light of socio-economic changes, land-use change and the climate crisis, the collateral damages and remnants of war constitute a major challenge for regional and international security. Joint bilateral, regional and international cooperative projects and programs in landscape fire science, integrated landscape fire management and policy development are exemplary for realizing joint interests in environmental protection, wildfire disaster risk reduction and sustainable integrated fire management capabilities.

Contribution of FirEUrisk project to risk assessment and prevention of forest fires in the Chornobyl Exclusion Zone

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

Oleksandr Soshenskii[1, 2]
Domingos Viegas[3], Viktor Myroniuk[1, 2], Dmytro Holiaka[1, 4], Valerii Kashparov[2, 4], Serhii Sydorenko[1, 5], Vadim Bogomolov[1, 5], Oleksandr Borsuk[6]
[1] Regional Eastern Europe Fire Monitoring Center (REEFMC), Kyiv, Ukraine
[2] National University of Life and Environmental Sciences of Ukraine (NUBiP), Kyiv, Ukraine
[3] Associação Para O Desenvolvimento Da Aerodinâmica Industrial (ADAI), Porto, Portugal
[4] Ukrainian Institute of the Agriculture Radiology (UIAR) of NUBiP, Chabany, Ukraine
[5] Ukrainian Institute of Forestry and Forest Melioration after G.M.Vysotskii (URIFFM), Kharkiv, Ukraine
[6] Chornobyl Radiation and Ecological Biosphere Reserve, Ivankiv, Ukraine

Abstract: The Chornobyl Exclusion Zone (CEZ) were established after the disaster 26 of April 1986 that contaminated of environment by radionuclides (RN): Sr-90, Cs-137, Pu-238-240, Am-241. The CEZ territory was fenced with area 260 000 ha, including most contaminated 10-km core zone around ChNPP. Special State Forestry Enterprise “Chornobyl Forestry” were established to prevent radioactive forest fires. Due to climate change and lack of funding regular large fires have been occurred in CEZ: 1992 (17000 ha), 2003 (5000 ha), 2015 (15000 ha), 2016 (1200 ha), 2020 (80 000 ha). Russian military invasion 24.02.22 resulted in damage fire engines and contamination of CEZ with unexploded ordnance (UXO) and land mines. From 12 forest fire stations only 2 left undamaged with few fire engines.

While details maps of radioactive contamination exist and allow to predict doses for fire personal, unexploded ordnance (UXO) and land mines were not mapped and create huge uncertainties and high risks for life and health of firefighters and engines. Under these conditions scientific products (models, data sets, maps), special technologies of prescribe burning and armored vehicles to protect fire personal from UXO are only solution to manage risks and prevent fires.

EU Horizon FirEUrisk project (project number 101003890) will develop, evaluate and disseminate a science-based integrated strategy to: 1) expand current wildland fire risk assessment systems, including critical factors of risk previously not covered; 2) produce effective measures to reduce current fire risk conditions, and 3) adapt management strategies to expected future climate and socioeconomic changes.

Regional Eastern Europe Fire Monitoring Center (REEFMC) within the project developed two products and DSS to address risk for personal and forests from fires in CEZ: 1) Combining Landsat time series and GEDI data for improved characterization of fuel types and canopy metrics in wildfire simulation; 2) Modelling of the extinction moisture content for main fuel types of the CEZ; 3) DSS system for prevention and safe suppression of radioactive fires on terrains contaminated by UXO. All products will be demonstrated in CEZ and extended on larger area of Ukrainian Polissia based on Ukrainian Landscape fires portal (www.wildfires.org.ua).

Damage to Ukraine's forests due to Russian aggression: estimates for the year 2022 based on satellite data

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

[6] International Institute for Applied Systems Analysis, Agriculture, Forestry, and Ecosystem Services Research Group, Austria

Abstract: The Russian-Ukrainian war (since 2022) has already entailed multiple negative consequences for Ukraine's natural environment. Shelling and accompanying fires have reportedly ravaged agricultural and grassland ecosystems in vicinity to active battles. Resulting fires, mechanical shelling damage, and tree harvest for fortification purposes severely fragmented Ukrainian forest landscapes that are already a complex mosaic. The greatest amount of damage was reported along the frontline in southern and eastern regions of Ukraine. However, also severe wildfires occurred in Chornobyl Exclusion Zone (CEZ, north of Ukraine) after Russian forces left it in April 2022.

We estimated damage to forests in three areas of interest (AOI): East (20 counties in Donetsk, Luhansk, and Kharkiv regions); Kherson (8 counties in Kherson and Mykolaiv regions); CEZ. We used Sentinel-1 and Sentinel-2 imagery to predict pre-war land cover and derive a forest mask, and high-resolution satellite imagery to digitize visually damaged forest cover. We calibrated a binary classification model using spectral Sentinel-2 to determine the difference between August-September medians for the years 2021 and 2022. Our model derived damage estimates with 88% overall accuracy.

24,180 ha were damaged in East AOI (9% of 2021 forest cover). Damage estimates for Kherson AOI (7,293 ha, or 16% of pre-war forests) and CEZ (7,116 ha, or 5% of 2021 forest cover) are similar. Additionally, we found that 89% of damaged forest patches in Kherson AOI are highly fragmented and share an edge with highly-flammable open landscapes. For East AOI and CEZ this estimate is lower, at 70%.

Forests in southern and eastern parts of Ukraine are extremely crucial for the ecological functioning of local landscapes. Precise estimation of war-related damage is important for designing post-conflict forest regeneration.

Demining of Ukrainian forests

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

Hansjorg Eberle[1]
Nickolai Denisov[2]
[1] FSD, Geneva, Switzerland
[2] ZOI Network, Geneva, Switzerland

Abstract: Humanitarian demining is high on the agenda of Ukraine and its allies, as it is the unsurmountable condition for fully reclaiming the territories that have been freed from occupation or simply used to be close to front lines for an extended period of time. Without demining roads, settlements and agricultural fields, neither normal everyday life nor economic activities can fully resume, as large areas will remain mortally dangerous or inaccessible. Yet a large part of country that has suffered from the war still lacks such attention: these are Ukraine's forests and other natural landscapes. Not the responsibility of the State Emergency Service, forest lands are left to the devices of forest management authorities, who are overstretched with their core tasks and do not possess the expertise, capacities and indeed the budget for carrying out demining operations at the required scale. The contamination of Ukraine's forests with landmines and unexploded ordnance already regularly puts at risk and kills forest guards and local inhabitants. And as long as forests will remain contaminated, neither regular maintenance nor emergency interventions, e.g., in case of fire, are going to be possible. While the former endangers forest conditions in the longer-term perspective, the latter bears the tangible risks of losing even more forest land than what has already been lost during the war. The contaminated forests will remained barred for the local population, depriving people of their essential livelihoods and recreational resources. Even more critically, the mined forests will continue to put at risk those who dare to venture into the dangerous terrain notwithstanding warning signs and roadblocks. Children are particularly prone to such behaviour. For an effective response to this large-scale challenge, a collective international effort is needed to specifically focus on surveying and demining Ukraine's forests. Along with that, urgent and systematic efforts are required to make people fully aware of the risks and to help them contribute to their mitigation.

Enhancing Close-to-Nature Silviculture in Ukraine: The Utility of martelage.sylvotheque.ch in Fostering Post-War Forest Recovery

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

Christian Rosset[1]
Oleksandr Soshenskyi[2], Mariana Melnykovych[1]
[1] Bern University of Applied Sciences, School of Agricultural, Forest and Food Sciences BFH-HAFL, Switzerland
[2] National University of Life and Environmental Sciences of Ukraine NUBIP, Education and Research Institute of Forestry and Park Gardening, Ukraine and Regional Eastern Europe Fire Monitoring Center REEFMC, Ukraine

Abstract: Close-to-nature silviculture (CTNS) covers a broad variety of techniques that rely on natural processes to influence forest development to provide essential forest ecosystem services. A profound understanding of forest ecosystems and their underlying processes is crucial, alongside the ability to adapt to local conditions and choose appropriate silvicultural methods that align with societal and forest owner expectations. Creativity plays a vital role in discovering innovative approaches to climate adaptation and enhancing resilience, particularly in Ukraine, where 690,000 ha of forest affected due to the war.

This paper presents the potential of combining the "marteloscope" concept with digitalization to train forest students and practitioners in Ukraine to address the challenges of post-war forest recovery.

The “marteloscope” concept has proven to be useful for teaching CTNS. It helps to enhance knowledge, but also to develop ones “own know-how”. A large network of marteloscopes is useful to cover the manifold aspects of CTNS. Digitalization has been instrumental in establishing and managing such network, enabling data analysis, comparisons of marteloscopes, and promoting experience sharing both in the forest and through virtual reality. The *martelage.sylvotheque.ch* (MSC) internet platform, along with the complementary *MSC Mobile smartphone app*, were developed for this purpose. Currently, there are over 200 marteloscopes in four countries.

With extensive experience in applying CTNS in Switzerland and leveraging digitalization, BFH-HAFL has developed a course of action in collaboration with NUBIP to support Ukrainian forest stakeholders in building capacity for post-war recovery. Through workshops and knowledge transfer events, we have shared Swiss expertise with Ukrainian researchers, students, and practitioners. *Martelage.sylvotheque.ch* has served as a catalyst for promoting CTNS among Ukrainian stakeholders. We have successfully established a dedicated network of researchers and practitioners committed to implement CTNS in Ukraine. The potential and limitations of Marteloscope and MSC have been assessed, and efforts to establish MSC plot networks are underway. Our next objective is to develop guidelines on different CTNS approaches and elaborate training concepts for students and practitioners. By facilitating knowledge sharing with policy makers, we will promote CTNS principles into forest management practices in Ukraine, fostering sustainability and resilience in post-war forest recovery endeavors.

Impact of armed conflict on Tigray's arid-land ecosystem restoration efforts: a remote sensing approach

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

[8] World Agroforestry Center, Nairobi, Kenya

Abstract: Over the past century, there have been numerous civil wars and interstate wars in Africa, some of which are still raging today. Many of them have resulted in dramatic environmental consequences, including biodiversity loss. One among the many, Ethiopia's Tigray region sustained immense environmental damage. However, this has not received due attention, ostensibly due to people's sensitization to the overwhelming devastation to lives and livelihoods. Here we aim to investigate changes in forest cover during the war period (2020 to 2022) using the advances in earth observation techniques, supplemented by field testimonies and secondary data. Vegetation indices such as the Normalized Deviation Vegetation Index (NDVI) and Gross Primary Productivity (GPP) are considered to indicate the extent of change. The magnitude, direction as well as the drivers of change in vegetation cover varied throughout the study period. Preliminary results suggest that woody vegetation cover (NDVI >0.3) over Tigray's dry Afromontane forest declined from about 16% in 2020 to 11.43% in 2021 and 9.8% in 2022. This indicated that 39.4% of the forest cover in the region has been lost in two years period. Land restoration practices meant to avert desertification were interrupted; warfare accompanied by shelling ravaged dry Afromontane forest landscapes, further modifying weather and climate; and the denial of essential services such as electricity for household or industrial use created a heavy reliance on natural resources such as firewood and charcoal. Tigray being at a very high risk of desertification and sandwiched between desert areas, the magnitude of damage, which went unattended, over the last two years leaves a top alarm. Continued ecosystem damage could eventually make the domain part of a wider desert connecting the Sahel to the Afar Triangle, a scenario which may render the area uninhabitable.

Impact of war in Ukraine on wildfire regimes, fire management and carbon emissions

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

Sergiy Zibtsev[1, 2]
Johann Goldammer[3], Viktor Myroniuk[1], Oleksandr Soshenskyi[1, 2], Roman Vasylyshyn[1], Nickolai Denisov[4], Vasyl Gumeniuk[1, 2], Serhii Sydorenko[5], Oleksandr Borsuk[6], Volodymyr Braiko[7], Iryna Zibtseva[2]

Abstract: Military aggression of Russian Federation against Ukraine heavily impacted forests and fire regimes of landscapes. Direct impacts included shelling, mechanical damage of trees and soils, trenches, increasing ignition sources as collateral damages during combat. Indirect impact resulted in unaddressed fires on occupied territories during weeks, loss and limitation of fire management capacities, lack of personal and equipment, contamination of large areas of forests with unexploded ordnance and land mines that pose high risk for personnel. For assessment of impact of war, all fires in Ukraine in 2022 were manually delineated and classified using Sentinel 2 imagery. We defined three discrete burn severity classes using the following delta NBR (Normalized Burn Ratio) thresholds: low (0.090-0.179), medium (0.180-0.549), and high (0.550 and higher). The Copernicus Dynamic Land Cover map was used to attribute the burned area to a specific land cover (coniferous forests, deciduous forests, croplands, other natural vegetation, and urban territories). Average values of burn severity obtained for each land cover type were used in carbon loss calculations over Ukraine. Carbon emissions were estimated using averaged data on the structure of forest biomass (Shvidenko et al., 2014) and yields of agricultural lands. The total area of landscape fires in Ukraine during 2022 reached 755 638 ha, including croplands (419 313 ha), forests (56 719 ha), and abandoned lands (273 987 ha). In total 19 948 fires were occurred. They were mostly (50.3%) burned within 60-km buffer zone along a daily front line, while 42.3% of all fires occurred in occupied territories. The war directly affected about 25% of the protected areas of Ukraine. The area of fires burned on the Emerald Network reached 88 427 ha. Over entire Ukraine, landscape fires in 2022 resulted in more than 1.3 million tons of carbon emissions. Almost 48% of carbon emissions were caused by fires within occupied territories of Ukraine. We expect that fuel loads in landscapes due to the impacts of war will create high risks of wildfires at level of emergency situations, similar to 2020. In future, the development of a national interagency system of landscape fire monitoring and management is required.

Mapping forest conflicts – what did we learn?

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

Daniela Nousiainen[1]
Blas Mola-Yudego[1]
[1] School of Forest Sciences, University of Eastern Finland, Finland

Abstract: The efforts to combat the negative effects of climate change are large. Forests as one of the most promising allies in this battle are therefore under enormous pressure. Increasing demand for forest products and services for commercial and non-commercial use positions forests at the centre of various conflicts around the globe. This study focuses on the forest conflicts in 28 member states of the European Union (27 + UK) to map different conflict cases, describe their main characteristics and observe potential emerging patterns among them. Content analysis of academic literature from the period 1999-2020 resulted in 84 conflict cases, where each case was assigned a location, type of conflict, intensity and main stakeholders. Based on these characteristics, we can discuss that the most common forest conflicts occurred in and around urban areas, followed by conflicts over forest conservation. The majority of the mapped conflicts were characterized by low intensity, i.e. restrained conflicts, followed by open conflicts. Open conflicts are those often involving protests, petitions or lawsuits. Six conflicts involved violent actions like attacks and were under the category of violent conflicts. The analysis of the observed forest conflict features resulted in the development of three emerging patterns: conflicts over forest protection, conflicts over the development of forests and conflicts over the recreation in forests. Based on the information obtained during the analysis it can be discussed that effective communication, transparent planning process and proper involvement of all stakeholders are the key approaches to prevent harmful high-intensity forest conflicts.

Pest management and forest health monitoring of forests contaminated by UXO

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

Valentyna Meshkova[1]
Kateryna Davydenko[1]
[1] Ukrainian Research Institute of Forestry & Forest Melioration

Abstract: The stands with a predominance of host trees, with low density, adjacent to clear-cuts, burnt areas are most favorable for forest pest mass propagation. During hostilities, the forest structure over a large area is disturbed due to the construction of fortifications, fires, and damage to trees by shells. Forest defragmentation brings to a weakening of trees, an increase in their vulnerability to phytophagous insects and pathogens, and the formation of permanent outbreaks of these pests. With the intensive movement of people, troops, and equipment, the risk of the establishment of alien pest species increases.

Traditional methods of early detection of pests and diseases, prevention, localization, and elimination are impossible in a significant part of the territory of Ukraine, which is mined or contaminated with explosive objects during battles or shelling. The detonation of unexploded ordnance and mines can cause the death of personnel during forest protection measures, as well as cause a fire, and the death of trees and forest animals. At the same time, the detection of pests and pathogens in the forests contaminated with explosive objects is necessary to prevent the spread of forest decline and obtain wood in the event of an irreversible weakening of the stands.

In forest enterprises, first of all, it is necessary to demine the seed stands, seed orchards, the territory of greenhouses, nurseries, and unclosed plantations, and, first of all, protect these objects from pests.

Pest outbreaks in massive forests should be detected by remote sensing. At the macro level, Landsat or Sentinel images with a spatial resolution of 10–30 m should be obtained at different periods of the year. At the micro level, the plots of forest deterioration must be identified using fire surveillance cameras. Such images must be taken once every two weeks from mid-April to the end of August in coniferous forests, and once a month in May, June, and August in deciduous forests. If a change in crown color, or density is detected, images obtained on adjacent dates are compared to assess the rate of forest health deterioration, and damaged area, and to plan forest protection measures.

Postfire forest management: science-based assessment, monitoring and restoration

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

Serhii Sydorenko[1]
Ihor Budzinskyi[2], Yevhen Melnyk[1], Ihor Tymoshchuk[1]
[1] Ukrainian Research Institute of Forestry and Forest Melioration named after G. M. Vysotsky (URIFFM), Kharkiv, Ukraine
[2] State Forest Resource Agency of Ukraine, Kyiv, Ukraine

Abstract: Due to the climate change, the risk of forest fires in Ukraine remains high while the massive military Russian invasion multiplied those risks. Therefore it`s relevant to develop science-based silviculture approach to mitigate loses caused by wildfires. This creates additional risks for human safety and health. Forest health deterioration of the damaged stands leads to significant economic (losses of timber that can be obtain after salvage logging) and ecological losses (forests after severe wildfires are not able to fully provide most of ecosystem services).

As a result of forest fires, areas with completely or partially dead stands are formed. If, in the first case, forestry treatments are focused of salvage logging of stands and reforestation of these areas, then in the second case, decision-making process is more complicated. To evaluate the post-fire development of burnt areas and the possibilities of their restoration, researchers from URIFFM have developed a set of recommendations and guidelines to support postfire assessment and forest restoration for different climatic conditions (including restoration in severe condition of South Steppe) and specific natural features of each area. Multiple regression analysis as well as logistic regression analysis were used to develop tree mortality models. Postfire monitoring (forest health monitoring) of damaged stands are performed using remote sensing methods. Similar approach with the active use of LIDAR and optical sensors now also under development (Myroniuk, Zibtsev, 2023).

To predict tree mortality and the possibility of damaged forest to restoration, an experimental three level framework was proposed: I) stand level – prediction of the share of trees that will die, depending on the type and intensity of fire damage as well as forestry characteristics of tree stand (age, DBH etc.); II) individual level – estimating the mortality probability of each tree in the same stand; III) remote level – monitoring of forest health changes of each damaged stand for several years (up to six years) after the fire (vegetation indices for the control period and after fire damage were used).

These approaches combined with adequate forestry treatment can be used to significantly mitigate both ecological and economical losses caused by forest fires.

Preliminary assessment of environmental damage during the war in Ukraine in 2022

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

Nickolai Denisov[1]
Doug Weir[2]
[1] ZOI Network, Geneva, Switzerland
[2] The Conflict and Environment Observatory (CEOBS), United Kingdom

Abstract: Russia's war against Ukraine has had devastating humanitarian, social, economic and environmental consequences. The OSCE preliminary assessment of the environmental damage and risks caused throughout the first year of the war between February 2022 and February 2023 has contributed to shaping response and recovery planning in Ukraine. The report has covered the environmental context before February 2022; military conduct; the impacts of the war on industrial and energy infrastructure, nuclear facilities and other radioactive sources, the built environment, the rural environment, freshwater resources and infrastructure, the coastal and marine environment and the climate and climate policies; as well as the evolving legal and regulatory environments.

Although the dynamics of the war varied throughout the year, it remained a high intensity armed conflict characterized by severe damage to settlements, environmentally hazardous infrastructure and landscapes. Long-range weapons affected sites nationwide, while the indiscriminate use of explosive force devastated areas along mobile and static front lines.

The war has seen the unprecedented occupation of current and former nuclear energy-generating sites, and underscored the range of direct and indirect threats to nuclear and radiation safety, and nuclear security, which can be triggered by armed conflicts.

Alongside the environmental damage linked to the fighting itself, natural resources and geographical features proved strategically important for the conflict parties. This included woodlands and forestry, rivers, canals, reservoirs and coasts, offshore islands and infrastructure, agricultural shelter belts and industrial spoil heaps. The use, targeting and militarization of these features contributed to environmental harm. Fighting also affected nationally and regionally important habitats and protected areas, with a wide range of direct and indirect impacts.

Based on the findings and an assessment of Ukraine's needs, the report suggested a set of specific recommendations for improving the information and knowledge base, building Ukraine's capacity for assessing and addressing the environmental impacts of the warm, and mainstreaming the environment in recovery policies and planning altogether.

Seeing the Forest for the Trees: A Multi-Actor Approach to Trigger Sustainable Forest Governance in Post-War Ukraine

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

[11] Swiss Federal Institute of Technology (ETH), Switzerland

Abstract: This paper aims to contribute to the conceptual and practical understanding of sustainable transformations in forest landscape governance within a post-war environment, using Ukraine as a case study. By employing a multi-actor approach that integrates the participation of local communities, policymakers, and experts from forestry and agriculture, we propose an innovative tool for fostering discussions and devising strategies to promote sustainable and resilient landscapes. Recognizing the dialogue process as a valuable instrument for disaster risk reduction and conflict resolution, we emphasize the importance of ensuring the inclusion of all relevant stakeholders, particularly local communities, who play a crucial role in shaping the future of their landscapes. Our research findings demonstrate that a sustainable and inclusive landscape governance dialogue, which adopts a holistic perspective by considering the intricate interconnections between the environment, economy, and society, should be firmly rooted in principles of inclusiveness, transparency, and collaboration. By facilitating evidence-based decision-making through comprehensive data gathering and analysis, forest landscape management effectively supports informed discussions among all stakeholders. We believe that modeling human-environmental interaction using a multi-actor approach that integrates people, landscapes, and policy represents an effective means of fostering sustainability in post-war Ukraine. Through the implementation of this comprehensive framework, we can effectively address the complex challenges faced by post-war forest landscapes and promote long-term resilience.

The Restoration of Ukrainian Damaged Forests by War: a Way to Providing Improved Planting Material

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

[4] Senior Research Fellow of the Institute for Evolutionary Ecology NAS Ukraine, Lebedeva str. 37,Kyiv, 03143, Ukraine
[5] Associate Professor of Department of Ecobiotechnology and Biodiversity, Faculty of Plant Protection, Biotechnology and Ecology, National University of Life and Environmental Sciences of Ukraine, 03041 Kyiv, Ukraine
[6] Head of Department of Botany, Dendrology and Forest Tree Breeding, Education and Research Institute of Forestry and Landscape-Park Management, National University of Life and Environmental Sciences of Ukraine, 03041 Kyiv, Ukraine
[7] Senior Researcher at the Zabolotny Institute of Microbiology and Virology, National Academy of Sciences (NAS) of Ukraine, Akademika Zabolotnoho St., 154, Kyiv, 03143, Ukraine

Abstract: Europe's forests, particularly in Ukraine, are highly vulnerable to climate change. In connection with the frequency, intensity and timing of fire events, hurricanes, droughts, ice storms and insect outbreaks resulting from human activities and global climate change, forest ecosystems are even more prone to damage.

Since 2022 due to Russian aggression, Ukrainian forests have experienced a new negative impact. As per preliminary data from Ukrainian experts, over 2.5 million hectares of forests were lost due to military operations. High-quality plant material will soon be needed to restore the Ukrainian forest.

The maintenance and improvement of forest health are high-priority issues, and various stakeholders have shown an interest in understanding and utilizing ecological interactions between trees and their associated microorganisms. Endophyte microbes can influence the health of trees either by directly interacting with the damaging agents or modulating host responses to infection. In the framework of this work, ten morphotypes of endophytic bacteria from the tissues of unripe acorns of *Quercus robur* L. were isolated. Based on the results of the sequenced 16S rRNA gene, four species of endophytic bacteria were identified: *Bacillus amyloliquefaciens, Bacillus subtilis, Delftia acidovorans*, and *Lelliottia amnigena*. Determining the activity of pectolytic enzymes showed that the isolates *B. subtilis* and *B. amyloliquefaciens* could not cause maceration of plant tissues. Screening for these isolates revealed their fungistatic effect against phytopathogenic micromycetes, namely *Fusarium tricinctum, Botrytis cinerea*, and *Sclerotinia sclerotiorum*. Inoculation of *B.*

subtilis, *B. amyloliquefaciens*, and their complex in oak leaves, in contrast to phytopathogenic bacteria, contributed to the complete restoration of the epidermis at the damage sites. Inoculation of *B. amyloliquefaciens* and *B. subtilis* isolates into oak leaf tissue were accompanied by a decrease in the total pool of phenolic compounds. The ratio of antioxidant activity to total phenolic content increased. This indicates a qualitative improvement in the overall balance of the oak leaf antioxidant system induced by potential PGPB. Thus, endophytic bacteria of the genus *Bacillus* isolated from the internal tissues of unripe oak acorns have the ability of growth biocontrol and spread of phytopathogens, indicating their promise for use as biopesticides.

Towards developing forest monitoring capacity in Ukraine in the post-war reality

T4.20 Managing Safety and Resilience of Forests and Forestry affected by Armed Conflicts and the Climate Crisis: Past and Future Contribution of Forest Science

Viktor Myroniuk[1]
Sergiy Zibtsev[1, 2], Viktor Melnychenko[3], **Maksym Matsala**[4]
[1] National University of Life and Environmental Sciences of Ukraine (NUBiP), Kyiv, Ukraine
[2] Regional Eastern Europe Fire Monitoring Center (REEFMC), Kyiv, Ukraine
[3] State Forest Management and Planning Enterprise, Ukraine
[4] Swedish University of Agricultural Sciences, Southern Swedish Forest Research Center, Sweden

Abstract: Effective post-war forest management in Ukraine requires accurate and timely information on forests in a spatially explicit form. Since 2022, large forests in Ukraine have been affected by the russian invasion, leading to increased vulnerability of forest stands under climate change or total forest loss in the war zone. Assessment of the impact of the war on the environment and decision-making can be supported by the use of innovative solutions. Forest monitoring capacity in Ukraine can be strengthened through close scientific cooperation with the international community, technology exchanges, and training.

Large areas in Ukraine will remain restricted by landmines and unexploded ordnance, so forest monitoring requires more advanced use of remote-sensing data. Since forest inventory information cannot be collected in such areas, research into advanced technologies to propagate spatially explicit estimates becomes crucial. Thus far, efforts in Ukraine have been fragmented and therefore ineffective for long-term management. The forest information in Ukraine in the post-war period is expected to be little updated. To improve the situation in the future it is important to update data collection with innovative solutions. Satellite time series and airborne scanning technologies (i.e., LiDAR) can provide strong support for strategic forest inventories to inform forest management. Thus, there should be a systematic basis for regularly updating forest information in accordance with new disturbances, as well as forest growth forecasts.

Forest monitoring technologies based on the combined use of forest inventory data, satellite time series and LiDAR scanning data have been used in many developed countries, so their experience can reinforce the potential of forest monitoring in Ukraine. We also note professional expertise as an important component of strengthening forest monitoring capacity in Ukraine. This can be improved by developing the essential skills through trainings involving leading international experts.

T4.21 National perspective of Forest resources policy and governance in countries of Latin America under a sustainable perspective

Building policies for a just transition: Challenges and opportunities in national incentive programs for land restoration in Latin America

T4.21 National perspective of Forest resources policy and governance in countries of Latin America under a sustainable perspective

Victoria Rachmaninoff[1]
[1] World Resources Institute

Abstract: Through the Bonn Challenge and Initiative 20x20, countries in Latin America and the Caribbean have pledged to begin restoring over 50 million hectares of land by 2030. As countries move from pledge to plan to on-the-ground implementation, it is increasingly clear that incentive policies are necessary to meet these ambitious targets. However, governments face difficult decisions when building these programs to meet a wide range of complementary and competing goals. For example, should government programs target smallholders to increase community benefits or private landowners to increase scale? How can programs include women and traditionally marginalized communities where land tenure may be a challenge? And how should governments weigh social, economic, climate, and biodiversity benefits?

This talk will share honest perspectives on the challenges and opportunities for governments in building effective and equitable incentive policies through experiences in the Landscape Policy Accelerator and Landscape Monitoring Accelerator. These two innovative peer-to-peer capacity development programs for policymakers and government officials support the improvement or design of incentive programs for restoration as well as policy monitoring to track performance and impacts. The discussion will highlight work from Chile, El Salvador, Guatemala, and Costa Rica and consider pathways forward for countries aiming to develop restoration incentive programs.

Challenges and opportunities in the implementation of policies of Payment for Environmental Services for forest conservation in the Brazilian Amazon

T4.21 National perspective of Forest resources policy and governance in countries of Latin America under a sustainable perspective

Paulo Cezar Gomes Pereira[1, 2]
Vitor Afonso Hoeflich[2, 3]
[1] Federal Rural University of the Amazon, Campus Paragominas, Brazil
[2] Federal University of Parana, Post-graduate Program in Forest Engineering, Brazil
[3] Federal University of Paraná, Department of Rural Economy and Extension, Brazil

Abstract: The study aimed to evaluate the scenario of federal public policy instruments aimed at Payment for Environmental Services (PES), as an alternative for forest conservation in the Brazilian Amazon, highlighting its advances, challenges and opportunities. The research method adopted was exploratory, based on bibliographic research, which consisted of identifying, locating, compiling and summarizing information and ideas on the subject. The main source of research for the elaboration of the study was carried out through consultations related to the theme, in the current legislation, projects and programs, official websites, scientific journals, reports, guides and manuals. The results showed 13 instruments of PES policies at the federal level, in almost two decades. Although they are not directly PES policies, the National Fund on Climate Change and the National Policy on Climate Change - mention the modality. In the Forest Code economic instruments were established as an alternative to reconcile the economic activity in rural properties with nature conservation through PES, being an old demand from the productive sector. After the Forest Code, PES gains more strength in the years 2020 and 2021 with the creation of the Green Rural Product Bill and the Floresta+ Program and its axes: Bioeconomy, Carbon, Entrepreneur and Agro, all with goals and guidelines to promote the valorization of activities developed in the Amazon, such as sustainable forest management and integrated production systems. In the same period the National Policy for Payment for Environmental Services is enacted, a fundamental law to guide state and municipal PES actions. After the launching of the policies and programs, PES actions started as pilot projects in the states of the Legal Amazon, helping in the environmental regularization and transfer of resources. We can conclude that despite the important advances observed in the last two years, the regulation of PNPSA is urgent in order to provide legal security to PES actions. It is recommended to create clear rules about the forms of valuation and definition of environmental services provided, as well as to encourage the participation of the private sector, so that PES does not remain a policy of income transfer.

Forest policy and governance in Uruguay: evolution and projections of a strategic sector

T4.21 National perspective of Forest resources policy and governance in countries of Latin America under a sustainable perspective

Virginia Morales Olmos[1]
Amalia Stuhldreher[2]
[1] Departamento de Ciencias Económicas, Universidad de la República-Sede Tacuarembó, Tacuarembó, Uruguay.
[2] Instituto de Desarrollo, Inclusión e Innovación Social (IDIIS), Universidad de la República-Sede Tacuarembó, Tacuarembó, Uruguay.

Abstract: Uruguay developed its forest sector within the framework of a specific regulation that strategically positioned it in terms of the country's economy and development. Forestry Law 15.939 of 1988 was approved by all the members of Parliament. Despite the alternation of the majority parties in the government, the Law was not changed. However, after thirty-five years, Uruguay is still facing the challenge of diversifying the sector. On the other hand, critical voices have emerged regarding the evolution of the sector, both from the political spectrum as well as from non-governmental organizations and environmental movements. This paper aims to analyze the current situation of governance in the Uruguayan forest sector and its implications in terms of its development. The concept of governance has evolved from origins anchored in institutional economics (early 20th century), as well as with the school of regulation (1970s). It has subsequently expanded its application in the field of social sciences, where it is now used to address different processes from a multilevel perspective, encompassing the global, regional, national, subnational, and local levels, analyzing development processes in their multidimensionality. On the other hand, the conceptualization focuses on participation and relationships that go beyond the traditional political format of government hierarchies, encompassing links with civil society actors and the private sector. Considering the Uruguayan case, this framework is particularly interesting to analyze the initiatives that have been promoted during the last decade by the government to promote the forest sector. In this regard, the results have been uneven depending on the emerging coalitions: while in some isolated cases governance has been strengthened, in others there is a lack of coordination to generate cumulative processes in a strategic sector of the country. A substantive aspect in the projections is the role to be assumed by STI (Science, Technology, and Innovation) policies as well as the possibilities of the so-called 'green finance'.

Forest Policy Reform and Implementation in Peru

T4.21 National perspective of Forest resources policy and governance in countries of Latin America under a sustainable perspective

Kathleen McGinley[1]
[1] USDA FS International Institute of Tropical Forestry

Abstract: Peru is among the top ten countries in the world in terms of forest extent (ranked ninth in 2020 according to FAO) and has undertaken significant forest policy reforms aimed at reducing deforestation and enhancing forest sustainability in the past two decades, including the 2011 Forestry and Wildlife Law (No. 29763), the 2014 National Pact on Legal Timber, and the National Multisectoral Strategy to Combat Illegal Logging 2021-2025. Despite increases in participation and transparency in forest policymaking, devolution of forest authority to regional governments, incorporation of community based and economic instruments, and forest policy integration across sectors, forest loss and degradation persist across much of the country. As reported by FAO, forest loss in 2020 was the highest in Peru's recorded history. We examine forest policy reforms and their implementation in Peru through an historical institutionalist lens taking into consideration internal and external factors as well as the critical junctures, feedbacks and recursive dynamics that influence policy formulation and implementation. We explore the institutional factors that have shaped new forest policy approaches and instrument mixes, including the role of state and non-state actors, the influence of international agreements and initiatives, the effects of historical paths and legacies on policy reform and broader sociopolitical and environmental factors. We also incorporate top-down and bottom-up perspectives on policy implementation to shed light on policy effects and effectiveness. We aim to identify strategies for enhancing the effectiveness of policy design, reform, and implementation and to contribute to broader discussions on the state of and advances, challenges, opportunities and perspectives of forest policy and governance in the tropics.

PROSPECTS OF PINUS AND EUCALYPTUS PRODUCING COMPANIES IN THE STATE OF PARANÁ

T4.21 National perspective of Forest resources policy and governance in countries of Latin America under a sustainable perspective

Ailson Loper[1]
Vitor Hoeflich[1], Alexandre Almeida[2], João Carlos Silva[1], Joésio Siqueira[3]
[1] Federal University of Paraná, Rural Economy and Extension Department. Curitiba, Paraná, Brazil.
[2] University of Brasilia, District, Brazil
[3] Federal University of Paraná, Retired Professor.

Abstract: The forestry industry supplies raw materials for fuel, cellulose, mechanical pulp, paper, reconstituted panels and solid wood products that supply other industrial segments and/or the end consumer. More than 10% of Brazil's wood product companies and one of the most diverse industrial parks in the Brazil's entire forestry setorare located in the state of Paraná. The objective of this study was to analize the forest production phase in the supply chain – pine and eucalyptus in particular – through the lens of policy drafting principles. To this end, perspectives for the next 5 years with respect to planted forest area, forest productivity, investment intent and staffing prospects were identified. Critical factors in the forestry supply chain were identified and prioritized using factor analysis (to determine critical factors) and the Friedman Test (to verify differences between factors and rank them). A Wilcoxon test was used to verify differences in perception between integrated and non-integrated companies with respect to the critical factors. A content analysis technique, grounded in a PESTEL structure for theoretical foundation, allowed us to examine the external environment, and identify challenges and opportunities and their respective macro environmental causes. Results suggest a perspective where planted area grows by 10% and productivity grows by 18% between 2017-2021 and where non-integrated industries form a group that proportionally grow more than the integrated companies, especially the TIMOs. Integrated companies in the solid wood and reconstituted panel were the most affected by the domestic and international economic conditions, negatively in fact. Given the peculiarities of pine and eucalyptus companies of Paraná, two additional conditions were identified beyond the six dimensions proposed by the Pestel structure: Infrastructure and Market. The economic dimension includes most of the threats and opportunities to which companies are sensitive, wherein the current economic recession is seen as the greatest threat. The chief opportunities are perceived to hinge upon the recovery of the domestic economy. Legal and regulatory instruments, and especially labor and environmental laws, are seen as the greatest threats to the industry. The most important critical factors were: demand, technology, macroeconomy, and logistical, social, and legal costs.

Regulating deforestation through the Brazilian Amazon Soy Moratorium: a hybrid environmental governance mechanism

T4.21 National perspective of Forest resources policy and governance in countries of Latin America under a sustainable perspective

Rafaella Ferraz Ziegert[1]
Metodi Sotirov[1]
[1] University of Freiburg

Abstract: This paper analyses the Soy Moratorium agreement for the Brazilian Amazon signed in 2006 between non-governmental organizations (NGOs) and transnational soybean commodity traders. The current literature describes the Moratorium as an effective solution for halting deforestation, as well as a replicative model for other regions or commodities. Yet, to date there is no explanation of its emergence and maintenance as a hybrid governance mechanism. To narrow this knowledge gap, we applied the Baptist and Bootlegger political economy theory of regulation and analyzed data through content analysis of qualitative interviews and documents, to describe and explain the adoption and governance mechanisms of the Moratorium over a 15-year timeframe. Our results show that the agreement implements a hybrid governance mechanism, firstly developed as a non-state market driven governance, but integrating state-like regulation ("bans"), enforced through a longstanding strategic alliance between NGOs, industries, and later in collaboration with state institutions. Our analysis provides a clearer distinction of each actor's role in the agreement, and how this influences who 'gains' or 'loses' from its regulatory design, contributing to overall lessons of its replicability for environmental governance of forest-risk agricultural commodities.

Systems analysis as a tool in land use planning with special reference to Northwest of the Colombian Amazon.

T4.21 National perspective of Forest resources policy and governance in countries of Latin America under a sustainable perspective

Jesica López[1]
Deniz Koca[1], Asaf Tzachor[2]
[1] Centre for Environmental and Climate Science (CEC), Lund University
[2] Cambridge Global Food Security Research Centre, University of Cambridge

Abstract: Deforestation caused by cattle ranching in the Colombian Amazon has been a persistent issue that poses a threat to both food security and biodiversity. Our aim is to provide a system analysis of deforestation in the Colombian Amazon region through Causal Loop Diagrams (CLDs) showing the causal relationships between cattle ranching, deforestation, biodiversity loss, and food security. Causal loop diagrams were developed based on the knowledge obtained from literature, semi structured interviews, and stakeholder participatory workshops. The complex feedback mechanisms behind cattle ranching-driven land use change and its consequences in the Colombian Amazon were captured by the CLDs. The system analysis reveals that deforestation poses a significant threat to food security and biodiversity, with land use change causing the loss of tree cover, soil degradation, decreased agricultural productivity, and reduced access to nutritious food. The study also explores potential policy interventions that could break the negative feedback loops and promote sustainable land use practices in the region. The findings of the study can help policymakers and stakeholders to understand the underlying causes of deforestation and degradation, and to target and develop strategies to mitigate its negative impacts on food security, biodiversity, and other ecosystem services.

T4.22 Nature-climate Solutions: Lessons to move from buzzword to transformative practice in tropical forest landscapes

Can REDD+ safeguards 'do better' for Indigenous Peoples and local communities? Perspectives from comparative research in the DRC, Indonesia and Peru

T4.22 Nature-climate Solutions: Lessons to move from buzzword to transformative practice in tropical forest landscapes

Juan Pablo Sarmiento Barletti[1]
Anne Larson[1]
[1] CIFOR-ICRAF

Abstract: Safeguards for the UNFCCC's REDD+ mechanism arose in response to concerns voiced by forest-dependent communities over its potential to infringe upon their rights and territories. Since then, several institutions have also developed voluntary standards for carbon markets, in addition to safeguards guidelines adopted by multilateral funding institutions. Across these standards and guidelines, safeguards are conceptualized and articulated in different ways: as bulwarks against the impacts of interventions ("do no harm"); as means to achieve sustainable development outcomes ("do good"); or as mechanisms to catalyse the transformation of forest-dependent communities ("do better").

It is urgent to clarify and understand the role of safeguards as the climate crises prompts interest on the part of countries and corporations in 'nature-based solutions' to meet their emissions reduction targets and commitments to biodiversity. This influx of investments in tropical forests can bolster sustainable development objectives, but also poses risks to communities, including the creation of perverse incentives and the deepening of existing social and economic inequities.

This paper will present the results of comparative fieldwork on the design and implementation of REDD+ safeguards in the DRC, Indonesia and Peru to understand when safeguards work, for whom, and why. We found that while safeguards have become a mainstay of REDD+ discourse and practice, there is considerable variation in their underlying objectives, the ways in which they are formulated, and the extent and effectiveness of their implementation. Thinking through safeguards, we will present a typology to understand their potential for change, how nature-based solutions may re-engage with the men and women of IPs and LCs and their rights and justice concerns, and synthesised factors to enable initiative to support and protect those rights.

Does it pay off to try harder? The role of REDD+ treatment intensity for forest and livelihood impacts

T4.22 Nature-climate Solutions: Lessons to move from buzzword to transformative practice in tropical forest landscapes

[5] Wageningen University
[6] Federal Office for the Environment, Switzerland

Abstract: Impact evaluations have shown that REDD+ has significant, but disappointingly modest, impacts on both tropical forest conservation and livelihoods. However, these impact evaluations typically abstract from the heterogeneous and often small-scale and short-term interventions applied in the numerous but small-scale pilots of REDD+. We move beyond a traditional 'treated' vs. 'non-treated' binary analytical framework, to investigate whether and how treatment intensity – i.e., how many people were reached, with how much of resources, and for how long time – matters for the size and significance of the intended forest conservation and livelihood-improving impacts. We draw on quasi-experimental data from 16 REDD+ sites in Brazil, Peru, Cameroon, Tanzania, Indonesia, and Vietnam, as part of CIFOR's Global Comparative Study on REDD+, combining remote-sensing data with surveys applied in nearly 130 villages to 4,000+ households in 2010-2011 (pre-intervention), 2013-2014 (post-intervention I), and 2018 (post-intervention II). We characterize the highly variated treatments applied in these sites as incentives, disincentives, or enabling factors, as well as more graduated measures of the intensity of treatment. Our analysis suggests that it matters not only just whether or not 'something' has been done in targeted sites, but also 'how hard' these interventions have tried. Methodologically we thus contribute to a previously called-for extension of the literature on heterogeneous conservation impacts. Our results may also have important policy implications: the ongoing shift from REDD+ projects towards jurisdictional approaches may be associated with higher treatment intensities, which have implications for both costs and effectiveness. Future research should look closer at the implications for the comparative cost effectiveness of different forest interventions.

Impacts of Transnational Aids for Climate Change Mitigation: Evidence from Ghana

T4.22 Nature-climate Solutions: Lessons to move from buzzword to transformative practice in tropical forest landscapes

Suhyun Jung[1]
Reem Hajjar[1]
[1] Department of Forest Ecosystems and Society, Oregon State University

Abstract: Much like development aids, a multilateral environmental financing mechanism provides developing countries with climate change mitigation and adaptation funding. For example, the EU and other developed countries pledged to provide 100 billion USD annually until 2025. This fund is used toward financing projects or investments that help mitigate climate change and increase the adaptative capacity of the vulnerable population. A major focus of these projects at national and sub-national levels has been to sustainably manage forests by curbing deforestation and promoting conservation by providing training and resources for tree management and improving livelihoods.

In this paper, we estimate the impacts of the Forest Investment Program (FIP) on households' tree-planting activities and livelihood outcomes using a household panel survey in Ghana. Our investigation involves whether and how those programs that aim to conserve/restore forests and improve livelihoods have effectively promoted forest conservation/reforestation and livelihoods. Ghana was selected as a pilot country for the FIP under the Climate Investment Fund (CIF) in 2010. It aims to reduce greenhouse gas emissions by reducing deforestation and forest degradation while improving people's livelihoods and generating income sources. It reduces pressure on existing forests by restoring forest cover in off-reserve areas by planting trees and increasing monitoring of illegal activities, and enforcing laws.

We find significant and positive impacts of FIP activities on households' participation in tree planting. People who have participated in FIP activities are 4-10 times more likely to have been involved in tree planting than those who have not participated in those activities. However, the FIP has not significantly impacted total income or expenditure. This might indicate that the benefits from participation in FIP could have offset the potential loss resulting from reduced access to forests due to increased monitoring and enforcement. This reduces concerns for negative livelihood impacts of increased enforcement and monitoring when coupled with livelihood-promoting activities. Intergovernmental and government agencies, non-governmental organizations, donors, and other stakeholders, including the science community interested in environmental conservation and economic development interventions, will find the results of substantial interest.

Promoting Nature Based Technologies for Enhanced Resilience to Climate Change in Horn of Africa

T4.22 Nature-climate Solutions: Lessons to move from buzzword to transformative practice in tropical forest landscapes

Wanjiku Josephine[1]
Musingo T. E. Mbuvi[1], Josephine Wanjiku[1], Paul Tuwei[1], Honjo Yuki[1], Sylvia Mwalewa[1]
[1] Kenya Forestry Research Institute

Abstract: Much of the Horn of Africa is dry and highly degraded and suffers from frequent and severe droughts. Therefore, accelerating technology transfer through knowledge sharing and promoting adoption of existing good practices was identified as a strategy to collectively address natural resource management (NRM) challenges in Horn of Africa (HoA). A regional Initiative known as Africa Initiative for Combating Desertification (AI-CD) was developed in 2016 for implementation in seven HoA countries namely; Djibouti, Eritrea, Ethiopia, Kenya, Somalia, South Sudan and Sudan. The Initiative aimed to address NRM challenges and contribute to making nations and communities resilient to climate change. The partnership was formalized through Terms of Reference (TORs) developed and adopted to guide participating HoA countries to work harmoniously. Tools for identifying, collecting, and documenting good practices in NRM from farmers within the region were developed. A series of workshops and meetings for Horn of Africa AI-CD participating countries were held for policy and technical level officers. The objectives of policy level forums were for participants to familiarize with the Initiative activities, and facilitate dialogues among member countries. The aim of technical level workshops was to build capacity of technical officers on field data collection and repackaging of information for farmers and other community based end users. Participating countries identified and documented good practice information from the field in home countries. Information collected was used to develop good practice knowledge materials which included; books, manuals, guidelines and brochures, which were shared through internet and non-internet based platforms. A major lesson from farmers was that they preferred integrated farming approach as it guaranteed food security, ensured income generation and provided ecological benefits such as soil and water conservation, biodiversity conservation and promoted adaptation to climate change. The farming approach encompassed various time-bound farm enterprises namely: Short-term enterprises which involve food crop growing; medium term enterprises mainly fruits trees farming and livestock keeping; and long-term enterprises which involve tree growing. Good practices that have shown high adoptability by farmers in one area, should be promoted widely to enable HoA to collectively combat land degradation, desertification, and enhanced resilience to climate change.

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

(How) does tree diversity influence insect herbivory in urban trees?

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Alain Paquette[2], Gabriel Marcotte[2], Swane Cobus[2], **Bastien Castagneyrol**[1]
[1] BIOGECO, University of Bordeaux, INRAE, 33612, Cestas, France
[2] Centre for Forest Research, Département des sciences biologiques, Université du Québec à Montréal, Montreal, Canada

Abstract: Cities exacerbate the impact of global change on trees. Higher temperature and impervious surfaces make urban trees strive closer to their physiological limits, in addition to increasing their vulnerability to insect herbivores. Because of the essential role trees plays in the functioning of urban socio-ecosystems, it is crucial to understand which ecological factors could buffer the impact of urbanization on insect herbivores and their impact on trees. Theory predicts that tree species diversity promotes the abundance, diversity and activity of herbivores' enemies, therefore resulting in a stronger top-down control of herbivory in tree species rich stands. We tested this hypothesis in the city of Montreal (Canada), using 24 urban forest plots defined as 200 m radius circular buffers in which we exhaustively identified every single tree, being in the public or private domain. Plots were uniformly distributed along gradients of canopy cover, population density, and deprivation index. We selected four trees per plot, belonging to the most frequent species (13 species in total). We excluded birds from one branch per tree with a mesh, and identified a second branch as a control, and attached 20 dummy caterpillars to each. We estimated bird predation attempts as the proportion of dummy caterpillars with beak marks and assessed the top-down control of insect herbivores through the comparison of insect herbivory measured on leaves from the control and bird-exclusion branches. In parallel, we characterized bird communities using passive acoustic monitoring. The direct effect of tree diversity on insect herbivory and its indirect effect mediated by changes bird diversity and predation attempts will be analyzed using structural equation models .

Analyzing multiple values of a complex peri-urban forest system under climate change

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Marc Djahangard[1]
Rasoul Yousefpour[1, 2]
[1] University Freiburg, Chair of Forestry Economics and Forest Planning
[2] University of Toronto John H. Daniels Faculty of Architecture, Landscape, and Design

Abstract: In our study, we analyze the peri-urban forest system of the city Freiburg in southern Germany. The forest system holds multiple values with the most important being recreation and eco-tourism, timber production, carbon sequestration, biodiversity protection and water services. With an area of over 5000 hectares, it is a complex and highly divers forest that ranges from lowland deciduous dominated to mountainous conifer forests. The combination of multiple functions and the forest's complexity possess high challenges to the local forest management, especially for adaptation strategies to climate change.

We simulate the forest system with the process-based forest growth model LandClim on the landscape-scale under climate change until 2100. Hereby, we integrate the local forest service's management plan for the next decade and repeat it until 2100. We evaluate the management strategy on achieving resilience to climate change and sustaining the multiple values.

For the simulation, we apply a state-of-the-art initialization process that makes use of a detailed inventory network (+2000 inventory points in the area) and integrates GIS data to depict the forest's initial conditions (e.g., species distribution, stem number, ages, DBH) in high resolution. We apply climate change data of different RCP scenarios and different underlying climate models to address uncertainties.

Our analysis focuses on changes in productivity and mortality, caused by stress factors (e.g., droughts) and disturbances (e.g., storms, beetles). Hereby, we evaluate feedbacks to the multiple values and identify areas where values are threatened, e.g., loss of forest cover in water protection area for drinking water recharge. In addition, we link the results to socio-economic data of the corresponding applied climate change scenarios to evaluate changes in economic conditions for selected values.

Summarizing, our study contributes to understanding future ecological and economic challenges under different climate change scenarios for a complex peri-urban forest system with multiple values. Furthermore, we assess the local forest management strategy's adaptation potential and help to identify trade-offs but also synergies between the multiple values.

Biodiversity conservation in the Leipzig Floodplain Forest – Using a demographic forest model to support conservation planning

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Jack Boyce[1, 2]
Lucian Elles[2, 3], Markus Schorn[1, 2], Adam Clark[3], Stefanie Henkel[4], Hans Kasperidus[5], Martin Quaas[1, 2], Andreas Sickert[6], Mathias Scholz[5], Michael Vieweg[5], Christian Wirth[1, 4, 7], **Nadja Rüger**[1, 2]

[6] Leipzig Stadtforsten, Germany
[7] Max-Planck Institute for Biogeochemistry, Jena, Germany

Abstract: The Leipzig Floodplain Forest is a biodiversity hotspot of national significance. Much of this biodiversity is associated with characteristic hardwood floodplain forest tree species, especially pedunculate oak (*Quercus robur*) and European ash (*Fraxinus excelsior*). However, the share of oak and ash has been declining over the last decades due to regulation of the hydrological regime, recurrent droughts, and invasive pests and pathogens. A revitalization of the hydrological regime (higher groundwater table, more floods) has started, but it is unclear whether this will be sufficient in ensuring the conservation of oak, or whether active oak planting is required.

To answer this question, we apply the Perfect Plasticity Approximation (PPA) forest model. The PPA model is a demographic forest model which simulates changes in forest dynamics according to growth and mortality rates in dynamic discrete canopy layers, as well as recruitment rates. We use forest inventory data from the 'Lebendige Luppe' project, including approximately 8000 trees growing in either ambient conditions or artificially flooded plots, to quantify these demographic rates for eight focal tree species and to characterize their dependence on the hydrological conditions. In addition, we use data from small-scale oak plantations with differing sizes (0.1-0.5 ha) to inform potential management scenarios.

In the baseline scenario (no revitalization of the hydrological regime, no oak planting), the basal area of oak trees is projected to decline by half in the next 50 years, indicating that natural regeneration alone is insufficient to conserve oak and its associated biodiversity. Likewise, a scenario where the hydrological regime is revitalized does not ensure sufficient oak recruitment. However, oak planting on <0.2% of the area per year ensures the long-term conservation of oak. Our results can support the design of an optimal biodiversity conservation strategy for the Leipzig Floodplain Forest.

Emerging fungal pathogens of Aesculus hippocastanum across Europe and the worsening condition due to the correlation with Cameraria ohridella

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Yasin Korkmaz[1]
Kathrin Blumenstein[1]
[1] Chair of Pathology of Trees, Institute of Forestry, Faculty of Environment and Natural Resources, University of Freiburg, Bertoldstr. 17, 79098 Freiburg, Germany

Abstract: The Horse Chestnut tree (*Aesculus hippocastanum*) is a widely distributed urban area and forest species across Europe. However, in the last two decades, it has encountered significant challenges due to a climate change promoted emergence of various fungal pathogens, and infestations of the destructive leaf miner (*Cameraria ohridella*).

To monitor the tree health along a climate gradient, a comprehensive study was conducted along a Southwest to North Europe transect across six countries and ten urban forest areas. Approximately 700 trees were investigated, and 750 symptomatic leaves were sampled to isolate fungal pathogens. Molecular markers were used for species determination of the pathogens. Additionally, the study aimed to examine the composition and distribution of fungal communities along the transect, accounting for local variations.

During the monitoring phase, notable observations suggested a potential correlation between the presence of specific pathogens and the activity of the leaf miner, *C. ohridella*. Therefore, a field experimental study was undertaken using insect nets to enclose 40 individual trees to explore this association further. Four different treatments were implemented, with ten trees assigned to each group: 1) moths transporting fungal spores by exposing five litres of fungal-infected and moth-infested leaves from the previous year; 2) enclosing five litres of fungal-infected and moth-infested leaves in insect nets, allowing spores to infect the enclosed leaves while retaining the moths; 3) moths only; and 4) control group (untreated trees). Additionally, two methods were employed to differentiate between airborne and moth-transmitted fungal spores. Illumina MiSeq sequencing analysed fungal spore traps to assess the entire fungal community composition, while media Petri-dishes captured cultivable spores using an air particle sampling device.

The study results underscore the presence of specific fungal communities exhibiting distinct patterns along the Southwest to North Europe transect. In addition, these findings highlight the influence of climate and geographic regions on the distribution of fungal populations. Moreover, the study supports the correlation between specific fungal communities and the presence of the Horse Chestnut leaf miner, *C. ohridella*. The elevated temperatures and growing correlation significantly threaten urban environments and heighten the mortality risk of Horse Chestnut trees.

Enhancing ecosystem services of urban trees under a changing climate

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Thomas Rötzer[1]
Astrid Reischl-Moser[1], Mohammad A. Rahman[2], Eleonora Franceschi[1]
[1] TU München, Chair for Forest Growth and Yield Science, Germany
[2] TU München, Chair for Strategic Landscape Planning and Management, Germany

Abstract: Urban trees and shrubs will be critical to maintain and improve the human well-being of our cities as climate change continues. They are very effective in modifying the climate of a site, a neighborhood or even of an entire city by providing a range of ecosystem services such as cooling by transpiration or shading, mitigation of the urban heat island effect, carbon sequestration or storm water runoff. The extent of these modifications, what they depend on, how they vary with climate change and what can be done to mitigate negative effects of global change are largely unclear. By using the process-oriented climate-sensitive urban tree growth model CityTree, simulations can be done that give answers to these questions. We will present a simulation study for different cities along a climate gradient through Europe that quantifies growth and ecosystem services of common urban tree species under current conditions as well as under changed anthropogenic conditions. Hereby, possible site conditions and their changes include variations of soil sealing percentage, soil water storage capacity or the radiation reduction (sky view factor). Information and quantification to maximise or at least maintain ecosystem services in the face of climate change, drought stress and other anthropogenic stressors will be provided. Preliminary results indicate that ecosystem services for temperate cities will decline significantly under future climate conditions. The level, however, strongly depends on the small-scale local conditions. For example, reducing soil sealing under trees, increases carbon sequestration and cooling, and reduces storm water runoff. For healthy and efficient urban tree populations, it is essential to improve growing conditions, including soil water storage, nutrients and radiation. At the same time, tree species should be chosen to enhance ecosystem services, particularly with regard to climate change. In our presentation, we will quantify and discuss growth and ecosystem services of common urban tree species for cities along a climate gradient, and identify mitigation measures for the negative impacts of climate change.

Exploring Urban Forests in Europe: Access, Usage Patterns and Insights from 33 Countries

Abstract: Urban forests in Europe cover around 10-15% of city areas, varying in extent and quality across regions and countries. They offer numerous ecological, social, and economic benefits. Accessibility to these forests is important and can be influenced by factors like distance, transportation options, motivation for visiting, and citizen preferences. However, not all residents have equal access to or spend the same amount of time in forests, emphasizing the need to enhance accessibility, quality, and management for inclusive community benefits.

To investigate these issues, an exploratory research was conducted in 33 European countries to investigate the patterns of use and access to urban forests. The study utilized a standardized online survey, resulting in a sample size of 10,462 participants.

The initial results reveal that a majority of respondents visit urban forests regularly, with 58.8% visiting 2-3 times a month or more frequently. The preference for accessing forests or parks by foot was indicated by 53.0% of the participants. Interestingly, variations exist among countries regarding the types of forests visited. Almost half of the countries predominantly favor 'Parks in cities or towns', while other countries show a relatively even distribution between 'Forests in the countryside' and 'Forests in or nearby cities or towns' (10-50%). The study further highlights that the intrinsic

motivations for visiting urban forests in Europe, including the enjoyment of climate and beauty, seeking respite from daily routines, and the desire to learn about nature, are predominant. Extrinsic motivations, on the other hand, revolve around spending quality time with children and engaging in physical exercise. Notably, South-West and South-East European countries place higher importance on accessibility facilities in urban forests, including parking spaces, public transport, and secure bike stalls. In terms of intrinsic reasons for green space visits, such as physical exercise, escape from everyday life, climate enjoyment, and appreciation of nature, these regions also demonstrate stronger inclinations.

This research illuminates the diverse patterns of urban forest use across Europe. The findings underline the importance of considering socio-demographic factors and regional differences when planning and managing urban forests to cater to the needs and expectations of diverse populations.

Green balconies: enhancing urban spaces through environmental contribution

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Carine Ghassibe[1]
Serge Sarkis[2], Dany Abou Jaoude[2], Ibrahim Issa[3], Salma Talhouk[1]
[1] Department of Landscape Design and Ecosystem Management, American University of Beirut, Beirut, Lebanon
[2] Department of Mechanical Engineering, American University of Beirut, Beirut, Lebanon
[3] Department of Electrical and Computer Engineering, American University of Beirut, Beirut, Lebanon

Abstract: Urban greening is the planning and management of all urban vegetation to create or add value to the local community in an urban area. Hence, urban greening is increasingly being considered as a possible sustainable urban design and development alternative. In urban greening studies, the contribution of vegetation to urban spaces is only studied at the level of streets, green roofs and green walls. There is no consideration for urban residential transitional spaces such as balconies and terraces, which represent the third dimension of space greening. With an increasing urbanization rate, residents of countries with mild climates have planted their balconies. In this context, our investigation aims to examine the impact of balcony plants by quantifying their small tree canopy equivalent. In order to achieve this objective, structure from motion was applied to ornamental plants. Multiple images will be collected around the plant (360°). Commercial photogrammetry software such as Agisoft Metashape is used to obtain the 3D shape from the images. This shape will be divided into a voxel grid. From the resulting grid, and after applying semantic segmentation, the volume of the canopy can be approximated by calculating the fraction of voxels that contain leaves. The resulting canopy volume will be used to calculate the small tree canopy equivalent of each recorded species. Results of this study provide quantitative estimates that shed light on the potential role that residents of urban dense neighborhoods can play in contributing to urban greening. However, due to the ongoing progress in this field of study, the results of this research will not be immediately accessible. Therefore, a presentation regarding the validation methodology will be provided.

Impact of neighborhood-scale urban site factors and soil conditions on street tree health

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Susanna Keriö[1]
Faisal Qaseem[1], Leigh Whittinghill[1], Nubia Zuverza-Mena[2]
[1] Department of Environmental Science and Forestry, The Connecticut Agricultural Experiment Station
[2] Department of Analytical Chemistry, The Connecticut Agricultural Experiment Station

Abstract: Street trees are a critical part of the green infrastructure that provides valuable ecological and economical benefits to cities. Urban conditions pose several challenges for healthy tree growth, and climate change along with urban heat island effects will further amplify urban tree stress. However, the impact of micro-scale site conditions on street tree condition has not been sufficiently explored. Quantifying how site conditions impact urban tree health and growth could support developing more targeted management plans to improve street tree health. We present findings from a neighborhood-scale tree survey where we rated tree condition for 118 Norway, red and sugar maples (diameter 36-67 cm) growing as street trees or in park-like settings. The tree survey was adapted based on the International Society of Arborists (ISA) Tree Risk Assessment Manual and the ISA Basic Tree Assessment Form. Diameter, tree height, living crown height, canopy size, branch mortality, root damages, branch dieback, and signs of leaf senescence were recorded. Soil metrics including soil temperature, pH, conductivity, and compaction were measured. Mineral profiles were analyzed with inductively coupled plasma optical emission spectroscopy. Wood samples were collected from a subset of dormant trees for nonstructural carbohydrate analyses with enzymatic digestion and spectroscopy. We will discuss the impact of impermeable surface, soil conditions, soil mineral profiles, and urban heat island effects on street tree health. We will also discuss the potential of using non-structural carbohydrate levels as a proxy for street tree health. The results of this project may have applications for early detection of stressed street trees, targeted management, and in predicting the impacts of urban heat island effects on tree growth and the carbon budget of urban trees.

Increasing social-ecological resilience of urban and peri-urban forests through inter and transdisciplinary research

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Iulia Almeida[1]
Angela Beckmann-Wübbelt[1], Annika Fricke[1], Axel Albrecht[2], Andreas Matzarakis[3], Mareike Hirsch[4], Marcel Gangwisch[3], Mario Köhler[5], **Somidh Saha**[1]

[3] Research Centre Human Biometeorology, German Weather Service, Freiburg, Germany
[4] Chair of Forest Growth and Dendroecology, University of Freiburg, Freiburg, Germany
[5] Horticulture Department (Gartenbauamt) of the City of Karlsruhe, Karlsruhe, Germany

Abstract: The concurrent increase in the supply of ecosystem services and resilience in urban and peri-urban forests (UPF) warrants involving multiple stakeholders and disciplines. Therefore, we applied holistic inter-and transdisciplinary research approaches in the "GreenLung" ("GrüneLunge") project (2018-2023, https://www.projekt-gruenelunge.de/) in Karlsruhe region, southwest Germany. We executed an inventory and health survey by installing 201 random circular plots (404 m² each) in the study area. Further, we sampled City Tree Register's (CTR) trees for dendroecological, tree-ring stable-isotopes (C, O, and N stable isotopes), biodiversity, and meteorological analyses. During heatwave conditions, mobile measurements allowed us to study the thermal influence of land use, urban morphology, tree species density, and diversity to atmospheric conditions. A participatory map-based questionnaire survey with the respondents from the two cities was carried out to identify the perceptions of cultural ecosystem services, especially during the COVID-19 pandemic. During a series of excursions, training, expert meetings, and workshops in real-world labs with citizens and stakeholders, we identified possible solutions for improving the current management of UPF. Our study revealed a significant trade-off between supporting and regulating ecosystem services. For example, exotic oak species (*Quercus rubra*), for example, had less microhabitat diversity, abundance, and bat activities than native oaks (*Quercus robur*) but had a higher supply of regulating ecosystem services than native oaks. An increase in drought tolerance at the species level reduced the magnitude of dieback in our study area. Dendroecological and stable isotope analyses revealed high plasticity in climate-growth relationships between species. *Quercus robur* and *Platanus* hybrids had the highest tolerance to periodic droughts. The relative air temperature (2m from the surface) cooled with increasing vegetation cover during night and morning during heatwaves. The participatory map-based questionnaire survey revealed a high public appreciation of cultural ecosystem services. During the pandemic, citizens without access to private gardens and balconies visited public green spaces more often to reduce psychological stress. Our project was a unique attempt to combine inter- and transdisciplinary research to develop solutions for climate change adaptation and mitigation in urban forests.

Plant diversity mitigates the effects of urbanization on soil organic carbon stocks

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Yihua Xiao[1]
Hongbing Yang[2], Zhigao Fu[1]
[1] Research Institute of Tropical Forestry, Chinese Academy of Forestry
[2] Ecology and nature conservation institute,Chinese Academy of Forestry

Abstract: Urbanization is increasing worldwide, which can have a major impact on ecosystem functions such as soil carbon (C) sequestration. Although the effects of urbanization on forest ecosystems have been addressed, little is available to quantify the effects of urbanization on soil C sequestration, C stocks, and the underlying microbial mechanisms. To investigate the relationship between urbanization and soil organic carbon (SOC) sequestration-related properties, we quantified the spatial patterns of plant diversity along the urban-suburban-rural gradient and measured the relationship between plant diversity and the effect of urbanization on SOC stocks (SOCs). Plant diversity was significantly and positively correlated with nutrient concentrations and SOCs, while it was weakly correlated with the degree of urbanization, and the correlation between plant diversity and urbanization varied between forest types. Urbanization regulates forest SOCs by affecting temperature, soil C: P ratios, and the relative abundance of key enzymes for C sequestration and degradation, while plant diversity mitigates the negative effects of urbanization on SOCs by affecting soil C: P ratios and microorganisms. Urbanization significantly reduced surface SOCs but had no significant effect on substratum SOCs. Effects of plant diversity were greater than those of urbanization on SOCs. Results imply that plant diversity is influenced by urbanization but can mitigate the negative effects on soil C sequestration in the context of global warming, which provides a sound theoretical basis for effectively improving forest quality and ecological functions.

Preserving and improving the integrity of urban forests: Insights from Shai-Hills Forest Reserve

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Fatima Eshun[1]
[1] University of Environment and Sustainable Development

Abstract: Forests in urban areas are threatened as a result of increased population growth and the pressure on forest resources. Shai-Hills is one of the three forest reserves in the Greater Accra region of Ghana and faces a series of threats from surrounding communities. Preserving and improving the quality of urban forests is critical for reducing climate change, enhancing urban quality, and progressing the sustainable development agenda. However, knowledge of urban forest health and changes within land classes urban is inadequate. This study investigates land use and land cover (LULC) changes within the Shai-Hills Forest Reserve using images from 2002, 2012, and 2022. The Normalized Difference Vegetation Index (NDVI) of these images was analyzed to provide information for policymakers to devise strategies for improving the integrity of urban forests. The results indicate the presence of a primary forest in the 2002 image which was not present in the 2012 and 2022 images. From 2002 to 2012, the land cover change showed that 67% of the secondary forest changed to grassland. 2012 to 2022 LULC showed that 19% of secondary forests remained as secondary forests and 0.007% changed to grassland. The Kappa coefficient for 2002, 2012 and 2022 classified images are 0.81, 0.81, and 0.85 respectively. The NDVI of the 2022 image ranges between 0.05 to 0.4. This suggests the need to intensify forest restoration measures to improve the quality of the forest.

Re-visiting the concept of urban forests' ecosystem services in the cultural context of West African cities: A participatory study from Kumasi, Ghana

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Angela Beckmann-Wübbelt[1]

[4] Institute of Geographical Sciences, Freie Universittät Berlin (FU-Berlin), Malteserstraße 74-100, 12249 Berlin, Germany

Abstract: Numerous studies on ecosystem services of the urban forest in Europe and the US found that cultural ecosystem services are perceived as more important than provisioning services. The local population in Europe generally rates ecosystem disservices as less important. However, we hypothesize that in the context of West African tropical and sub-tropical forests, patterns may be found that contradict the Western understanding of ecosystem services fundamentally. Therefore, it is crucial to understand and adapt the concept of ecosystem services to the local context. Doing so may serve as an efficient framework to support the sustainable management of the urban forest in West African cities in the future.

With more than 3 million inhabitants in the Kumasi metropolitan region, it is one of the largest cities in the country and, like many cities in sub-Saharan Africa, is characterized by rapid growth and high population density. As late as the 1960s, the city was considered the "Garden-city of West Africa". However, especially since 2009, much of the green space in the city has been lost, and remaining fragments of urban forests are under pressure from increasing urbanization and extreme weather events.

To increase the knowledge base on urban forests' ecosystem services in West African cities and to understand the population's use, access, and perception of the urban forest, we conducted in-depth group discussions and participatory mapping exercises. The study included each three groups - male, female, and youth - in three different communities in Kumasi, including the gradients from diverse socio-economic backgrounds and from highly urbanized to peri-urban areas. This approach creates an in-depth understanding of the historically grown human-nature relationship in tropical urban areas and how global and environmental changes influence it. It allows an analysis on the place attachment, cultural identity and negative implications of urban trees and the local population's expectations regarding urban forests. This will have significant implications for managing future urban forests to increase social-ecological resilience.

Smart Canopies: Optimizing Tree Layouts for Enhanced Thermal Comfort -- An Edinburgh Case Study

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Tianze Luo[1]
Mingze Chen[2]
[1] Edinburgh School of Architecture & Landscape Architecture, University of Edinburgh, United Kingdom
[2] Faculty of Forestry, Department of Forest and Resources Management, University of British Columbia, Canada

Abstract: Urban forestry plays an important role in improving thermal comfort, mainly due to their layout to mitigate temperature and improve the microclimate. Current urban forestry articles focus on simulation of microclimate or land practices. However, there are few researches mention about upgrading the existing landscape especially canopy structure to realize a better outdoor thermal comfort (OTC). Therefore, how to enhance the design and layout after simulation, particularly improving urban forestry layout will be a bright spot in the future.

In this study, an open green space was selected to test the mean radiation temperature (MRT). Some of common tree species in UK cities were selected to propose in the site for landscape improvement. The prediction used 3D-LiDAR and point clouds to construct urban model, applying a deep-learning algorithm to improve the accuracy of existing tree location in the site. After that, the discrete anisotropic radiative transfer (DART) was used to calculate MRT of above-mentioned model. On the other hand, in order to realize the tree layout diversity, genetic algorithm (GA) was utilized to simulate different kinds of tree planting. 10 typical layouts were selected into MRT calculation. Then through comparison of the fore-and-aft temperature changes, a better tree layout was chosen.

The results confirm the potential of urban tree to reduce the open space temperature. Moreover, the abundant canopy structure and the more numbers of tree can significantly enhance outdoor thermal comfort in the city open green space.

The method shows a high accuracy of site modeling, especially the simulation of urban forestry. Because manually producing dense annotations of LiDAR 3D point clouds of vegetation is a laborious task, thus using deep-learning method (weakly supervised learning) for realistic outputs. While, the simultaneously providing visual and interpretable predictions of urban tree layout. The using of GA provides sufficient layout outcomes, which reduces the risk of falling into locally optimal solutions.

The Urban Tree Observatory: monitoring stress and resilience of urban trees

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Eleanor Absalom[1]
Jill Edmondson[1], Holly Croft[1]
[1] University of Sheffield

Abstract: Urban trees provide a range of important ecosystem services, including carbon sequestration, evaporative cooling and flood mitigation. As urban populations increase, growing and maintaining urban forest is crucial to create sustainable places to live. However, less is known about how urban environments impact the health and function of trees themselves, with urban settings presenting several challenges to tree health and function, as well as some potential benefits. As climate change threatens to exacerbate already stressful urban conditions, for people and trees, a greater understanding of how urban trees respond to urban conditions is needed.

This study utilises a network of over 60 Internet-of-Things tree sensors installed on four common UK tree species *(Tilia x europaea, Betula pendula, Acer pseudoplatanus, Quercus robur)* along an urban intensity gradient in Sheffield, UK. The tree sensors allowed near real-time, temporally-continuous measurements of sap flow, growth rate and canopy structure, every 60 minutes over a 3-year time period; capturing diurnal, weekly and seasonal and inter-annual variations in tree health and function. Additional manually-collected data included leaf chlorophyll content, leaf area index and leaf C:N, approximately every 10 days.

Preliminary findings show that trees in more urbanised areas were generally not water limited, but were less resilient in the face of extreme heat and drought events, taking longer to recover afterwards. However, the extent to which trees were impacted was species dependent, with *Acer pseudoplatanus* affected more than *Tilia x europaea*. Different species also exhibited different levels of ecosystem service provision, with, for example, slower growth rates in *Betula pendula*. Our findings also highlight the particular need to consider ecosystem service trade-offs in tree disease management, with *Tilia x europaea* trees at early stages of *Phytophthora spp* infection maintaining similar levels of ecosystem function as healthy trees of the same species. Improving our understanding of how different tree species respond to changing urban conditions is critical to guide planting and management strategies for healthier urban forests and more sustainable cities.

Translating forest ecophysiology to urban trees; introducing the Urban Trees Ecophysiology Network (UTEN)

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

[13] University of the Witwatersrand, Johannesburg, South Africa

Abstract: As urbanization continues to increase, the majority of the world's population resides in urban areas that are exposed to a range of environmental stressors. As cities experience temperatures up to 10°C higher than nearby rural areas due to energy consumption and urban infrastructure, urgent measures are required to mitigate and adapt to these stressful conditions, particularly in the face of climate change and projected urban population growth.
Increasing tree canopy cover has emerged as a powerful tool to enhance the quality of urban life. Trees offer numerous benefits such as reducing energy consumption, mitigating air pollution, and improving overall well-being. Through shading and transpiration, trees can effectively lower local temperatures and the heat index, and increase human thermal comfort. However, urban trees face multiple abiotic and biotic stressors, further intensified by climate change, risking their functionality, productivity, and survival and reducing their cooling potential.
Understanding the complex relationship between urban environments and the ecophysiology of trees is crucial for addressing climate change, promoting urban forest health, and making informed decisions.
In response to all that, we have established the Urban Tree Ecophysiology Network (UTEN), a global collaboration platform involving multiple researchers around the world, stakeholders, and municipal governments.
UTEN aims to investigate two fundamental questions: how the urban environment affects tree functioning and health, and how trees modify the microclimate of cities.
Through a comprehensive campaign-based approach, we continuously measure trees' transpiration, growth, and diameter changes, as well as the surrounding temperature and relative humidity using IoT technology. Additionally, we employ seasonal physiological measurements to assess tree health

and functionality.
These shared and aggregated data, enable researchers to address common questions related to tree health and stress in the face of a changing climate. Additionally, network nodes can utilize the accumulated knowledge to explore site-specific inquiries tailored to their own urban realities.
By fostering international collaboration and data sharing, UTEN aims to maximize the ecosystem services provided by urban trees. This global network, currently comprising 10 cities, endeavors to enhance our understanding of the intricate interplay between trees and the urban environment.

Understanding the cooling mechanisms of trees in contrasting climatic and growth conditions

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

[3] Institute of Soil, Water and Environmental Sciences, ARO Volcani Center, Rishon LeZion 7505101, Israel

Abstract: Urban forests have emerged as one of the most feasible strategies for promoting adaptive capacities of cities to climate change by alleviating urban heat island and thus heat stress for humans. However, a detailed understanding of the two cooling mechanisms, namely shading and transpiration from different tree species under different climatic conditions is still lacking. A study in Munich, Germany where we compared two ecologically contrasting tree species: *Tilia cordata* and *Robinia pseudoacacia* under contrasting meteorological and edaphic conditions showed that shading is the prominent mechanism of cooling, in particular, when the atmospheric aridity is high. In temperate or oceanic climate with soil moisture availability, comparatively light shaded tree canopies might induce higher grass evapotranspiration. Therefore, we propose dense tree canopies over built environment but over grass surfaces, light shaded tree canopies could be preferred. To further investigate the cooling mechanism over contrasting climatic conditions, we studied local tree species at ‘tree lab’ sites in Munich, Germany (temperate climate) and in Beer Sheva, Israel (hot arid climate), within various settings (park, street, square) with natural and sealed surface conditions. The comparison of transpiration cooling was based on linear relationship of midday canopy resistance to atmospheric vapor pressure deficit (VPD), where the slope is proportional to tree hydraulic conductance and midday stem water potential. Even though irrigated, trees in Beer Sheva showed higher hydraulic resistance that limits transpirational cooling (regression slopes of 0.25–0.44 in Beer Sheva vs. 0.10–0.18 in Munich). Analysing the proportion of latent heat to total available energy, we found transpiration cooling was about 40% less significant at noon hours in summer in Beer Sheva than in Munich. In addition, the linear relationship of midday canopy resistance to VPD showed promise to be used as an operative tool for comparing transpiration cooling between local trees in different climatic regions. These results suggest that with anticipated higher atmospheric aridity, shading will become even more important, thereby, denser tree canopies would be of higher importance. Whereas, irrigation maybe in combination with the grey water recycling would ensure optimization of shade and transpiration cooling benefit in temperate and oceanic climate in future.

Urban Tree Guard- Safeguarding European urban trees and forests through improved biosecurity

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Johanna Witzel[1]
Dinka Matosevic[2], Mariella Marzano[3], Anna Maria Vettraino[4]

[2] Department for Forest Protection, Croatian Forest Research Institute, Croatia
[3] Forest Research, Northern Research Station, United Kingdom
[4] Department for Innovation in Biological Systems, Agriculture and Food (DIBAF), University of Tuscia, Viterbo, Italy

Abstract: Green infrastructure, including urban forests, has been proposed by European Commission as a strategy to support climate adaptation capacity and sustainable development in the urban areas where over 70% of the EU's population live. Alarmingly, the green infrastructure and especially its characteristic elements, trees, are increasingly threatened by alien pests (insects and pathogens) that are introduced via trade and transport. In a new environment, these pests may become invasive, causing devastating environmental and economic losses, and threatening also unique cultural values such as those linked to veteran trees. The current biosecurity system fails to capture alien pests that often also benefit from the altered climate. New tools and better integration of different knowledge pools are urgently needed to support better biosecurity in urban settings. COST action (an interdisciplinary research network that brings researchers and innovators together to investigate a specific topic (funded by the EU) brings together a pan-European and international network of scientists and stakeholders to meet this challenge. The network 1) Collects, shares and harmonizes scientific and stakeholder knowledge, 2) Accelerates the development of innovative technological tools and solutions for biosecurity purposes, 3) Informs policy and supports the implementation of the EU plant health regime while providing science-based recommendations for decision-makers, especially at operational levels, 4) Fosters an inclusive and open research environment, with explicit support to young professionals, and 5) Increases European competitiveness in the field of biosecurity, improving also the quality of everyday life for people, especially urban dwellers, in Europe and beyond. A co-created Wiki database, teaching tools for education in urban forest health, and a decision support tool will ensure the long-term impacts of the Action.

Urban tree insect pests and pathogens: awareness, risk perceptions and responses

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Susanne Raum[1]
Stephan Pauleit[1], Monika Egerer[2]
[1] Technical University of Munich, Chair of Strategic Landscape Planning and Management
[2] Technical University of Munich, Chair of Urban Productive Ecosystems

Abstract: Tree insect pests and pathogens are a growing threat to the urban environment and human wellbeing. There is, however, little data on the knowledge and risk perceptions of different stakeholders and on how these might respond to this growing threat. We undertook a survey of a wide range of stakeholder groups associated with urban trees in Germany and assessed their level of awareness and the tree health measures they are taking. We present the results of this survey and what implications they have for policy and practice. The findings will help increase urban tree health in an increasingly challenging environment.

Urban trees for a cooler future - Growth patterns of urban trees in a changing climate

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Valentina Vitali[1, 2, 3]

[4] Institut des Sciences de la Foret Tempérée, Université du Québec en Outaouais. Ripon, Canada

Abstract: Urban trees provide essential environmental services and are indispensable for regulating a city's climate, whilst growing in stressful conditions with low water and space availability. However, little is known about urban trees' capability to cope with climate change compared to their forest counterparts. Due to the heat island effect, Montreal has already experienced 1.4°C higher temperatures, creating increasingly challenging conditions for urban trees. To minimize the efforts needed to ensure their health and performance and the provisioning of environmental services it will be of utmost importance to plant trees resilient to new climatic conditions. Through dendrochronological analyses, we have compared the growth rates of four common urban tree species Norway maple (*Acer platanoides*), silver maple (*Acer saccharinum*), lime (*Tilia cordata*), common hackberry (*Celtis occidentalis*). Trees were sampled in the metropolitan area of Montreal across an urban gradient, from trees growing in pavement pits to lawns in residential areas, and in parks. Contrary to expectations, in the last decades, the least accommodating conditions of the urban centre have been showing an increase in growth rates. Both *Acer* species growing in pavement pits have shown a significant increase in growth rates, reaching the ones achieved by park trees. Climate correlations indicate a strong positive effect of autumn temperature, indicating an increase in the vegetative period in this area and therefore an increase in growth. Eastern Canada has recorded an increase in temperature as well as precipitation, explaining the consistent increase in growth in the last decades. Dendrochronological results proved to be a necessary assessment to understand the complex system of urban forestry.

Which trees are suitable in urban environments at risk of flooding in northern Europe?

T4.23 Preserving and improving the integrity and functioning of urban forests in the context of global change

Astrid Fridell[1]
Henrik Sjöman[2, 3, 4], Johan Uddling[1], Annemieke Gärdenäs[1], Jenny Klingberg[3, 4], Lasse Tarvainen[1]
[1] University of Gothenburg, Biological and Environmental Sciences, P.O. Box 461, SE-40530, Gothenburg, Sweden

[3] Gothenburg Botanical Garden, Carl Skottsbergs gata 22A, SE-41319 Gothenburg, Sweden
[4] Gothenburg Global Biodiversity Centre, Box 461, SE-41319 Gothenburg, Sweden

Abstract: Urban trees provide numerous ecosystem services of which many are dependent on large and old trees. It is therefore important that we plant trees that can tolerate the harsh urban environments as well as the changing climate of the future. In Northern Europe, the frequency and intensity of heavy precipitation events are expected to increase in the future, increasing the risk of flooding. Urban settings, such as dense built-up areas, compacted soils, and non-permeable surfaces, enhance the risk of flooding, making urban trees especially vulnerable to heavy precipitation. Hence, the demand for water management solutions, such as rain gardens with trees tolerant to flooding, will increase. Currently, the species diversity of urban trees in northern European cities is low, further increasing the vulnerability of urban forests to both biotic and abiotic stressors. This study investigates the flooding tolerance in a large number of trees with varying physiological and morphological traits to assess their suitability for planting in northern European cities. Previous studies have been focused on one or two species, by increasing the number of species we can explore more tree traits and connect those traits to stress tolerance, further expanding the number of tree species for city planners to choose from. This study includes species that are both common as well as rare in northern European cities today. 16 species will be exposed to three treatments: control, short flooding (3 days of flooding), and long flooding (8 days of flooding) in August 2023. After the flooding period, the trees will have a recovery period of two weeks. The tree responses to flooding and their among-species variation will be investigated by ecophysiological measurements including gas exchange, morphological measurements including the formation of adventitious roots and leaf loss, and measurements of the meteorological factors and soil conditions. The results from this study can be used as a guide for stakeholders when planting new trees in areas that are at risk for flooding, thereby increasing the chances for urban trees to grow large and old.

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Application of the typical enterprise approach in forestry: a pilot study to collect economic key figures in small-scale private forest enterprises

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Lydia Rosenkranz[1]
Mario Peters[1], Björn Seintsch[1], Matthias Dieter[1]
[1] Thuenen-Institute of Forestry

Abstract: In the EU, forestry as a supplier of wood and other ecosystem services, is an important source of employment and income and has a high ecological, social and cultural significance. About 50% of the European forest area is managed by private forest owners. In this context, small-scale private forest owners with less than 20 ha of forest account for about 33% of the total privately owned forest area (Hirsch et al. 2010). As a result of the need to adapt forest management to climate change as well as increasing societal demands, European (small-scale) private forests are facing major challenges.

For evidence-based policy decisions, knowledge about the economic situation of small-scale private forest enterprises (SSPFE) is of high importance. So far, however, there are no or only few operational key figures on forest management in SSPFE in many EU Member States. Furthermore, the few existing key figures are hardly internationally comparable. Against this background, the collection and comparative analysis of economic indicators of forestry production in SSPFE is of great importance. For this purpose, an EU-wide harmonized approach for data collection in SSPFE is necessary, but does not exist yet.

Therefore, in a pilot-study within the joint research project "Valorising small scale forestry for a bio-based economy (ValoFor)" comparable key figures on forest management in SSPFE in Germany, Finland, Austria, Sweden and Slovenia were collected, using a modified "typical enterprise approach". For each country, a typical SSPFE with typical management measures and economic indicators was created through in-depth literature analysis and expert interviews. On this basis, comparable key figures for forest management in the five partner countries were derived for the first time. Exemplary, it was found that in the reference year 2021, the highest timber revenues in typical SSPFE were achieved in Austria (66 €/m³). This was followed by Germany with 57 €/m³. For the typical enterprises in Finland, Sweden and Slovenia, timber revenues of 41 - 42 €/m³ were calculated.

The "typical forest enterprise" approach, which can be realized with comparatively little effort, can serve as a valuable basis for further forest economic impact assessments for EU policy processes.

Climate Credits: a new tool to incentivize the provision of forest ecosystem services in small private forests.

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Teresa Baiges Zapater[1]
Teresa Cervera Zaragoza[1], Iñaki Gili Jauregui[2]
[1] Forest Ownership Centre of Catalonia (NE Spain) - Catalan Ministry of Climate Action
[2] Catalan Office of Climate Change - Catalan Ministry of Climate Action

Abstract: Climate change and biodiversity loss are two of the planet biggest challenges to which forest-based solutions can make a significant contribution. However, the lack of context-specific integrative solutions along with the lack of incentives and governance problems are hindering their adoption in regions with a high share of small private forest owners. Based on this, the LIFE CLIMARK project consortium (2017-2022), proposed an innovative approach to incentivize the provision of ecosystem services (ES) from forest management in Catalonia (NE Spain): the creation of a local voluntary market of "climate credits". The aim was to design a tool capable of matching the willingness of companies to invest in nature-based solutions (NbS) in Europe, with the need to find new ways to finance improved forest management (IFM) in privately owned forests. Inspired by current carbon markets, the Climate Credit market aims to overcome their limitations by addressing the joint provision of different ecosystem services in an integrated manner and through high integrity and quality projects. Three characteristics make the market of climate credits unique: i) the concept "*Climate* Credit" itself, which integrates into a single unit the benefits of IFM on 3 ES: carbon balance (including fire prevention), blue water availability and biodiversity conservation; ii) the inclusion of a broad set of IFM practices, beyond tree planting, which are context-adapted; and iii) a bottom-up participatory landscape approach to overcome fragmentation, tackle trade-offs between different ES, make a bigger impact and strengthen social resilience. Since 2022, the market is being tested in eight pilot sites and it is expected to be formally created in Catalonia during 2023. The results of these tests show the high existing demand by both parties, sellers (forest owners) and buyers (companies and local institutions) and highlight the role that these PES-type schemes can play in the policy mix, beyond the economic return, by granting the forest owner a new role as provider of ecosystem services demanded by society. The pilot tests have also allowed the identification of levers and bottlenecks for the broad replication of the market, as well as future lines of improvement.

Coordinating landowners for wildfire prevention: socio-economic lessons learned from incentive schemes

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Elena Górriz-Mifsud[1]
Marc Rovellada[1]
[1] Forest Sciences and Technology Center of Catalonia (CTFC)

Abstract: Wildfires do not understand from property boundaries; thus, their effective risk reduction (a regulating ecosystem service) needs to take into account spatial scales beyond the individual landowner. Yet, incentive mechanisms to reduce fuel load are typically designed without zoning nor with minimum intervention areas.

Our study aims at drawing lessons from the few economic incentive mechanisms in Catalonia (Spain) that foster collaboration among adjacent landowners to reach intervention areas critical for effective wildfire risk reduction effects. The analysis grounds on document review, complemented with in-depth interviews during 2023 with incentive managers and participating landowners. We followed a deductive-inductive approach, employing pre-identified variables as initial content analysis codes, complemented with emerging variables. Studied factors span from (i) social capital characteristics (ex-ante and post) considering interpersonal trust and, local networks of information or collaboration, (ii) payment magnitude, (iii) transaction costs, (iv) perceived direct and indirect benefits, (v) degree of innovativeness, (vi) wildfire risk perception, and (vii) duration of the commitment.

Preliminary results indicate that the pre-existence of social capital (previous networks) facilitate the decision to participate in collaborative commitments towards fuel load reduction. The risk aversion (fear to fire-related losses) prevails over other potential profit-oriented variables yet modulated by fire probability perception. The presence of a facilitating agent emerges as key factor to catalyse different interests and profiles, to bridge the administration-technical-practitioner divide, while it implies transaction costs. These factors seem to allow the necessary agreements among participating forest owners. Being the initiatives rather young, further implementation is needed to ascertain the potential consolidation of these social innovations backing coordinated wildfire risk management. These findings help designing future incentive mechanisms aiming at landscape-scale coordination.

Forest Certification as a Tool to Support Forest Ecosystem Services

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Antonio Brunori[1]
Hubert Palus[2]
[1] PEFC Italy
[2] Technical University in Zvolen

Abstract: Sustainable Forest Management (SFM) certification provides a way to demonstrate the positive impacts of SFM on ecosystem services. Ecosystem services provide society with a wide range of benefits, from carbon sequestration to soil erosion control, from clean water and biodiversity protection to the production of wood and non-wood products. We evaluate forest owners' and managers' perceptions of forest certification as a tool to support SFM and forest ecosystem services in several Countries among PEFC endorsed systems. Among the important factors influencing the level of understanding of forest certification and its role in ensuring forest ecosystem services is the size of the managed forest area and the implemented certification scheme. The results of this study indicate that forest certification is positively perceived as a supporting tool for ecosystem services, and certified forest owners are sufficiently aware of the objectives of SFM. In general, forest certification is mainly perceived as a supporting tool for the ecosystem services related to the control of erosion, soil formation, and natural composition, as well as the function of species and ecosystem diversity, followed by the provision of aesthetic, scientific, and educational values.

From Profit to Added Value: A Portfolio Selection Model for Optimizing Ecosystem Services of Private Forests

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Victoria Yavorskaya[1]
[1] Institute of Environmental Systems Sciences, University of Graz

Abstract: Originating in financial economics, the portfolio approach has been widely applied in environmental decision-making in various fields of study, including forestry. Most of the studies pursued ecosystem service (ES) profit optimization, where return and risk are often measured via financial return and price, respectively. Simultaneously, there is evidence that private forest owners, who own approximately 60% of European forests, do not orient their management choices primarily based on the rationale of profit, with some of them lacking entrepreneurial thinking.

Following the objective to develop a portfolio selection model that supports private forest owners in optimizing the forest ecosystem services (FES), this study accounts for the potential nonprofit orientation of the landowners and includes both market and non-market values of FES. Returns from FES are measured as the added value for the forest owner, whereas risks are interpreted as the effort required to change management practices.

The scope of the study is limited to the Alpine forests due to their biophysical similarity. In addition to collecting data on biophysical indicators of the study area and retrieving real market values of FES (e.g., timber, recreation), private forest owners are surveyed to normatively assess the added values of FES and changes in management practices. The survey is framed according to the analytic hierarchy process methodology. Collected data are aggregated into a portfolio selection model to estimate the most optimal FES portfolios.

Measuring returns from FES through a combination of market prices and non-market values will demonstrate how much change is acceptable for a forest owner to maximize the added value of the forest. We expect that forest owners could be further categorized as innovative (i.e., ready for a high-effort change despite a low added value) and conservative (i.e., prefer a high added value for a low effort). The final results will be presented at the conference.

A normative perspective on the portfolio selection model will allow for developing a tool that communicates potential solutions for the FES provision and required management changes, while simultaneously aligning to the nonprofit orientation of private forest owners.

FSC's Ecosystem Services as a solution for small forest owners; challenges and perspectives from Portugal and Sweden

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Anne Van Der Bruggen[1, 2, 3]
[1] Jan Ihre – Marketing manager FSC Sweden, FSC Ecosystem Services marketing and development
[2] Anne van der Bruggen – Forestry and Certification Coordinator FSC Sweden, FSC Ecosystem Services development
[3] Sofia Ferreira – FSC Portugal - Forest Department, Normative Development and Ecosystem Services

Abstract: In FSC certified forests, valuable ecosystem services are protected. FSC's National Forest Stewardship standards require forest owners to preserve or restore ecosystem services and to preserve forests with high conservation values. In 2018, FSC introduced a procedure to verify the effects and measure results in FSC certified forests. In this way, forest owners can demonstrate and communicate about the positive impact of their responsible forest management on ecosystem services. Impacts can be verified for biodiversity, carbon, watershed services, soil conservation and recreation services. Verified positive impacts can be used to access payments for ecosystem services by businesses that want to communicate their dedication and contribution to sustainability.

For smallholders, that often has a more diversified aim with their ownership than companies. FSC Ecosystem Services can incentivize smallholders to get certified and verified positive impacts can be used to access payments for ecosystem services that are not recognized by traditional markets. For areas that are focused on conservation purposes this can make a huge difference, and act as a way to promote responsible forest management in such areas.

Portugal and Sweden are two countries from different parts of Europe where FSC ecosystem services has been introduced for smallholders. One of challenges in introducing the Ecosystem Services procedure in these countries are in providing simple and clear methodologies for measuring some of the ecosystem services. Another challenge has been to find the right match between smallholders and businesses willing to finance or sponsor the Ecosystem Services claims. Also the principle of additionality in the Swedish context, where the landscape is already very forested, is a challenge that requires careful communication and good methodologies.

In Portugal it has been challenging to demonstrate the value of all the ecosystem services that are possible to verify according to FSC's Ecosystem Services Procedure, in a market that is very "carbon oriented". It is crucial for smallholders to have access to methodologies that demonstrate the complete value of the forest they manage and to be able to communicate it.

Future development of ecosystem services in European forests, the role of small-scale forest owners and how to engage them

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

[5] Slovenian Forestry Institute

Abstract: Forests are one of the most important ecosystems to counteract today's challenges such as accelerated climate change or the biodiversity crisis. They provide a broad range of ecosystem services (e.g. carbon stock, wood and non-wood products, biomass for energy production, biodiversity), yet it is often unclear to which extent these ecosystem services might encounter trade-offs in multifunctional forest management. As around 60% of Europe's private forests are managed by small-scale forest owners, the impact of their decisions on future provision of ecosystem services should not be underestimated.

We used national forest inventory data from five European countries (Finland, Sweden, Germany, Austria, Slovenia) to simulate the future development of forests until 2100 under different climate change (no climate change, RCP4.5, RCP8.5) and management scenarios (no management, business as usual, low intensity, high intensity). The simulations allowed us to calculate future ecosystem services, to analyze potential synergies and trade-offs among them and to better understand the role of small-scale forest owners.

Overall, the simulated change (e.g. in growing stock or timber harvest) was driven more by the forest management scenarios than by the climate change scenarios. Further, we generally found limited synergies and trade-offs among different ecosystem services, e.g. carbon stocks did not correlate with forests' biodiversity indices. The great potential for/of small-scale forest owners was highlighted e.g. by the finding that their modeled timber harvest was above the overall average.

Our study shows the importance of engaging small-scale forest owners and the ability of adapted forest management to mitigate climate change-induced risks, without inevitably leading to conflicts of interest. To make our scientific results easily accessible to forest owners and to show them the significance of the choices they make today, we develop an online tool with 3D-visalisations of the different possible future forest developments in an ongoing project. By additionally providing information on different ecosystem services, potential risks as well as economic factors, our tool aims at supporting (small-scale) forest owners in their decisions, as their active participation in climate smart forestry is essential for securing the future of resilient and multifunctional forests.

Neutral taxation of the income from different forest ecosystem services and types of agreements in Finland

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Jussi Leppänen[1]
[1] Natural Resouces Institute Finland (Luke)

Abstract: In Finland, after the end of areal site-productivity taxation, the allocation problem related to progressive taxation caused by annual variations in timber sales income have been resolved by defining timber sales income as capital income taxed at a fixed tax rate and using the forest deduction procedure. The definition of income from timber sales as capital income has led to a situation where forest income is taxed in two separate sources of income, according to the Income Tax Act and the Agricultural Income Tax Act. The Income Tax Act has an exhaustive list of gross capital income from forests, which includes especially income from the sale of wood, but also public support for forestry, including environmental support that preserve the natural values of forests. Forestry incomes other than those listed in the Income Tax Act are taxed as agricultural income. The forest income received from the rental of the forest area is agricultural income, regardless of the content of the rental income. In agricultural income taxation, net income is divided into earnings and capital income based on the net assets of agriculture. The forest is excluded from agricultural capital, which leads to taxation of forest income as earned income. In addition, the forest deduction, based on the cost of acquisition of the forest and reducing the final tax rate, is set to be deducted only from the capital income of forestry. When the earned income of the forest owner is taxed at a progressive tax rate that increases in relation to income, and capital income is taxed at a fixed tax rate, the taxation of forest income that is taxed as agricultural income can become much greater compared to the final tax rate of forestry capital income. This leads to unneutral forest taxation and places forest owners' income from the sale of wood as trade agreements and compensation received as public support in a more favourable position from a tax point of view than the income and compensation received from private operators from other ecosystem services of forests and all income from rental agreements.

Non-timber forest products in French metropolitan forests: Assessment of an ecosystem service

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Aline Vaes Massagli[1]
[1] AgroParisTech

Abstract: Forest recreation allows a connection between forest owners and society and supplies goods and services that are responsible for human welfare. Several non-timber forest products (NTFPs) such as mushrooms, berries and chestnuts are collected during recreational activities in France. These NTFP also have cultural values associated with forests, called value for forest goods and services. A survey conducted by EFESE (2020) was used as the basis for statistical analysis. In addition, geographic information layers were used to identify the type of forest ownership around the respondents residence, and how these information are directly related to the collection of NTFPs. The results provided some indication in terms of forest visits that are positive and significantly correlated with French NTFPs collectors. From the econometric models, it was possible to analyze that pickers have a tendency to frequent private forests with the presence of deadwood more often. In addition, the travel cost method demonstrated that the willingness to pay is higher when visitors go to collect NTFPs in the forests. This information can help the forest owner to generate income from the recreational activities that occur on his property.

Payment for Environmental Services as an income alternative for small rural producers in Central Amazonia

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Paulo Cezar Gomes Pereira[1, 2]
Pedro José Steiner Neto[1], Vitor Afonso Hoeflich[1, 3]
[1] Federal University of Paraná, Postgraduate Program in Forestry Engineering, Brazil
[2] Federal Rural University of the Amazon, Campus Paragominas, Brazil
[3] Federal University of Paraná, Department of Rural Economy and Extension, Brazil

Abstract: Payment for Environmental Services (PES) has been considered an alternative tool for the maintenance of forests in the Amazon and their ecosystem services and for the remuneration of the providers. This work aimed to evaluate the potential for applying PES schemes in small rural properties with implemented forest management projects. The method consisted of a case study in the central Amazon, municipality of Rurópolis/PA. Secondary data were evaluated, available in the online platforms of the managing agency, corresponding to the period from 2007 to 2022. The eligibility criteria were: having the Rural Environmental Registry (CAR) and having the environmental license for the forest management activity. Included in the study were properties of 1ha to 300ha (up to 4 Fiscal Modules-MF). The remuneration value was US$ 81.22/ha/year, using the Floresta+ Conservation Project as reference. The results show that the municipality has 3,473 properties registered in the CAR, of which 96.7% are in areas up to 4 MF (up to 1 MF = 29%; >1 to 2 MF = 60.0%; >2 to 3 MF = 5.3%; >3 to 4MF = 2.4% and >4 MF = 3.4%). A total of 123 properties (3.5%) with environmental licenses for forest management activities for timber production were identified during the period evaluated. The average area per property with forest management in the municipality is 91.6ha (min. 42.08ha; max.168.76ha), which can remunerate the small producer on average US$ 7,439.49 per year (min. US$ 1,510.53; max. US$ 13,706.12). After executing the forest management, the small producer has this area immobilized for a period of 25 to 35 years, which corresponds to the cutting cycle established in the legislation, having during this time the cost of maintaining the area. The financial incentive in the form of PES would be a way to encourage the practice of forest management, which contributes to forest conservation and the legal production of wood. PES on small properties, adopting forest management as an eligibility criterion, has the potential to become an income alternative for small producers. The information can help the government, in partnership with farmers and the private sector, to develop PES schemes in the municipality.

Private forest owner's priorities and motives of the voluntary protection of biodiversity and forest ecosystems

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Diana Lukmine[1]
[1] Lithuanian Research Centre for Agriculture and Forestry

Abstract: New green transition policy in a context of climate change empowered the process of protected areas increase in Lithuania. Main goals of the forests protection issue are expanding and optimal shaping a network of Natura 2000 territories, and increasing the total protected areas in Lithuania. Private forests play the significant role on these goals achievement. There is a lack of knowledge about voluntary forest protection initiatives in private forests and nature conservation management practices in voluntary set-aside forests in Lithuania. The objective of this study is to analyse biodiversity and ecosystems voluntary protection priorities and motives of private forest owners in Lithuanian and to foresee possible financial promotion mechanisms for the transition from mandatory to voluntary protection. The Delphi method was used for gathering the views of experts. More than 25 experts from various target groups (foresters, forest management advisors, ecologists, representatives of governing institutions, private forest owners etc.) have been invited to participated in the survey. The survey results showed that private forest owners would disagree or partially disagree with the state regulatory or voluntary protection of biodiversity and ecosystem models without compensations. Two types of Protection Agreements would be most suitable in Lithuania: 1) Long-term (permanent) protection with retention of forest ownership and compensation of incurred economic losses and 2) Sale of forest land to the state. External motives (compensations), when the compensation amounts to 100-125 per cent from losses, are the most important for private forests owners in Lithuania. Experts also rated as the most important internal motives, which are related to a person's intention to realize his biodiversity and ecosystems conservation idea. High attention should be paid to the intensity of compensation rate when drawing up loss compensation schemes. Low-intensity loss compensation schemes should not be applied in Lithuania. The results of the expert's survey provided a scientifically proved basis for further voluntary protection of biodiversity and ecosystems model and compensation schemes development in Lithuania.

Provision of ecosystem services from private forest owners in southern Sweden

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Erika Olofsson[1]
Rikard Jakobsson[1]
[1] Linnaeus University, Department of Forestry and Wood Technology, Sweden

Abstract: In southern Sweden, private forest owners own about 80% of the productive forest land. Consequently, in this region, these owners significantly impact the provision of forest ecosystem services. We collected data through in-depth interviews with 23 private forest owners aiming to, from their perspectives, examine the potential to develop environmental and other values on private land and to examine existing barriers. The owners were 36-84 years old and owned 10-825 ha of productive forest. 26% of the owners were female. Collected data were analyzed with semantic content analysis resulting in themes. The study showed that there is a potential to provide ecosystem services on private land since 1) What matters most to forest owners in forest management and ownership was demonstrated in a diversity of factors, above all that relate to social and emotional dimensions, 2) Forest owners desired management included a range of management ideas that could bring a diversity of benefits and 3) Forest owners already carry out a variety of forestry measures that intentionally or unintentionally benefit environmental and other values. The forest owners also perceived that there are barriers in forestry primarily related to financial aspects, rules, lack of time and forest estate site conditions. Some barriers could be reduced by financial incentives and by designing policy instruments that encourage forest owners' initiatives.

Survey of Forest Owners: Attitudes towards Climate Change Mitigation and Adaptation

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Paula Horne[1]
Marjo Maidell[1], Olli-Pekka Ruuskanen[1]
[1] Pellervo Economic Research PTT

Abstract: Carbon sequestration is one of the most crucial ecosystem services provided by forests. Forests play a vital role in mitigating climate change by absorbing and storing carbon dioxide from the atmosphere through photosynthesis and the growth of trees. Forest owners, therefore, have a significant opportunity to contribute to climate change mitigation through their management practices.

This study presents the results of a survey conducted among non-industrial private forest owners during early summer 2022. The survey aimed to assess forest owners' attitudes towards climate change, its mitigation, and adaptation measures. The data included 1,224 usable responses, yielding a response rate of 20.4%.

The results reveal forest owners' perspectives on climate change and their willingness to implement mitigation and adaptation measures. It was found that various climate change mitigation actions are not yet widely adopted among private forest owners, with less than 10% of respondents reporting engagement in most of the assessed measures. However, more commonly practiced actions include following current forest management recommendations. Adaptation measures were more widely used with more than 25% engagement rate.

Utilizing a multinomial regression model, we analyze the factors influencing forest owners' intentions to implement selected measures, their uncertainty about implementation, or their lack of intention to implement. The preliminary results indicate that, in addition to demographic variables, attitudes towards climate change and its impacts and forest ownership goals influence the implementation of climate change mitigation and adaptation measures.

Additionally, forest owners have diverse motivations for engaging in climate change mitigation actions, such as protecting biodiversity, a sense of responsible forest management, and economic benefits. These varied motivations should be considered when designing policy instruments to encourage the implementation of different measures. Recognizing and incorporating these underlying reasons can enhance the effectiveness and acceptance of climate change mitigation strategies among forest owners. These insights can inform policymakers and stakeholders involved in sustainable forest management practices, aiding in the development of targeted strategies to promote climate change awareness and encourage forest owners' active involvement in mitigation and adaptation efforts.

The Need to Establish a Social and Economic Database of Private Forest Owners: the Case of Lithuania

T4.24 Provision of Ecosystem Services from Small-scale Private Forests - Is it viable?

Marius Aleinikovas[1]
Mindaugas Škėma[1], Dalia Perkumiene[2], Asta Doftartė[3]
[1] Institute of Forestry, Lithuanian Research Center for Agriculture and Forestry.
[2] Department of Business and Rural Development Management, Faculty of Bioeconomy Development, Agriculture Academy, Vytautas Magnus University
[3] Department of Forestry, Faculty of Forestry and Landscape Architecture, Kaunas Forestry and Environmental Engineering University of Applied Sciences

Abstract: In Lithuania, as in other analyzed countries, greatest attention is concentrated on the protection and monitoring of state forests, while the situation in the private forest sector is quite unclear and uncertain. In most European countries, as well as in Lithuania, there are a lack of socio-economic data, and there are no planned forest monitoring methods and permanent programs. We claim that the problem of achieving sustainability in the forest sector, in the case of the estates of the private forest owners, could be partially solved by implementing the monitoring of social and economic indicators. This study proposes the need for the establishment of a social and economic database of private forest owners in Lithuania. In this article, we have carried out a detailed analysis of scientific sources and selected socio-economic indicators to help the adoption of optimal management solutions for sustainability in the private forest sector. To explore the need to establish a social and economic database of private forest owners in Lithuania, we conducted an empirical study by applying the method of semi-structured interview to a group of experts/specialists in the forestry field. Summarizing the results of the research, it can be concluded that the need for socio-economic information about the owners of private forests in Lithuania is obvious, as it would clarify the most pressing problems that forest owners face when farming in their forest estates. This information would also allow the improvement of policy formulation and implementation, the adoption of legal regulations, and the organization of the necessary changes in private forestry. Therefore, it is necessary to establish criteria and indicators that could ensure more sustainable forest management.

T4.25 Public engagement to keep urban trees and communities healthy

A tale of two cities: Assessing changes in street tree health in NYC and Philadelphia

T4.25 Public engagement to keep urban trees and communities healthy

Richard Hallett[1]
Michelle Johnson[1], Lara Roman[2], Rachel Holmes[3]
[1] USDA Forest Service, NYC Urban Field Station
[2] USDA Forest Service, Philadelphia Field Station
[3] The Nature Conservancy, North America Cities

Abstract: Every tree in an urban forest is expected to provide a multitude of benefits to the city. Because of this, municipalities invest tremendous resources in their urban trees, making their growth and success even more important. The ability to quantify how healthy a tree is provides added value to urban forest managers allowing them to be proactive in their management decisions and able to plan for stress mitigation instead of tree replacement. In addition, fine scale health metrics that can be deployed across large areas of a city may also help with early detection of new invasives such as Asian long-horned beetle and emerald ash borer.

We have created a tree health assessment protocol for urban trees by adapting and refining methodology used in rural forest health protection and monitoring. This protocol and accompanying statistical techniques are at the core of the “Health Check” module in the Healthy Trees Healthy Cities mobile app. This app is freely available.

This protocol has been used in eighteen cities in the United States by scientists, community groups, and in job training programs. Here we present the results of a study designed to rigorously assess street tree health changes over time. In Philadelphia, PA 2,690 street trees were assessed in 2015 and these same trees were visited again in 2021. In New York City 3,646 trees were assessed in Bronx and Manhattan in 2015 and again in 2022/2023.

This study and the associated methodology is one example of how both scientists and civic ecologists can use the same methodology to get more eyes on trees in cities. This in turn can provide managers with valuable information about the health of the street trees they are responsible for managing.

Community engagement can enhance biosecurity

T4.25 Public engagement to keep urban trees and communities healthy

Joseph Hulbert[1]
Marianne Elliott[1], Gary Chastagner[1]
[1] Washington State University

Abstract: People are part of ecosystems and biosecurity is a shared responsibility. Protecting our forests from invasive pests requires constant and broad monitoring, beyond the capacity of any individual agency or sector. Programs designed to empower more people as guardians can increase capacity for biosurveillance and strengthen the resilience of our communities to respond to forest threats. Many programs exist to empower participants as first detectors and respond to the impacts of invasive species. This presentation will review approaches for engaging the public across the stages of biological invasions and summarize the merit of public engagement within the Forest Health Watch program (https://foresthealth.org/).

Correlating characteristics of urban trees with human wellbeing in Singapore and Wellington, New Zealand

T4.25 Public engagement to keep urban trees and communities healthy

Peter Edwards[1]
Seanglidet Yean[2], Yun Si Goh[2], Eleanor Absalom[3], Jan Schindler[1], Bu Sung Lee[2], Robyn Simcock[1], Gradon Diprose[1]
[1] Manaaki Whenua Landcare Research
[2] Nanyang Technological University
[3] University of Sheffield

Abstract: There has been a significant amount of research on the effects of urban greenspaces, and by association, urban trees on human health and wellbeing. The majority of these studies have examined the relationship between greenspace and/or trees and specific medical conditions, or more generally mental health. In this study, we examine the relationship between the urban forest, encompassing both individual street trees *and* trees in greenspaces, and overall human wellbeing. Using the OECD wellbeing framework, we developed a weighted index of human wellbeing, comprising the following domains where data was available: income and wealth, work and job quality, housing, health, knowledge and skills, environmental quality, subjective wellbeing, safety, work-life balance, and civil engagement. The examined urban tree measures and characteristics included those which have rarely been considered in this context before, such as tree age, size, and species (native and exotic), as well as tree density and remote-sensing derived proxies of canopy cover.

Disease risk mapping has rarely been used outside of its specified purpose. Since our research questions/hypotheses are concerned with how the various measures and characteristics of urban trees affect human wellbeing and several other indicators, we have adopted several modelling approaches for disease mapping – logit models, Bayesian hierarchical modelling, and Lasso models. All of these models appear to be appropriate in this instance as they are often used to measure spatial variation in disease. While we are not measuring disease per se, we will be measuring the “condition” of wellbeing on the population of Singapore and Wellington.

Early logit results have shown weak correlations between the different urban forest characteristics and individual data components that make up the weighted index of wellbeing for Singapore. Results of the modelling of for Wellington will be complete by the end of the year. Our preliminary study in Singapore examined the relationship between income and greenery using correlations and map visualization. The study revealed relatively high correlations for greenery per capita and income per capita in a planning area. Further investigation to verify the study's results and sampling of other indices are ongoing.

INQUIRES ABOUT GOVERNANCE MODELS TO APPLY IN URBAN FOREST AT THE CITY OF LUJAN, IN ARGENTINA

T4.25 Public engagement to keep urban trees and communities healthy

Analía Scarselletta[1, 2]
Clara Minaverry[1, 2, 3], Elena Craig[2, 4], Mariano Ferro[1, 2]
[1] Departamento de Ciencias Sociales, Universidad Nacional de Luján
[2] Instituto de Ecología y Desarrollo Sustentable (INEDES)
[3] Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET)
[4] Departamento de Tecnología, Universidad Nacional de Luján

Abstract: The concept of 'good governance' requires transparency, accountability, and social participation and it is related to good citizenship. Sustainable governance then is the set of written and unwritten rules that link ecological citizenship with institutions and norms of governance. Good governance is reflective of community empowerment and ecological wisdom, the absence of good governance is characterized by the lack of either or both. In this context, this proposal will identify various levels and types of good governance and describe the decision-making system related with the urban forest of the city of Luján, province of Buenos Aires, in Argentina, to recognize strengths, weaknesses and gaps - of a legal, administrative, technical or other nature - that need to be addressed to consolidate a governance model. It is a bibliographic-documentary, descriptive and qualitative type of research and a bibliographic survey has been carried out. Scientific papers, regulations and public documents have been taken as sources of information. Also, interviews have been carried out with key informants as a mechanism for corroborating the information and a survey of the perception of the population of Luján regarding the city's urban forests has been carried out through surveys of the population. As an analysis technique we apply legal hermeneutics and we implement an adaptation of the conceptual framework proposed by the study The Economics of Ecosystems and Biodiversity. We can conclude that to implement a governance model with an ecosystem approach, in any environment, it is necessary to work with various sectors and disciplines. A favorable political context is one of the most important conditions when applying this approach, since it can enable all the others (mainly human, financial and institutional resources). However, it is essential that there is a society that recognizes the value of urban forests and participates in the application of the approach. Not only from the demand and claim, but also from the commitment and participation. In turn, the university occupies a key role for the articulation between parties and for the development of research-action projects.

Nutritional Composition and Phytochemical Content of Ceiba pentandra and Vitex doniana leaves in Maklurdi, Benue State, Nigeria

T4.25 Public engagement to keep urban trees and communities healthy

Amonum Joseph Igba[1]

[1] Usman, J.A. and Udugh, A.S.

Abstract: *This study investigated the nutritional composition and phytochemical content of the leaves of Ceiba pentandra and Vitex doniana. The leaves were collected from Makurdi, Nigeria. The leaves were ground into powder with a mortar and pestle and put into a clean, dry container. The dried powdered leaves were then taken to the Chemistry Laboratory of Federal University of Agriculture, Makurdi for proximate and phytochemical analyses. The proximate and phytochemical compositions of these tree species were determined according to standard method. The results showed that the Ceiba pentandra* ***s****ample has an appreciable amount of fiber (27.861.1%), followed by carbohydrate (27.492.4%), while the least was moisture (8.77±0.3%). The Vitex doniana* ***s****ample has an appreciable amount of carbohydrate (25.62±0.5%) followed by fiber (22.03±0.3%) while the least proximate content was moisture (9.94±0.03%).The phytochemical screening revealed that flavonoids and tannins (+++) were very strong in Ceiba pentandra. Terpenoids and phenols (++) were present in strong quantity. Saponins (+) were present in weak proportion while alkaloids, glycosides, steroids, anthraquinone, resins, and balsam were absent. The results also revealed that saponins and tannins (++) were strong in Vitex doniana. Alkaloids, flavonoids, anthraquinone, and terpenoids (+) were weak in Vitex doniana, while glycosides, steroids, phenols, resins, and balsam were absent. These results imply that these species are good sources of nutrients and could have ethno-medicinal potential for drug formulations. Thus, the consumption of these species (Ceiba pentandra and Vitex doniana) should be encouraged as they could help lower cholesterol and regulate body sugar.*

Keywords: Phytochemicals, Ceiba pentandra, Vitex doniana, etho-medicinal, Proximate analysis

Pubic engagement to integrate urban city forests and university forests through service learning

T4.25 Public engagement to keep urban trees and communities healthy

David Kulhavy[1]
David Creech[1], Daniel Unger[1], I-Kuai Hung[1], Victoria Williams[1], Yanli Zhang[1]
[1] Arthur Temple College of Forestry and Agriculture Stephen F Austin State University

Abstract: Building public engagement between cities and universities can be enabled through community action that incorporates aspects of service learning in both the establishment and connection of the urban forest to each organization. The tenets of service learning call for frank and earnest engagement in the long term success or each partner. The first is to recognize the resources of each partner and to compare and contrast these current resources and resources for the future. Examples are group plantings and GIS data base management. Next is to assess long - term partnerships for the future. Examples include Tree Capital of Texas; Tree City USA; Ladybird Johnson Wildflower Center affiliate garden; and Tree Campus USA and to assess how each benefits the partners. Third, to be attentive to the goals and visions of each partner. Examples include connecting the urban landscapes through trails and web-based story boards in ArcGIS Online that tell public stories and interactions. Fourth is to share the legacy of the program. Examples include assessing the monarch butterfly and the American bumble bee as integral parts of the urban forest as both are being considered for endangered species status. Additionally, hazard rating of the urban forest to evaluate change over time can be completed either using standard on the ground methods or by the use of drones with comparable results. Fifth is shared responsibilities for completion and evaluation of the change in the urban forest. Examples include a renewed planting campaign using sustainability dollars at the university and to establish a tree nursery in both the community and the university. Lastly is to to evaluate the human dimension of the partnerships and to match individuals in each organization on tree boards and urban forest activities. As public engagement increases, the quality of the urban forest will increase through renewed commitment to the beautification of the community and the planting of the future urban forest.

Reaching out to the public – Feelings of human wellbeing and the wellbeing of urban trees in Wellington, New Zealand

T4.25 Public engagement to keep urban trees and communities healthy

Peter Edwards[1]
Robyn Simcock[1], Gradon Diprose[1], **Eleanor Absalom**[2]
[1] Manaaki Whenua Landcare Research
[2] University of Sheffield

Abstract: Urban trees provoke many different feelings in people: joy, wonder, peacefulness, relief, sadness, anger. Wellington City Council in New Zealand receives more complaints about urban trees than accolades. To understand what is behind these feelings towards urban trees, we have designed "tree walks" through Wellington City. These are designed to elicit peoples feelings and the reasons behind them as they interact with trees along streets, pocket-parks, and in the Wellington Botanical Gardens. Initially, seventeen trees in the Botanic Gardens along pedestrian commuter paths have a QR code attached to them, inviting people to scan it. Twenty street trees will follow.

The QR code directs to a website that provides brief narrative information about the particular tree and species. This includes information about the tree's health, history and information about the species – its native range, and how it came to be in New Zealand (if exotic). Readers are invited to answer three short questions about how their interaction with the tree made them feel, why, and what they would like to see done about trees in Wellington. The collection of this data is ongoing, and will be completed early next Antipodean autumn.

We have also assessed the wellbeing of the urban trees themselves, observing how the trees have been placed, planted, their management, and using the 3-30-300 "rule", their ability to "see" other trees, are part of 30% local canopy cover, and less than 300m from a greenspace. These observational findings show that many of Wellington's street trees suffer compared with those in the Botanic gardens. While all street trees had close neighbours and were within 300 m of a park, they form just 6.4% of cover, and are smaller, younger and with less diverse neighbours than trees in the Botanic Gardens. Street trees also have high proportion of injury and adverse impacts from poorly planned lighting, signs and linear urban infrastructure; canopies deformed and restricted by buildings and highly managed 'clear zones' and paving often extends up to and around the trunk. However, this diminished tree wellbeing does not appear to impact the feelings of wellbeing people receive from trees.

Ten years of Observatree: The evolution of a tree health citizen science project and the challenges that lie ahead

T4.25 Public engagement to keep urban trees and communities healthy

Peter Crow[1]
Ana Perez-Sierra[1], Gerard Clover[1]
[1] Forest Research UK

Abstract: Ten years ago, Observatree, a UK-based partnership project was initiated to investigate whether a network of volunteers could be trained to identify and report on a number of priority tree pests and pathogens. Could citizen scientists support official tree health surveillance activities and help to form part of a tree health early warning system? Many professional tree health surveys focus on the large public forests managed by government bodies, the tree nursery sector, or at dockyards, where imports of trees and wood products are inspected. But professional inspectors have a finite capacity, and may be less active in many urban and semi-urban environments. Raising awareness of tree health concerns within the wider community increases our surveillance network, helping to protect the trees in urban green spaces and the wider environment.

Ten years later, Observatree continues to train members of the public to identify tree pests and pathogens and to date, over 20,000 reports have been submitted. Some of our volunteers have been with the project since its launch and now help to guide and support new people who join the network. During these ten years, the project has evolved, responding to feedback from the citizen scientists engaged with the project, from tree health inspectors, researchers and policy makers. The project now forms an important part of the GB national plant biosecurity strategy and whilst the volunteers continue their routine monitoring and surveillance, the network can also be called upon to provide additional support to respond to incursions when necessary.

This presentation will focus on some of the lessons learned during the last ten years and how the project has adapted in response to stakeholder requirements. We have invested in new methods of data capture and engagement, but there are further challenges ahead in reaching a wider range of community groups and continuing to broaden our network of people who regularly monitor the health of their local trees.

The economics of engaging the community in forest health surveillance programmes

T4.25 Public engagement to keep urban trees and communities healthy

Susan Hester[1, 2]
[1] Centre of Excellence for Biosecurity Risk Analysis, University of Melbourne, Australia
[2] UNE Business School, University of New England, Australia

Abstract: It is widely acknowledged that the community can play a key role in preventing and responding to exotic, new and emerging pests and diseases, including those that affect urban trees. Community members might provide the first reports on the location of new and pests and diseases, or form networks that are useful in invasive species management responses. However, the economics of involving the community in urban forest health campaigns is unclear because programmes and activities are seldom subject to economic analysis. Without this information we do not have any insights into the appropriate level of funding to enable community engagement in forest health surveillance, or how best to use the community to complement government surveillance and monitoring efforts. This presentation discusses how we might undertake useful economic analysis of community engagement programmes that aim to improve urban tree health. It considers data collection and the planning that is required to ensure appropriate evaluation can take place.

Tree health and urban heat: engaging communities to study urban forest disparities

T4.25 Public engagement to keep urban trees and communities healthy

Joseph Hulbert[1]
Marianne Elliott[1], Gary Chastagner[1]
[1] Washington State University

Abstract: More than 80% of people live in cities and rely on healthy, functioning urban forests. Urban trees provide critical services for keeping communities healthy, such as mitigating the impacts of heat waves, but these benefits are not equally distributed, and more research is needed to improve the services or urban forests equitably. In the northwestern United States, there is enormous need—and opportunity—to equitably increase the resilience of communities by advancing knowledge and stewardship for growing healthy and vibrant urban forests. In this presentation we summarize how community scientists have assessed tree health across urban heat islands as part of the Forest Health Watch program.

Who are urban tree bodyguards? Birds, schoolchildren, or both

T4.25 Public engagement to keep urban trees and communities healthy

[4] Univ. Brest, LABERS Laboratoire d'études et de recherche en sociologie UR 3149

Abstract: Trees play a critical role in the ecological functioning of urban socio-ecosystems, in addition to being favourable to the physical and mental health of city dwellers. Tree health is therefore tightly linked to that of people in the city. But do they (people, not trees) know it? Maybe not, because trees and their ecology are poorly known by the majority of people living in cities. We engaged a network of schools in the study of the top-down control of insect herbivory in oaks (*Quercus robur*) along urbanization gradients. Our goal was two-folds: produce sound ecological knowledge on tree health and promote ecological and scientific literacy. Schoolchildren and their teachers were invited to identify trees in the immediate vicinity of the oak they selected. Additionally, they monitored trophic interactions by assessing oak leaf area impacted by insect herbivores, and by counting predation marks on dummy caterpillars they exposed in oaks for 15 days. We used the percentage of impervious surface in a buffer of 200 m radius centered upon oak trees as a proxy for urbanization. We analysed the effect of urbanization and surrounding tree abundance and diversity on the potential top-down control exerted by insectivorous birds on insect herbivores. In parallel, we collected feedback from schoolchildren and teachers involved in the project through online questionnaires and interviews.We present the results of the research in ecology as well as data illustrating the process of a school-based citizen science project focusing on urban tree health.

T4.26 Questioning Urban Forest Canopy Cover Goals - Best Practices for Setting and Achieving Canopy Cover Targets

Questioning Urban Forest Canopy Cover Goals - Best Practices for Setting and Achieving Canopy Cover Targets

T4.26 Questioning Urban Forest Canopy Cover Goals - Best Practices for Setting and Achieving Canopy Cover Targets

Justin Morgenroth[1]
[1] University of Canterbury

Abstract: Tree canopy cover (TCC) is the total area of tree crowns projected onto the ground. It expresses canopy area as a percentage of total ground area. TCC is commonly used to describe the amount and horizontal distribution of urban forest canopy within a given city. Tree canopy cover is easily understood by various stakeholders, including government, urban foresters, arborists, planners, urban designers, and developers.

Because tree canopy cover has been linked with ecosystem service provision and benefits for local communities, numerous cities around the world have set targets to increase their urban forest canopy cover. However, these global TCC targets largely appear to be aspirational, rather than being justifiably informed by current research. This panel discussion addresses the topic of urban forest canopy cover targets. A group of international experts will use their personal experiences with canopy cover, as well as knowledge of grey and scientific literature to consider answers to the question of how much tree cover is desirable, or appropriate, in the world's cities.

Early work by panel members confirms that research no longer supports a universal tree canopy cover recommendation. Instead, different canopy cover targets should be tailored to individual cities, based on local context. The international literature also shows that some cities are moving away from setting a single, city-wide, target, opting instead for different targets across electoral wards, local boards, neighbourhoods, or land uses. It's also noted that targets do not preclude cities from aspiring to greater canopy cover, though overly-ambitious targets may be unachievable and undesirable for a variety of reasons. This panel discussion will conclude with recommendations for cities to successfully set and meet canopy cover targets.

Questioning Urban Forest Canopy Cover Goals - Best Practices for Setting and Achieving Canopy Cover Targets

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Analysis of Sustainability of People's Organization: The Case of NED Landcare Association in Barangay Ned, Lake Sebu, South Cotabato, Philippines

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Louise Bernadette Del Castillo[1]
Lorena Sabino[1]
[1] Department of Social Forestry and Forest Governance, University of the Philippines Los Baños

Abstract: The main purpose of the study was to develop an indicator for assessing the sustainability of people's organizations (POs), with a specific focus on the Ned Landcare Association (NLCA) in Barangay Ned, Lake Sebu, South Cotabato, Philippines. NLCA is a farmer-led people's organization that has been operating since 1999 owing to their natural resource management and conservation efforts despite the geographical remoteness from service providers. The rationale for this research stems from the scarcity of relevant literature concerning the sustainability of POs and their corresponding indicators. Consequently, it is imperative to identify these sustainability indicators in order to ensure the long-term viability of organizations and their programs aimed at enhancing local communities and facilitating comprehensive community development and natural resource management. To achieve its objectives, the study employed a combination of methods. A comprehensive literature review was conducted, specifically focusing on the development of PO indicators designed to assess the sustainability of POs classified into internal and external aspects, with each focusing on social, economic, and environmental factors within the context of NLCA.

The study's findings indicate that the NLCA exhibits a high level of sustainability, primarily attributed to its strong linkages and networks, effective leadership, successful projects and activities, sound governance, and clear vision, mission, and goals. However, there are specific areas of the organization's overall development and sustainability that require attention. Particularly, emphasis should be placed on membership engagement, policy formulation, livelihood initiatives, and enterprise activities. Moreover, the study reveals that age plays a significant role in influencing the sustainability of NLCA. Therefore, it is crucial for the organization to ensure that the younger generation of Landcare members actively embrace Landcare strategies and maintain collaborative partnerships with external stakeholders. It is important to continue implementing new projects and activities, enhancing governance systems, and effectively communicating the organization's vision, mission, and goals to both existing and new members. To foster sustained engagement, the NLCA should prioritize efforts to motivate members to remain actively involved in the organization's activities. By encouraging continued participation, NLCA can enhance its overall sustainability and ensure the effective implementation of its initiatives.

Assessing the community benefits of EU woodland nature-based solutions - A Systematic Review

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

TIMOTHY PITTAWAY[1]
LEANNE TOWNSEND[1], CLAIRE HARDY[1]
[1] Social, Economic and Geographical Sciences Department, James Hutton Institute, Scotland, UK

Abstract: Background: Nature-based solutions (NBS) are initiatives that sustainably manage and restore natural and modified ecosystems that address societal challenges effectively and adaptively, benefiting people and nature (International Union for Conservation of Nature, 2020). Most NBS provide various co-benefits, addressing societal challenges and enhancing community health and wellbeing alongside their primary objectives. NBS locations can also offer recreational opportunities such as walking trails, bird watching and fostering social cohesion. Woodland-based NBS can impact environmental factors such as biodiversity, carbon sequestration, filtering pollution and absorbing excess water. Although there is substantial literature on how NBS can benefit human well-being, there is a limited understanding of how the NBS-enhancing community aspects differ across the EU. As countries become increasingly urban, rural settlements approach woodland-based NBS to address societal and environmental challenges. This paper will provide an overview of recent research on NBS social benefits in EU woodlands alongside findings from our research, on the COEVOLVERS Horizon Europe project, on the benefits of woodland-based NBS in Scotland. The paper provides insights into the role of NBS and related activities in community health and well-being.

Methods: A systematic literature review was conducted with a web collaboration platform across several academic and online databases. ATLAS.ti software assisted in categorising articles for easy identification and transparent methodology. Each article is screened using appropriateness criteria through a three-stage process: title, abstract, and full text, with the objective of mapping and analysing these reviews for associations between the Europe woodlands and NBS social benefits. The main themes and findings were extracted using a predefined coding strategy. The paper also presents findings from qualitative interviews and questionnaires with stakeholders of a community woodland in Scotland, exploring the benefits of nature-based activities and initiatives.

Keywords: community benefits, EU woodlands, nature-based solutions

Communal forest management in native communities in the Peruvian Amazon and its potential for implementing REDD+ initiatives

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Zoila Lasmit Cerón Cancharis[1]
Yolanda Ramírez Villacorta[1], Jaime Nalvarte Armas[1]
[1] Asociación para la Investigación y Desarrollo Integral

Abstract: Since 2000, the native communities of Ucayali, Peru and AIDER have been co-creating a proposal to sustainably use communal forest resources. The Communal Forest Management (CFM) proposal seeks to comprehensively manage forest resources in native community territories, taking into account the geographic, social and cultural characteristics of the different indigenous peoples, thus achieving the proposed environmental, socioeconomic and climatic objectives. It is through this holistic management of the territory, communal governance, the right of the peoples over their territory and sustainable forest management, that the benefits obtained are translated into: (i) improvement of the quality of life of indigenous peoples living together harmoniously and with social inclusion, (ii) security and diversification of livelihoods and income, (iii) recovery of the productive potential of communal forests, (iv) conservation of Amazonian forests and their biodiversity, (v) mitigation and adaptation to climate change with the reduction of greenhouse gas emissions and (vi) resilience of indigenous peoples and Amazonian forests.

The CFM allows obtaining benefits from ecosystem services, developing REDD+ initiatives thanks to the production of carbon credits in the communal forests; these credits are the financial leverage that gives sustainability to the productive economic activities implemented in the native communities. This CFM is being developed in seven Shipibo Conibo and Cacataibo native communities in the Ucayali region, where the financing obtained through the REDD+ Nii Kaniti initiative has allowed the implementation of sustainable inclusive activities and businesses that care for and conserve the forests, such as: governance, legal physical sanitation, forest control and surveillance, agroforestry, commercial forest plantations, handicrafts, fisheries management and timber and non-timber harvesting.

Comparison of Small-scale, Community, and Indigenous Forestry among the Norway, Sweden, and United States

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Brett J. Butler[1]
Hanne K. Sjølie[2], Francisco X. Aguilar[3]
[1] USDA Forest Service, Northern Research Station, USA
[2] Inland Norway University of Applied Sciences, Department of Forestry and Wildlife Management, Norway
[3] Swedish University of Agricultural Sciences, Department of Forest Economics, Sweden

Abstract: Forests exist within complex socio-political-economic systems. A key component to these systems is the people who own and manage these lands as they are the ones who make the primary decisions on if and how the land should be used, within contextual political, economic, and biophysical constraints. Forest ownership histories and patterns vary across the globe, but there are many areas where cross-country comparisons can help. Such analyses may increase knowledge about the barriers and opportunities that different ownership and user communities face to progress forest management in a time with global climate change and increasing public concerns about the impacts of forest management on ecosystem services. Norway, Sweden, and the United States all have extensive forest cover and forest ownership that is dominated by private owners, 80%, 75%, and 58%, respectively. All three countries have well-established National Forest Inventories (NFIs) and national forest ownership surveys, the one in the U.S. tied to the NFI. This presentation will compare histories of forest ownership, current ownership patterns, and a more detailed comparison of the demographics, attitudes, and behaviors of small-scale, family forest ownerships across the countries. Preliminary data explorations suggest that demographics, reasons for owning, and management activities are fairly similar. Factors such as size of holdings have similar impacts across counties, but the impacts of various national and local policies and economies present substantially different constraints and opportunities for forest ownership and management. These findings have important implications in terms of understanding the future of forest ownership and forests and how policies and programs might impact these futures.

Designation of World Natural Heritage and challenges of traditional small-scale forestry in Okinawa

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Chiharu Maeda[1]
Ikuo Ota[1]
[1] University of the Ryukyus, Japan

Abstract: Yambaru area, the northern part of Okinawa Island in Japan, was designated as a World Natural Heritage in 2021 with three other islands in the Ryukyu Archipelago. Because of its geographic and climatic significance as an isolated subtropic islands, the area is rich in biodiversity and famous for many endemic species of plants and animals. However, people have lived in this area for a long time and engaged in economic activities such as forestry and fishery. The Ryukyu Kingdom remained independent for 450 years between China and Japan, Yambaru had been continuing to supply timber and firewood to the people in the capital city Shuri and populated Naha.

This study aims to recall the historical and concurrent importance of local forestry activities in Yambaru as well as to identify the characteristics of rich biodiversity of the forest and to explore the need for its protection. Small-scale local forestry can be said to be quite powerless against major environmental movements. Even so, local forest owners' cooperatives and people involved in the forest industry have no choice but to continue the forestry business on a small-scale. The authors interviewed such forestry related people and environmental groups, and tried to consider a constructive future plan to sustain small-scale forestry against the strong pressure for protecting rare and endangered species and rich biodiversity in the World Natural Heritage and surrounding buffer zones.

Ecotourism must be an answer, but it is important to see how local forestry people get involved in tourism while continuing forestry activities including timber production and others. We are hoping to discuss with participants of the IUFRO session who have similar kind of experiences in different place of the world.

Examining space for indigenous peoples and local communities in community forestry

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Sindhu Prasad Dhungana[1]
[1] Ministry of Forests and Environment, Government of Nepal

Abstract: The roles of indigenous peoples and local communities in sustainable forest management have widely been acknowledged in Multilateral Environmental Agreements and national policies. Regardless, a tension persists where legal arrangements are inadequate to recognize, address and respect the rights and roles of indigenous peoples and local communities in a balanced approach in forest management. Taking Nepal's community forestry as a case, this paper aims to explore to what extent the space for indigenous peoples and local communities is accepted in policies, laws and practices for sustainable forest management. The conflicts between indigenous peoples and local communities in community forestry and other forms of forestry are also analyzed in the light of international environmental instruments, local needs, sustainable use, gender equality and space for transformative change. Literature survey was the main source of information, while some key informant interviews of indigenous and community leaders were also carried out. It was found that local communities were adequately recognized by policies, laws and programs particularly in community forestry, while indigenous peoples were slightly addressed in policies and some aid-funded projects but not in programs and practices. In rest of forestry programs, neither indigenous peoples nor local communities are recognized, respected or addressed. Marginalization of indigenous peoples from forest landscapes started long before the community forestry was initiated and institutionalized. The study also found that blaming the local communities for excluding indigenous peoples due to community forestry was not evidence-based. Instead, community forest user groups in many places tried their best in practice to address the issues of indigenous peoples within the existing policy and legal frameworks. In order to fully incorporate the rights and roles of indigenous peoples in forested lands and their tenure, a transformative revision in domestic forest laws and adequate sensitization of policy makers, forestry officials and practioners are recommended.

Forest conservation incentives and benefits distribution for Indigenous communities --a case from Peru with scalable lessons

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Lauren Cooper[1]
Rowenn Kalman[1], Cristina Miranda Beas[2], Deborah Delgado Pugley[2], Ciro Castro Pacheco[2], Anne Larson[3], David MacFarlane[1], Patricio Zanabria[4]

[2] Pontifical Catholic University of Perú
[3] Center for International Forestry Research (CIFOR-ICRAF)
[4] Asociación Servicios Ecosistémicos Perú

Abstract: Forest-dwelling Indigenous Peoples and local communities (IPs and LCs) make decisions for over 36% of forests globally. Particularly in tropical forest countries, communally held land is central for the subsistence and livelihoods of Indigenous people. Major climate negotiations prominently feature forest protection as a key mechanism to reduce emissions from the land sector. However, despite an estimated USD 12 billion pledged to address tropical deforestation, only a fraction of funding for tropical forest monitoring conservation is reaching decision-makers on the ground. Best practices to distribute incentives for conservation activities to small-scale and indigenous communities is poorly understood. This research explores the strengths of mechanisms to directly transfer incentives to communities to grow equitable conservation partnerships and develop long-term commitments.

Peru holds the second largest share of Amazon Forest – locally and globally important for biodiversity, climate regulation, and carbon storage - and communal landholders make decisions over more than 65% of this ecosystem. As part of an ambitious plan to conserve 79% of its tropical forest (54 out of 68 million hectares), Peru's Ministry of the Environment (MINAM) has pursued a strategy of using incentives to shape behavior and decision-making to stop deforestation. The mechanism, called Conditional Direct Transfers (TDC, in Spanish), signed nearly 200 conservation agreements with communities overseeing 2.9 million hectares in its first 10 years, with plans for continued scaling.

Our research assessed current performance and interactions of the TDC program, including implications for long-term outcomes. We asked: How can the TDC be improved to achieve long-term conservation and development objectives?

To analyze this question, we developed a rich dataset that included interviews with qualitative and quantitative components, TDC programmatic documents (Policies, implementation guides, PGI examples, community reports, etc.), and community data from multiple public sources as well as from fieldwork. We used strategic categories in the theoretical framework—Governance, Economics, Participation, and Social Impacts—to construct research questions, identify methods, and undertake data analysis.

Our framework provides generalizable recommendations with an assessment of program implementer responsibility and best practices. In this way, we offer a strong foundation for

implementation and subsequent monitoring of forest conservation incentive programs around the world.

Forestland concession, land rights and livelihood of ethnic minorities: Evidence from the Sal forest of Bangladesh

Abstract: Forestland concessions have in the recent past been the dominant governance tool for the acquisition of state-owned forest resources in many tropical countries, including Bangladesh. The Sal forests of Bangladesh are treated as one of the most concession forests, and a number of ethnic minorities use these forests for their daily lives. Therefore, the objectives of the study were to identify the impacts of Sal forestland concessions and land rights on the livelihood development of the ethnic minority living in the Madhupur Sal forest area of Bangladesh. Using both qualitative and quantitative data collection techniques, the study found that about two-thirds portion of the original Sal forestland was grabbed by state and non-state actors. As a result, the inhabitant ethnic minorities have lost their traditional land and free access rights to the Sal forests. The process of losing ethnic minorities land and access to forests has been enhanced by the institutional arrangements of the state, which have also created severe conflicts between the forest department and the ethnic communities. The study also revealed that the land concession has negatively affected the five livelihood capitals development of the ethnic minority; consequently, their livelihood basis has shifted to non-securing jobs or poor income sources like daily wage labor. Therefore, the study would recommend to establish a legitimate process in order to settle down the issue of traditional land and forest access rights of ethnic minorities; which could also attain the conservation and development goals of the degraded Sal forest.

GOVERNANCE DYNAMICS OF COMMUNITY BASED FORESTS IN KENYA: CASE STUDY OF LOITA FOREST IN NAROK

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Roxventa Ongugo[1]
Charles Koech[1]
[1] KEFRI

Abstract: Forests in Kenya were under traditional community management regimes up to 1891.Formal management of forests by state started in Mangrove forest along the Kenya coast at Vanga and, later the entire country in 1900. In 1997 decentralized forest governance was successfully piloted through Participatory Forest Management in Arabuko-Sokoke forest at the Kenyan coast. This informed review of the Forests Act, Cap 385 to The Forests Act, 2005 subsequently revised to Forest Conservation and Management Act, 2016. The Act has explicit sections on decentralized forest management with special focus on communities. The devolution of forest governance especially through Community Forest Associations (CFAs) has given the communities a sense of legal ownership and management. Through the CFAs the communities participate in the management of forests close to their residences. They organize themselves in groups to facilitate management and extraction of products and services from the forests. This study was carried out to document status of the management structures of Loita forests currently managed by community under traditional rules represented by the Oloibon institution. The objective of the study was to document the governance structures applied in these forests and their effect on the management of the forests including its conservation**.** Data was collected through interviews with the officials of the CFA, other organizations with stake in the forests. Results indicated that there is population increase putting pressure on the forest and its resources. There is improved infrastructure and mechanization in the area. Currently there are challenges on the governance system which poses a risk to the existence of the forest. The Oloibon institution which has safeguarded the forest is losing its effectiveness due to factors like emergence and spread of Christianity and land demarcation. There is encroachment into the forest for production of food crops and charcoal burning.

These challenges pose the question on the success of devolved structures based on community governance institutions. Another issue to address is the role of indigenous management structures in safeguarding forests and ensuring their ability to provide the required ecosystem products and services over time.

Indigenous endangered species in small-scale forest and valuing carbon stock: a success story of climate smart forest

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Mohammed Al Amin[1]
[1] UNIVERSITY OF CHITTAGONG, INSTITUTE OF FORESTRY AND ENVIRONMENTAL SCIENCES, BANGLADESH

Abstract: This study focused on the restoration programme of small-scale forests at University of Chittagong, Bangladesh of 600 hectare of land with indigenous endangered species not only generating ecosystem services to the inhabitants of the society but act as a measure to save watershed area of river Halda, only natural breeding ground of carp fishes in the world, and a major source of water for irrigation and drinking. This study assessed the forest resources applying a spatio-temporal time series analysis of landuse changes using satellite images from 1990 to 2020 and measured tree vegetation with species composition, diversity and density of natural regeneration of tree species, carbon stock with major timber species, using field experimentations. Restoration programs on hilly part of the area with indigenous and 52 endangered species. The results revealed that plantations restricted runoff during monsoon and also be a germplasm repository of endangered species for the nation which provide positive impact on management of watershed of river Halda. Organic carbon content by six major timber species (with different age classes) namely Garjan *(Dipterocarpus turbinatus),* Mehogoni *(Swietenia macrophylla),* Shal *(Shorea robusta)* Chapalish (*Artocarpus chama), Gamar (Gmelina arborea), Akashmoni (Acacia auriculiformis)* and soil organic carbon stock were measured. Six allometric equations of stated species were developed for effective management. This reforestation program on small-scale forest and carbon valuation put forward an effective venture to the nation and earned national best award on tree plantation for 2023 as well. This approach of reforestation program with carbon management for small scale forests may provide an instrument to combat climate change and rebuild a healthy forest, may be apply to any part of the world as it has a generic nature.

Innovative ways of linking small scale forestry enterprises to markets: a review

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Abdalla Kisiwa[1]
Joram Kagombe[1], Jonah Kiprop[1], Antony Macharia[1, 2]
[1] Kenya Forestry Research Institute, Nairobi, Kenya.
[2] Ministry of Environment Climate Change and Forestry, State Department of Forestry, Nairobi, Kenya

Abstract: Small scale producers are considered the world's largest private sector, making up about 80% of forest enterprises and contributing to 50% of forest related jobs. However inadequate market mechanisms and lack of institutional instruments to connect the small scale enterprise to markets, threaten their prosperity. This article reviews and analyses innovative ways in which small and medium forestry enterprise in East Africa access markets and services for their products, as part of developing National forestry investment and innovation hubs to link producers to markets and services. We present analysis from forest producer organisations, forest dependent communities and institutions within East Africa on existing policy, institutional frameworks, support programmes and constraints in linking small scale producers to markets. Analysis uses a framework of 10 indicators on best practice in supporting small scale enterprise. Findings indicate that small scale enterprises have great potential to grow through forming aggregated groups for marketing products and improving marketing networks, diversifying distribution channels and uses of forest products and participation in various secondary processing and value addition process. However, challenges of isolation between practice and policy frameworks, limited financing mechanisms and lack of documentation of forest value chain information systems still exist. We conclude that national investment initiatives are required to connect small and medium enterprises to markets, enhance visibility of the enterprises, and provide communication channels for provision of advisory service and networking.

Key words: Small scale, forestry enterprises, market linkages, bio-economy, investment hubs

Introducing a lean forestry practice in a rural community context

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Gun Lidestav[1]
Stefan Sandström[1], Per Sandström[1]
[1] Department of Forest Resource Management, Swedish University of Agricultural Sciences

Abstract: In Sweden, there is an evident interdependence between small-scale forestry and large-scale forestry. Typically, the management systems, the technology and the logistics, primarily developed in large-scale forestry, are now also applied on small-scale forestland. The pursuit of reduced costs for timber for industrial purposes, through rationalization and simplification along the entire production chain, has resulted in a mono-measures forestry i.e. routinely; the same measures are done at all times and everywhere. Although small-scale forestry also may benefit from the rationalization gains, there are drawbacks of the "one-method-fit-all" principle that needs to be addressed. One way of doing this, is by introducing the *lean forestry* concept, which can be expressed as silvicultural measures that are as precise and resource efficient as possible, not only to minimise expenses and maximise high biomass and wood production, but also to maintain the potential for other forest ecosystem services (Rautio et al 2023). This requires exact spatial information that can be obtained by using remote sensing data from satellites or sensors on drones or attached to machines operating in situ. To explore how *lean forestry* can be applied in practice, what system and technological changes that might be required, and which gains that might be achieved, the ArcticHubs project are introducing the concept in a series of workshops with stakeholders in Malå. In this paper, the outcome of these workshops will be presented and discussed, particularly with regard to how small-scale forestry can benefit from the potential of more fine scale operations which also may support the preservation of other forest functions and thereby mitigate land use conflicts.

Key words: case study, exact spatial information, silvicultural measures, workshops

Moving towards join forest management at landscape level in Portugal: the case of Coimbra Region

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Jorge Cunha[1]
Virgínia Rocha[1], Sandra Valente[1], Alexandra Marques[1]
[1] CoLAB ForestWISE - Collaborative Laboratory for Integrated Forest and Fire Management

Abstract: Portugal is one of the European countries with the highest percentage of private forest. Land fragmentation is dominant, where forest areas are owned by more than 400 thousand small landowners and 85% of the holdings have an area of less than 3ha. These conditions discourage active forest management and are often pointed out as one of the causes of rural fires. Nevertheless, Portugal has a significant forest area (36% of the territory) and favorable conditions for the development of forestry activity, especially in low-density territories, where growth rates of forest species and the added value of forestry are among the highest in Europe. The effectiveness of forest management in small land areas depends to a large extent on how the owners' structure and organize their joint decision-making processes. Public policies in recent decades have promoted the implementation of join management instruments to increase the scale of intervention. More recently, two legal instruments were created - the Integrated Landscape Management Areas (AIGP) and the Village Condominiums (CA), in the umbrella of the Portuguese Landscape Transformation Program (PTP). One of the goals of these recent programs is to contribute to overcome property fragmentation by developing solutions that promote land consolidation and the consequent scale increasement to promotes resilience to fires, enhancement of natural capital and rural economy. For the creation and maintenance of the AIGP and CA to be more successful, it is important to create mechanisms to monitor the different initiatives, allowing good practices to be identified and generalized. This study implemented in the region of Coimbra, integrated in the RESIST project, co-funded by the European Union, aims to: understand the acceptance by the agents involved, namely forest owners; assess the impacts on the territory arising from the adoption of integrated forest and fire management practices, including silvicultural practices adjusted to climate change; identify and propose valorization models that boost the local economy. The relationship of the new AIGP and CA structures with other past join management initiatives will also be analyzed, such as the Forest Intervention Areas (ZIF), some of which are still active in the territory.

Opportunities for cooperation in multi-objective forest management – a case study of forestry stakeholders in Finland

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Liina Häyrinen[1]
Katriina Soini[1], Eija Pouta[1]
[1] Natural Resources Institute Finland (Luke)

Abstract: Forest owners (FOs) have various forest ownership objectives, and they simultaneously face manifold external expectations related to the use and management of their forest, such as forests' carbon sequestration, preventing biodiversity loss, and conservation of ecosystems. As many ecological functions (e.g., water conservation) are not restricted by forest property boundaries, the cooperation between FOs and other forestry stakeholders could offer novel opportunities for multi-objective forest management and reconciliation of diverse objectives. In the best-case scenario, this type of cooperation could, enhance the implementing of new voluntary activities, increase knowledge about different forest management options, and produce practical benefits in ecosystem conservation activities as well as financial reward.

Yet, there is relatively limited research knowledge on forestry stakeholders' perceptions on cooperation in forest management. Thus, the objective of this study is to investigate forestry stakeholders' interest in cooperation in forest management and to examine their perceptions on the benefits, opportunities, and barriers of cooperation. The research was conducted in two phases during 2022-2023 in Finland. The qualitative data were collected through 22 forestry stakeholder online interviews and were analyzed with content analysis. The data were enriched by quantitative survey data pilot collected from FOs (n=39) that were analyzed with quantitative methods.

Preliminary results indicate that there is a willingness to increase local awareness and interaction in forestry issues among forestry stakeholders. However, more information on the benefits and possibilities of cooperation is needed. Furthermore, there is a need for a coordinator of cooperation and such FOs who have sufficiently similar objectives in terms of the management and use of forests. The quantitative results show that one third of the FOs considered cooperation as fairly or very necessary in forest management related issues (e.g., carrying out of jointly agreed practices, such as loggings). Shared experiences with other FOs, new contacts, and interaction opportunities were seen as the most important benefits of cooperation. Moreover, cooperation would likely to improve water conservation possibilities and enhance biodiversity. The findings provide tentative understanding on stakeholders' cooperation opportunities and suggest that cooperation could provide opportunities to foster more sustainable forest management and use in Finland and beyond.

Perceived Opportunities and Challenges from Agroforestry Technologies Adopted by Kapit-Bisig Farmer's Association in Atimonan, Quezon, Philippines

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Rhyla Joy Aldipollo[1]
Lorena Sabino[1], Elsa Santos[1]
[1] Department of Social Forestry and Forest Governance, College of Forestry and Natural Resources, University of the Philippines Los Baños, Philippines

Abstract: This study examined the perceived opportunities and challenges from agroforestry technologies adopted among members of the Kapit-bisig Farmer's Association Incorporated (KBFAI) which was established in 1989 and became a partner farmer organization of the Department of Environment and Natural Resources (DENR) to implement the Community-Based Forest Management (CBFM) program. This program intended to rehabilitate, improve, and manage natural resources under the Certificates of Stewardship Contracts awarded to the 331 legitimate members with a total of 2,207.3 hectares. Agroforestry farming techniques are adopted by the members within the 4-7 has of land wherein 20% of which should be timberland and the 80% for any cash crops or livestock. Among the fifty (50) active members interviewed in 2019, their memberships to the KBFAI and as recipients to the DENR-CBFM program through trainings and seminars have equipped them with the knowledge and skills to implement an agroforestry system as main source of livelihood. Majority (90%) adopted the multi-storey type of Agroforestry system for the social, economic, and environmental benefits to farmers. In 2018, KBFAI was awarded the Best CBFM Model in the CALABARZON region. Leadership skills and collective efforts among them have improved as well as linkages/networks and good rapport with other government agencies were established. Economically, agroforestry provides farmers better yield and regular monthly income from the multi-storey system since they do not only integrate forest/fruits trees and agricultural crops, but also with poultry, bees, and livestock. The "*coprahan" venture*, selling of seedlings, basket weaving and whisk broom also contributed to the income sources of the KBFAI members. In terms of its environmental benefits, members observed that trees improved soil quality, provided shades for crops and livestock, restored water supply and reduced erosion. However, a study revealed that KBFAI also experienced both successes and setbacks in implementing this practice. Many of the members are senior citizens and having trouble managing their agroforestry farms and are facing challenges in convincing their children to carry on the work. The study recommends that local governments and agricultural institutions should create programs and incentives to encourage the younger generation to sustain agroforestry in the Philippines.

Socio-Economic Contribution of Small Scale Tree Nurseries to Smallholder Farmers in Kenya

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Emily Njagi[1]
Sylvia Mwalewa[1], Abdalla Kisiwa[1]
[1] Kenya Forestry Research Institute

Abstract: Forests and forest-based industries are moving towards a sustainable forest-based bio-economy. Forestry is a key financial resource, and supply of raw material for small scale entrepreneurs. It is, in principle, renewable, re-usable and recyclable. Small scale tree nurseries are a lucrative source of livelihoods to numerous households. They provide planting materials for afforestation, rehabilitation of degraded landscapes for climate action, and commercial forestry opportunities. The enterprise has not been fully embraced as an investment because little information exists on costs and return on investment. The specific objectives were to: identify preferred tree species raised in tree nurseries, evaluate the monetary value for the seedlings, identify market sources for the tree seedlings, evaluate the contribution of tree nurseries as a source of livelihoods and document constrains facing the tree nursery small scale dealers. The data was collected in Nyeri and Laikipia Counties, Kenya. Random sampling of tree nurseries was done and data was collected using semi-structured questionnaires administered to 400 nursery owners. Parameters evaluated included: socio-economic characteristics of nursery owners, tree species raised, costs and returns, cash flow of the enterprise, rate of return on investment and cost-benefit ratio. The data was cleaned, coded, entered and analyzed. A total of 86.1% of tree nursery owners were between 18 and 43 years old with male dominating (78.9%). The main tree species were *Melia volkensii, Senna siamea, Grevillea robusta*, fruit tree species (citrus, mangoes, and avocado), and ornamental species. The profit of a small scale tree nursery was between Ksh 100,000 – Ksh 300,000 annually and the rate of return was 90%, with cost-benefit ratio at 2.76. Challenges faced in tree nursery investment included: water shortage 35%, lack of quality tree seeds 25%, lack of proper potting materials 15%, lack of ready markets 15%, evictions by authorities 6%, pest and diseases 2% and inadequate funds 2%. Small scale tree nursery is an economically viable enterprise hence operators should be provided with entrepreneurial skills, access subsidized costs and environment friendly potting materials from economic stimulus programmes, and trained on producing high quality seedlings.

Key Words: Small scale, Cost benefit ratio, Tree nursery, Seedlings

Sustainable Community Forestry Development in Mexico

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Concepción LUJÁN-ÁLVAREZ[1]
Jesus Miguel Olivas-García[1], Susana Vázquez-Álvarez[1], Javier Hernández-Salas[1], Luis Ubaldo Castruita-Esparza[1]
[1] UNIVERSIDAD AUTÓNOMA DE CHIHUAHUA

Abstract: Climate change, biodiversity loss and socioeconomic conditions are important challenges for achieving sustainable community forestry development in Mexico. These challenges have created the need for building capacities in forest ejidos and communities (common property land), since they are who live with effects of any action in their communities. For that, it was necessary to apply a participatory strategic management model (different to traditional processes) in forest ejidos and communities for sustainable development. The integral model is based on three principles: strategic thinking, holistic vision, and participatory democracy. The model included: a) Multisearch Conference, which is a participatory and decision-making of "bottom up" process, and b) participatory strategic management model for the competitiveness of community forest enterprises. It includes strategies for designing, implementing, and monitoring strategic plans for managing sustainable forestry development. The application of the model allowed to the local people better motivation and appropriation levels of participatory decision making processes for driving their own development. Examples of outputs of this model are: a) Participatory strategic master plan for sustainable forestry development in the state of Chihuahua, Mexico; b) Integral forestry development project of the forest Ejido “El Largo and Anexas”, Madera, Chihuahua, Mexico (the largest forest ejido in Mexico), and c) Forest Productive Chain “Baja Tarahumara, S.C.”, Urique, Chihuahua, Mexico. In sum, the participatory strategic model promoted anticipatory and self-managed sustainable community forestry development. The model represents a paradigm shift in order to get sustainable community forestry development.

The De Carballo community forest, a remarkable case of sustainable self-management in north-western Spain

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

José M. Yglesias-Espiño[1]
Alberto Rojo-Alboreca[2]
[1] Comunidade de Veciños da parroquia de Carballo. Manxadoiro s/n, Carballo, Friol, 27228 Lugo, Spain
[2] Unidade de Xestión Ambiental e Forestal Sostible (UXAFORES), Departamento de Enxeñaría Agroforestal, Escola Politécnica Superior de Enxeñaría, Universidade de Santiago de Compostela. Benigno Ledo s/n, 27002 Lugo, Spain

Abstract: Spanish communal forests are currently only found in some regions of the country, especially in the region of Galicia (NW Spain), where communal forests are of a type called "Montes Vecinales en Mano Común" (which translates roughly as "neighbourhood communal forests"), a traditional and specific type of collective form of private land tenure with high economic, social and environmental importance. The De Carballo community forest (Friol, Lugo) is a paradigmatic case of the self-management and enhancement of the multiple uses and services that forests can generate. This forest (716 ha) was managed by the Galician public forest authorities through agreements reached in 1944 and 1953 and then by a further agreement, signed in 1982, which was finally rescinded by the community owners in 2009. The community members now manage the forest by themselves, with help from a forestry consulting company. This has enabled the community to fulfil the forest management plan in relation to the traditional timber uses, as well as to launch several initiatives involving other types of use (silvo-pastoral use with native horses, pigs and goats, mushroom foraging, honey and resin production) and services (promotion of social activities, including local festive events). The De Carballo forest was the first Spanish community forest to be awarded FSC certification, and it has since also been certified by PEFC. In conclusion, the De Carballo forest is a model example of a viable community forest and of how forestry can best serve the collective needs of people through self-management and leadership involving local communities.

Twenty years' review of Community Forestry Program in Taiwan.

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

An-Chi Lou[1]
Dau-Jye Lu[2], **Mei-Chih Yeh**[3]
[1] Taiwan Forestry Research Institute
[2] School of Forestry and Resource Conservation, National Taiwan University, TAIWAN
[3] Providence University

Abstract: While Taiwanese community forestry program, focusing on biodiversity conservation, has been implemented for more than 3,000 projects and become an important communication tool between forestry agencies and local communities in the past 20 years, this study aims to describe its contents and contributions, and discuss its influence on community participation, empowerment, local livelihood development and the following forestry policies. We adopted literature review, participant observation and interview to collect relevant information. Totally, about 400 relevant project reports, publications and papers were reviewed, and we have been involved in 22 occasions by participant observation, and conducted 16 semi-structured interviews from 2020 to 2022.

Almost Taiwanese community forestry projects belonged to the first stage, while with original design of three stages to empower local communities for co-management and/or co-governance of national forests step by step. Only about ten cases have been engaged and three of them have completely implemented the 2nd stage projects, as there isn't any 3rd staged project. The results showed that Taiwanese community forestry program could contribute to local social and human capital but do not work well on financial capital and livelihood development. Its content mainly focused on capacity building of local people and organizations, survey of fauna and flora, and those relevant to ecotourism development, which could play some role to improve local livelihoods. The sponsored program funding was mainly used on supporting operations of community organizations, promoting the internal and external social network, and creating job opportunities. The major deficiencies or weaknesses of Taiwanese community forestry program might be limited participation of communities and local people in forest governance. In recent years, Forestry Bureau has developed several new participatory policies to increase interactions with indigenous and local communities. Nevertheless, the community forestry program still one of the most popular and effective ways for the forestry agencies to build up partnerships with local communities on site. In this regard, this study suggests that Taiwanese community forestry program could be the empowerment tool and platform to integrate with above different policy programs for the forestry agencies to engage indigenous and local communities.

Two models for organising small-scale forest owners to receive income from timber sales: A comparative analysis between Japan and Sweden

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Masahiro Hayajiri[1, 2]
Vilis Brukas[2], Gudmund Vollbrecht[2]
[1] Hokkai-Gakuen University, Sapporo, Japan
[2] Southern Swedish Forest Research Centre, Swedish University of Agricultural Sciences, Alnarp, Sweden

Abstract: OECD countries in Northern Europe and Northeast Asia have a high share of privately owned forests crucial for sustainable forest management in both regions. Forest owner cooperatives (FOCs) constitute an important institutional arrangement for facilitating forest management and supporting profitability of family forestry. This study presents a comparative analysis between the economic models of organizing FOCs in Japan and Sweden.
In Japan, over 600 cooperatives largely rely on public subsidies and provide services in planting and harvesting. Most members' income comes from the standing timber sale. Their current income level is historically low and only about 30% of clearcut areas are reforested. In Sweden, forest owner cooperation is concentrated in three large-scale forest owner associations (that are in principle, FOCs), in northern, middle and southern parts of the country. Forest owner association Södra operates in the south, where the area of privately owned forests reaches 75% and 50 % of the area belongs to 52 000 members of Södra. Södra is the largest FOCs in the country and operates sizeable pulpmilling and sawmilling capacities. Having a large share of the roundwood market, Södra keeps down the standing timber price but shares the profits from the wood processing sector with its members.
The very different economic models of organizing FOCs in Japan and Sweden highlight the underlying economic conflict, when sawn timber and pulp sector strives to source logs for the lowest possible cost but forest owners try to sell their standing timber for as high price as possible. As sawn timber and pulp sector of Södra are large scale and internationally competitive, it can pass the profits from the processing to the shareholders, thus compensating the members for lower stumpage. Whereas most Japanese FOCs are primarily involved in forest management with no or insignificant own industrial capacities. Japanese FOCs have little influence on the log market due to the small scale operation per FOCs. Our comparison will highlight pros and cons for respective models, which can provide interesting lessons also for other countries.

What can transaction costs can teach us about managment structures in small-scale forests and their owners in Germany

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Gundula von Arnim[1]
Amelie von Behren[1], Bernhard Möhring[1]
[1] Georg-August-University Göttingen

Abstract: It is known that small-scale forest owners fall short of their forest utilization potential. This is often reasoned by a socioeconomically driven goal of preserving the forest value for their descendants. Their behavior could also be explained by the costs they need to incur to participate in the forest market, considered as transaction costs. Transaction costs belong to any economic activity, but they are specific, individual and not easily generated – especially for small-scale forest owners. Applying the transaction cost theory on small-scale forestry could open new solutions for mobilizing forest owners. Therefore, the aim of our study is to define transaction costs for small-scale forestry, to evaluate their impact on harvesting decision-making, and to estimate them empirically.

Firstly, we performed a literature review and expert interviews to build a concept for estimating transaction costs for small-scale forestry. Next, a harvest decision model was created to estimate the impact and the relationship of transaction costs and forest owners´ behaviors. Finally, we conducted an online survey to gather empirical data on transaction costs for private forest owners in Germany.

Analysis of literature exhibited the need for an empirical study on transaction costs. The implementation of transaction costs to the model showed an apparent effect on the behavior of forest owners. Increasing costs reduce the activity of forest owners and intensify the logging measure. The online survey confirmed these results. The expert interviews showed that existing basic management structure, larger forest area per forest owner or measure, and outsourcing to professionals lead to less transaction costs for forest owners. In contrast, determinants like smaller forest estates, or less education on forestry and a "do-it-yourself" strategy promote higher transaction costs.

This study emphasizes the importance of reducing transaction costs and the improvement of market efficiency and access, especially for small-scale forest owners.

Who are the owners of private forests in Poland and what is the importance of ecosystem services to them?

T4.27 Small-scale, Community, and Indigenous Forestry: Global Challenges and Opportunities

Emilia Wysocka-Fijorek[1]
Piotr Gołos[1]
[1] Forest Research Institute

Abstract: Constant process of generational change among forest owners, which was further intensified after 1989 in the countries of Central-Eastern and Southern Europe by the appearance of "new owners" as a result of reprivatization processes of forest property and a new group of owners who benefited from the financial support of the Common Agricultural Policy for the afforestation of land excluded from agricultural use. The positive effect of these processes is the increase of private forest area, while the negative consequence is further fragmentation of private forest area. The social phenomenon that accompanies the described changes is the weakening of the relationship between the "new" owners and agriculture or rural areas. A large part of the owners are not interested in forest management because it is not important for them as a source of income.

Forest ecosystems, regardless of ownership or management type, are suppliers of many products and services, both market goods and public goods and services. The main difference in the provision of the latter by private forests, as opposed to public forests, is that owners must assume the obligations arising from their property rights, as reflected, among other things, in numerous programs to compensate forest owners, for example, for the costs of protecting biodiversity or for lost income due to the abandonment or curtailment of timber harvesting. Thus, if private forestry is expected to engage in biodiversity, climate, water, and soil conservation on a large scale, it is necessary to know not only the expectations of owners, but also the level of their knowledge and awareness of nature, which is shaped by the value system of forest owners that governs the implementation of forest management. Knowledge on the above scale is necessary to implement the best solutions for multifunctional forest management, whose main objectives compete with each other to varying degrees. In addition, the objectives set in both the planning and implementation phases need to be increasingly modified, taking into account the increasing impact of extreme weather events in recent years that threaten the sustainability of forest ecosystems.

T4.28 Towards quantitative explanations of forest governance and its complexity

Advancing quantitative statistics in governance research – case study examples from tropical forest policy

T4.28 Towards quantitative explanations of forest governance and its complexity

Richard Fischer[1]
[1] Thünen Institute of Forestry, Thünen Institute, Germany

Abstract: Different and increasingly diverse demands on forests and their ecosystem services require an increasingly complex forest policy, which usually relies on various single policy instruments. In addition, combinations of individual instruments in different mostly country specific policy mixes must be considered. These are related to and driven by different stakeholders. Governance research requires adequate methods to analyse the interplay of governance components and the effectiveness of policy instruments. Using case studies on current tropical forest policies in Ecuador, Zambia and the Philippines, quantitative approaches to forest policy analysis are presented. These rely on classical governance (field) assessment methods like literature reviews, interviews and focus group discussions which are as well widely used in qualitative approaches. However, through coding and scoring, numerical data are produced that are the basis for statistical evaluations. Selected results include examples for parametric and non-parametric comparisons of means for different governance components in order to analyse governance quality across landscapes and tenure regimes. Multiple regression analysis is applied to determine the significance of underlying (e.g. governance) and direct drivers for deforestation. In another application, preferences of stakeholders for different policy instruments and their combinations are determined by means of principal component analysis in the three study countries. Social network analysis is used to quantify the power of individual stakeholders. Relations between preferences for policy instruments and power can form the basis for recommendations for individual instruments. Based on these examples it can be concluded that such reproducible and stochastic quantitative designs are needed to allow for generalization of results. However, specifically the formulation of research questions and the interpretation of results need a deep procedural understanding, e.g. resulting from qualitative research. This shows that a polarization between quantitative and qualitative approaches is neither useful nor intended.

Assessing changes in Brazil's international forest policy engagement and capacity

T4.28 Towards quantitative explanations of forest governance and its complexity

Ana Alice de Oliveira Tavares[1]
Sarah Lilian Burns[1, 2]
[1] Institute of International Forestry and Forest Products, TU Dresden, Germany.
[2] Laboratorio de Investigación de Sistemas Ecológicos y Ambientales, Facultad de Ciencias Agrarias y Forestales, Universidad Nacional de La Plata, La Plata, Argentina

Abstract: In the last decades, Brazil has been under increasing scrutiny regarding its policy towards forests, especially during Bolsonaro's presidency (2019-2022). While both domestic and international forces have a considerable influence over the foreign policy of a country, Brazilian presidents have often acted as drivers of changes in diplomatic strategies, shaping them to their own beliefs and interests. Such changes in diplomatic strategies translate into issue-specific shifts in the policy capacity and engagement of the country. While previous studies showed the overarching shifts in Brazil's foreign policy under different presidencies, this study focused specifically on variations in capacity and engagement on forest issues. This was done by determining changes in resources allocated to diplomacy (as a proxy for capacity) and in the degree of interaction with other countries (i.e., engagement). To reach this goal, we carried out a quantitative analysis of the bilateral and multilateral agreements signed by Brazil from 1995 to 2022, as well as the size of delegations sent to international forums on forests, climate change, and biodiversity. The choice of the timeframe used in this analysis captures the surge in presidential engagement in diplomatic issues, and its further development throughout the terms of five executive leaders. The quantitative data were further complemented by expert interviews and qualitative content analysis of presidential declarations. Our results indicate a trend of increasing engagement and capacity, followed by a noticeable decrease during Bolsonaro's presidential term.

Comparative analysis of wildfire policies across European and South-American countries

T4.28 Towards quantitative explanations of forest governance and its complexity

Gabriela Huidobro[1]
Lukas Giessen[1], Sarah Burns[1, 2]
[1] Technische Universität Dresden
[2] Universidad Nacional de La Plata

Abstract: Wildfires and societies have co-evolved during millennia, with fire being a cost-effective management tool. However, in recent decades, unprecedented wildfire seasons have disrupted the coupled human and natural system due both to climate conditions and inadequate policies, mostly targeting fire exclusion and emergency suppression as ad-hoc reactions. Wildfire policies, composed of goals, instruments and implementing actors, can be influenced by different factors, including the salience of fire as an issue, the political system of the country as well as its domestic capacities. Hence, the aim of this study is to compare and explain wildfire policies in countries with different development status, issue importance, and political system. In order to do so, following a most different research approach countries in South America and Europe were selected as cases. In each country fire policy issues were identified based on a document and media content analysis. Data was obtained from nationally distributed newspapers as well as professional journals, regulations, and programs within a specified time period. Simultaneously, actors and policy instruments were identified and characterized following Krott (2005). The identified wildfire policies were classified according to a proposed classification system that can be applicable to other cases. Data was analysed with a qualitative comparative analysis (QCA), with issue salience, policy system and the countries´ capabilities as explanatory conditions explaining the fire-policy (outcome). Our results show that wildfire policies relate to the general and issue specific countries´ capacities and polity. This study will allow us to better comprehend which factors are playing a role in wildfire policies.

Evolution of cooperation networks of forest governance system in China: Based on Bibliometric Analysis of 2571 Policy Documents, 1949-2020

T4.28 Towards quantitative explanations of forest governance and its complexity

Shuirong Wu[1]
Yangting Yu[2], Xufeng Zhang[3]
[1] Research Institute of Forestry Policy and Information, Chinese Academy of Forestry, Beijing 100091
[2] Shaanxi Forest Seedling and Farmland Conversion Project Management Center, Shanxi 710054, China
[3] School of Management and Economics, Beijing University of Technology, Beijing 100124, China

Abstract: Forest governance is intrinsically complex, comprising forest use and conservation and dealing with ecological and socio-economic issues from multiple levels. The independent or pluralistic cooperative relationship of forest governance authorities is an important part of the process of policy decision-making. It is of great significance to analyze the cooperation network and its evolution trends among policy-making authorities to further clarify the policy development path and improve the coordination mechanism of forest governance. Taking the 2571 forestry policy documents issued at the national level from 1949 to 2020 as research samples, applying social network analysis method, this paper analyzed the evolution characteristics of the cooperation networks of Chinese forest governance authorities and their roles in the network by drawing the cooperation networks and the two-dimensional matrix with breadth and depth of cooperation. The results show that the number of annual forestry policy documents issued at national level in China has a trend of first fluctuating upward and then slowly downward during 1949-2020, with distinct phased characteristics. The main body of forest governance has shown the characteristics of extensive and dominant coexistence, involving up to 150 departments. However, the national forestry administrative department, the finance department, the development and reform committee and the national agricultural administrative department are the leaders of forestry policy joint issuance, and the national forestry administrative department has always been the authoritative body of the forestry policy releases, accounting for 82% of the total number of forest policy documents. The cooperation among the main authorities in the network has evolved from the loose situation with the national forestry administrative department as the core to the situation with it as the core of the network and the multi-sectors partial core equilibrium. This indicates that in recent years the national forestry administrative department has been playing a dominant role in promoting the forestry development and the construction of ecological civilization together with multi-sectors in a coordinated way. In the context of increasingly prominent forest externalities and environmental problem complexity, interdependency and cooperation among sectors are effective ways to solve the environmental problems and promote the construction of ecological civilization.

Global governance for deforestation-free cocoa

T4.28 Towards quantitative explanations of forest governance and its complexity

Haeun Lee[1]
Mi Sun Park[2]
[1] Swedish University of Agricultural Sciences
[2] Seoul National University

Abstract: As a commodity crop, cocoa has been developed globally to tackle cocoa-related issues such as price stabilization, deforestation, child labor, and smallholder farmers' living income. This study examined global cocoa rules through quantitative content analysis of global documents related to the cocoa sector. The research explores over 60 years of global cocoa rules since 1962, the year of establishing the Intergovernmental Cocoa Organization with member countries (22 exporting countries and 26 importing countries) under the auspices of the United Nations, to 2023. Global society has made efforts to reduce deforestation in cocoa production through hard and soft laws. In the 1970s and 1980s, International Cocoa Agreements by International Cocoa Organization more focused on alleviating price and market difficulties. However, starting from the 5th Agreement in 1993, the Agreements included agenda with environmental aspects and sustainable production. In the 2010s, Global Cocoa Declarations appeared as a new rule of the global cocoa sector, including the deforestation agenda. Global Cocoa Farmers Conference in 2018, organized by the International Cocoa Farmers Organization, declared farmers' participation in the global cocoa communication and decision-making processes, which included climate change, deforestation, and sustainability. The declarations also provide specific guidelines for collective action for sustainable cocoa production and forest protection. Recently European Union adopted Deforestation-Free Regulation targeting six global commodities, including cocoa. Global cocoa governance indicates the changes in the rules for controlling deforestation in the cocoa industry. Hard laws are necessary to improve the effectiveness of achieving the goal. However, this effectiveness must entail the much more precise norms adopted through the soft law institution. The cocoa sector shows a synergetic design between the hard law, including International Cocoa Agreements and EU Deforestation-Free Regulation, and soft law, including declarations.

The forest-climate interface: Exploring drivers of state participation in informal forest-related climate governance arrangements

T4.28 Towards quantitative explanations of forest governance and its complexity

Fredy David Polo Villanueva[1]
Simon Schaub[2], Laura Rivadeneira[1], Sarah Burns[1]
[1] Chair of Tropical and International Forestry, Institute of International Forestry and Forest Products, Dresden University of Technology, Dresden, Germany
[2] Institute of Political Science, Heidelberg University, Heidelberg, Germany

Abstract: The 1992 Earth Summit marked both the UN's failure to create a global convention on forests and its success in creating a convention to address climate change (i.e. the UNFCCC). However, years later, out of the UNFCCC negotiations would emerge arguably the most relevant international forest policy to date: Reducing Emissions from Deforestation and Forest Degradation (REDD). The REDD mechanism exemplifies how a climate-focused agreement can nonetheless have a major influence on forest governance. While forest and climate policy scholars have independently explored the specific features and challenges, as well as assessed the effectiveness of the REDD mechanism, other similar forest-related climate initiatives remain understudied. Therefore, to contribute to filling this knowledge gap, we aim to explore issue-specific explanations for state involvement in the growing number of informal forest-related climate governance arrangements (FCGAs). To achieve this goal, we will map and characterise a large number of FCGAs using the Yearbook of International Organisations as a primary source, binary code our variables of interest and (possibly) use binomial logistic regression to model state involvement. In addition, we will contrast our results with responses to semi-structured interviews with key government actors. Drawing on scholars of international relations, we hypothesise that countries with higher forest economic indicators (e.g. value of exported forestry products) will engage in more informal settings to avoid having to comply with strict forest conservation rules linked to climate change mitigation commitments.

The subnational government power influence in the management of forest protected areas in Patagonia

T4.28 Towards quantitative explanations of forest governance and its complexity

Rocio Melina Garcia[1]
Pablo Yapura[2]
[1] Institute of Research on Natural Resources, Agroecology and Rural Development (IRNAD) (UNRN-CONICET)
[2] Laboratory of Research in Ecological and Environmental Systems (LISEA) (UNLP)

Abstract: Protected forests are territories of power struggles between different private and state actors at different levels of governance with increasingly land use pressures. In federal countries, where forests are under a subnational jurisdiction, subnational actors have a strategic role in the management of forests, resulting in power distributions. In Argentina, the aesthetic attractiveness and environmental value of the Andean Patagonian Forests resulted in the protection of the ecosystem under different features, turning the ecological region into one of the most protected with both national and subnational protected areas. Against this background, the aim of this study was to analyse and compare the power balance of the actors involved and define the role of the subnational government in two protected areas with different jurisdictions. In order to do so two protected areas in the Andean Patagonian region were selected, in the first case the subnational government is the main authority and in the second case the subnational government shares the administration of a forest territory with the national government and indigenous communities. By applying the Actor Centred Power approach that considers the power expression into three elements: information, incentives and coercion we compared the governance structure in both areas. Our results showed that in both cases the subnational government was one of the actors with most coercive and incentive power, although the information power remained with other actors. However, subnational governments did not show enough coercive capacity to develop effective regulations to prevent the appearance of conflicts of interest.

Towards quantitative explanations of foreign forest policies

T4.28 Towards quantitative explanations of forest governance and its complexity

Sarah Burns[1, 2]
Ana Alice de Oliveira Tavares[1], Lukas Giessen[1]
[1] Institute of International Forestry and Forest Products, TU Dresden, Germany
[2] LISEA, Faculty of Agriculture and Forest Sciences, National University of La Plata

Abstract: Foreign forest policies can be defined as the processes which regulate the conflicts of interests around forests having known consequences for actors external to a nation state. With globalization the capacities of central foreign bureaucracies to oversee all foreign affairs, especially issue specific ones, are exceeded allowing other bureaucracies to expand and build up own units dealing with these issue-specific international relations . Following the core theses of bureaucratic politics theory, the bureaucracies in charge of these emerging sectoral foreign policies are striving for autonomy from other sectors, including foreign affairs, with whom they must coordinate with. Countries' bureaucracies have included forests as an issue in their foreign policy agendas with forest related bureaucracies becoming increasingly relevant in foreign policy. However, the forest sector has strong relations with the environmental, agricultural and industry sectors competing but also making coalitions based on the overlapping portions of their interests. Latin America, relatively more forested than any other region of the world and containing the Amazon rain forest, has received a lot of international attention. However, most research on foreign policy focuses on developed countries from the Global North, with a lack of studies on Latin America.

In this context, bureaucracies in Latin American countries have included forests as an issue in their foreign policy agendas, with forest related bureaucracies becoming increasingly relevant. However, the importance of forests as an issue widely varies between countries, which can be assumed having severe implications on a country's foreign forest policy. This paper aims at analyzing and comparing foreign forest policies in Latin American countries. Through social network analysis, our results showed that in those countries where forests are a salient issue more actors and their coalitions were involved in the development of foreign forest policy, resulting in complex policy networks and limiting the autonomous agency the coalitions could perform. Contrary, in the countries where forests are not a salient issue, a limited set of actors and coalitions engaged, providing them with high degrees of autonomy. In all countries, however, the resulting foreign forest policy was greatly shaped by the most powerful actors in the networks.

T4.29 Tradition in Transition Social and cultural aspects of sustainable forest management in the context of climate challenges

Building resilience for sustainable livelihoods in forest-reliant communities: 15 years of collaborative work with Indigenous Peoples and smallholders

T4.29 Tradition in Transition Social and cultural aspects of sustainable forest management in the context of climate challenges

Monica Gabay[1]
Noel Carlos Paton[2], Hugo Arce[3]
[1] Ministry of Environment and Sustainable Development - Argentina
[2] Formoseño Model Forest
[3] National Parks Administration

Abstract: Local communities and Indigenous Peoples have been widely recognized as stewards of forests and their biodiversity, a fact reflected in the Kunming-Montreal Global Biodiversity Framework of the Convention on Biological Diversity. However, these important actors are usually in a vulnerable situation, struggling with their local livelihoods and poverty. This presentation synthetizes the experience and lessons learnt from 15 years of bottom-up collaborative work with Argentine Indigenous Peoples and local communities with the valuable support from the Austrian Government.

Within the framework of the 2030 Agenda for Sustainable Development, these actions promote sustainable management of forest landscapes to enhance resilient and sustainable livelihoods for Indigenous communities and creole peasants, social inclusion and women and youth empowerment, in line with sustainable development goals 1 (no poverty), 2 (zero hunger), 5 (gender equality), 13 (climate action) and 15 (life on land). They include small-scale projects on conservation and sustainable management of forests and non–timber forest products, capacity building for local production, agroforestry, traditional crafts production and commercialization, and valorization of traditional knowledge. A key enabling factor of these experiences is a robust governance, achieved through strengthening dialogue spaces among grassroots organizations and local stakeholders with an emphasis on Indigenous and peasant communities' involvement and gender-responsiveness.

These projects involve the active participation of indigenous communities (qom, wichí, mbyá guaraní, qolla, mapuche-tehuelche, diaguita), creole peasants and grassroots organizations in every step from project design to implementation, in six Argentine provinces, and joint work of these actors together with public agencies, academia, NGOs and the private sector.

Governing EU's forests on the route to Paris: identifying leverage points for the facilitation of just sustainable transitions

T4.29 Tradition in Transition Social and cultural aspects of sustainable forest management in the context of climate challenges

Auvikki de Boon[1]
Johanna Johansson[2], Andreas Eriksson[3], Camilla Sandström[1]
[1] Umeå University, Department of Political Science, Sweden
[2] Södertörn University, School of Natural Sciences, Technology and Environmental Studies, Sweden
[3] Swedish University of Agricultural Sciences, Department of Forest Resource Management, Sweden

Abstract: Following the Paris Agreement and the European Parliament's declaration of a climate emergency, the EU has developed multiple directives and strategies, including the European Green Deal, which describe EU's forests as a key contributor to the aimed for sustainability transition and agreed climate goals. In addition, the EU has made commitments that these transition processes are conducted in a just manner. We examine whether the translation of the EU's ideas around forests' roles to the national contexts of the member states create national level, tangible, leverage points for change. We aim to gain deeper understanding of differences in framings of the forest at different levels, potential synergies and trade-offs between different prescribed roles to forests at different levels, what policy instrument mixes are proposed to motivate forest owners to manage their forests so as to contribute to the fulfilment of these roles, and in what way just transition considerations, including the balancing of diverse interests, are incorporated in these policy instruments. We conduct a case study in which we analyse and compare the Paris Agreement, EU climate and biodiversity directives and strategies, and Swedish government bills, strategies, and action plans for forestry. We find that, whilst there are many roles and goals ascribed to EU's forests, there are no clear leverage points for the facilitation of a just sustainability transition in the forest sector both at the EU and in Sweden. The current setup provides opportunities for synergies in the short-term, but risks goal conflicts and trade-offs in the long-term. Furthermore, there is divergence in focus of policy instruments, where EU climate policy builds on rules and regulations and economic instruments, whilst the Swedish forestry policy focusses on social and information-based instruments. Neither include rights-based instruments and the EU's commitment to create just transitions has no prominence in the proposed policy instruments and national level policy documents. We conclude that the current translation of EU goals to the national level in Sweden provides insufficient leverage points for forest owners to engage with the sustainability transition and risks a lack of perceived legitimacy through its limited attention to considerations of justice.

Integrating Scientific and Indigenous Ecological Knowledge in Conservation of Threatened Woody Tree Species in Kenya

T4.29 Tradition in Transition Social and cultural aspects of sustainable forest management in the context of climate challenges

[2] Kenya Forestry Research Institute, Forest Biodiversity and Environment P.O Box, 20412 - 00200, Nairobi, Kenya

Abstract

The indigenous ecological knowledge has been poorly incorporated into conservation and management of natural resources due to its perceived insignificant contribution. Lately, scientific community and policy makers have recognized the importance of integrating indigenous and scientific knowledge to address challenges in natural resource conservation as reflected in international strategies such as Convention on Biological Diversity. This study combined qualitative and quantitative approaches to identify, rank and prioritize tree threatened species through Focus Group discussions. Community members were guided to free list all the tree species known to have existed in the area. Prioritization of the species of conservation importance followed gender based Hierarchisation and prioritisation methods aligned to IUCN classification system of population trend and threat analysis against a baseline of 1970. Species with population decline of ≥ 80%, ≥ 50% and ≥ 30% were classified as Critically Endangered, Endangered and Vulnerable respectively according to IUCN category A4 population reduction class. The key drivers of degradation perceived to have contributed to species loss or population decline were illegal and overharvesting for diverse products (0.22) driven by high poverty levels (0.12). Others limitations were low natural regeneration potential for certain species and climate change. Prioritisation of species for conservation varied across gender due to differences in perceived use values and threats. Fourteen species were listed as critically endangered with population decline now and in the future of ≥ 80%. *Oldenia alpina*, *Schefflera volkensii*, Podocarpus sp and *Vepris nobilis* were among the species perceived to require urgent conservation measures. Integration of indigenous knowledge in scientific research provides a low cost and local practical solutions to biodiversity conservation.

Lessons from the Global South: Forest-related cooperation and the importance of local knowledge and communities

T4.29 Tradition in Transition Social and cultural aspects of sustainable forest management in the context of climate challenges

Jesús García Latorre[1]
[1] Ministry for Climate Action, Environment, Energy, Mobility, Innovation and Technology

Abstract: The world's forests are being devastated at a rate of 10 million hectares annually. Most of this catastrophe is occurring in the countries of the global south. Agribusiness and consumption patterns, particularly in developed countries, are of great relevance in contributing to this serious problem. International cooperation can play a relevant role in avoiding deforestation and supporting the maintenance of forest ecosystems. In this regard, this contribution, based on the author's experience working with cooperation projects, highlights the importance of focusing on local and indigenous communities to strengthen their capacities and resources. Such initiatives must be based on a participatory approach and should be characterized by absolute respect for the cultural and spiritual context and the rights of these communities. The interest of the communities in sustainably managing the natural resources on which they depend, illustrated by the concept of "the environmentalism of the poor", can also be reinforced by cooperation initiatives. Practical experience shows that this approach with a focus on supporting local and indigenous communities is a very efficient form of cooperation. On the contrary, the eventual donor country's belief in the superiority of its approach to forest management can lead to its uncritical transfer to the recipient country. This may be encouraged by the host government's perception of everything that comes from abroad, particularly from a more prosperous country, as better. The transfer of know-how from the donor country without critically assessing its possible negative impacts must be seriously questioned.

Stone enclosures in the Šumava Mountains. Mysterious structures or prosaic traces of past forestry?

T4.29 Tradition in Transition Social and cultural aspects of sustainable forest management in the context of climate challenges

Dagmar Dreslerová[1]
Michal Dyčka[1], Čeněk Čišecký[1], **Jiří Woitsch**[2]
[1] Institute of Archaeology of the Czech Academy of Sciences, Prague
[2] Institute of Ethnology of the Czech Academy of Sciences

Abstract: The upper parts of *Šumava* (*Bohemian Forest*) in the Czech Republic and the *Bavarian Forest* in Germany represent some of the most valuable ecosystems in Europe and are protected as national parks. The mountain spruce forests here are considered to be almost pristine and unaffected by exploitation and management. However, modern airborne laser scanning (LIDAR) methods have revealed numerous surface relics of past human activity: Square or rectangular stone enclosures with edge sizes ranging from 20 to 40 m. Around 400 of these formations are currently known in an area of approx. 600 sq km, but the number is not definitive. They are all located at altitudes of around 1100 m.a.s.l.

The stone structures are difficult to see and find in the rugged mountain terrain, which, together with the loss of historical memory following the displacement of the German population after WW II, has caused a complete lack of awareness of this phenomenon. Combination of radiocarbon dating, observed age of the present-day vegetation, and historical maps allows to estimate origins of the enclosures between 1650 and 1850. Avaiable literature does not contain any data on enclosures and research in archives is at early stage.

Interpretation of the stone enclosures is therefore only at the stage of estimation, but at least the majority of them can be considered seedbeds and forest nurseries. If assumption, that the dozens of forest seedbeds in such high altitudes were founded before the great forest calamities of the 1860s-1870s, proves true it will be necessary to completely rewrite the history of forestry in Šumava and in general re-evaluate data relating to the origin of forest stands and their management in the early modern period.

This can then lead to a better understanding of - now forgotten - local practices linked to the harsh natural conditions, which were based on both indigenous knowledge and the principles of modern forestry. This knowledge, destroyed by the events of the 20th century, can at the same time contribute to improving conservation mechanisms and forest management in a region that is massively affected by the consequences of climate change (esp. bark beetle outbreaks).

The fate of Mijikenda Sacred Kaya Forests: Is there hope for their restoration in the wake of emerging threats?

T4.29 Tradition in Transition Social and cultural aspects of sustainable forest management in the context of climate challenges

Leila Ndalilo[1]
Chemuku Wekesa[1]
[1] Kenya Forestry Research Institute

Abstract: *Kaya* forests, located along Kenya's coastal landscape are sacred forests of the Mijikenda community and have existed since the 16th century. In the recent years, these forests have been diminishing in size mainly due to encroachment and over-exploitation begging questions as to whether they can withstand the enormous threats over time. A study was conducted to assess the emerging threats to Kaya forests and develop strategies for their mitigation, and sustainable conservation of the forests. The study covered four Mijikenda Kaya forests namely Kaya Mudzi Mwiru, Mudzi Muvya, Bomu and Fimboni in Rabai, Kilifi County. Participatory rural appraisal methods comprising household questionnaires, Focus Group Discussions, Key informant interviews, transect walks, and oral narrations were used to collect data. Our study found that the main threats to Kaya forests are rapid population growth, infrastructural development and proximity to Mombasa city, cultural erosion and over-exploitation of forest resources which have resulted to their extensive degradation. The loss of indigenous knowledge systems that underpin the conservation of these sacred forests further compounds the threats with potential for significant negative impacts on the livelihoods of local communities who are dependent on the forests, biodiversity conservation and climate change mitigation and adaptation. The main strategies proposed for addressing the threats were community sensitization on the importance of conserving the forests, development of sustainable alternative sources of livelihoods for local communities and creation of employment opportunities for the youth to reduce degradation pressure on the forests, and establishment of a biocultural heritage territory in Rabai to enhance collective governance of the landscape by the community to reduce threats. The study findings reinforces the need to protect indigenous knowledge systems and strengthen traditional governance systems which underpin the conservation of kaya forests for enhanced conservation and socio-economic benefits.

The possibilities of using different spatial data in the mapping of non-protected cultural heritage

T4.29 Tradition in Transition Social and cultural aspects of sustainable forest management in the context of climate challenges

Jürgen Kusmin[1]
[1] Estonian State Forest Management Centre

Abstract: The description and mapping of non-protected signs of human activity in the landscape, that is, cultural heritage sites, began in Estonia in the early 2000s. For example, old farm sites, historic forest roads, stone fences and many other objects that have value to the landowner or the local community. At the initiative of the State Forest Management Centre and with support from international cooperation projects, more than 43,000 cultural heritage sites, which have been described regardless of ownership and land use type, have been entered into a database in Estonia. The prepared public map layer is in the public domain and is a source of information for both landowners and those that plan various activities affecting the landscape (mainly state and local agencies and companies involved with planning). As Estonia's forest cover has increased in the last 80 years (covering over 50 per cent of land area now), many signs of human activity that were previously found in the open landscape are now located on forested land. Logging is an important factor affecting their condition. The National Forest Register has also been established to provide information about cultural heritage sites when registering a forest notification that permits felling in an area that overlaps with records entered in the database. The object-saving working methods are part of the trainings for forest management specialists and forest workers in Estonia. There is also a subsidy for private forest owners for the maintenance and exhibiting objects of cultural heritage. The mapping work was done with the help of local people, where in addition to oral tradition and landscape inventory, historical maps and other written materials were used to find objects. In the last years it has become possible for the public to use various GIS-data created by the Estonian Land Board. The cross-use of spatial data for the pre-selection of cultural heritage objects before fieldwork in the landscape has been simplified. The article deals with the synthesized use of georeferenced historical raster maps, Lidar relief data, the Estonian Topographic Database and oblique aerial photographs for the identification and mapping of new cultural heritage objects.

Traditional forest related knowledge's contribution to rural livelihoods, food security and sustainable forest management in Africa

T4.29 Tradition in Transition Social and cultural aspects of sustainable forest management in the context of climate challenges

Doris Mutta[1, 2]
Alfred Oteng-Yeboah[3], Dominic Byarugaba[4], William Armand Mala[5]

[2] Kenya Forestry Research Institute, Nairobi, Kenya
[3] Department of Botany, University of Ghana, Legon, Ghana
[4] Department of Biology, Faculty of Science, Mbarara University of Science and Technology, Mbarara, Uganda
[5] Department of Plant Biology, Yaoundé I University, Yaoundé, Cameroon

Abstract: The rich body of traditional forest-related knowledge in Africa has been widely acknowledged as important for its contribution to current global efforts towards sustainable forest management, biodiversity conservation and adaptation to climate change. While many rural communities in Africa continue to observe their age-old traditions in relation to forests to ensure the provision of their livelihoods, other communities have lost their traditions for many reasons, including their forced or voluntary cultural alienation from forests, reduced dependence on forests for rural livelihoods, and extensive urbanization. Nonetheless, many communities throughout Africa are still living in or near the continent's diverse range of forest ecosystems and continue to depend on these forests for their livelihoods and in adapting to environmental stress. A documentation of how communities have successfully managed these forests to provide for their needs until the present day can serve many useful purposes, including for evidence-based sharing of experiences or case studies, research adoption and uptake, and knowledge transfer and training in forestry curricula. In this paper, based on a review of scientific literature on exploratory studies conducted among forest proximate indigenous people in Cameroon Ghana, Kenya and Uganda we provide a general background on traditional forest-related knowledge in Africa; its historical and present contributions to food security, and rural livelihoods; the present challenges faced by the holders and users of this knowledge; and institutions governing the use; and opportunities for its preservation, enhancement, and application to help solve pressing environmental, economic, and social challenges, including the conservation and sustainable use of forest biodiversity, and responses to climate change.

W8banaki forestry stewardship: Managing culturally keystone species on Indigenous territory

T4.29 Tradition in Transition Social and cultural aspects of sustainable forest management in the context of climate challenges

Laurence Boudreault

Abstract: W8banaki basketry is a very important practice based on indigenous knowledge and depend on black ash (*Fraxinus nigra)* availability and viability. W8banaki basketry consists of weaving strips of black ash wood and sweetgrass into baskets. This practice is intrinsically linked to a way of being. Black ash is a ring-porous hardwood, that is used for basketry and that also plays fundamental cultural importance and is tied to the cosmology of many indigenous nations, including the W8banakiak (ak indicates plural). In the context of global changes, indigenous forest users face many challenges right now. External pressures are threatening ecosystems and traditional basketry activities, and therefore all the traditional knowledge associated with it. Like other cultural keystone species, the importance of black ash is not always known, recognized, and often not taken into account by forest managers and other territory stakeholders. The implementation of adaptation measures by the Nation about black ash is also hindered by the fact that the ancestral territory of the W8banakiak is now highly privatized, which limits access to the land and the resource. The Nation has mobilized many times in history, performing acts of resurgence to maintain the relationship that unites them to black ash.

Laval's University and the Grand Council of the W8banaki Nation has partnered in order to propose black ash management tools to support the Nation's adaptation process. The first step of this project allows us to understand that to be used for basketry, annual ring of black ash needs to be of a certain width on of a certain density. They can be then transformed into very thin and flexible strips that will be woven. Those properties being influenced by climate and biophysical condition are influenced by management. Knowing the growing condition that support black ash quality and viability, we will then be able to propose innovative measures for the management of the species based on the W8banakiak stewardship vision and knowledge that can enhance and sustain both black ash and basketry has to ensure the transmission and securing of knowledge and practices.

T4.30 Urban green against air pollution and climate change

An analysis of the thermal environment of scenario-based urban greening types

T4.30 Urban green against air pollution and climate change

Jae-Yeon Lim[1]
Jin-Kyu Min[1], Ju-Hyeon Park[1], Jeong-Hee Eum[1]
[1] Dept. of Landscape Architecture, Kyungpook National University

Abstract: Rapid urbanization has reduced green spaces in cities, increased artificial pavements and buildings, and caused various urban environmental problems, including worsening thermal environment. Green spaces are evaluated to be effective in improving the thermal environment, such as reducing the urban heat island phenomenon. In particular, the degree of thermal environment improvement may differ depending on the types, forms, the method of construction of urban greenery. It is necessary to find the optimal green space construction scenarios for efficient thermal environment improvement. This study aims to categorize the types of green spaces that exists in urban areas, design detailed construction scenarios, simulate thermal environment using ENVI-met 5.1.5v, and suggest effective green space construction methods. This study area is Jung-gu district in Daegu Metropolitan City, which is one of the hottest cities in South Korea. An area of 1.5km*1.5km including a 10-lane boulevard and a large urban neighborhood park was designated as the analysis range. The types of urban green spaces were classified into 'roadside trees', 'urban parks and school forests', and 'greening of redevelopment areas'. Based on them, several urban green scenarios were derived to simulate their effects of degree of thermal environment improvement. By comparing the air temperature and surface temperature of each green space scenario with those of the current situation, the most effective scenarios for improving the thermal environment in the study area were derived. This study is meaningful in that it quantitatively compared the effects of improving the thermal environment according to various green space scenarios. It is expected to be used as basic data for efficient and economical thermal environment strategies and planning measures.

An analysis on cooling effects of urban forests in densely built-up areas : A case study in Daegu, South Korea

T4.30 Urban green against air pollution and climate change

Jeong-Min Son[1]
Hyun hwa Jung[1], Jeong-Hee Eum[1]
[1] Dept. of Landscape Architecture, Kyungpook National University

Abstract: While the thermal environment problem is serious due to the urban heat island, the importance of urban forests is increasing as a solution to this problem. As Korea's urban areas are developed with high land use density and buildings, the temperature reduction effect of urban forests in these urban areas can be greater. Many previous studies have found that urban forests cool and humidify the surrounding environment through heat exchange and form a park cooling effect. In addition, the cooling effect of parks varies depending on the size and interior factors of the park, and the diffusion intensity varies in climate and urban spaces with different characteristics. Thus, the temperature reduction effect of urban forests has been extensively investigated. However, relevant research is lacking in cities such as Korea, which are characterized by climate and dense development. While urban forest policies are being actively implemented to improve the urban thermal environment in Korea, it is necessary to establish a comprehensive plan to expand the function by clarifying the temperature reduction effect of urban forests and analyzing factors that affect the cooling function of urban forests.

Therefore, this study quantitatively investigated the effect of urban forests on the thermal environment by targeting parks located in densely built-up areas in Korea. This study aimed to analyze the diffusion range of the cooling effect of parks located in the densely developed city center of Daegu. In addition, the relationship between the various characteristics of parks and the thermal environment was identified, and plans for effective urban forest planning and park design were proposed. For this purpose, previous studies on the relationship between the characteristics of urban forests and the thermal environment were reviewed, and the factors and effects of urban forests affecting cooling were considered. The thermal environment of the park was analyzed using ENVI-met simulation and field measurement. As a result, the effect of urban forests on reducing city temperature was confirmed, and the cooling effect determined by the characteristics of the park was different. This study can be used to prepare strategic urban forest plans to improve the urban thermal environment.

ASSESSMENT OF ANTHROPOGENIC DISTURBANCES AND HEALTH STATUS OF BENGUET PINE FOREST UNDER VARYING LAND USES In BAGUIO CITY, PHILIPPINES

T4.30 Urban green against air pollution and climate change

Adreana Remo[1]
[1] Department of Environment and Natural Resources - Ecosystems Research and Development Bureau

Abstract: Urban forests are ecosystems consist of interacting natural and anthropogenic systems. Because humans play an important role in maintaining an urban ecosystem, it is crucial to determine how various land uses affect the health of urban trees in an urban ecosystem. In the absence of studies dealing on both quantitative and qualitative assessment of health status of Benguet pines in the Philippines, this study aims to determine the health status of Benguet pines in Camp John Hay, Baguio City vis-à-vis six varying land uses and eventually, identify if there is a relationship that exist between the two. This study included 434 trees in six varying land uses, namely, recreational, residential, commercial, managed and protected forest, and infrastructure and facilities. Despite the presence of various human activities in the study site, the results positively showed that majority of the Benguet pines are not sick and/or dying, however, mostly are characterized with failure and defects in its crown which is a symptom of dieback and tree decline. Results revealed that there is a relationship that exists between land use and tree health. Data correlated that the most number of healthy Benguet pines are found in the land use with the least number of human activities which in this study is the protected forest. Soil compaction was also found to be the most common effect of human activities and influx of people in the study site. Land uses related to recreational activities were more prone to soil compaction while commercial areas were mostly affected by construction activities of buildings, infrastructures, roads, or landscapes. Residential places or land uses near residential places often exhibited failure on the trunk of Benguet pines because of intentional and unintentional mechanical injuries. Further studies that will delve on the other drivers of urban tree condition such as environmental factors are strongly recommended.

ASSESSMENT OF URBAN GREEN SPACES' POTENTIAL FOR AIR PURIFICATION AND LOCAL CLIMATE REGULATION IN WARSAW (POLAND)

T4.30 Urban green against air pollution and climate change

Anna Kowalska[1]
Magdalena Kuchcik[1], Jacek Wolski[1], Andrzej Affek[1], Edyta Regulska[1], Jarosław Baranowski[1], Kaja Czarnecka[1], Katarzyna Lindner-Cendrowska[1], Sandra Słowińska[1]
[1] Institute of Geography and Spatial Organization, Polish Academy of Sciences

Abstract: The urban heat island and air pollution are now serious threats to the health of urban residents. Actions aimed at improving life quality in cities using natural processes require knowledge of the potential of existing urban green spaces to provide ecosystem services (ES) such as air purification and local climate regulation. Warsaw, the largest city in Poland, is inhabited by nearly 1.8 million people and covers the area of 517.2 km^2. Green spaces make up almost 47% of its area and play a very important role as major providers of regulating ES. The objective of this study is to assess the potential of Warsaw's urban parks and forests for particle matter (PM) removal (in winter and summer) and air temperature regulation (in summer) using remote sensing data and long-term in-situ measurements carried out on selected test sites. The total amount of PM accumulation is largely influenced by the cover and structure of vegetation, a good indicator of which is the leaf area index (LAI) - the ratio of the leaf area to the ground area. The cooling effect of vegetation was determined using the evapotranspiration (ETA – amount of water evaporated from plant cells and soil under conditions of unlimited presence of water in the ground), selected because of its linear relationship with latent heat. Both ES indicators were calculated based on satellite data provided by European Environment Agency, in line with the verified formulas. More detailed research was done in six Warsaw's parks of different size and vegetation composition and structure. Air temperature was measured in the parks and in the neighbouring built-up areas to assess the impact of parks on people living in their vicinity (e.g. cooling range of parks). To determine the diversity of green spaces' structure, a cartographic analysis, field inventory and mapping were done. Our findings allow to point out the most beneficial features of urban green spaces to maximize the studied ES provision. The outcomes of the research can be used by city planners in developing urban greening strategies.

Comparisons of PM2.5 mitigation between coniferous and broad-leaved forest in peri-urban region of Seoul metropolitan area, Republic of Korea

T4.30 Urban green against air pollution and climate change

Jeonghyun Hong[1]
Minsu Lee[1], Tae Kyung Kim[1], Woojin Huh[1], Hojin Lee[2], Jihyeon Jeon[1], Kunhyo Kim[1], Chanoh Park[1], Siyeon Byeon[3], Hyun Seok Kim[1, 2, 4]

[4] Research Institute of Agriculture and Life Sciences, Seoul National University, Seoul 08826, Republic of Korea

Abstract: Owing to industrialization and urbanization in recent decades, fine particulate matter ($PM_{2.5}$) in the atmosphere has become a major environmental problem worldwide. This environmental issue pushed the use of forests as air purifying tools. However, there is a lack of continuous and long-term forest management to efficiently mitigate $PM_{2.5}$. In this study, we assessed the potential of different forest types to control air pollution, by measuring the seasonal $PM_{2.5}$ concentrations inside and outside the forest for one year. In addition, the $PM_{2.5}$ reduction efficiencies (PMREs) of different forest types were compared, and their relationship with stand characteristics after forest density control was analyzed. Results showed that the average PMRE inside the forest was approximately 18.2%; the seasonal PMRE was highest in winter (approximately 28.1%) and lowest in summer (approximately 9.6%). The average PMRE of the Taehwa deciduous broad-leaved forest (TDF) (approximately 18.8%) was significantly higher than that of the Taehwa Coniferous Forest (TCF) (approximately 17.5%)($P < 0.001$); the differences showed a seasonality. The PMRE was higher at TCF in spring and summer ($P < 0.001$), while it was higher at TDF in autumn and winter ($P < 0.001$). Furthermore, the PMRE of TDF was negatively correlated with the stand density ($P = 0.003$) and positively correlated with the average diameter at breast height (DBH) ($P = 0.028$). However, the PMRE of TCF did not significantly correlate with stand characteristics. This study revealed the differences in $PM_{2.5}$ mitigation according to stand characteristics, which should be considered in urban forest management.

Contribution of urban forestry in compensating the CO2 emissions in Niger: case of the city of Maradi

T4.30 Urban green against air pollution and climate change

Moussa Massaoudou[1]
Ousmane Manzo Laminou[1], Moussa Na Abou Amina[1]
[1] University of Dan Dicko Dankoulodo of Maradi (UDDM)

Abstract: The trees in urban environment play a fundamental role in the life of the city-dwellers. However, the service of sequestration of carbon and attenuation of the effects of the climatic change that they return is very little known. Conducted in the city of Maradi, the present study aims at valuating the answer of the parklands and the plantations to the broadcasts of the CO2 due to the consumption of the wood-energy of the households. The adopted methodology was based on trees inventory including the dendrometrics measurements and the survey conducted to the households. The survey listed eighteen thus (18) woody species distributed in sixteen (16) genera and fourteen (14) families with a strong preponderance of the exotic species. The species *Azadirachta indica* dominates the stand with 57,95%. The mean diameter of the population is of 22,10 ± 9,15 cm against 7,46 ± 3,13 m of mean height. The mean density of the woody species is of 97,37 ± 49,61 trees/ha for a mean base area of 3,29 ± 0,01m²/ha. The mean global biomass of the stand rises to 3,70 ± 0,04 t/ha for a mean stock of carbon of 1,85 ± 0,02 tC/ha. Also, the survey showed that the wood-energy was the main source of energy for 95,56% of the households of the city. The mean of wood consumption by household rises to 1,72 ± 0,32 t/year and 0,39 ± 0,12 t/year of charcoal for a household of mean size of 9 ± 3 people. The resulting carbon emission was 25.49 ± 12.36 tC/ha/year. This emission is very high compared to the amount of carbon stored by green spaces and households in the city. However, the contribution of these in the mitigation of CO2 emissions is far from negligible because they can offset up to 2.14% of the annual CO2 emissions resulting from the consumption of wood energy by households. It is then more than necessary to multiply reforestation, to protect the available forest capital and to substitute wood energy with other energies that do not pollute the environment and emit less greenhouse gases.

Diversity and the condition of green spaces and woody plants in 3 Lithuanian cities

T4.30 Urban green against air pollution and climate change

Lina Straigytė[1]
[1] Department of Forest Sciences, Agriculture Academy, Vytautas Magnus University, Kaunas, Lithuania

Abstract: In urban areas, the ecological quality of life of the residents is determined by existing greenery. Municipalities aim to ensure that each city has a sufficient area of greenery, and that woody plants are healthy and suitable for that area.The inventory of green areas and woody plants provides municipalities with knowledge about the diversity, condition, and abundance of plant species, and helps organize management and maintenance.

The aim of the study is to assess the diversity of woody plants, health status, and abundance of greenery in 3 Lithuanian cities.

The inventory of greenery was carried out in 2022, in 3 cities located in different region of Lithuania: Pakruojis, Švenčionys and Birštonas. The area of public parks was calculated, the species and condition of each woody plant was determined, plant heights and trunk diameters were measured.

The results showed that all cities have more parks areas than the proposed minimum area. Woody plants of alien species dominate, but the number of native individuals is much higher than that of trees of alien species. Shrubs are grown less than trees. Invasive woody plants grow in all cities, of which ash maples are the most common. Most of the plants are in good condition.

Ecosystem Services of solitary city trees of four common species in Germany

T4.30 Urban green against air pollution and climate change

Zoe Petridis[1]
Sebastian Schmidtlein[2], Mario Köhler[3], Somidh Saha[1]
[1] Institute for Technology Assessment and System Analysis (ITAS), Karlsruhe Institute of Technology (KIT)
[2] Institute of Geography and Geoecology (IfGG), Karlsruhe Institute of Technology (KIT)
[3] Horticultural Department of Karlsruhe City (Gartenbauamt), Karlsruhe Germany

Abstract: Solitary trees in a city are a key component of urban forests, and it is essential to quantify their benefits to improve the management and care of these trees. Therefore, this study quantifies and compares eight ecosystem services (ESS) among solitary trees near streets and inside parks of four common species in Karlsruhe City, southwest Germany. Additionally, the study aimed to identify the influence of growing habitat and crown pruning intensity on the variation of these ESS. We randomly selected 320 urban street and park trees consisting of Norway maple (*Acer platanoides*), horse-chestnut (*Aesculus hippocastanum*), Black locust (*Robinia pseudoacacia*), and small-leaved linden (*Tilia cordata*). Those four species represent 12% of Karlsruhe City's approx.— 150,000 trees owned by the municipality. A complete dendrometric inventory of the trees was conducted following the guidelines of the *i-tree Eco* program. The ESS were calculated by using the *i-tree Eco* program.

The carbon storage of park trees was 1.28 times higher than that of street trees. Park trees provided 24 % more leaf biomass than trees near streets. The four different tree species showed substantial variation in ecosystem services, with black locusts and small-leaved linden showing the greatest differences in provisioning and regulating ecosystem services. Horse-chestnuts were found to be the tree species with the highest air-cleaning capabilities, removing up to 50% more pollutants from the air than black locust trees. Further, comparison-of-mean tests showed that Norway maple park trees provide significantly more ESS than street trees of the same species. Tree pruning and crown dieback had a negative effect on provisioning and regulating ESS. The crown light availability positively influenced regulating ESS, like carbon sequestration, oxygen production, or pollution removal. Tree size (diameter) was shown to be a strong predictor for all ecosystem services.

The results underline the importance of balancing the conservation of large living urban trees, their appropriate crown pruning intensity, and the maintenance of taxonomic biodiversity in the urban environment, which becomes even more crucial when considering the impacts of climate change.

Effects of urban environment on BVOC emissions by street and park trees

T4.30 Urban green against air pollution and climate change

Kaisa Rissanen[1]
Juho Aalto[2], Jaana Bäck[2], Heidi Hellén[3], Toni Tykkä[3], Alain Paquette[1]
[1] Centre d'Étude de la Forêt (CEF), Département des sciences biologiques, Faculté des sciences, Université du Québec à Montréal, Montréal, Canada
[2] Faculty of Agriculture and Forestry, Institute for Atmospheric and Earth System Research/Forest Sciences, University of Helsinki, Helsinki, Finland
[3] Atmospheric Composition Research, Finnish Meteorological Institute, Helsinki, Finland

Abstract: Urban trees can reduce air pollution by capturing particulate matter and gaseous pollutants. However, trees also release biogenic volatile organic compounds (BVOCs) that participate in the production of ground-level ozone (O_3) and particulate matter in the form of secondary organic aerosols (SOA). To quantify the net effect of urban tree species on air quality in cities, reliable estimates of tree BVOC emissions are thus needed. Yet, direct measurements of urban tree BVOC emissions are rare, and whether estimates of tree BVOC emissions in natural environments are applicable in urban environments is unclear. As one of the important roles of BVOCs in trees is stress mitigation, the stress factors of urban environments that differ in quality and quantity from those in natural environments may importantly change the BVOC emission rates and composition.

We measured BVOC emission rates and composition of five common urban tree species in parks and streets of two northern cities (Montreal, Canada and Helsinki, Finland) using shoot enclosures and adsorbent tubes analysed with a gas-chromatograph mass-spectrometer. We compared the measured BVOC emissions with earlier emission estimates from natural environments and between park and street trees, and calculated the species' potentials for O_3 and SOA formation.

Urban tree BVOC emission rates corresponded generally well with the earlier species-wise estimates from natural environments. Potentially due to the higher heat and pollution loads, street trees had generally higher isoprene and sesquiterpene emissions compared to park trees in Montreal. As expected, O_3-forming potentials were large for species with high isoprene emissions (e.g., *Quercus* species). SOA-forming potentials were important also in species with high monoterpene emissions (*Betula pendula*) and occasionally high sesquiterpene emissions (*Tilia cordata, Acer platanoides*).

According to our results, using BVOC emission estimates from nonurban conditions for modelling and species selection of urban trees may be appropriate. We however note that the applicability may depend on the degree of urbanisation – for example, the intensity of the heat island effect and pollution. Moreover, species- or genus-wise estimates are lacking for many urban species, such as *Gleditsia triacanthos* in our study, encouraging further efforts to map BVOC emissions by urban trees.

Effects of Urban Public Greenspace on Carbon and PM2.5 Reduction

T4.30 Urban green against air pollution and climate change

Seong-Gyeong Choi[1]
Hyun-Kil Jo[1]
[1] Dept of Ecological Landscape Architecture Design, Kangwon National University, Chuncheon 24341, South Korea

Abstract: The increasing concentrations of greenhouse gases and fine particulate matter (PM) are serious environmental problems globally, and require urgent policy and scientific action. Increasing CO_2 concentrations exacerbates environmental and social systems via the impact of climate change, including sea level rise, extreme weather events, and biodiversity loss. $PM_{2.5}$ is a class 1 carcinogen, as designated by WHO, and it causes various respiratory diseases and strokes. In cities dominated with carbon and $PM_{2.5}$ emissions, urban greenspace plays an important role via the uptake of atmospheric carbon during photosynthesis and the adsorption of particulate pollutants, including $PM_{2.5}$, through its leaves, branches, and stems. However, information on the effects of urban greenspace is still lacking globally. Therefore, the purpose of this study was to quantify the carbon and $PM_{2.5}$ reduction effects of urban public greenspace, including urban parks, street trees, and forests, in Gangneung, a medium-sized city located in the coastal region of South Korea. This study sampled a total of 35 urban parks and 42 street trees. All the trees in these sample urban parks and streets were field-surveyed, and their planting structure were quantitatively analyzed. The area by type and age class of Gangneung's forests was calculated using statistical data. Annual carbon and $PM_{2.5}$ reduction of these public greenspace was calculated by applying quantitative models by tree species and size. The mean tree cover of study parks and street trees was 44.5 ± 3.0 and 11.2 ± 1.4%, respectively. Among the total forest area, mixed forests with age class IV occupied the largest area (26.3%). Total annual carbon and $PM_{2.5}$ reduction of public greenspace in Gangneung were 557.5 kt/yr and 767.2 t/yr. In addition, the public greenspace was observed to offset 31.6% and 1.8 times of the total carbon and $PM_{2.5}$ emissions in the study city, respectively. Based on these results, a greenspace planning strategy is explored to maximize carbon and $PM_{2.5}$ reductions, including conservation, improvement, and enlargement greenspace. This study is expected to be useful as practical planning to improve carbon and $PM_{2.5}$ reduction in urban greenspace projects.

Estimation of Plant Pollution Removal Based on Intensive Air Quality Measurements

T4.30 Urban green against air pollution and climate change

Abstract: Understanding the role of vegetation in mitigating environmental pollution requires an accurate estimation of plant pollution removal. This study aims to investigate the effectiveness of various plant species in removing pollutants from the atmosphere by utilizing an existing air quality networks database.

The research methodology involved collecting air quality data from multiple monitoring stations placed in urban and suburban areas. These stations measured concentrations of air pollutants, including nitrogen dioxide (NO2), particulate matter (PM2.5 and PM10), sulfur dioxide (SO2), ozone (O3), metals, and meteorological parameters (only at specific locations).

The study is conducted in Bucharest, which is situated in a plain area and is recognized as one of the most polluted metropolitan areas in Europe. Currently, Bucharest is under an infringement procedure for PM10 pollution. However, despite its high pollution levels, Bucharest has one of the lowest tree cover percentages. Within the city limits, the tree cover is only 3%, but if all metropolitan areas are considered, including two significant forests, Stefanesti with 450 hectares and Baneasa with 800 hectares, the tree cover increases to 22%.

This study employs non-parametric methods for receptor-orientated analyses to assess and identify potentially contributing areas to air pollution in Bucharest and its surroundings, considering specific characteristics as well. Analyses based on meteorological parameters, particularly wind speed, and direction, allow for cluster analyses. The study investigates the absolute and relative comparison of air pollutant concentrations (between 2017 -2022) from sites directly exposed to pollution sources (Bucharest air quality station B1, B3, B6) or surrounded by vegetation (B2, B4, B5, Stefanesti periurban forest station), considering the phenological phase of the vegetation.

Up-to-date research indicates significant variations in the pollution removal efficiency among different plant species. Certain species demonstrate a higher capacity to absorb and reduce pollutant concentrations, thereby contributing to improved air quality in their vicinity.

Nevertheless, the objective of this study is to illustrate the quantifiable impact of plant capacities in influencing air pollution concentrations.

In conclusion, estimating plant pollution removal based on intensive air quality measurements is a

significant step toward understanding and underlining the benefits of vegetation in mitigating environmental pollution.

Evaluating Urban Green Space Governance and Management in Kenya: Unlocking the Potential of Urban Forestry for Safe, Resilient, and Sustainable Cities

T4.30 Urban green against air pollution and climate change

James Maua[1]
Michael Mukolwe[1], George Etindi[1], Joram Kagombe[1]
[1] Kenya Forestry Research Institute

Abstract: Cities globally are increasingly focusing on contributing to the Sustainable Development Goals by implementing tree planting and land restoration initiatives. In Kenya, urban forests play a significant role in meeting national and global restoration targets, such as the government's ambitious plan to plant 15 billion trees by 2032. However, several challenges hinder the sustainable management of urban green spaces, including conflicting interests, weak institutional structures, and funding gaps. A study was conducted in Nairobi, Mombasa, Kisumu, and Nakuru in Kenya to assess the status of urban forestry activities, identify challenges and opportunities, and assess policy and management options. The research employed a combination of quantitative and qualitative methods, including desk research, interviews with key stakeholders, site visits, tree and shrub identification, and data analysis. A total of 251 respondents participated in the study.The findings revealed that nearly half of the respondents (49.9%) considered shade and relaxation as the greatest benefit of urban green spaces. Other benefits cited included playgrounds, recreational sites, aesthetic value, and environmental services. To improve urban green spaces, 58.4% of the respondents suggested creating awareness about the importance of development strategies, involving urban communities in management and maintenance, and engaging NGOs, private organizations, and local communities. The survey also highlighted the need for additional green spaces in all cities due to overcrowding in existing areas. In each city, over 116 tree and shrub species were identified, indicating rich biodiversity. However, several challenges were identified, such as the absence of urban forestry policies and management plans, poor matching of trees to their planting sites, lack of protection against grazing livestock, and weak enforcement of city by-laws. The study identified opportunities for improvement, including Public-Private Partnerships for green space management and renovation, as well as integrating urban forest plans into city planning processes. The adoption of adaptive management practices was recommended to ensure continuous enhancement of urban forestry in the cities

Greenspace planning guidelines for a low-carbon city

T4.30 Urban green against air pollution and climate change

Hyun-Kil Jo[1]
Hye-Mi Park[1]
[1] Dept of Ecological Landscape Architecture Design, Kangwon National University, Chuncheon 24341, South Korea

Abstract: The potential negative impacts of climate change on the environments have necessitated the creation of low-carbon cities. Urban greenspaces can reduce the level of atmospheric carbon, a major agent of climate change. They sequester carbon during photosynthesis and avoid carbon emissions by saving building heating and cooling energy. This study proposes desirable planning guidelines to establish a low-carbon city by urban greenspace type. Urban greenspaces are categorized as streets, parks, gardens, riparian corridors, and suburban zones. In Korea, gardens on residential, commercial, and Institutional lands are characterized by small sizes and poor tree planting. In addition, urban parks are potential sources for the creation of carbon sinks through tree planting within the limited greenspace of cities. The carbon reduction of a park can vary depending on factors such as tree size, planting density, species, vertical structure, and land cover type, even if the park area is the same. Nevertheless, the extensive impervious and grass areas, single-layered plantings, and the dominance of small trees limit the carbon reduction of urban parks. In addition, the excessive annual pruning, insufficient root growth space, and inappropriate tree species of street trees limit their carbon reduction. The planning guidelines included a proper layout of trees around buildings in gardens to enhance building energy savings through shading, evapotranspiration, and wind reduction. Minimization of unnecessary impervious and grass areas and multi-layered/clustered planting were recommended as a desirable park planning. This study also suggested planting of tree species with good growth rates and creation of multilayered greenways in streets, and nature-friendly development in suburban zones to decrease carbon emissions from the damage of existing trees and soils and uses of heavy equipments. Future studies on urban greenspace should consider estimating especially the size of greenspace supply to offset carbon emissions and net carbon reduction using life cycle analysis. This study can contribute to various land use and spatial planning to help create a low-carbon city.

Particulate matters and metal elements in snowpacks of urban forests in NE China: Implications for winter air pollution control

T4.30 Urban green against air pollution and climate change

Donghui Han[1]
Wenjie Wang[2], Lixin Chen[1]
[1] Northeast Forestry University
[2] Zhejiang A&F University

Abstract: High latitude northern hemisphere cities usually face serious winter particulate mater (PM) pollution, and tree-species-specific PM deposition in amount and metal composition are not well defined yet. This study was conducted in Harbin city in Northeast of China during the winter heating periods, the most serious PM pollution season. We collected snow samples from seven urban forest plantations (J(*Juglans mandshurica*); Pa(*Phellodendron amurense*); Q(*Quercus mongolica*); L(*Larix gmelinii*); Ps(*Pinus sylvestris* var. *mongolica*); Pt(*Pinus tabuliformis*); Pm(*Picea koraiensis*) with full recording of all tree diameter at breast height(DBH), height, live branch height, and tree density, and one control plot.And the snowpack depth, density, snow water equivalent(SWE) were measured. Furthermore, the PM contents at different diameters ($W_{10\mu m\text{-}2mm}$, $W_{2\mu m\text{-}10\mu m}$, $W_{0.45\mu m\text{-}2\mu m}$) and eleven metal concentrations (Ca,K,Mg,Fe,Zn,Cu,Mn,Ni,Cr,Pb,Cd) in snowmelt water were analyzed. Our results showed broad-leaf forest plantations had greater snow depth and SWE than coniferous forest plantations, whereas coniferous forest plantations had greater PM contents in snowpacks than broad-leaf forest plantations (especially $W_{10\mu m\text{-}2mm}$ in coniferous forest plantations was significantly greater than in broad-leaf forest plantations. Overall, coniferous forest plantations had higher levels of metal concentration than broad-leaf forest plantations, where K, Ca, Cu and Mn had significant differences ($p < 0.01$). In addition, *Picea koraiensis* plantation forest (Pm) had higher metal concentration, as well as the larger metal storage and $W_{10\mu m\text{-}2mm}$. And it indicated that the forest opening plot had lower PM accumulation, metal concentration and storage, illuminating urban forest functions in the heavy metal deposition in wintertime. Moreover, snowpack depth and SWE showed significant negative correlation with DBH and individual above-ground biomass; but the concentration and storage of most metals in PMs with different diameters showed significant positive correlations with DBH, tree height, above-ground biomass. Our findings highlighted that coniferous trees with more above-ground biomass could favor the snow deposition of PMs in total amounts and specific metals, favoring forest-based urban air particle control in winter via snow interception.

Polycyclic aromatic hydrocarbons (PAHs) accumulation in urban areas: A study of Platanus x Acerifolia, Celtis Australis, and Tilia Grandifolia

T4.30 Urban green against air pollution and climate change

Saša Kostić[1]
Marko Kebert[1], Nemanja Teslić[2], Dejan B. Stojanović[1], Martina Zorić[1], **Saša Orlović**[1]
[1] Institute of Lowland Forestry and Environment, University of Novi Sad, Antona Čehova 13d, 21000 Novi Sad, Serbia.
[2] Institute of Food Technology, University of Novi Sad, Bulevar cara Lazara 1, 21000 Novi Sad, Serbia.

Abstract: Accumulated Polycyclic Aromatic Hydrocarbons (PAHs) in leaves and one-year-old branches of three common tree species that were grown in middle-sized city in a moderate climate zone were estimated. *Platanus x Acerifolia, Celtis Australis,* and *Tilia Grandifolia* specimens from highly urbanized, frequent, and highly PAH-contaminated streets were compared with non-contaminated same species originated from the parks in the same urban core with the aim to define PAH profiles, diagnostic pollution emission sources, and finally to define organ- and species-specificity of PAH uptake potential as a PAHs remediation '*green tool*' in urban ecosystems.

Obtained results indicated that the leaves accumulated higher PAH concentrations up to ~20–30%, compared to branches. Also, following all three species, street trees accumulated more PAHs, while highest concentrations were observed for heavy-weight PAHs with five and six rings. Out of 17 tracked PAHs, Benzo[a]anthracene, Benzo[a]pyrene, Dibenzo[a,h]anthracene, and Pyrene were accumulated in the highest concentrations in all analyzed species and sites, and they account more than half of the total of detected PAHs.

Following Σ_{17} PAHs, *P. acerifolia* and *C. australis* have greater potential for PAHs remediation, via leaves and branches, than *T. grandifolia* whose in their leaves accumulated up to ~40% less PAHs than *C. australis*. In detail, the highest foliar PAH concentrations of trees that growth at streets were detected in *C. australis* (502.68 ng g^{-1} dry weight (DW)), slightly less in *P. acerifolia* (488.45 ng g^{-1} DW), while *T. grandifolia* accumulated the least PAHs in their leaves (339.47 ng g^{-1} DW). On the other hand, *C. australis* (414.89 ng g^{-1} DW) accumulated the most PAHs in their branches, while *P. acerifilia* and *T. grandifolia* accumulated significantly lower concentrations (327.58 and 342.99 ng g^{-1} DW, respectively). Finally, '*black box*', about species- and organ-specificity, as well as specific drivers that limited PAHs uptake capacity by trees, was opened, and future perspectives in PAHs remediation were suggested.

[4] Department of Agriculture, Food, Environment and Forestry (DAGRI), University of Florence, 50145 Florence, Italy

Abstract: Cities are facing socio-environmental challenges as far as the rising trend in summer temperatures and the spreading effect of Urban Heat Island (UHI), the changes in air quality, in land use and soil sealing, in runoff control and, finally, the biodiversity loss are generating severe health and wellbeing problems to contemporary urban people. Green areas and trees can play a key role by mitigating temperature and pollution and by preserving or even enhancing the ecological sustainability and resilience of cities. In this context, urban trees' vitality and health are facing several challenges due to high temperatures, water deficit and exposure to pollutants. To assess how urban trees respond to climate variation and traffic emissions, and to understand physiological processes related to tree vitality and health, we investigated C, O and N isotopes in tree rings. The survey was carried out in Central Italy, in Pisa and Firenze, comparing an urban and a periurban site for each city. Cores samples of fifteen *Pinus pinea* trees in each site were collected and $\delta\,^{13}C$, $\delta^{18}O$, ^{15}N and ^{14}C isotopes were determined in the last seventy tree rings, from 1952 to the present. The general hypothesis is that urban sites, characterized by environmental constraints as water deficit and high temperatures, show a higher $\delta\,^{13}C$ and a lower $\delta^{18}O$ than in periurban ones. Regarding the characterization of the ^{15}N and ^{14}C concentrations in the tree rings of *P. pinea*, we assume that the signals of exposure to traffic emissions are more evident in the urban neighbours than periurban contexts. The expected results might support the crucial challenge of the urban trees health monitoring in the context of "re-greening the cities" as a win-win strategy, besides that, it could represent a useful tool for municipalities and city planners to quantify tree benefits.

Urban tree pollen as air pollution: improving allergy management through advanced pollen identification and spatial modelling.

T4.30 Urban green against air pollution and climate change

Abstract: Urban trees play a crucial role in improving the quality of life in cities, providing numerous ecosystem services. However, they can also contribute to worse air quality through the production of pollen. Exposure to allergenic airborne pollen is a risk factor for respiratory allergies and a major public health concern, especially as climate change is lengthening the pollen season. Pollen concentrations vary spatially and temporally, which makes pollen monitoring a critical tool for research and healthcare improvement. However, little is known about how pollen levels – for all pollen types, such as grass, weeds, and trees – vary within a city and whether this variation affects the development and exacerbation of allergic reactions. Pollen concentrations are often obtained from a single station assumed to represent exposure over a large geographic area. Furthermore, due to negligible morphological differences between related species, pollen grains are rarely identified at the species level. In this project, we focus on pollen from urban trees, which are the first to bloom, collected using 25 gravimetric traps placed throughout the island of Montreal, Canada. The results of our study are based on 950 pollen samples collected between 2021 and 2023. To improve the process of pollen identification, we developed an innovative integrated approach that combines flow cytometry with machine learning enabling faster and more accurate identification of specific types of pollen at the species level. Then, we developed spatial models to enhance pollen forecasts by combining the collected pollen data with environmental predictors, such as vegetation composition and meteorological data. Our results revealed that the pollen in the air is influenced by much more than nearby trees. The distribution of airborne pollen on the island of Montreal is complex and influenced by external factors such as the weather, built density, and farther vegetation. These findings, coupled with our innovative approach, represent a major step towards better-informed, science-based urban greening plans, aiming to minimize allergy impacts.

When does a new urban forest become a real CO2 sink? A case study in Florence, Italy

T4.30 Urban green against air pollution and climate change

Abstract: Carbon Dioxide (CO_2) is one of the most impactful greenhouse gases (GHG) leading to global warming. Trees uptake CO_2 from the atmosphere and store carbon in their tissues thanks to photosynthesis process. Therefore, planting a new urban forest can help to mitigate climate change. However, to set up a new urban forest GHG emissions occur during cultivation in the nursery, planting and maintenance operations. Within the AIRFRESH project (LIFE19 ENV/FR/000086), 170 new urban trees belonging to 4 genera (*Tilia*, *Acer, Ulmus* and *Cupressus*) were planted in Florence (Italy) to set up a new green area of 0.55 ha. To estimate their net CO_2 assimilation, we used a leaf-level approach and light response curves were carried out (PAR: 0, 25, 50, 75, 100, 200, 300, 400, 700, 1000, 1500, 2000 μmol m^{-2} s^{-1}) for each species by infrared gas analyzer (LI-6800, Li-Cor Inc. Lincoln, NE, USA). Using the measured data, a non-rectangular hyperbola function was developed in order to estimate the CO_2 assimilation with photosynthesis and carbon loss through respiration. Moreover, instantaneous measurements of net photosynthesis (A_n) were performed along the day to assess the midday depression of photosynthesis due to stomatal closure in the early afternoon. Finally, scaling-up from the leaf to tree level was accomplished considering crown size and Leaf Area Index (LAI). In addition, seasonal soil respiration was measured by EGM-4 Soil Respiration Chamber with the SRC-1 System (PP-Systems, Herts, UK). The Carbon Footprint (CF) linked to the nursery cultivation, planting and maintenance was assessed throughout Life Cycle Analysis (LCA). In conclusion, we calculated the Carbon balance of a new urban forest considering both emissions and CO_2 assimilation by trees. This study allows to determine when a new urban forest becomes a real carbon sink, thus helping to achieve the European goal of carbon neutrality.

WRF-Chem simulations at different scales for urban air quality assessment

T4.30 Urban green against air pollution and climate change

[3] CNR

Abstract: In the framework of the project AIRFRESH "Air pollution removal by urban forests for a better human well-being" (LIFE19 ENV/FR/00086) we used the WRF-CHEM model to estimate the impacts of urban forests on air quality and meteorology in the city of Florence and Aix-en-Provence. In particular, our aims are to: i) estimate the air pollution removal capacity by a reforested test area; ii) estimate and quantify the environmental and health benefits provided by urban tree at city-scale; and iii) propose recommendations for reforestation policies for attainment of the air quality standards in both cities.

We used the Corine Land Cover (CLC) database as initial condition for land cover, allowing to identify several urban features, like industrial areas or highly/low residential areas. These information are needed by the model when using the urban scheme over the different selected city-domains.

In our simulation we decided to use a triply-nested domain to downscale the ERA5 forcing data from a coarse domain to a fine scale city domain. The urban domain has 1 km resolution, 35 vertical levels, extending from land surface up to 50 hPa and the time period chosen for the simulations is 2019. For the European domain we also use the spectral nudging that allows transmitting forcing information not only from the boundary conditions but also and directly within the domain; this allows for a more stable model increasing the consistency with the reanalysis.

Here we present results for the Florence and Aix municipalities. To analyse the impacts of the urban forests we elaborated 4 different scenario modifying the vegetation in a circular area around the municipality of Florence of 5 km. The 4 different scenarios are: the current vegetation scenario, the evergreen and deciduous scenarios, realized replacing the 50 % of dominant vegetation of the original landcover (fraction mixed forest and crops) with Evergreen low BVOC emitting trees (Pinus Pinea) and Deciduos high BVOC emitting trees (Querqus Robur), and the no vegetation scenario realized replacing all the vegetated of the original landcover with the category bare soil or sparsely vegetated.

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Creation of a point-based scoring system for valuating ecosystem services of urban forests and assessement of its implementation potential

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

[2] Karlsruhe Horticultural Office, Nördliche Uferstraße 8, 76189 Karlsruhe- Germany

Abstract: Urban and peri-urban forests (UPF) are crucial for human health and well-being. Tangible benefits from regulating and provisioning ES can be precisely estimated, and their economic values can also be modeled (e.g., by the *i-tree-eco* program from the US Forest Service). However, intangible benefits from cultural ES are only quantifiable qualitatively through human perceptions, and supporting ES, such as biodiversity and habitats for flora and fauna, are quantifiable as indexes (e.g., Shannon diversity index, Gini index). Moreover, cultural and supporting ecosystem services could not be realistic to assess in monetary terms. We, therefore, aimed to 1) develop a novel non-monetary and point-based scoring system that can integrate ALL types of ecosystem services under one framework and 2) analyze stakeholder perceptions on the implementation possibility of such a scoring system in urban forest management practice and planning. The study was conducted in the UPF of Karlsruhe City in southwest Germany. For the first objective, we randomly installed 201 plots (each 404m²) in size to quantify all regulating, supporting, and provisioning ES at the tree (N=2978) and city level using *i-tree-eco* and other software. The estimates of those ES were normalized scores, which can be further used to add ranks. The cultural values of forests and trees were measured in codes by questionnaire surveys (N=501) and literature research and also normalized to add to the scores from supporting, regulating, and provisioning ES. For the second objective, stakeholders' perceptions of the new concept are analyzed, interviewing stakeholders (N=21) from four stakeholder groups: Politics, Administration, Civil Society, and Experts. The questionnaire comprises several subjects that need to be discussed regarding developing the ES point system for valuing UPF. The results showed high support by stakeholders in implementing the new valuation method, considering the criteria and expected challenges mentioned by the stakeholders. A stakeholders' consensus was found on integrating cultural ES by combining qualitative and quantitative data. We concluded that political frameworks and legislation must be addressed in the next step before considering implementing a score-based system in the ES valuation in UPF management.

A Rapid Assessment of Bird Community in the Selected Areas in Calamba City, Laguna

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

LOURDES BREVA[1]
Yrah Joy Panizales[1]
[1] Ecosystems Research and Development Bureau

Abstract: Birds are important indicators to determine the health and quality of habitat. This study aims to determine the species of birds and its diversity of the six selected green spaces in Calamba City, Philippines. To estimate bird diversity, a total of six transects were established randomly in the urban city. There were 105 individuals belonging to 12 genera and families recorded to include Passeridae, Apopidae, Pycnonotidae, Esrtrildidae, Laniidae, Motacillidae, Rhipiduridae, Sturnidae, Ardeidae, Acanthizidae, Nectarriniidae, and Oriolidae. Out of the 105 bird species observed, ten residents and two Philippine endemics were observed. The most abundant species were Eurasian Tree Sparrow (*Passer montanus* Linnaeus, 1758) followed by Glossy Swiftlet (*Collocalia esculenta*, 1837) with 30 and 18 individuals, respectively. Most of the species observed were commonly found in urban communities, agroecosystem, and forest edge. Diversity analysis revealed a low level of diversity with H' = 0.93 which requires more sampling effort and new technology for identification. With the presence of the endemic bird species in the sampling sites indicates the need to take into consideration the fauna and habitat conservation vis-à-vis ecotourism. We recommend to preserve and increase the green spaces, trees planted, high gardens and rooftop gardens be included in the landscape architectural design.

Assessment of campus green space exposure and its association with university students' mental health before and during the Covid-19 pandemic

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Jiayu Zhu[1]
Liqing Zhang[1], Yue Wu[1], Liyao Zou[1], Chang Ye[1]
[1] Department of Landscape Architecture, School of Design, Shanghai Jiao Tong University

Abstract: The mental health of university students has been widely discussed in recent times, with studies indicating that exposure to green spaces has a positive impact on mental well-being. Given that campus green space (CGS) is the primary natural environment that university students are exposed to, it is crucial to examine the health benefits associated with CGS exposure for students. Specifically, it is important to investigate how CGS exposure affects the mental health of university students during the Covid-19 pandemic. In this study, we utilized behavioral trajectory data, activity logs, and questionnaires to comprehensively assess university students' CGS exposure and its association with mental health before and during the pandemic, using the Minhang campus of Shanghai Jiao Tong University as our case study. Our results indicated a significant correlation between the two subjective indicators of CGS exposure based on activity logs and questionnaires. Additionally, subjective CGS exposure did not have a significant correlation with objective CGS exposure based on behavioral trajectory data. Furthermore, the indicator of CGS exposure based on activity logs during the pandemic was significantly and positively correlated with the mental health of university students. This correlation was stronger than the correlation between mental health and family harmony, as well as satisfaction with residential facilities and services in the quarantine residence. We also found a significant and positive correlation between the number of indoor plants and mental health. Based on these findings, we propose recommendations for constructing campus green spaces and improving the mental health of university students.

Causal network map for sustainable urban riparian management: a case from Souel of South Korea

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Taeheon Choi

[2] Kangwon National University, The Department of Forest Management

Abstract: Urban riparian play a critical role in promoting ecological resilience, mitigating urban biodiversity loss and enhancing the quality of life in urban areas. Due to the intricate interplay of socio-ecological and political determinants, a systematic analysis of drivers is essential. Necessitated an understanding of not only the direct but also the indirect influences on urban riparian circularity, the visualization of causal networks becomes indispensable for facilitating this systematic analysis. This study provides a comprehensive causal network map on the multiple impacts of urban riparian that can inform urban riparian policy and response to manage sustainability. The methodology consists of two procedures. It begins with a thorough exploration of prevailing academic literature, to identify initial variables and causal relationships. Then, Delphi analysis is applied to reconcile the perspectives of various stakeholders and formulate a consensus-based management strategy. To achieve this, the SDGs-based DPSIR framework is chosen to examine the causal relationships influenced by policy responses. Relevant to urban riparian, 15, 11, and 6 targets from the SDGs are selected and used to classify factors. Previous research consistently indicated the positive impacts of urban riparian on air and water quality, water temperature, and biodiversity. Based on the findings, three key policy topics are derived as a comprehensive plan for effective urban riparian management. This plan outlines strategies including the establishment of a legal framework, capacity building initiatives for public officials associated with waterfront forests, and public outreach efforts. This study's results offer significant insights that can inform the development of city-level waterfront plans and policies, fostering a harmonious coexistence with nature. Moreover, the visualization of driver interactions provides stakeholders with valuable understanding, highlighting the most effective measures for sustainable urban riparian management.

Changes in citizen perception or urban trees 2018 - 2023

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Fran Poštenjak[1]
Karmelo Poštenjak[1]
[1] Arboring j.d.o.o.- independent researcher

Abstract: Management of urban arboriculture elements, predominantly trees, is sometimes very complex due to the conflicting interests from various stakeholders. Main drivers of such attitude between demographics could be different perception of environmental and monetary values of arboriculture elements.

The goal of this research was to estimate if recent pandemic restrictions have influenced people's attitude and perception towards urban arboriculture elements. We have distributed the same questionnaire on perception of urban arboriculture elements and analysed respondents data on two separate occasions. Survey was conducted in Croatia in 2018 and 2023 and we have completed the 1501 individual surveys- (723 in 2018 and 778 in 2023).

Overall, in both groups, respondents perceived trees as a positive element of urban infrastructure, and for this matter we found no statistically significant differences between the two groups. The perception of quality of tree maintenance has and perception of the overall condition has slightly decreased in 2023. The importance of damage caused by trees decreased for urban inventory and physical injury decreased while importance of biodiversity sustainability increased slightly in comparison with 2018 survey results.

Inclusive governance of urban forests is a key for making efficient, sustainable and biodiverse urban environment and allowing guided citizen participation can relieve shortcomings induced by budget constraints. This study also indicates that citizens may be willing to commit their own time and effort in order to improve the state of their urban trees.

Keywords: urban trees perception, inclusive governance, biodiversity, tree risk tolerance

Comparison of the prevalence of ASaV-infected flowering ash (F. ornus) trees in two Germany Cities

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Kira Köpke[1]
Susanne von Bargen[1], Martina Bandte[1], Malgorzata Rybak[2], Carmen Büttner[1]
[1] Division Phytomedicine, Humboldt-Universität zu Berlin, Lentzeallee 55/57, D-14195 Berlin
[2] Plant Protection Service Hamburg, Ministry of Economy and Innovation, Free and Hanseatic City of Hamburg, Brennerhof 123, 22113, Hamburg, Germany

Abstract: Viral diseases play a particular role in tree health as predisposing factors (Büttner et al, 2013, 2023). Therefore, the virus infection could counteract trees resilience, especially in cities with anticipated extreme climate conditions. Flowering ash (*Fraxinus ornus L.*) infected by the ash shoestring-associated virus (ASaV) develop symptoms like chlorotic ringspots, mottle and leaf deformation such as curling and shoestring (Gaskin et al., 2021). The tree species is considered as a potential "climate tree" in urban environment. In this study, we assessed the prevalence of ASaV in this tree species, which is increasingly planted in German cities, in the cities of Hamburg and Berlin.

In the vegetation periods 2019 and 2020, a survey on the occurrence of ASaV-associated symptoms was carried out in selected street sites of Hamburg considering 50 % of the 466 flowering ash trees planted in the city state. The trees were visually inspected twice per year. A selection of symptomatic and symptomless leaves was sampled and tested for an ASaV-infection by virus-specific RT-PCR.

In 2021, we examined 65% of the 1150 flowering ash trees grown in Berlin for ASaV symptoms. Visual scoring of the trees was followed by sampling of 82 symptomtic leaves. Additionally, 85 samples without virus suspected symptoms and 32 with discoloration and deformation atypical to an ASaV-infection, and 14 samples with mild ASaV-symptoms were taken and tested by ASaV-specific RT-PCR. The occurrence and distribution of ASaV-infected trees in these two cities make aware that viruses have to be listed as a considerable member of potential pathogens in trees.

Defoliation and dieback of Sitka spruce in Reykjavík, Iceland

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Olafur Eggertsson[1]
Juliane Kuckuk[2], Jan Esper[2], Edda Oddsdottir[1]
[1] Icelandic Forest Research, Mogilsa, IS-162 Reykjavík
[2] Department of Geography, Johannes Gutenberg University, 55128 Mainz, Germany

Abstract: The green spruce aphid (*Elatobium abietinum)* is an important defoliating pest of Sitka spruce (*Picea sitchensis*) in Iceland. A comparison of two urban Sitka stands in Reykjavík, from 2013-2017, reveals a distinct difference in defoliation due to the green spruce aphid between trees located near a main road (94% defoliated) and several hundred meters away from heavy traffic (47%). Chemical analyses of the spruce needles demonstrate substantially higher nitrogen ratios in trees near traffic. Furthermore, the recently warming winter temperatures promoted larger overwintering aphid populations since 2003, as well as a shift of mass outbreaks from autumn to spring, accompanied by distinct growth suppressions one year after an aphid population spike in the post-2003 tree-ring data. The results of this study indicate that the mechanisms triggering Sitka spruce dieback in Reykjavík include a combination of increasing winter temperatures, more frequent and severe green spruce aphid outbreaks, as well as elevated N values in the needles of urban trees. During recent years the Sitka spruce stands have partly recovered from the defoliation.

Dynamics of Street Tree Populations in Urban Areas: Understanding Mortality Rates and Associations with Age and Size Classes

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Leila Parhizgar[1, 2, 3, 4]
[1] Leila Parhizgar
[2] Hans Pretzsch
[3] Thomas Rötzer
[4] Astrid Reischl

Abstract: ***Keywords:*** *Urban Trees, Urban Tree Mortality, Street Trees, Tree Growth*

Urban green spaces (UGSs) play a critical role in mitigating the climate change challenges by offering multiple ecosystem services, such as regulating air quality, increasing shade, cooling, and air humidity, enhancing biodiversity, and offering erosion control. Trees are a vital component of UGSs and provide significant environmental, economic, and human health benefits in urban ecosystems.

Our study focused on understanding the dynamics of street tree populations in urban areas, which are built through cycles of planting, growth, death, removal, and replacement. In this study, we used the cadaster dataset of 12 cities in Germany with 5-10 years of street tree monitoring. Our research objectives were to a) calculate annual mortality rates for the most common urban tree species; b) analyze the association between mortality rate, age and Diameter at breast height (DBH) size classes with multivariable logistic regression models.We hypothesized that the mortality rate varies across species. Furthermore, the mortality rate is associated with age and DBH size classes, with high mortality rate for young and small classes and low mortality rate for middle, large age and DBH size classes.Annual tree counts and mortality observations were used to calculate the elements of the street tree demographic modified balancing equations, and to determine annual mortality rate and population growth.

Since demographic concepts, such as survivorship and mortality curves are useful to analyze urban tree mortality rates, we will assess the size and age-based shape of the street tree mortality curve in the next phase of the study. By analyzing the mortality curve, we aim to identify the factors that contribute to high mortality rates and that change as the trees age and grow.

Our study provides a framework for future urban tree mortality research and may fill the knowledge gap on mortality rates of urban trees, aiding in the design of effective urban forestry strategies. It can be replicated in other cities with similar climates for further comparisons.

Environmental DNA Analysis as a Supporting Tool for Assessing Soil Biodiversity Changes in new Urban Forests

[6] Institute of Biosciences and BioResources (IBBR), National Research Council, Via della Madonna Alta 130, 06128, Perugia, Italy

Abstract: The growth of urban populations and associated development has profound effects on biodiversity. Urban forestry and green spaces are imperative to improve the quality of life in urban areas. In this context, urban and peri-urban forests hold particular significance to provide essential ecosystem services such as biodiversity improvement. Indeed, the recovery of biodiversity, encompassing fauna and flora, can be significantly aided by establishing new tree plantations in urban regeneration projects. The AIRFRESH project (LIFE19 ENV/FR/000086), supported by the LIFE 2019 Environment and Resource Efficiency sub-programme, aims to reduce air pollution through the planting of a new urban forest in Florence, central Italy and Aix-en-Provence in South-eastern France. The project includes a total of about 2 ha experimental green area hosting 170 and 400 trees in Florence and in Aix-en-Provence respectively, belonging to highly performing genera (e.g. *Tilia*, *Acer, Ulmus*) in the absorption of pollutants. Concurrently, faunistic surveys have been conducted to monitor changes in biodiversity throughout the project duration, using direct observations, camera traps, and bat boxes. Initial results from observational surveys have indicated an increase in faunal biodiversity, particularly birds and mammals. However, soil diversity has not been assessed yet, although it may represent a pivotal element in determining the local environmental quality. Thus, with this work, we collected soil samples before/after and inside/outside tree plantations and we performed environmental DNA analysis with a focus on soil organisms. This method has gained popularity in environmental sciences and biodiversity conservation, providing valuable information for monitoring rare, threatened, or invasive species and studying organismal ecology and ecosystems. Furthermore, we also used environmental DNA as an alternative method to the Qualitative Biological Soil Assessment (QBS) for studying soil arthropods and beneficial soil bacteria involved in promoting plant growth. In conclusion, eDNA constitutes an important tool to evaluate in a reproducible and objective way the improvement of biodiversity in new urban green areas.

Equitable Climate Action: leveraging open-source tools to integrate forests and trees into local land use planning

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Erin Glen[1]
Nancy Harris[1], Richard Birdsey[2], Calyn Hart[3]
[1] World Resources Institute
[2] Woodwell Climate Research Center
[3] ICLEI USA

Abstract: World Resources Institute, ICLEI – Local Governments for Sustainability, and several partners are equipping community leaders with the tools they need to plan for and monitor locally-led nature-based solutions and equitable programs for climate change mitigation. Cities, counties, and landowners are taking proactive steps to mitigate climate change and build resilience, but to do so they need reliable and consistent information on how tree canopy is changing over time and the related the greenhouse gas (GHG) impacts of land management decisions. The LEARN (Land Emissions and Removals Navigator) tool is a free platform which provides automated spatial analysis of the GHG impacts of urban trees and forests within a community or area of interest. LEARN enables land managers to make data-driven plans for urban forests and efficiently monitor the implementation and impacts of those plans over time. The tool analyzes national datasets from the U.S. Forest Service (USFS) and U.S. Geological Survey to derive spatially explicit estimates of carbon emissions and removals from land cover change, forest disturbances, and changes to tree canopy on non-forest lands. A key feature of LEARN is the disaggregation of tree canopy and tree canopy change data by land use type, which is critical for community planning. High resolution (1-meter) tree canopy change data is also available for the Chesapeake Bay watershed, which provides users in the eastern U.S. with enhanced analysis capabilities, particularly for urban areas. Several anticipated updates to the LEARN tool would improve user experience and content while helping communities understand and act on mitigation and adaptation opportunities across forests and trees. Priorities for updates include disaggregation by census block and socioeconomic information, expansion of high-resolution tree canopy coverage, and functionalities for planning and decision-support. Another key improvement may involve working with the USFS to dynamically integrate with the Forest Inventory Analysis database to improve carbon estimation. Through continual updates and improvements to the LEARN tool, we are easing the burden on local and regional governments and accelerating the transition from planning to implementation on the ground.

From Ecosystem Service Prioritization to Species Distribution: selecting native street tree species for ecosystem service optimization in Ethiopia

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Gebretsadik Melak Tamene[1]
Asa Ode Sang[1], Kumelachew Yeshitela[2], Henrik Sjoman[1], Anna Levinsson[1]
[1] Swedish University of Agricultural Sciences (Department of Landscape Architecture, planning, and Management
[2] 3.Addis Ababa University (professor of Urban ecology at the Ethiopian Institute of Architecture, Building Construction and City Development (EiABC)

Abstract: Urban street trees (UST) provide multiple ecosystem services (ESs) against multi-scaled problems facing urban areas associated with climate change, pollution, and health. Selecting the right tree species providing the needed ESs, while matching urban site conditions can maximize ESs delivery and thereby improve the quality of life for the urban population. There is political and scientific recognition of the role that urban greening and urban trees have in enhancing urban resilience, towards climate change. However, the growth behavior of USTs, prioritization of ESs from UST, and preferences for UST species remain unstudied in many parts of the world, including East Africa as shown in a systematic literature review. The primary aim is to present the methodological approaches that will be used to evaluate USTs suitability and immunity to environmental stress, and preliminary results for a range of native Ethiopian species. Once we identified the potential USTs, leaf morphological, and chemical functional traits: leaf area, specific leaf area, leaf water content, specific leaf dry mass, specific leaf nitrogen, phosphorus, and carbon content, specific wood density, and leaf turgor loss point are measured to evaluate and compare their adaptation strategies. For better adaptive species, drought, and waterlogging resistance thresholds will be determined under greenhouse experiments in early 2024. Our findings of both the field measurement, laboratory measurement, and greenhouse experiment will be discussed about the challenges facing UST selection and how different native species could be used to deliver cooling services in the warmer seasons of Ethiopia and/or in general tropical cities.

Growth and cooling potential of urban trees across an imperviousness gradient

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Nayanesh Pattnaik[1]
Eleonora Franceschi[2], Astrid Reischl[1], Thomas Rötzer[2], Hans Pretzsch[2], Stephan Pauleit[1], Mohammad A. Rahman[1]
[1] Chair for Strategic Landscape Planning and Management, School of Life Sciences, Weihenstephan, Technische Universität München
[2] Chair for Forest Growth and Yield Science, School of Life Sciences, Weihenstephan, Technische Universität München

Abstract: The Urban Heat Island phenomenon, primarily caused by increased impervious surface cover replacing evaporative vegetation surfaces, has contributed to increased heat stress experienced by city dwellers. Climate change forecasts indicate that the UHI effect will worsen in the future, which will have a profound impact on human thermal comfort and could pose a public health threat. Urban trees, which cool the environment through shading and evapotranspiration, are an effective tool to mitigate the heat stress. However, their cooling potential is highly influenced by ecological characteristics, above and below ground conditions. Furthermore, the impact of impervious surfaces on tree growth and cooling potential across a range of urban environments remains largely unexplored. Our study addresses these knowledge gaps by comparing the growth rates and cooling potential of four different urban tree species along a eight kilometer transect which covers highly densified, city center to less impervious sub-urban areas in Munich, Germany. By assessing the impact of imperviousness on microclimatic regulation and growth patterns, we sought to provide insights into the selection and deployment of tree species to enhance thermal comfort. A field campaigned was carried out in the summer months where various parameters relating to the microclimate, tree morphology and physiology, dendrochronology and human thermal comfort of 38 tress of four different but contrasting species were measured. Results showed significant differences among the different tree species with regards to growth, vitality and cooling potential. Notably, dendrochronological analysis revealed that trees in low impervious zones (LIZ) exhibited larger sizes on average compared to those in high impervious zones (HIZ) of the same age. The light-demanding, fast-growing species,*P. x acerifolia*, exhibited the highest growth rate across all impervious zones. Furthermore, the cooling potential varied considerably among species, with diffuse-porous *P. x acerifolia* and *T. cordata* outperforming the ring-porous *R. pseudoacacia* due to higher stomatal conductance, transpiration rates, and leaf area index (LAI). The findings from our work can guide urban planners and landscape architects to select those species that are particularly effective in certain areas when the aim of planting is to improve human thermal comfort.

Health status of the street trees along the Urban – Rural gradient in the Garden city of Bengaluru, India

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Baragur Neelappa Divakara[1]
Chitradurga Umesh Nikhitha[1], Vindya Prasad Tewari[1]
[1] ICFRE - Institute of Wood Science and Technology, Malleshwaram, Bangalore - 560003 India

Abstract: Urban forestry deals with the management of the trees in the urban environment to improve and provide ecosystem services to the residents in the urban set-up. Trees play a crucial role in improving urban biodiversity and ecology, mitigating greenhouse gas emissions, reducing urban flood, and modifying local climate by reducing urban heat island effects. In addition, trees in urban ecology provide aesthetic benefits and enhance functional diversity. They also contribute towards economic benefits like attract tourism, increase property value and investments. Our study was focused on determining the tree health status in urban environment since they are constantly exposed to different anthropogenic pressures. For the study, 23 plots were selected in northern and 25 plots in southern transact of Bengaluru city in which trees with dbh $\geq$ 10 cms were taken for study. The size of each plot was one ha and the plots were classified as urban, transition and rural based on the percentage of tree cover and built-up. Common tree species from each domain were selected for Air pollution tolerance index in both transacts. The fresh leaf samples collected from the plots were analyzed for p^H, ascorbic acid content, relative water content and chlorophyll content. In addition, the trees' interior health was checked through Electrical Resistance Tomography which is a non-destructive method aiding to understand the sapwood, heartwood, stress and decay in the living trees through coloration. The finding from our study helps the urban decision makers, including planners and administrators, to plan and maintain the street trees in a holistic manner.

How do the increases in air temperature affect the cooling delivery of trees?

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Abstract: Rising air temperatures and the urban heat island effect are causing public health concerns worldwide. Green infrastructure provides cooling benefits to urban environments by absorbing radiation, using this energy for transpiration, and by direct shading. In the UK, 30% of urban areas comprise domestic gardens, while 90% of the population live in urban or peri-urban areas. Within gardens, trees play a central role in providing environmental cooling benefits. However, there is a knowledge gap on responses of common garden trees to increases in air temperatures associated with climate change, and uncertainty regarding recommendations of tree species appropriate for a variety of environmental conditions in gardens.

To provide gardeners with species-specific information on ecosystem service-delivery by trees during warmer periods, transpiration in response to meteorological fluctuations was monitored on a variety of tree species common to UK gardens. A 2-year replicated field trial was carried out on nine different species of containerised garden trees, maintained under irrigated conditions. Measurements included continuous assessment of sap flux, substrate moisture, tree growth, leaf area index, crown volume, leaf gas exchange and summer leaf water potential. This paper reports on data obtained during the warmest month of the study period (July) for the two consecutive years of the study. A mixed model was applied to assess responses of sap flux to meteorological conditions.

Eight out of nine species displayed maximum transpiration when air temperatures were between 28-30˚C (±3), however maximum transpiration for the *Prunus* was beyond the observed temperature (up to 37˚C). For relative transpirational cooling potential (accounting for size), the *Crataegus persimilis* was most promising up to a certain threshold (33˚C), while the fast growing *Pyrus calleryana* delivered most transpirational cooling in absolute terms (largest tree, up to 33 ˚C). Findings suggest that the tree species tested will continue to deliver a cooling service during the majority of future UK summer temperatures, providing they have access to sufficient soil moisture. However it also indicates that the majority of tree species are increasingly hitting their upper thresholds in terms of transpiration potential under warming UK summers.

Incorporating tree structural complexity and neighborhood effects into urban forest monitoring systems

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Abstract: Trees and forests in urban areas provide critical ecosystem services to support human well-being worldwide, yet urban-forest specific tools for monitoring are lacking, compared to those for other (rural) forest types and plantations. For example, the Forest Inventory and Analysis (FIA) program of the U.S. Forest Service has been monitoring US forests for about a century, yet have only implemented urban forest inventories in the last decade (Urban FIA). Further, urban forest monitoring systems typically rely on models of trees developed for trees growing in rural landscapes. It is important to understand how trees of different species are adapting to urban environments and how these environments affect tree form, function, and production of ecosystem services, such as mitigation of urban heat islands and carbon sequestration. Here, new data and models are presented to show how tree 'neighborhoods' in cities effect tree structural complexity, branching architecture, volume and surface area growth and biomass allocation, and how this knowledge can be incorporated to improve urban forest monitoring systems, such as Urban FIA. The potential of non-destructive methodological approaches derived from ground-based lidar are emphasized in both data collection and modeling approaches.

INEQUALITY IN THE PROVISION OF ECOSYSTEM SERVICES FROM URBAN FORESTS ACROSS DIFFERENT NEIGHBORHOODS IN ONE JURISDICTION. CASE STUDY OF LUJÁN ARGENTINA

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Analia Scarselletta[1, 2]

[4] Departamento de Tecnología, Universidad Nacional de Luján

Abstract: Urban forests play a crucial role in maintaining favorable environmental conditions for public health. They provide essential services such as improved air quality, climate regulation, and biodiversity promotion, contributing to healthier and more sustainable urban environments. However, ensuring equal access to these ecosystem services across different neighborhoods is essential to address potential inequalities. This research presents a case study conducted in Luján, Buenos Aires Province, in Argentina focusing on the access to urban forest ecosystem services and highlighting the importance of equity in their provision. The study employs a combination of methodologies to assess the distribution and fairness of ecosystem services provided by the urban forest in each neighborhood. By examining residents' connection with urban trees, their engagement in governance models, and disparities in accessing these services, this research aims to inform strategies for reducing social inequalities and enhancing residents' quality of life in Luján. It identifies and quantifies various ecosystem services, including air quality, climate regulation, biodiversity, and access to green spaces. To gather comprehensive data, official documents related to urban planning and green space management are analyzed to understand existing policies and regulatory frameworks. We conduct perception surveys among residents to obtain information about their connection to urban trees and their involvement in natural resource management. Additionally, the study uses the Normalized Difference Vegetation Index (NDVI) as an indirect indicator of urban forest ecosystem services, integrating it with economic and biophysical valuation. The research sheds light on social dynamics, perceptions, and utilization patterns of urban forests in Luján's neighborhoods. Findings reveal significant variations in residents' access to ecosystem services, emphasizing the importance of residents' connection with urban trees in both public and private spaces. The study also explores residents' potential participation in the governance and management of urban forests through various models. As the result, this research provides a foundation for creating more equitable and resilient urban environments, ensuring that all residents in Luján can fully benefit from the ecosystem services provided by urban forests.

Influence of urban expansion and land use/cover dynamics on ecosystem service value trade-offs and synergies in Tigray, Ethiopia

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Muluberhan Biedemariam[1, 2]
Emiru Birhane[2], Biadgilgn Demissie[3], Tewodros Tadesse[4]
[1] Aksum University, Forest Rehabilitation and Management Program, Soil Resources and Watershed Management Department, Shire-Indasilassie, Ethiopia
[2] Mekelle University, Land Resources Management and Environmental Protection, Mekelle, Ethiopia,
[3] Mekelle University, Department of Geography and Environmental Studies, Mekelle, Ethiopia,
[4] Mekelle University, Agricultural and Resource Economics, Mekelle, Ethiopia

Abstract: Understanding the influence of urban expansion and LULC dynamics on ecosystem service values (ESV) is an important basis for incorporating ecosystem services and their trade-offs and synergies into urban green infrastructures (UGIs) planning and decision-making processes. Proper UGI planning can help maintain the health of urban ecosystems and their services. In this study we evaluated the impact of LULC change, urban expansion and landscape dynamics on ESVs and their trade-offs and synergies in Mekelle, Aksum and Shire-Indasilassie cities of Tigray in Ethiopia. Landsat satellite images were used to analyze LULC for the years 1984, 1994, 2003, 2014 and 2020. Fifteen ESs were selected for analysis. We used global and local ESV coefficients to estimate ESV using benefit transfer technique. In 1984, farmland represented the most dominant LULC class covering about 80% (25,739 ha), 73% (2537 ha), and 66% (2294 ha) in Mekelle, Aksum and Shire-Indasilassie cities, respectively. While built-up land had the lowest coverage in all areas during this period. However, built-up land has been increasing with an increasing trend from 1984 – 2020 at the expense of farmland and UGIs. The study shows ESV reduction of 15.6% (Mekelle) and 18.98% (Shire-Indasilassie) but an increase of 2.75% in Aksum when using the global ESV coefficients. Based on local coefficient ESV decreased by 19.9% in Mekelle but increased by 13.6% in Aksum and 26.25% in Shire-Indasilassie. While based on estimates of local coefficients, provisioning ecosystem services value decreased by 31.2% (Mekelle), by 20.2% (Aksum) and by 38.7% (Shire-Indasilassie). Food production, biological control and pollination ecosystem service values had decreased through time. From 1984 – 2020 the per-capita ESVs decreased by 86.5% in Mekelle, 73.95 % in Aksum and by 93.86% in Shire-Indasilassie. The decrease in the ESV is probably contributed by urban expansion. The variations in the trade-offs and synergies of the ESs were significant, indicating the need for area specific UGIs planning and monitoring. Long-term monitoring of ES trade-offs and synergies would be essential for making policy decisions and land use planning and management improvements in urban areas.

Mapping preferred positions of visitors in an urban garden: an analysis of correlation with green structures

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Marco Piragnolo[1, 2]

Abstract: The behavior of people visiting green spaces is affected by several factors. An important aspect is the horizontal and vertical spatial structure of the vegetation, with respect to the accessibility and other features of the green area. In this work we tested a framework for real-time geolocation and mapping of visitors of an urban garden that is part of the VARCITIES project, Villa Revedin Bolasco. An app was developed for smartphones that are given to volunteers that visit the garden. The app is very light in terms of memory footprint and records every second the spatial coordinates of the device, sending it in real time to a server that collects the information in binary format in a file. The app can also be used offline, in case of low or absent connectivity, it will store the coordinates in the phone memory, and then sync whenever the connectivity is available. Data are visible online on a web-gis portal. The collected data are used to assess which areas are significantly more visited, and thus reasonably provide to visitors an added sense of wellness. This part, that is more related to the psychological aspect, was tested by a dedicated team from the Psychology department. Initial analyses related to the identification of clustering and spatial patterns have highlighted that there are two / three areas in the urban garden that seem significantly more visited than others. These areas are in more quiet parts of the park and in more pleasant scenery. To cross-validate these assumptions, a group of volunteers was also asked to take pictures of the areas that they preferred, and the spots that were photographed had a high correspondence to the hotspots of visitors positions. At this stage the correspondence was evaluated visually, but the next step is to assign similarity indices to the two heatmaps to objectively assess common hotspots and diverging results, in order to provide a more rigorous assessment of the output.

Microhabitat provision of solitary city trees of four common species in Germany

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

[3] Horticultural Department of Karlsruhe City (Gartenbauamt), Karlsruhe Germany

Abstract: Today's cities need sustainable planning to address the challenges of our time, such as climate change, ongoing urbanization, and the loss of urban biodiversity. Assessing biodiversity provision is essential in this regard. Large trees contribute significantly to biodiversity as they support the life of numerous other species. Therefore, inventorying, and monitoring tree-related microhabitats (TreM) can be a promising approach assessing urban areas' biodiversity. This research aimed to investigate the abundance, richness, and diversity of TreMs in common broadleaf urban tree species in Karlsruhe City, southwest Germany. Additionally, we aimed to identify the influence of tree-related variables, such as growing habitat and crown pruning intensity, on the occurrence of TreMs. We randomly selected 320 urban street and park trees was selected, consisting of Norway maple (*Acer platanoides*), horse-chestnut (*Aesculus hippocastanum*), black locust (*Robinia pseudoacacia*), and small-leaved linden (*Tilia cordata*). TreMs were recorded and inventoried, alongside a complete dendrometric inventory of the trees.

We found that small-leaved linden trees had a high abundance but low diversity of microhabitats. Park trees of Norway maple exhibited a greater microhabitat richness than street trees of the same species. Individual tree microhabitat groups such as cavities and fungi were less prevalent on black locusts, whereas rot holes and nests were more frequent on this species.

The frequency and diversity of TreM increased with tree size (diameter), which is a good predictor for the occurrence of microhabitats. Increasing pruning intensity and crown dieback had a positive influence on microhabitat occurrence. Growing habitat positively influenced TreM abundance in park trees of horse-chestnut. Comparison-of-mean tests showed that TreM richness and diversity were higher in park trees than in street trees of the horse-chestnut.

The results highlight the need to balance the conservation of large living urban trees, their appropriate management, and the maintenance of taxonomic diversity of trees in urban areas while considering diverse growing habitats such as parks and streets. Maintaining this balance becomes even more critical to minimize the trade-off between a healthy urban tree population with high leaf area versus trees with microhabitat structures for flora and fauna.

Monetary evaluation of multi-ecosystem services in an urban park designed for countering the adverse effects of climate change in Bangkok, Thailand

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Nisa Leksungnoen[2], Dokrak Marod[2], Pantana Tor-Ngern[3]
[1] Thai Forest Ecological Research Network, Department of Forest Biology, Faculty of Forestry, Kasetsart University, Bangkok, Thailand
[2] Department of Forest Biology, Faculty of Forestry, Kasetsart University, Bangkok, Thailand
[3] Department of Environmental Science, Faculty of Science, Chulalongkorn University, Bangkok, Thailand

Abstract: Thailand is a sought-after tourist destination, with an expansion pressure on this metropolis apart from a rapid urbanization. However, the expansion in green spaces has not been able to keep pace with this urbanization. Due to high population density and land prices in downtown, new urban parks are almost impossible to establish. Fortunately, a small park, named CU 100 Park, was established with an area of 4.48 ha in 2016 with a design to mitigate the effects of climate change. However, the important lingering question about the feasibility of such parks is "Can such a small park provide any ecosystem services (ES) to humans?". To answer this question, we conducted a study which focused on quantifying and evaluating the ES in terms of monetary value, as such a quantification can be conveyed easily to everyone from commoners to policy makers. Even for a relatively small sized park, the CU 10 Park provided all four services, including provisioning, regulating, culturing, and supporting services, which amounted to a total monetary value of USD 303.925. the most contributed ES was to the cultural services (46.79%), as the perspective of most people for coming to the park was of recreation. This was followed by provisioning services (27.81%), from the timber price, as the park manager intentionally selects the high value timber species. The contribution to supporting services was estimated at 19.86% of the total evaluation. These services are important to maintain the biodiversity of an ecosystem by providing habitat for organisms and genetic diversity. Interestingly, the least contribution was to the regulating services at 5.54%, even when the park was specifically designed for microclimate regulation. This could be due to the tree canopy being of a small size such that the leaf area index was not large enough for regulating the microclimate. It is proved that the specifically designed parks based on microhabitats are in need to provide various ecological function to attract and ensure adequate resource sharing by the flora and fauna apart from facilitating human community services related to physical activities and social interaction are crucial even with the small park size.

People's Perception on Use and Management of Urban Green Spaces of Gurugram, India

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Subhash Chander Yadav[1]
Kushagra Rajendra[2], Seema Yadav[3]

[3] Dr Seema Yadav, Senior Project Associate, World Resources Institute (WRI), New Delhi

Abstract: Urban Green Spaces are considered to be beneficial for health and wellbeing of urban residents. The need for more Urban Green Spaces is worldwide high on the policy agenda of the cities. Urban Green Space includes parks, community gardens and cemeteries, but also rooftop gardens and vertical gardens, meadows and woods. Urban Green Space is also referred to as blue-green zone, because urban water such as ditches, canals, inland waterways and rivers and riverbanks, is considered as Urban Green Space. Urban Green Space reduces the risks of flooding in cities, cools the city in the summer and provides biodiversity. UGS contributes to the well-being of cities and its residents, to better health, and social cohesion. Besides these regulating and provisioning services urban greenery also provides a gateway to enhanced socio-cultural bonding to its users. World health organization has highlighted the delicate link between green spaces and mental health.

There are about 1200 small and big city parks in the city of Gurugram located in North Indian State Haryana. There are other green spaces like bundh, biodiversity park and nature trails created on waste and open lands which are being used by people of the city for vsrious purposes. A study was carried out in three big parks and one nature trail created on a bundh to know the users' perception on use and management of these green spaces. The responses were received from males, females and children of various age groups on social-economic matters, purpose of visit of green spaces, time spent, frequency of visit etc. and management related issues in parks.

The results of the study will be presented in the Congress.

Quantifying the aboveground proportion of sapwood-heartwood volume of urban trees with the use of terrestrial laser scanning technology.

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Georgios Arseniou[1]
David MacFarlane[2], Pasi Raumonen[3]
[1] College of Forestry, Wildlife and Environment, Auburn University, Auburn, Alabama, USA
[2] Department of Forestry, Michigan State University, East Lansing, Michigan, USA
[3] Computing Sciences, Tampere University, Tampere, Finland

Abstract: Estimating the aboveground sapwood and heartwood volume is important for evaluating wood utilization and monitoring tree health and internal decay patterns in urban trees. However, quantification of the wood composition of trees is challenging because they typically must be harvested to obtain the data. Previous studies have primarily focused on the main stems of rural forest trees, excluding the branch component, but branches make up a major portion of urban tree wood. Here, we demonstrate a method for estimating total tree sapwood and heartwood volume, using a model of sapwood and heartwood distribution in stems and branches, combined with terrestrial laser scanning (TLS) technology, which provides detailed three-dimensional point-clouds of trees that can be used to quantify their aboveground woody volume in a non-destructive manner. Twenty-four urban *Gleditsia triacanthos* trees were laser scanned in leaf-off condition on the Michigan State University campus. TLS point-clouds were used to generate quantitative structure models, which provided detailed quantification of the woody volume of main stem and branches of the study trees. To calibrate models of heartwood-sapwood distribution a subset of the study trees were destructively sampled after scanning, and woody disks of stems and branches were collected. The resulting models provided estimates of total tree, stem and branch sapwood and heartwood volume and showed opposite patterns of vertical accumulation of heartwood and sapwood volume for stems versus branches. The method developed in this study has broader implications for monitoring the growth and the wood quality of urban trees. Future studies should explore the use of main stem increment borer samples, combined with branch disks of urban trees that are regularly pruned, because tree harvesting for model calibration may not be applicable or desirable in urban settings.

Remote sensing monitoring of urban canopy dynamic across heterogeneous urban habitats

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Yasong Guo[1]
Wendy Y. Chen[1]
[1] Department of Geography, The University of Hong Kong

Abstract: Urban trees are receiving increasing attention from both scholars and policy-makers to serve as a green prescription for addressing various challenges facing human society. The canopy development of urban trees is an indicator of their physiological health. Adequate monitoring of canopy dynamics based on remote sensing can help to detect plant growth in different urban habitats in order to inform management practices to maximise the benefits of urban trees. Using the Kowloon Peninsula, Hong Kong, as a case study site, this study explores tree canopy dynamics in four habitats, including road verges, residential lands, parks, and natural terrains. Four approaches are compared to segment adequately individual tree canopy using WorldView-2 remote sensing data. Then the individual tree canopy is combined with freely available Sentinel-2 satellite data to obtain canopy growth dynamics for each season from 2016 to 2020. The three indicators representing leaf chlorophyll density, density of woody branches and twigs, as well as canopy water content are applied to reflect tree canopy status. This study reveals that urban trees show varying canopy growth trends, the poorer status of trees in three urban habitats relative to nature land, indicates the inhibition of trees' natural growth by the urban environment. Additionally, two super-typhoons during the study period also provide evidence for urban tree resilience in different habitats, of these, the trees in road verges are the least resilient and in natural lands the most resilient. This study also finds that urban tree canopy preferentially recovered leaf after suffering losses from typhoons, while the recovery of non-leaf woody parts and water content lagged behind. This study demonstrates how remote sensing data can be used to provide a better understanding of long-term tree canopy dynamics across different urban habitats, which is key to monitoring urban trees' dynamics and incorporating management practices to maintain the health and growth of urban trees.

Remote sensing-based tree species classification for estimating ecosystem services

Abstract: Urban trees play a vital role in enhancing community health and well-being by providing environmental, social, and economic functions, collectively known as ecosystem services. Urban tree growth models have attempted to estimate the extent of these ecosystem services using allometric equations, growth factors and physiological functions. Nevertheless, these models require detailed information on individual tree characteristics, particularly tree species. Traditional data collection methods for tree attributes can be expensive and time-consuming. This study proposes a cost-effective approach utilizing remote sensing products, specifically multi-temporal satellite imagery and a canopy height model with very high spatial resolution, in conjunction with machine learning techniques for single tree classification.

Our object-based classification method incorporates various features, including vegetation indices, spectral, geometrical, and phenological attributes to differentiate the most common tree genera in Munich, Germany. To enhance classification accuracy, we adopt a hierarchical approach that considers land use, physiological characteristics, genus, and species. The model was applied over a large-scale area, successfully classifying more than 160,000 trees. Evaluation of the results revealed variations in classification accuracy based on land use and tree genus, achieving an accuracy of up to 88.9% for certain species. Our results are further validated for the estimation of ecosystem services by testing our tree metrics in the CityTree model.

This research demonstrates the efficacy of remote sensing and machine learning techniques for accurately classifying urban trees and obtaining detailed tree attributes necessary for ecosystem services models. The findings contribute to a more detailed understanding of urban tree dynamics and provide valuable insights for monitoring urban trees and their ecosystem services.

Seasonal dynamics of the Leaf Area Index of selected tree species in urban environments

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Astrid Moser-Reischl[1, 2]
Eleonora Franceschi[1], Mohammad Asrafur Rahman[2], Thomas Rötzer[1]
[1] Chair for Forest Growth and Yield Science, Technical University of Munich, Hans-Carl-von-Carlowitz-Platz 2, 85354 Freising, Germany
[2] Chair for Strategic Landscape Planning and Management, Technical University of Munich, Emil-Ramann-Str. 6, 85354 Freising, Germany

Abstract: The leaf area index LAI is one of the most important parameters for the acquisition and calculation of ecosystem services (ESS) of vegetation such as carbon fixation, cooling by evapotranspiration or shade density. These ESS are important aspects of urban greening in cities to naturally reduce human heat stress and mitigate climate change. In this context, different species and vegetation types show different EES depending on age, vitality, crown size and season. The present study deals with the variation of the LAI of different urban tree species at several public places in Munich over the course of a year. Thereby, both the "branching index" before leaf emergence, the increase of the LAI with leaf unfolding and the maximum foliage were recorded, as well as the decrease of the LAI in autumn.

In this study, the LAI was determined non-destructively using the indirect method of hemispherical photography. A total of 111 urban trees of six different species (59 *Tilia cordata*, 38 *Aesculus hippocastanum*, seven *Acer pseudoplatanus*, five *Platanus acerifolia*, and two *Robinia pseudoacacia*) were studied in six public places within the city of Munich. The 14 recording dates span from the end of March to the end of October 2019.

The results showed species-specific developments of the leaf area index. Thus, *T. cordata* and *A. pseudoplatanus* showed the highest LAI, while *P. acerifolia* displayed the lowest LAI values. The LAI curve of *R. pseudoacacia* developed significantly different from all other species with a late leaf emergence, sharp increase in summer and strong decrease afterwards. Leaf emergence happened similarly for all diffuse-porous, shade-tolerant species (*T. cordata, A. pseudoplatanus* and *A. hippocastanum*) between 09.- 16. April, while it was much later for light-demanding, ring-porous species *R. pseudoacacia* and the late leaf sprouting species *P. acerifolia* (after 30. April). Further analyses also revealed the relation between LAI and the degree of soil sealing and tree phenology. The obtained data can be used as a basis for the determination of the LAI and the ESS of different tree species in the city and thus be used for a more sustainable tree management.

Shrinking urban green spaces, increasing vulnerability: Solving the conundrum of demand-supply gap in fast expanding urban area in Global South

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Shalini Dhyani[1]
Jayshree Shukla[1]
[1] CSIR-National Environmental Engineering Research Institute (NEERI), Nagpur, Maharashtra India

Abstract: Urbanization is fast-growing still, urban green spaces (UGS) are observed to be cushions to many urban risks and issues that are not limited to pollution, habitat and disaster risk reduction. Unplanned and exponential urban growth in the Global South in last few decades been mammoth has led to loss of large area of UGS, associated ecosystem services and interlinked urban resilience. Urban growth in India faces continuous pressure from unprecedented expansion, immigration for livelihood opportunities leading to substantial loss of UGS. We attempted to understand and capture the relevance of public UGS because of ease of access to all. Dynamics of declining UGS due to rampant concretisation to address the demand-supply gap for urban green spaces was explored taking in Nagpur has a model city. GIS tools were used to assess decadal land-use change (1990–2021) in the city's buildup area and its impact on the urban green and blue spaces. Urban blue-green ratio was also assessed as an indicator for increasing flash flood risk and loss of habitats for water birds. A participatory survey approach was used for understanding the urban risks, relevance of UGS and local perspectives regarding their benefits based on accessibility to the urban green-blue spaces and continously widening demand-supply gap. Results clearly reflected that UGS were far behind WHO and National standards. The blue green ratio was insufficient to support benefits of UGS for reducing air, noise and ground water infiltration issues that are now emerging as obvious scenario for many fast sprawling urban areas in Global South. Per capita public UGS shortage can compromise resilience and will be insufficient to support the further urban sprawling. Investment in urban areas through the provision of creating efficiently planned healthy green spaces have clear evidence to ensure successful adaptation and mitigation for anticipated climate vulnerability. Suggestions on relevant trees for reducing air, noise and ground water issues will be discussed followed by their integration in site specific plantation along with enforcement of policies to keep 30% of each city area green as a strict compliance to improve urban resilience.

Social Media-based Analysis of Recreational Trail Use: A Case Study of a Protected Forest in Suburban Japan

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Shoma Jingu[1]
[1] Forestry and Forest Products Research Institute, Tsukuba, Japan

Abstract: Research on the recreational use of forest trails has been the main topic in greenery areas. With social media's widespread adoption, including platforms allowing users to share location-tagged content, new opportunities emerged for analyzing trail usage. However, previous research has been limited to specific social media platforms, such as Twitter or Flickr, and has provided a comprehensive analysis mainly in a larger area, such as at the national scale with national parks. This limited scope hinders a detailed understanding of recreation hotspots and preferences at the local scale (e.g., within urban green spaces). To address the gap and provide regional scale analysis, we focus on evaluating recreation hotspots along trails in a suburban forest. We collect data from multiple social media platforms to know recreational activities, visitor preferences, and the effects of various environmental factors along trails.

The study site is the "Ushiku Nature Sanctuary," located in Ibaraki Prefecture, the suburbs of the Tokyo Metropolitan Area, Japan. The sanctuary, previously a forest intended for resource supply to rural villages, has now transitioned its focus to biodiversity conservation under the management of the local government. Citizens can engage in non-destructive recreational activities, including walking, jogging, and birdwatching.

The methodology involves collecting and analyzing user-generated content, mainly photos, to gain insights into the activities and locations along the trails. We categorized landscape elements depicted in the pictures. Furthermore, we explored the relationship between the number of social media posts and various environmental factors associated with the tracks, e.g., zoning and management conditions, sky view factor, slope gradient, proximity to roads and parking areas, and the distribution of tourist facilities.

Our approach enabled a more detailed understanding of the specific activities and features that attract visitors to particular segments of the trails. We found hotspots of recreational activities along the tracks, indicating areas in high demand and appealing. Furthermore, we established correlations between environmental factors and the volume of social media posts, providing valuable insights for developing management strategies for enhancing visitor experiences and conserving natural resources.

Socio-economic value of cultural ecosystem services in urban green landscapes: evidence from a metropolitan public park

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Silvia Novelli[1]
Alessandro Corsi[2], Maria Letizia Borin[3], Simone Blanc[1]
[1] University of Turin, Department of Agricultural, Forest and Food Sciences, Italy
[2] University of Turin, Department of Economics and Statistics "Cognetti de Martiis", Italy
[3] University of Turin, Department of Life Sciences and Systems Biology, Italy

Abstract: Urban green landscapes provide urban dwellers with a wide range of ecosystem services, including cultural ecosystem services (CES), such as leisure, cultural education, aesthetic appreciation, and spiritual needs, but also physical and mental health, group identity, and social integration. Due to their intangible nature, evaluation of CES is less advanced than that on other ecosystem services, even in urban areas. However, estimating the monetary value of these benefits is essential to monitor the efficiency of public spending on urban green space management. The objective of this study was to analyse the CES provided by Parco Colonnetti, an urban green space of almost 40 ha, located in the Southern districts of Turin (Italy). This extensive area includes over 3,000 trees and shrubs, and three ponds. It is equipped with children's play areas, 150 benches, educational, gymnastic, and cycling paths. The specific aims of the research were to profile the park users based on the main benefits received and to estimate the use value visitors place on the park's CES. The survey was carried out through face-to-face interviews to 400 park visitors. Visitor profiles were defined using the principal component analysis (PCA) technique. The use value of the CES provided by the park was estimated with the Contingent Valuation method. Three main user profiles emerged: spiritual and convivial, stressed health-conscious, and parents seeking mental well-being. These profiles entered as explanatory variables in the model used to estimate the visitors' willingness to pay (WTP) function. More than half of the respondents stated a positive WTP to ensure the use of the park. The visitors' average WTP is about 50 euro/year corresponding to a mean value of 1.68 euro per visit, showing that local users seem to be aware of the benefits provided by the park and of its capacity to ameliorate the quality of city-life. These outcomes contribute to increasing the caseload of studies on CES in urban contexts worldwide, providing comprehensible information to policy makers, citizens and other stakeholders on the proper allocation of public resources for urban green landscapes.

Soundscapes and human well-being: acoustic indicators according to vegetational structure and site conditions in an urban historical garden

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Alessia Portaccio[1]
Marco Sozzi[1], Francesco Pirotti[1, 2], Marco Piragnolo[1, 2], Raffaele Cavalli[1]
[1] Department of Land, Environment, Agriculture and Forestry, Università degli Studi di Padova, Legnaro (PD), Italy
[2] Interdepartmental Research Center of Geomatics (CIRGEO), University of Padova, Legnaro (PD), Italy

Abstract: Natural sounds improve health, wellbeing, and positive emotions, and lower stress and negative feelings. Urban green landscapes such as gardens and parks represent places to listen to natural sounds and be exposed to less anthropogenic noise. The balance between natural and human-sourced noise can influence the experience of visitors. Vegetation plays an important role in shaping soundscapes, both by creating sound and attenuating noise from natural and human sources. The present study explores the spatial and temporal characteristics of the urban tree vegetation soundscape of the historic garden located in Castelfranco Veneto (TV, Italy) by setting up fix recording devices in multiple monitoring points for periods of 3 weeks during different seasons in 2022 (spring, autumn and winter). The acoustic indices (AI) such as Acoustic Complexity Index (ACI); Acoustic Diversity Index (ADI); Acoustic Evenness Index (AEI); Bioacoustic Index (BI); and Normalized Difference Soundscape Index (NDSI) have been computed for each point and for each single audio recording of 10 minutes per hour, for a total of about 6300 entries. The heights, basal area and density of the 1,299 trees in the historic urban garden are measured using a laser rangefinder and standard trigonometric methodology, while models for canopy height, cover and volume are derived from drone borne LiDAR data. Simulations of direct and diffuse solar radiation according to the canopy cover are assessed using a 3D point cloud model from LiDAR survey, considering the daily and hourly weather conditions reported by the local measuring station.

The responses of the AI to the vegetation-related variables are assessed considering covariates' effects in the analysis, in order to understand the role of tree vegetation in attenuating noise and creating hotspots for natural sound sources such as wild birds and fauna in an urban environment.

Monitoring the changes in the proportions of noise and natural sounds provides insight into biodiversity and the human experience of an urban ecosystem. Our analysis can inform urban planning that focuses on managing green areas while maximizing natural soundscapes to enhance human health and wellbeing.

Strengthening collaboration and knowledge exchange: Exploring synergies between Urban Forestry and Agroforestry

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Rita Sousa-Silva[1, 2]
Jürgen Bauhus[1]
[1] University of Freiburg
[2] Leiden University

Abstract: In recent years, the fields of urban forestry and agroforestry have gained significant attention for their potential as nature-based solutions to provide environmental, social and economic benefits and achieve more sustainable and resilient societies. While urban forestry primarily focuses on trees and green infrastructure within urban areas, agroforestry explores the integration of trees into agricultural landscapes. And although urban forestry and agroforestry share common objectives, such as enhancing biodiversity and ecosystem services, they often operate within distinct research domains. Our study identifies several key areas where urban forestry and agroforestry converge, fostering opportunities for collaboration and knowledge exchange, as well as highlights the different emphases that characterize each discipline.

First, we explore the interactions between trees and their environment, including the roles of trees in mitigating climate change and delivering multiple benefits to the local communities and society at large. Second, we delve into the crucial topics of monitoring and operational management of trees and green infrastructure in both urban and agricultural contexts. We highlight the importance of species selection and adaptive management strategies to address the challenges of changing environmental conditions and urbanization. Furthermore, we investigate the governance and planning frameworks of urban forestry and agroforestry, emphasizing the need for integrated approaches that consider both urban and rural landscapes, the significance of multi-stakeholder involvement, and the potential for transformational change in achieving sustainable urban and agricultural systems.

Our work serves as a call to action for researchers, practitioners, and policymakers to foster greater collaboration and synergy between the urban forestry and agroforestry communities. By facilitating closer collaboration and knowledge exchange between urban forestry and agroforestry, we can capitalize on their strengths and expertise, leading to enhanced research outcomes and innovative strategies to address complex environmental challenges. Through collaborative efforts, we can unlock the full potential of trees in transforming our cities and landscapes, ultimately improving the quality of life for both urban and rural populations.

The 3-30-300 rule in practice

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Johan Östberg[1]
[1] Nature Based Solution Institute

Abstract: Based on the importance of viewing greenery, living amongst greenery, and using greenery, and the scientific evidence that lies underneath, Cecil Konijnendijk introduced the now world-famous 3-30-300 rule for greener and healthier. The rule states that everyone should see 3 trees from there home and workplace, have 30 % canopy cover in every neighborhood and live not longer than 300 meters (328 yards) from a greenspace.

So, how can this rule be implemented and used when working with urban trees and greenspaces? This presentation will present several cases where the rule has been used in e.g. communication with politicians, policies, protection of trees during construction, and how a whole region in Sweden has now been analyzed to see how well all larger towns and cities are following this important rule.

Cecil Konijnendijk has written the following regarding the 3, 30 and 300:

3 trees visible from every home, school, and place of work. Every resident in a city, town, or even village should be able to see at least three trees from their home, school, or place of work. These trees should ideally be well-established. Fewer large-sized trees impacted resident mental health more positively than a larger number of small ones.

30% tree canopy cover in every neighborhood. Based on current research, at the neighborhood level a 30% canopy cover should be a minimum, and cities should strive for even higher canopy percentage when possible. Note that the 30% is not at the city level, as this can result, for example, in an uneven distribution of trees over the city. Thus, every neighborhood needs to be targeted, as well as all new housing developments where there are opportunities to integrate trees from the beginning.

300 meters from the nearest park or green space. In line with research and with the World Health Organization recommendations, every citizen should have a large public green space within 300 meters, approximately a 5-minute walk, from their home. WHO suggests a public green space of at least 1 ha.

THE EFFECT OF URBAN AFFORESTATION ON WILD POLLINATORS - AN ONGOING MONITORING

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Chiara Gibertini[1]
Paolo Biella[2], Rosa Ranalli[2], Simone Cavenaghi[3], Ilda Vagge[1], Luca Malanchini[1], Matteo Vizzarri[1], Fabio Campana[4], Giorgio Vacchiano[1]

[2] Department of Biotechnology and Biosciences, University of Milano – Bicocca, Milan, Italy
[3] Agriculture, Environment and Food, Univerità del Molise, Campobasso, Italy
[4] Parco Nord Milano, Milan, Italy

Abstract: Pollinators are important biodiversity indicators and offer key ecosystem services. There are several studies on the effects of urbanization on pollinators which show the importance of having green areas in cities. However, not much is known about the influence of urban afforestation on wild pollinators.

Afforestation in urban environments offers various ecosystem services and an increasing number of cities are investing in these projects. But how are urban forests and pollinators linked? How do the abundance and the diversity of pollinators change with the age of the urban forest? How does forest structure interplay with the role of floristic composition of adjacent meadows? Is functional diversity of both plants and pollinators a better indicator of such dynamics than specific diversity?

To answer these questions, in spring 2023 we started a monitoring project in the metropolitan area of Milan, Italy, by sampling hymenoptera, hoverflies and beetles using pan traps and capture with an entomological net. We monitored twelve sites located in meadows near forests planted in different years between 1984 and 2014 in Parco Nord Milano, a site of active and ongoing urban afforestation on former abandoned agricultural fields. Other five sites were located west of Milan in areas that will be reforested between 2023 and 2024 and represent the control.

We will show the results of the first year of monitoring. We expect: 1) a better understanding of the links among pollinators, forest structure and flora; 2) to observe a difference in the specific composition of pollinators between the two types of sites, with the presence of species that nest in woods in sites near forests; 3) to detect a time-dependent change of richness and diversity among forests planted in different years, which could be mirrored in the five new afforestation areas for the next several years.

The European urban tree inventory: differences in tree composition are crucial for the establishment of invasive forest pests

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Benno A. Augustinus[1]
Marta Bełka[2], Martina Kičić[3], Eckehard G. Brockerhoff[1], Valentin Queloz[1]
[1] Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Forest Health and Biotic Interactions, Switzerland
[2] Poznań University of Life Sciences, Department of Forest Phytopathology, Poland
[3] Croatian Forest Research Institute, Department for International Scientific Cooperation in Southeast Europe – EFISEE, Croatia

Abstract: Most invasive forest pests are first introduced in urban or peri-urban environments before they spread further, making urban trees potential bridgeheads for pests of trees in other cities or surrounding forests. Species composition of urban trees therefore has an influence on how likely an invasive species can establish after introduction. Consequently, the biosafety of both urban trees and surrounding forest trees is influenced by which trees are planted in cities.

In Europe, urban tree composition is highly diverse and varies among cities, with many more tree species in urban environments than in surrounding forests. The differences in tree composition in European cities is driven by climatic and cultural factors. To map these differences and how they can affect susceptibility to tree pests, we collected European urban tree inventories as part of the eCOST-action ub3guard. We obtained tree inventories from >170 cities across Europe with a total of >8.5 million individual trees from >3500 species. Most trees planted in European cities are native European species but there is also a wide range of non-native trees.

To examine what the extraordinarily high species richness of urban trees means for biosafety, we explored how many of these urban trees are hosts of quarantine pests as defined by the European and Mediterranean Plant Protection Organization (EPPO). We found that there are considerable differences in the number of suitable hosts for quarantine forest pests among European cities. Considering the potential damage that can be expected from invasive forest pests on urban and forest trees in Europe, we suggest greater consideration of potential invasive pests when choosing urban tree species for future planting.

The forest cemetery in Stockholm – eternal forest bathing

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Johan Östberg[1]
[1] Nature Based Solution Institute

Abstract: One of the few UNESCO world heritage cemeteries in the world exists in Stockholm, Sweden. The whole cemetery is designed in close connection to the forest and thereby the cemetery shifts with the seasons and continuously when the trees grow and are field.

Even though this cemetery gets the highest of attention from managers the Swedish UNESCO counsel and many more, the cemetery faces sever challenges. Some of the most important areas of the cemetery is built around elms which are threatened by Dutch elm disease. The large pine forest are showing severe decline due to a combination of pathogens, stress and suspected root damages, and the spruce are being devastated by insects.

The cemetery administration has therefor contracted a consultant network to do a full review of the historical, current and future management. The work focuses on pests and pathogens, climate change, biodiversity and replanting. This presentation will give an overview of all the issues the cemetery is facing together with how these challenges will be analyzed and the suggested changes in management to preserve this world-unique cemetery for future generations.

The importance of monumental and protected urban trees: a comparison between different European contexts

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Nicola Menon[1]
Yoan Paillet[2], D. Johan Kotze[3], Massimiliano Bedin[1], Giuseppe Brundu[4, 5], Paolo Semenzato[1], Tommaso Sitzia[1, 5], Thomas Campagnaro[1, 5]

[4] Department of agricultural sciences, University of Sassari
[5] National Biodiversity Future Center

Abstract: Urban trees can be protected through planning instruments, which is particularly true for monumental trees. Monumental trees are defined based on different criteria, and vary between countries and cities. In this contribution, we present results from the MONUVERSITY "MONUmental and urban trees for biodiveRSITY: improving our knowledge on their origin and microhabitats" project and, specifically, we analyse and compare protected and monumental trees in the Veneto region, and the cities of Grenoble (France) and Helsinki (Finland). The presentation first focuses on similarities and differences in terms of criteria adopted as well as other relevant data for monitoring and biodiversity (e.g., tree species). Second, a specific analysis of tree-related microhabitats will help in understanding the potential role of these trees in urban biodiversity. This analysis focuses on the frequency and variability of tree-related microhabitats considering different types of protection and of monumental trees. This study provides a contribution to biodiversity monitoring in urban areas as well as further deepening our knowledge of monumental trees. These results may also orient urban planners to better integrate biodiversity in their management plans and daily treatment of urban trees.

The Influence of Urban Park Characteristics on Recreational Vitality

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Dan Chen[1]
Zheng Tao[1], Junqi Chen[1], Wenrui Wu[1]
[1] School of Design, Shanghai Jiao Tong University, China

Abstract: Urban green landscapes play a crucial role in providing recreational opportunities for residents and are considered important indicators of high-quality urban development. However, the specific characteristics of urban green spaces that influence recreational utilization remain largely unexplored. This study aims to investigate the factors influencing recreational utilization in 10 urban green spaces in Shanghai using social media data. By employing OLS and GTWR regression models, we analyze the relationship between recreation utilization and both internal spatial characteristics of green landscapes and external environmental factors. Additionally, on-site investigations provide data on recreational activities, allowing us to examine the relationship between green landscape characteristics and recreational activities using regression models, focusing on 3 urban parks. The results reveal the following key findings:(1) Recreation utilization of urban green spaces exhibits temporal variability and spatial aggregation, with significant spatial and temporal heterogeneity in the influence of green space characteristics on recreation utilization. (2) Indicators such as recreation facility density and lawn coverage positively influence recreation utilization, while the influence of water coverage and normalized vegetation index varies spatially and temporally. The number of roads and the ratio of residential-commercial land use significantly and positively affect green space utilization, while the effects of the number of subway lines and bus stops exhibit significant spatial variation. (3) Certain urban green space characteristics, such as convex terrain, vegetation coverage, planting design pattern, green vision rate, seasonal plant proportion, and accessibility, exert a significant positive influence on recreational activity density. However, connectivity and the number of streetlights have a negative impact. The area of activity venues, grassland types, and land use diversity in the surrounding areas of the park significantly contribute to activity diversity. These findings provide a theoretical basis and empirical evidence for the organic renewal and enhanced utilization of high-density urban green spaces, thereby improving the social services provided by such spaces.

Tree-related structure variables for biodiversity and ecosystem service provision: a comparative framework for urban and rural forests

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Hanna Fors[1]

[1] Swedish University of Agricultural Sciences

Abstract: As a consequence of climate change and habitat loss, sufficient biodiversity levels and broad ranging ecosystem service (ES) provision are currently heavily threatened on local, national and global scales. Both urban and rural forested landscapes are of key importance in solving this crisis. A central challenge is how to manage forested landscapes in a way that enhances biodiversity levels and balances between provisioning, regulating, supporting and cultural ecosystem services, rather than favouring only few ES. Although extensive literature exists on the topic, many studies are limited to either rural or urban forests and only deal with a single or few ESs. Hence, there is a lack of studies that take a holistic approach to sustainable tree management by including both rural and urban forested landscapes and their potential complementarity in terms of biodiversity support and broad and balanced ES provision.

The literature was searched for review articles dealing with urban or rural temperate or boreal forests in the northern hemisphere to explore which tree-related 'structure variables' that support biodiversity and provide which ES and ecosystem disservices (EDS). Based on this, a comprehensive framework of structure variables for biodiversity support and broad and balanced ES provision in both urban and rural forested landscapes is presented. The structure variables 'multi-layered vegetation', 'old trees', 'broadleaved trees', 'dead wood' and 'horizontal variation within the area' were found to support biodiversity and lead to the highest number of ES in both urban and rural forests. Further, the placement of the structure variable seems to be of greater importance in cities, in order to provide ES of importance on local scale and not to cause EDS to local green space users.

Urban forest EDS mainly matter on local scale, affecting urbanites where they live, and e.g. include pollen emission leading to allergy, dense vegetation making green space inaccessible and danger from falling branches. There are fewer rural forest EDS compared to urban ones, mainly since rural forests are less populated than cities. For biodiversity support and broad ES provision, local authorities could focus on the central structure variables identified here when managing urban green spaces.

Unsupervised Remote Sensing-Based Assessment of Complex Green and Grey Infrastructure in Rurban Environments

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Nils Nölke[1]
Lutz Fehrmann[1], Tobias Plieninger[2], Christoph Kleinn[1]
[1] University of Göttingen, Forest Inventory and Remote Sensing
[2] University of Göttingen, Department of Agricultural Economics and Rural Development

Abstract: Trees play a pivotal role in urban green infrastructure, providing various ecosystem services crucial for enhancing the quality of life in urban areas. Conversely, grey infrastructure consists of built-up areas characterized by impermeable surfaces. The interplay between urban green and grey infrastructure influences the overall quality of urban life and the ecological value of urban spaces. However, the conventional dichotomy of separating urban and rural contexts is inadequate for comprehensive assessments in rapidly urbanizing Global South regions.

This study presents an unsupervised remote sensing-based approach to categorize the complexity of green and grey infrastructure in rurban environments. Using Bengaluru, India as a case study, we integrated 3D information and identified five distinct categories that describe the composition and configuration of green and grey infrastructure. Our approach offers a quantitative characterization of these rurban configurations, providing valuable insights for effective planning and management of rapidly urbanizing regions. By bridging the urban-rural divide, our methodology facilitates a comprehensive understanding of the intricate relationships between green and grey infrastructure elements, contributing to the sustainability and livability of urban environments.

Unveiling the Swedish Urban Forest's Hidden Treasures: Decoding Forest Owners' Mindset towards Uneven-Aged Forestry.

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Pedro M. Obregon S.[1]
Camilla Widmark[1]
[1] Swedish University of Agricultural Sciences, Department of Forest Economics. Umeå, Sweden

Abstract: Sweden is characterized as having a worldly renown forestry model that goes back to the mid-1800s since the creation of the Swedish forestry act. The purpose of this law has changed through time – from a production perspective to a more holistic approach that is conscious of the impact that the forest sector has on society, nature, and climate.

Different forest management methods have been proposed in the last decades, with clear-cutting being the most popular one up to date. However, there is interest in looking for alternative management solutions if we are to meet SDGs, biodiversity goals, and solve climate change. Methods such as Continuous Cover Forestry have gained the interest of various stakeholders in Sweden, as a way to preserve forests with the premise of having a productive forest land while protecting biodiversity.

This research intends to provide updated information on uneven-aged forest management methods available in Sweden. Specifically, identifying the challenges of implementing techniques such as Continuous Cover Forestry in Urban forests, while understanding the behavior of both forest owners and visitors. The project consists of different stages with the first one being to identify which methods are currently being used in Sweden's urban forests. The later stages seek to interview both forest owners and visitors to find valuable insights that can support the transition to an uneven-aged forestry model.

This study addresses the challenges surrounding the analysis of urban forests in the Swedish context, specifically focusing on the pressing need for a unified and specific definition of the term "urban forest." Our findings aim to shed light on the dynamics of forest ownership observed throughout the country, while also providing valuable recommendations for effectively integrating various management approaches to enhance the recreational value of urban forests.

Urban trees under drought: stem growth monitoring in two temperate cities with contrasting climates

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Eleonora Franceschi[1]
Astrid Moser-Reischl[1, 2], Mohammad A Rahman[2], Thomas Rötzer[1]
[1] Technical University of Munich, Chair for Forest Growth and Yield Science, Germany
[2] Technical University of Munich, Chair for Strategic Landscape Planning and Management, Germany

Abstract: Urban trees are usually associated with the increasing quality of life in the cities, in particular, when they grow old and healthy. The ecosystem services that urban trees provide can help mitigating the urban heat island, reduce air pollution and contribute to lower the steady rising global temperatures of the last decades. At the same time, urban trees suffer from the climate change conditions of more frequent heat waves and drought events, causing changes in tree growth and therefore quantity of ecosystem services. To better manage and plan sustainable cities, changes in growth must be precisely assessed. In this study, tree growth and drought response of commonly planted urban tree species *Tilia cordata, Acer platanoides* and *Robinia pseudoacacia* are analysed in two temperate German cities: Munich and Würzburg by using dendrometer and dendrochronological data. Dendrometer data have been collected in ten different locations among the two cities since 2018, while we used increment core data of over 100 trees for the City of Munich. Growth trends and ecosystem services linked to the urban climate and to drought are analysed by linear mixed models, considering the development over the years, as well as within years, e.g., to link the length of the growing period with the seasonal climate. First results show species-specific growth trends during and after the dry years 1992, 2003 and 2015; as well as differences linked to growing location (urban vs. suburban) and analysed period of growth (1980-1999 vs. 2000-2019). Significant better growth was measured for *A. platanoides* and *T. cordata* in suburban areas, while *R. pseudoacacia* did not show strong differences linked to the growing location. Significant lower growth after the year 2000 was observed for *R. pseudoacacia* (over -40%) and *A. platanoides* (-36%) compared to the twenty years before, indicating a negative effect of recent climate change for these species. Combining these dendrochonological and dendrometer data as well as different data resolutions can increase the quality of monitoring of tree response to the urban climate during climate change.

Using airborne laser scanning data to assess the number of trees visible from the window

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Andrzej Affek[1]
[1] Institute of Geography and Spatial Organization Polish Academy of Sciences

Abstract: In the urban space, highly transformed by man and with a substantially reduced natural areas, people have limited opportunities to interact with nature. Therefore, each, even seemingly shallow, interaction with the living world takes on a special meaning. One of the examples of possible everyday interaction with nature in the city is experiencing/observing it through the window. Research clearly shows that the presence of nature in the window view, in particular trees, significantly increases the level of satisfaction with the place of residence and general well-being, and also promotes faster recovery (see the '3-30-300' rule).

The aim of this study was to assess the provision of aesthetic experiences and opportunities promoting health, recuperation or enjoyment through passive interaction with urban trees from the place of residence or work. An indicator dedicated to the local scale and local spatial planning was developed, showing the number of trees visible from the windows (5 m facade segment) on the top floors of buildings. To calculate the indicator, LiDAR-derived high-resolution digital elevation and terrain models were used, as well as vector layers of buildings and tree crowns. The preliminary analysis was performed for all residential and commercial buildings located in six selected housing estates in Warsaw, Poland: two tenement, two single-family and two large-scale multifamily.

The mean number of visible trees ranged from 8 in the tenement housing in the downtown to 277 in the large-scale housing estate on the outskirts of Warsaw. The obtained highest number of visible trees per window was 906, however, in every housing estate except one, windows located on the top floors of buildings, from which no trees were visible, were recorded.

It can be concluded that the use of trees to generate aesthetic experiences and promote health, recuperation or enjoyment is the highest in large-area housing estates, slightly lower in single-family housing estates, and the lowest in the areas of tenement housing. Nevertheless, the high variability within these residential types indicates that the land use in a given neighbourhood, related both to buildings and greenery, can substantially affect access to this ecosystem service.

"Quantifying Private Urban Trees: A Study of Berlin's Hidden Greenery"

T4.31 Urban trees & green landscapes: Monitoring and management for providing multiple services

Marion Stellmes[1]
Anika Sieber[1], Fabian Fassnacht[1], **Miriam Herrmann**[1]
[1] Remote Sensing and Geoinformatics, Freie Universität Berlin, Germany

Abstract: Berlin is renowned for its greenness and abundance of trees, which provide a multitude of essential ecosystem services and significantly enhance the urban experience. Trees in public spaces, i.e. streets and parks, are regularly catalogued in a database and are thus well-documented.

However, the number of trees on private property and their development over recent decades remains largely unknown. These areas include private property owned by individuals and housing cooperatives, as well as allotment gardens and other private land. The inclusion of this significant number of trees is crucial for urban planning and management.

Our study aims to address this knowledge gap by quantifying the total number of trees and their coverage in private spaces, and by examining changes that have occurred over the past two decades.

Since 2005, aerial surveys have been conducted at regular five-year intervals to evaluate the condition of Berlin's urban trees in public spaces. The digital imagery is freely available and forms a robust database for our analyses. Concurrently, deep learning approaches have made significant advancements. Techniques such as DeepForest now enable large-scale segmentation of tree crowns using high-resolution aerial imagery. Our study applies this algorithm to digital aerial images from 2005 and 2020 to address our research question. We will present the results of our study providing deeper insights into the entirety of Berlin's urban trees. Our analyses are supported by a large number of validation and in-situ data.

T4.32 Valuation of water and biodiversity co-benefits in carbon forestry schemes

Creating investor value from forest landscape restoration through integrating carbon, forest products, water, biodiversity and community benefits

T4.32 Valuation of water and biodiversity co-benefits in carbon forestry schemes

Paul Chatterton[1]
Rodney Keenan[2]
[1] Landscape Finance Lab
[2] University of Melbourne

Abstract: Markets for forest-based mitigation activities to meet emissions reduction targets are driving significant investment in landscape change through afforestation and other forms of landscape repair. However, concerns about the integrity of sequestration outcomes and a desire to contribute to other sustainable development goals such as improving water, biodiversity and local community benefits, are placing greater attention on the potential value of these co-benefits for carbon projects investors.

This paper explores different ways in which the value of these co-benefits is being captured for private sector investors using examples from forested landscapes, including those developed by the Landscape Finance Lab. This same methodology is being applied for landscapes in other habitats such as peatlands and river systems. This innovative funding approach bridges the gap between investors and land managers by supporting practitioners and investors to incubate sustainable landscape solutions that will generate impacts at scale and restore watershed functions or protect threatened biodiversity. Good project design is critical to avoid perverse water and biodiversity outcomes from climate mitigation investment. This begins with structuring landscape investment portfolios and investment vehicles and building blended finance models drawing upon different sources of finance: philanthropic, impact and full commercial. Suitable tools, guidance, training and knowledge are required to value different benefits and share this value equitably among project partners, value chain participants and stakeholders across the target landscapes. Effective tools for assessing value will be described including a landscape scorecard and the '4 Returns Framework' methodology that provides a common language and practical instrument to halt and reverse the losses from landscape degradation and stimulate thriving landscapes and communities at scale. A key shift is to move beyond valuing specific returns on a per hectare basis to generating multiple returns at a landscape scale.

Impacts of co-benefit accounting for nature-based project in voluntary carbon markets: examination of risks and benefits

T4.32 Valuation of water and biodiversity co-benefits in carbon forestry schemes

Oliver Miltenbeger[1]
[1] University of Melbourne

Abstract: Voluntary carbon markets (VCMs) are an important tool for achieving climate change targets and are expected to rapidly scale-up over the next decade. Nature-based solutions (NBS) are among the most cost-efficient means of producing the mitigations that VCMs trade as credits and represent a growing proportion of market activity. However, NBS projects' impact go beyond mitigations to include so-called co-benefits such as improvements for livelihoods, biodiversity, and water availability and quality. Various VCM schemes attempt to account for these co-benefits. This additional information on co-benefits affects several aspects of VCMs from project design and development to the pricing and sale of credits. However, co-benefit accounting is highly variable across projects and credit standards, creating issues around market information asymmetry and risks to project operations and reputation. This suggests co-benefit accounting can be either a benefit or liability to projects and further refinement of approaches is needed for VCMs.

This research examines different forms of VCM co-benefit accounting and implications for project risk and outcomes as well as how they can be improved. Specifically, it looks at how different co-benefits and associated availability and quality of data affects credit pricing. It further considers how credit pricing impacts project finances and translates to perceptions of project quality. Several NBS, primarily forestry-related, projects at different stages of development were selected to examine. Early-stage projects rely on projections, while more developed projects utilize VCM standards' methodologies for accounting and in some cases, are subjected to third-party credit rating agencies. The research considers how these different approaches impact data availability and quality.

Though preliminary, initial findings generally indicate that the number of co-benefits and robustness of accounting correlates with higher credit prices. Though, the consistency and magnitude of price increases varied across accounting approaches and stages of project development. It further suggests that these projects better manage risks related to securing capital investments, maintaining stakeholder buy-in, and accusations of greenwashing.

Quantification of Co-Benefits by the Agroforestry Carbon Project at Primary Schools in Arid and Semi-Arid areas (ASALs), Kenya

T4.32 Valuation of water and biodiversity co-benefits in carbon forestry schemes

Yasuko Inoue[1]
Bernard Kigwa[2]
[1] Expert on Forest Policy and Extention, JICA Project for Strengthening Forestry Sector Development and Community Resilience to Climate Change through Sustainable Forest Management and Landscape Restoration (SFS-CORECC), Republic of Kenya
[2] Senior Researcher, Kenya Forest Research Institute

Abstract: There is a large area waiting for re/afforestation in Arid and Semi-Arid areas (ASALs) in Africa, while majority of the investments are distributed to relatively humid and fertile areas considering the profitability and risks. The lack of sufficient rainfall during the past three years since 2020 has led to the death of 2.5 million livestock and malnutrition among some 940,000 children under the age of five in Kenya (UNICEF 2022). There is an urgent need to mitigate the negative impacts of climate change in those disadvantageous areas. By evaluation of co-benefits, such projects in ASALs can be regarded as more attractive to support.

A pilot carbon project by agroforestry was started in 4 primary schools in South Kitui, one of the driest areas in Kenya in 2023. The schools selected to grow indigenous tree species which shows a high tolerance in limited hydrological environment; Baobab (*Adansonia digitata*) and African Mahogany (*Melia volkensii*) in combination of legume crops such as cowpeas. Young leaves of baobab are used for school lunches as they are rich in iron, calcium and vitamins. African mahogany is grown to supply school desks and chairs that are always not enough for all children. An appropriate planting-harvesting rules as for the carbon project is applied. With the increased water supply and improved land management methods provided, the agroforestry methods including terracing enriched hydrological and nutrition cycles in the soils. The project is expected to enhance resilience and adaptative capacity of the school children and surrounding communities to the changing climate.

The authors will display the quantifiable methodologies to evaluate these co-benefits such as studying hydrological status of soil, crop-diversity enhancement and nutrition improvement of children as well as financial benefits by the project. Their associated SDGs contribution potentials and monitoring methods including day-to-day monitoring by school children will also be shared. In combination with the co-benefit values which is in line with the modality stated in the UNFCCC decision of 18/CP.21 on non-carbon benefit, it will be expected higher valuation as forest carbon projects and will be useful to be diffused to wider ASALs Africa.

The Climate Credit: a new concept to boost and value the interlinked benefits of forest management on carbon, water and biodiversity

T4.32 Valuation of water and biodiversity co-benefits in carbon forestry schemes

Teresa Baiges Zapater[1]
Teresa Cervera Zaragoza[1], Iñaki Gili Jauregui[2], Cristina Vega Garcia[3], Pere Casals Tortras[4]
[1] Forest Ownership Centre of Catalonia (NE Spain) - Catalan Ministry of Climate Action (CPF)
[2] Catalan Office for Climate Change - Catalan Ministry of Climate Action (OCCC)
[3] University of Lleida (UdL)
[4] Forest Sciences Center of Catalonia (CTFC)

Abstract: In Catalonia, a new voluntary market for Climate Credits is being developed to promote improved forest management (IFM) in private forests. Although inspired by current carbon markets, the Climate Credit market aims to go beyond carbon and beyond tree planting, addressing 3 key forest ecosystem services (ES) in an integrated way: carbon (including fire prevention), water supply and biodiversity. To this end, we have established a methodology for the ex-ante estimation of the impact of IFM on these 3 ES.

Regarding water supply, we assume that forest management, by temporarily reducing forest cover, can increase blue water. We built a new methodology from previous data on exported water values (m3/ha and year) obtained after applying a water balance model (MEDFATE) to the NFI plots. Regression equations were obtained by relating these values to a structural variable that is easy to measure, such as basal area (BA), which is indicative of forest management and correlates well with the leaf area index (LAI). Different equations were obtained as a function of the moisture index (HI) -based on the P/PET ratio- to include variations due to the location of the forest, and of the type of forest (coniferous/broadleaf) to reflect the different responses of the tree species.

Regarding biodiversity, the Climate Credit methodology quantifies *ex ante* the impact that the IFM has on biodiversity. To do so, we chose the Potential Biodiversity Index (IBP) methodology due to its cost-effective and non-expert implementation. The IBP is a proxy indicator of a forest's capacity to support biodiversity, based on field assessment of 10 key structural factors of the forest. It focuses on the stand scale and the ordinary taxonomic biodiversity (not rare or endangered species).

We propose the forestry projects participating in the market are develop from a bottom-up participatory landscape approach. This helps to address the trade-offs between different ES and to have a greater impact by prioritizing forests with a large supply of these ES or at higher risk.

The value of Ecosystem Services: A quantitative estimation from the Kakamega-Nandi Forest landscape

T4.32 Valuation of water and biodiversity co-benefits in carbon forestry schemes

David Langat[1]
Samson Ojunga[2], Kelvin Owange[3], Meshack Omuono[2], George Ayaga[3]
[1] Kenya Forestry Research Institute, Rift Valley Eco-region Research Programme, P.O. Box 382-Londiani,Kenya
[2] Kenya Forestry Research Institute, Lake Victoria Eco-region Research Programme P.O Box 5199 Kisumu 40108, Kenya
[3] Kenya Agricultural Livestock Research Organization, Food Crop Research Institute, P.O. Box 278 -50400, Busia, Kenya

Abstract: Natural forest ecosystem landscapes are important to human well-being, however, they are not appreciated and hence not considered in public policy decisions and do not receive adequate public support in resource allocations due to the undervaluation of economic contributions to human populations. To ensure justification, it is necessary to value the tangible and intangible values of forest ecosystems. This paper presents the results of the valuation of the monetary value of goods and services provided by the Kakamega-Nandi forest ecosystem landscape in Western Kenya. Primary data was collected from 480 households using structured and semi-structured interviews. Secondary information was obtained from service providers, other published/ unpublished sources and discussions with experts. Market prices, Contingent valuation, Cost-based and Benefit Transfer (BT) techniques were applied in estimating total economic values. Economic benefits generated from the selected forest ecosystem services in the Kakamega-Nandi landscape were about KES 9.1 billion per year (approximately USD 85.3 million). The bulk of the total benefits (48.3% (KES 4.4 billion per year or approximately USD 41 million) was from regulating services with carbon sequestration service forming 47.8% with a value of KES 4.37 billion annually (USD 41 million). The value of regulating and supporting services was estimated to be about KES 4.12 billion per year (approximately USD 41.2 million). The products and services enjoyed by local adjacent communities are about KES 3 billion (USD 28 million). These values are conservative estimates and may vary with changes in the market prices used to make the assessments. The study demonstrated that the forested landscapes provide substantial economic benefits to the local people and people adjacent to these ecosystems. These values can be applied to creating awareness of the importance of forest landscapes and for articulating the incentive mechanisms for local communities to conserve forest landscapes for sustainable flow and benefits of forest ecosystems. Resource managers/planners and policy-makers can apply the estimates in cost-benefit analysis and in support of appropriate conservation decisions. The estimated economic value of the ecosystem services provides a strong rationale for the need to conserve protected areas and the ecosystems they contain.

Towards a Woodland Water Code: encouraging Tree Planting for Water Quality, Flood Risk attenuation and Water Cooling benefits - a UK perspective

T4.32 Valuation of water and biodiversity co-benefits in carbon forestry schemes

GREGORY VALATIN[1]
THOMAS NISBET[1], ROSIE BROOK[2], ROMANY VASSELL[1]
[1] Forest Research, Alice Holt Lodge, Farnham GU10 4LH, UK
[2] Forest Research, Northern Research Station, Roslin EH25 9SY, UK

Abstract: As a commitment to ending the UK's contribution to global warming, in 2019 the UK Government adopted a binding target of achieving 'net zero' emissions by 2050, with an interim target of a 78% reduction by 2035 set in 2021. Recognising the need for land use change to help meet these commitments, the Government aims to treble tree planting rates in England by 2024, with woodland expansion targets to increase woodland cover from 15% to 24% in Wales, and from 17% to 25% of land area in Scotland by 2050. The aim is to plant an additional 30,000 ha of UK woodlands (90 million to 120 million trees) each year by 2025.

Government support for woodland creation includes funding in England to promote tree planting and underpinning research and development from a £750m Nature for Climate Fund. Drawing upon the pioneering example of the UK Woodland Carbon Code (https://woodlandcarboncode.org.uk) introduced in 2011 to underpin investment in woodland creation for carbon sequestration benefits – and widely viewed as very successful, there is increasing interest in developing a novel Code to cover water-related benefits of woodland creation. One of the Nature for Climate Fund projects led by Forest Research aims to develop a Woodland Water Code as a crediting mechanism covering water quality, flood risk attenuation, and water cooling (aquatic habitat) benefits.

This paper outlines recent progress on the new Code, including creating look-up tables quantifying the water benefits, developing methods and rules that fit well with those under the UK Woodland Carbon Code, and facilitating stacking carbon and water benefits while ensuring additionality. The paper traces the origins of the initiative to develop a Woodland Water Code building on the findings of the PESFOR-W COST Action - a network of researchers and practitioners from 40 countries interested in woodlands for water Payments for Ecosystem Services led by Forest Research. We conclude by describing next steps prior to the planned launch of an initial version of the Woodland Water Code covering water quality benefits in early 2025.

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

A novel indicator-based approach for capturing the multiple community-forest relations in a Canadian context

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Annie Montpetit[1]
Frédérik Doyon[1], Guy Chiasson[1]
[1] Université du Québec en Outaouais

Abstract: Forest-based communities share intricate complex relations marked by their attachments to the forest environment. The notion of sense of place identifies the social and natural components that forge these relationships, and the modalities of attachment to the forest biophysical environment. Sense of place research considers that a forest territory encompasses socio-natural dimensions that are difficult to separate and cannot be captured in isolation. Results from this literature also emphasize that natural dimensions such as the biophysical environment as well as social interactions are equally important for feelings of well-being and quality of life linked to attachment. Sense of place studies have thus shown that multitude of values, embedded in a territory, can characterize the community-forest relationship.

In Canada, national-level sustainable forest management (SFM) criteria and indicators aiming at describing the state of forest-based communities are mostly driven by economic values. There are two main limits to this preponderance of economic values in the conceptualization of SFM criteria and indicators for forest-based communities. The first is that it offers a limited comprehension of forest-based communities attributes. The second is linked to the context of climate change. Forest communities are undergoing complex socio-ecological changes that jeopardize the multiple values (not just economic) associated with the forest. The impacts of mountain pine beetle and spruce beetle epidemics, drought and increased forest fires have been well documented in the Canadian context.

This presentation highlights a new method that captures a wide range of forest-related values to better characterize community-forest relationships at a national scale. Using indicators developed with a combination of socio-economic census data (Statistics Canada) and geospatial data, it is possible to better capture the cultural, social, economic, and traditional values associated with the forest. The clustering analysis performed with those new indicators allowed to identify six types of forest communities. Analysis of the vulnerability of these six types to climate change demonstrate the relevance of innovative approaches to SFM criteria and indicators.

Balancing Sustainability and Legal Frameworks: Resolving Conflicts at the Urban-Rural Frontier caused by Urban Expansion in Sweden.

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Pedro M. Obregon S.[1]
Camilla Widmark[1]
[1] Swedish University of Agricultural Sciences, Department of Forest Economics. Umeå, Sweden

Abstract: The development and implementation of alternative forest management methods in rural areas with extensive forest land have received significant attention. The Swedish government recognizes the importance of exploring different approaches to forestry and the management of Ecosystem Services in order to achieve Sustainable Development Goals. Our research argues that it is crucial to focus on urban areas as well, especially on the border between urban and rural forests. This area serves as a perfect example of how growing urbanization can impact forest management and the challenges faced by forest owners in an urban context. Therefore, we conducted an analysis of the Swedish legal framework to assess the country's preparedness to address these governance challenges that will inevitably arise as populations and cities continue to grow.

As cities expand, conflicts arise between individual forest owners and urban forest owners, as municipalities encroach upon rural forest areas over time. The Swedish law of free access raises expectations regarding the preservation of recreational values on forested lands and with that higher expectations towards forest owners. This analysis challenges the notion of seamless integration between cities and nature, highlighting the tradeoffs that occur when both cities and urban forests expand. It also presents opportunities to maximize recreational values by adopting a different approach to forestry compared to the traditional methods used in non-urbanized forest lands.

This research emphasizes the need for city planners and the government to reconsider the way cities grow in order to avoid future governance issues. An alternative solution would involve adapting the Swedish law to effectively address these forthcoming challenges.

Beyond bio-physical inventory: human dimensions to plan for sustainable forestry

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Hanne Sjølie[1]
Brett Butler[2, 3], Mati Maltamo[4], Silvia Korth[5], **Francisco Aguilar**[1, 6]

[3] University of Massachusetts
[4] University of Eastern Finland
[5] University of Misiones, Argentina
[6] Swedish University of Agricultural Sciences

Abstract: Forest inventory has in various countries long and strong traditions and offers a wealth of information to infer forest conditions, from the property to the national level. Also, much thinking has been placed on the need and the possibilities to harmonize forest inventory data across political boundaries to facilitate regional initiatives advancing sustainable forestry. However, the human dimensions of forests, reflecting on the people who depend on, and whose actions are shaped by and shape forests, are crucial for understanding the larger set of drivers steering forest conditions as well as well-designing forest policy. Despite efforts of integrating socio-economic and biophysical data, the systematic forest inventory programs are in many countries not paralleled by data gathering of human dimensions or data are not gathered in conjunction. These limitations have several consequences. First, in many countries, the forest landbase is divided between ownership types whose strategies and management objectives vary widely. Management objectives and forest conditions may have two-way causality, making localized socio-economic and biophysical data integration necessary to infer relations. Without such information, there is a risk that the effectiveness of policies will not reach the desired goals. Second, forest conditions and forestry change due to multiple sources. Climatic factors amend the biophysical base while policies to support sustainable forestry, a green bioeconomy, and climate mitigation and adaptation are constantly developing at the same time as forest owners' attitudes are evolving. In order to advance complex objectives related to socio-economic wellbeing and forest sustainability, more data to draw substantiated links between the bio-physical and human factors are needed. At its core, forest planning whether at a property, national or global scale is intrinsically a human-centered process, and inclusion of socially-inclusive and representative data a necessity for driving sustainable forestry. We compare the biophysical-human forest inventory data gathering across countries, point to gaps and suggest steps to help our current generation of researchers and practitioners meet the needs and expectations of the future.

Exploring conflicts over forest futures: Methodological reflections on interweaving conflict analysis and conflict management

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Anna Sophie Brietzke[1, 2]
Deike U. Lüdtke[1, 3], Michael Kreß-Ludwig[1], Diana Hummel[1, 3], Katharina Heß[1]
[1] ISOE - Institute for Social-Ecological Research, Frankfurt/Main, Germany
[2] Institute for Archaeology and Cultural Anthropology, University of Bonn, Germany
[3] Senckenberg Biodiversity & Climate Research Centre, Frankfurt/Main, Germany

Abstract: Forests are currently undergoing unprecedented change. Against the backdrop of climate change and its manifold negative impacts on forests, conflicts on how to manage and conserve these ecologically, economically, socially and culturally significant landscapes in the future are intensifying. A deeper understanding of how different stakeholders envision the future of forests could contribute to addressing this issue.

In our presentation we show results from an inter- and transdisciplinary project on cooperative processing of forest-related negotiation processes in the context of climate change in Germany. In particular, we investigate the relation between future imaginaries and (un)certainties in negotiation processes about forest futures. By means of ethnographic fieldwork in two local case studies in Germany, we elaborate on how actors from forestry and nature conservation imagine forest futures, which forest-related (un)certainties they perceive, which practices they use to counter (un)certain forest futures and to what extent these aspects have an impact on the negotiation processes.

In our contribution, we will present first results from the constructive dialogues with relevant stakeholders and the application of formats such as roundtables, focus groups and conflict mediation. The conflict dynamics in these dialogues will be examined from an anthropological perspective. For this purpose, we conduct participant observation and in-depth interviews.

Our contribution will focus on a methodological reflection to discuss the potentials and challenges of interweaving conflict analysis and conflict management. This reflection is important in order to show to what extent transdisciplinary approaches can be fruitful in this context and to provide inspiration for upcoming research projects on forest futures.

Forests are also good to think with: the pluriverse and anthropology's methodological legacies

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Eeva Berglund[1]
[1] Aalto University

Abstract: Ways of being pluralist are becoming popular in discussions of environmental matters – 'multiverse', 'polycrisis' and 'pluriverse' being just three examples. At the same time, sustainable futures, though locally experienced, are highly dependent on global processes. This acknowledges that environmental damages and responses to them involve a single arena of activities and processes. But does this require a correspondingly uniform epistemology for ensuring its sustainable management? I propose it does not, based on an anthropological methodology that constantly travels between the proximate (or local) and the distant (or global).

Drawing from anthropological approaches to humans in their environments, I focus my discussion on what Arturo Escobar has popularised as pluriversal thinking as a methodological principle for research on forests and people. Above all, pluriversal thinking affirms ways of knowing that have been marginalised in modern times, and it foregrounds the 'radical interdependence of all that exists'. The level of holism that this implies has troubling implications for western epistemological practices and institutional structures, based as they are on historically constructed but often black-boxed notions of specialist expertise. When it comes to forest-proximate populations however, the critical comparative outlook embedded in the concept of pluriverse is quite good at producing evidence of (supposedly) non-modern or pluriversal ways of knowing even in unlikely places such as Finland, where people are committed in general to modern identities and, on the whole, modern science, including its black boxes.

As a methodology, the pluriversal approach can be elaborated as a derivative of anthropological ways of exploring knowing, doing and feeling, all at the same time, and adapting a point that anthropologist Claude Lévi-Strauss made decades ago: "animals / things / forests are good to think with". Perhaps this is particularly the case when the thinking involves complex problems with multiple and complicated drivers and indeterminate points of origin.

Forests as providers of cultural ecosystem services – an arts studies perspective

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Karoliina Lummaa[1]
[1] University of Turku

Abstract: How nonhuman nature influences human creativity has been a much studied topic within the environmental humanities, resulting in conceptualisations such as *ecopoetics*, *storied matter* and *nonhuman agency*. Interestingly, nature's contributions to cultural creations are nowadays also acknowledged within environmental policy via the ecosystem services (ES) framework. Cultural ecosystem services (CES) are defined as the nonmaterial benefits people obtain from ecosystems (MA 2005). While the concept of CES emphasises interconnection between natural and cultural processes, the CES approach has raised little interest within the environmental humanities. This is lamentable, since environmental humanities scholarship is acutely needed to analyse and communicate the importance of nature's contributions to cultural practices and ideas.

In my presentation I ask, how the idea of forests providing cultural inspiration appears in current Finnish art and environmental policy. I will first provide a review of recent research on CES, and then proceed to the case study, consisting of two types of data: Finnish contemporary forest poetry, and Finnish governmental strategies concerning forests, biodiversity and ecosystem services. With a thematical analysis of the strategies and an ecocritical close-reading of the poems, I will demonstrate the ways inspirational services of the forest are acknowledged in the data. After the analysis I will discuss the applicability of the ES framework in addressing the inspirational value of forests in environmental policy. I suggest that despite of its problems, the ES framework has potential as an exercise in communicating even the most private, experiential-inspirational meanings and values of forests.

Integrating Physical and Social Variables to Enhance Understanding of Urban Forestry key-Indicators: Insights from a Socio-Cultural Forest Monitoring

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Boris Salak[1]
Tessa Hegetschweiler[2], Marielle Freifel[3], Anne C. Wunderlich[2], Nicole Bauer[2], Marcel Hunziker[2]
[1] TU Wien, Research Unit Landscape Architecture and Landscape Planning. Karlsplatz 13, 1040 Vienna, Austria & Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Research Unit Economics and Social Sciences, Zürcherstrasse 111, 8903 Birmensdorf, Switzerland
[2] Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Social Sciences in Landscape Research Group, Research Unit Economics and Social Sciences, Zürcherstrasse 111, 8903 Birmensdorf, Switzerland
[3] Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Forest Resources and Management GIS, Zürcherstrasse 111, 8903 Birmensdorf, Switzerland

Abstract: Urban forestry plays a crucial role in enhancing urban residents' well-being and providing essential ecosystem services. This study integrated physical and social variables to comprehensively understand socio-cultural indicators related to urban forestry. Key indicators examined included visitation frequency, recreation satisfaction, scenic beauty, forest care and management, and the feeling of health. Data from Switzerland's 3rd socio-cultural forest monitoring survey were utilized.

A public-participation GIS module allowed respondents to map their frequently visited forest recreation spot. They were then surveyed about visitation motives, infrastructure and forest preferences, and the meanings associated with their chosen location. Physical forest characteristics and relevant infrastructure aspects were considered as variables and intersected with mapped coordinates for regression models.

Results revealed significant relationships between the implemented variables and "scenic beauty," "recreation satisfaction," and "forest care and management." Variables like "visitation frequency" and "feeling of health" were accurately predicted. These findings highlight the importance of incorporating non-ecosystem services, such as landscape and forest meanings, in future urban forest monitoring. These variables particularly demonstrated strong explanatory power for aesthetic attributes.

Successful urban forest monitoring initiatives should consider ecological and socio-cultural aspects. Recognizing the meanings people attach to urban forests enables policymakers to align strategies with community preferences and enhance residents' experiences. Findings also inform forest management practices, promoting visually appealing and sustainable urban forests.

Furthermore, these results have implications for ecosystem services provision. Prioritizing socio-cultural indicators like scenic beauty and recreation satisfaction leads to a holistic approach to urban forest management. Urban forest policies that consider socio-cultural dimensions better meet diverse needs and values, resulting in healthier and vibrant urban environments.

In summary, this study emphasizes incorporating physical and social variables, including landscape

and forest meanings, for a comprehensive understanding of urban forestry's socio-cultural indicators. Considering these factors in urban forest policy and management facilitates the creation of sustainable and inclusive urban forests that promote human well-being and ecosystem services.

Knowledge co-creation and co-research in social scientific natural resources governance studies

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Irmeli Mustalahti[1]
[1] Professor, University of Eastern Finland

Abstract: By applying action learning via knowledge co-creation and co-research methodologies, I have studied natural resources governance with my research group and our inter-action partners in Global North and Global South. During our different research projects, we have generated a set of novel research methods during real-time co-creation of social innovation rooted in principles of reciprocity. While social innovations are co-created through action research case studies and via "going back" method, we have implemented the following tasks: 1) Co-creation of knowledge through pre-study or fact finding missions, in-depth interviews and World Café workshops; 2) Development and implementation of a "going back" method with co-researchers through participant observation, autoethnography and field research diaries 3) Processing of co-created knowledge through participatory workshops, course series and writing workshops. Yet the current natural resources governance studies have underestimated the power of co-creation and active role of inter-action partners in social innovations and collaboration. Natural resources governance does not mean strict control of all areas of life, nor does it require accurate information about future changes, but rather implies a flexible, responsive and adaptive governance model and social learning. The key question in this paper is how us as researchers could support collaborative and deliberative natural resources governance via our research approaches such as action research, co-creation and co-research.

Negotiating the understandings and impacts of the ecocrisis in forest dialogues

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Eeva Houtbeckers[1, 2]
[1] University of Turku
[2] Untame research collective

Abstract: Eeva Houtbeckers, D.Sc. (Econ.&Bus.Adm.), is a scholar-activist working on sustainability transfornations. As part of their postdoctoral project (2017–2022), Eeva volunteered for a citizen forest movement that organized forest dialogues with various forest related stakeholders in Finland. Eeva's work in the field of human-forest relationship focuses on negotiating the understandings and impacts of the ecocrisis in the forest dialogues and the citizen movement.

Phenomenological approach to the ways of knowing about multiverse of human-forest relationships

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Tuulikki Halla[1]
[1] University of Eastern Finland

Abstract: Tuulikki Halla, MSocSci, Forest engineer works as project and doctoral researcher in the Finnish Academy UNITE Flagship Program coordinated by the University of Eastern Finland. In her research, she has contributed the conceptual development of human-forest relationship concept and studies these relationships within Finnish forest practitioners applying interpretative phenomenological method (IPA). She is also a board member of the scientific Human-Forest Relationship Research Club of the Finnish Society of Forest Science. in this T4.33 session, she acts as one of the session moderators.

Research strategy of an interdisciplinary case study when studying the developments in the value creation logic of the forest sector

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Anu Laakkonen[1, 2]
[1] University of Eastern Finland, School of Forest Sciences, Finland
[2] University of Helsinki, Department of Forest Sciences, Finland

Abstract: Numerous phenomena, such as sustainability challenges and the increasing importance of knowledge and digitalisation, have tremendous impacts on the global socio-economic system. These phenomena affect the dynamic and complex business environment where different actors from various sectors interact with each other. Responding to the phenomena and changes in the business environment pressurises established business sectors, such as the forest sector, to reconfigure their networks and value creation logic, i.e., the ways how actors perform value-co-creating activities.

In this dissertation, I investigated how the value creation logic of the forest sector is changing when entering the sustainable circular forest-based bioeconomy. The research design followed a qualitative theory-guided interdisciplinary case study strategy. I analysed scientific and non-scientific documents to determine the past and currently occurring adaptations within the forest industry's value creation logic. I conducted interviews to identify the possible future value creation logic of forestry service providers and the readiness of forest owners to respond to the occurring changes.

According to the findings, the forest sector's value creation logic is incrementally changing towards holistically sustainable, collaborative and cross-sectoral value co-creation logic. The sector has been able to reconfigure its networks and value creation logic in the past and it seems that the sector's actors have understood the importance of cross-sectoral collaboration and intangible resources in the sustainable value-creating activities. They have acknowledged that their attitudes and actions will affect the future value creation within the sector. To reach holistic sustainability, all actors within the sector need to consider the whole forest ecosystem as a capital and a resource base from where value and benefits for the common good are co-created in a forest-based sector.

Roundtable organisator / Spatial frames regarding forests, future and society

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Maija Halonen[1]
[1] University of Eastern Finland

Abstract: Maija Halonen, PhD, Human Geography, is a postdoctoral researcher in the Department of Geographical and Historical Studies, University of Eastern Finland. She is an organiser of the T4.33 Roundtable. Halonen is currently conducting research on Sixth Cycle in the Periphery – financed by the Kone Foundation (2020–2024). In her research, she has contributed to the understanding of relations between sustainability transitions, forest peripheries, and socio-economic development. She is interested in different spatial frames through which people approach the forests, future, and society. Halonen is also a board member of the scientific Human-Forest Relationship research club of the Finnish
Society of Forest Science

Roundtable organizator/biography

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Annukka Näyhä[1]
[1] Jyväskylä University School of Business and Economics

Abstract: Annukka Näyhä holds a Ph.D. in Corporate Environmental Management and a MSc. degree in Biology. She works currently as an Academy Research Fellow at Jyväskylä University School of Business and Economics (she is on leave from senior lecturer position 2021-2026). Her research interests include the transition to the circular bioeconomy; forest-based sector; sustainable, collaborative business models; strategic change management; and corporate foresight and future studies. Her ongoing Finnish Academy research fellow project
(https://www.jyu.fi/jsbe/en/research/projects/busut)
aims to answer the question of how the sustainability transition could be facilitated by future-oriented collaborative business models. The project is designed to respond current major societal challenges – the lack of sustainable, shared value creation, participative foresight and aligned efforts to advance transition – both in forest-based sector and in other natural resources-based sectors.

AnnukkaNäyhä is an organiser of the T4.33 Roundtable.

Stakeholder views on the future of Finnish forest utilization and new wood-based products

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Venla Wallius[1, 2]
Annukka Näyhä[1]
[1] University of Jyväskylä
[2] European Forest Institute

Abstract: Forests are an integral part of the Finnish society and culture. Still, the human-forest relationships in Finland are diverse, as all individuals have their own forest-related values and attitudes that fluctuate over time. It is generally understood that in the transition from our current fossil-based economy towards a sustainable circular bioeconomy, forests, wood and wood products play a key role. Especially novel, innovative products could be a part of the solution. However, there is not one universal, shared vision of the future of the Finnish forests and their utilization. Exploring the future visions of different stakeholders is crucial in creating consensus and supporting collaborations between various actors towards a sustainable future. The aim of this study is to explore i) how forests and their utilization is currently perceived in Finland, ii) what are the desired futures related to forest use and what are the pathways to these futures, iii) what is the perceived role of new and emerging wood-based products in the sustainability transition. To this end, we interviewed 65 stakeholders along the forest value chain and networks in Finland. Moreover, Finnish media sources were analyzed to comprehend the public discussion on how forests are perceived in the society and how the new wood-based products are presented in the discussion.

The preliminary results show that forests are perceived through various lenses depending on the stakeholder group in question, and the visions of the desired future for Finnish forests differ. By some stakeholders, forests are primarily seen as a source of raw material, income and employment, but others see them mainly as biodiverse ecosystems or targets of conservation efforts. Still, novel wood-based innovations are in general believed to have high potential in the future bioeconomy. In order to create a shared understanding of the future of Finnish forests and to support the sustainability transition, more collaboration is needed.

This study is a part of the "Future-oriented collaborative business models as a remedy for the sustainability transition: Finnish forest-based sector as an empirical arena for the creation of a transition framework" project funded by the Academy of Finland, project no. 340756.

The role and possibilities of Finnish forest nature in the Finnish social and health service system

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Kati Kiiski[1]
[1] Kiiski, Kati

Abstract: Many of the human physical and mental health challenges probably stem from our alienation from our natural environment. Alienation from nature and health challenges are part of the wicked problems we live in the midst of. At the same time, our social and healthcare system is in crisis.

There is some national and international research on the health and well-being effects of nature. The effects have been shown to be mostly positive. Harnessing the health and well-being effects of Finnish forest nature as part of the Finnish field of social and health services and increasing the well-being of the population has not yet been implemented on a large scale.

However, the concept of planetary well-being and planetary health has emerged in Finland recently. Intervention studies investigating the health and well-being effects of nature have been ongoing for ten years. With the help of these, the applicability of the services from the point of view of individuals (and certain customer groups) has been investigated, and the experiences of the target persons (customers) with nature-based services have also been studied. More research is still needed on this whole to assess how Finnish (forest) nature can be suitable as an effective part of the Finnish social and health service system.

The ongoing research project investigates the effectiveness of nature interventions in the rehabilitation of people who have experienced a brain stroke. My role in the research is to investigate professionals' perceptions of the suitability of nature interviews for rehabilitation.

The implementation of services occurring in nature as part of social and health services solves ongoing wicked problems from the perspective of sustainable well-being. It is an interview study based on which the aim is to find solutions for promoting sustainable well-being through structures.

The strength is in diversity. Qualitative methods as trespassers between disciplines in forest research.

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Stephanie Bethmann[1]
[1] FVA Freiburg, Societal Change Unit, Germany

Abstract: New theoretical perspectives and empirical challenges have stirred discussions about “new ways of knowing and studying forests and our interactions with them”. In this endeavor, there is much to be gained from considering the immense variety of methodological “schools” in diverse disciplines and adapting these to new, transdisciplinary contexts and questions. Based on an (SSK) analysis of qualitative research practices in sociology, and reviving the integrative impetus of Grounded Theory, I rethink qualitative methods as ideal trespassers between the disciplines. These trespassers provide new angles on the research problems that we articulate, but also come with challenges of (epistemological) translation.

Transformative Research and Methods for responsible forest resource management

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Linda Lundmark[1, 2]
[1] Umeå University, department of geography.
[2] The Arctic centre, Umeå university

Abstract: In this presentation, I will present different possibilities for doing transformative research from a geographical perspective. Some initial questions are covered, starting out with considering time and spatial scale as important point of departure for discussing issues of sustainable development and climate change for instance. The key question here is how we can produce knowledge that is relevant and will create the desired impact as soon as possible at every geographical level. Following on to that is how do we identify leverage points to make recommendations policy-relevant and effective for quick implementation at the desired level (industry level, public level, and individual level)? what research practices for transformative research will be best at different geographical and political levels, and how can local knowledge and practice inform organizational changes on other administrative levels in order to increase the value-added of the forest in terms of its contribution not only to the bio-economy in a traditional sense but also in more innovative and explorative ways?

‘Ways of Knowing about a Multiverse of Human-Forest Relationships’ session organizer

T4.33 Ways of knowing about multiverse of human-forest relationships: methodological approaches for sustainable futures for the forests

Eeva-Lotta Apajalahti[1, 2]
[1] Energy Technology, School of Energy Systems, LUT University, Finland
[2] Human-Forest Relationship Researcher Network

Abstract: Eeva-Lotta Apajalahti, Dr.Sc. (Econ. and Bus. Admin) is an Assistant Professor of Energy and Society at LUT University, Finland. She is a member of the human-forest relationship research network in Finland and is interested in various ways of doing research on the human-forest relationship, human and non-human relationships, and the affects of wood cutting. She is currently doing research on energy transition, societal impacts of energy systems change and renewable energy, as well as system interlinks of energy, transportation, and food sectors. With the roundtable session in IUFRO, she is expecting inspiring discussions on different ways of knowing and doing forest research.

T4.34 Work and employment in the forest sector: challenges and opportunities

Climate-Smart Forestry Education for Livelihood and Sustainability in South Africa (FOREST21)

T4.34 Work and employment in the forest sector: challenges and opportunities

Tatenda Mapeto
Josua Louw[1]
[1] Forestry and Wood Technology Department, Faculty of Science, Nelson Mandela University, 1 Madiba Drive, George, Western Cape, South Africa

Abstract: In South Africa, the forestry sector is critical for livelihood development, given the youth population bulge, high unemployment rates, the need to address global sustainability challenges and the potential of forestry to advance South Africa's National Climate Change Adaptation Plan. Higher Education Institutions (HEIs) should therefore naturally take a lead in preparing graduates to create sustainability-aligned economic opportunities. There is however a substantial discrepancy between what the forestry industry in South Africa sees as the key skills for future foresters, and what is being taught in HEIs offering forestry education. In 2019, a project (FOREST21) to develop and improve the constrained capacity of South African HEIs to prepare professional foresters of the future that can sustainably leverage forestry for livelihood development was conceptualised. The FOREST21 project is co-funded by the Erasmus+ Programme of the European Union and comprises five HEIs in South Africa and three HEIs from Finland and Norway. The project which is running from 2020 to 2024 seeks to promote climate-smart forestry and entrepreneurial innovativeness in forestry education that will lead to job creation as well as mitigation of climate change. FOREST21 is implemented through reforming the curricula in forestry education to equip graduates with problem-solving skills, an entrepreneurial mindset and climate-smart thinking. Problem-based learning (PBL) methods and students-centred teaching are the core of the project. Students learn through solving real-life business challenges in the field in international teams. FOREST21 is built on close collaboration with the industrial sector as well as academics and the managerial staff in partner HEIs. This paper presents the workings of FOREST21 by examining some of the educator and student development workshops and student challenges that have been part of the project. Opportunities and challenges encountered in the development of innovative approaches to develop 21st century foresters through the project's mechanisms are expanded. The future of South African forestry education in moving from teacher-centred knowledge sharing to knowledge co-creation through discovery as essential for climate smart forestry, mainstreaming climate issues in core courses and developing graduates that can leverage this knowledge for developing, exploiting, and growing sustainability-related forestry opportunities are discussed.

Current situation and future issues of forest-related work by persons with disabilities in Japan

T4.34 Work and employment in the forest sector: challenges and opportunities

Takuo Nagaike[1]

[1] Yamanashi Forest Research Institute

Abstract: Sustainable Development Goals (SDGs) aim to realize a sustainable, diverse, and inclusive society that leaves no one behind. The forest and forestry sector can contribute in order to achieve the many goals of the SDGs. Forest-related workforce as a decent work could contribute the goals, In Japan, compared to agriculture-welfare collaboration (AWC), forest-welfare collaboration (FWC), which was forest-related work by persons with disabilities, has only just begun. In promoting FWC, I clarified the current situation and future issues of FWC in 47 prefectures in Japan. For industry types of FWC, mushroom cultivation was the most common, followed by woodworking. There is no correlation between the number of workplaces for AWC and that for FWC. As an exception, Mie Prefecture, where forestry is active in Japan, had the highest number of both AWC and FWC. FWC is the "main task" of the Forestry and Forestry Management Division of the Mie government office. Most of the welfare workplaces was mushroom cultivation and woodworking, and producing broad-leaved tree seedlings was also raised. In Nagano Prefecture, which belongs to the cool temperate zone, although AWC was moderate, FWC was high. In addition to that, there was a lot of production and sales of firewood. There were also activities that took advantage of the characteristics of the prefecture, such as processing deer-related products and cultivating medicinal plants. In other prefectures, conifer seedlings were also produced in FWC (Hokkaido, Akita, Yamagata, Oita, and Miyazaki), as progressing reforestation and labor shortage in Japan.

Governmental collaboration through vocational training for nature conservation and forestry

T4.34 Work and employment in the forest sector: challenges and opportunities

Anna María Pálsdóttir[1]
Liz O´Brien[2], Ann Dolling[3]
[1] Department of People and Society, Swedish University of Agricultural Sciences, Alnarp, Sweden
[2] Forest Research, Society and Environment Research Group, Farnham, Surrey, UK
[3] Department Forest Ecology and Management, Swedish University of Agricultural Sciences, Umeå, Sweden

Abstract: In Sweden, the Swedish Forestry Agency, The Swedish Public Employment Service and the County Administrative Board have a long tradition of working together to combine vocational training and nature conservation. This presentation will detail the working mechanisms and success factors for a sustainable collaboration that moves people into employment, meets the European commitments of nature conservation, and supports public health and the integration of newly arrived in Sweden. It draws on a three-year evaluation of the program that included a mixed methodology of in-situ participant observation, interviews with trainees (n=29), working groups leaders (n=5) and stakeholders (n=5) as well as surveys with validated questioners for trainees (n=214). Through this collaboration, the organisations support each other in achieving their goals. The Swedish Public Employment Service provides trainees to the vocational program, the County Administrative Board is responsible for planning the nature conservation tasks and the Swedish Forestry Agency carries out the practical tasks of nature conservation in Skåne/Scania. Altogether, the work covers 350 nature concervation sites and three national parks. The organisations offer training programs for long-term unemployed Swedish residents (24 months), and since 2016, the program is also open to newly arrived migrants (12 months) needing vocational training. The nature-based vocational training includes practical and theoretical courses on nature conservation, forestry and urban green space management. The mixed working groups of Swedish and migrant participants provide social and cultural exchanges which evolve over time, and for the migrants, the work offers scenario-based language learning as well. This long-term organisational collaboration has all the major attributes of a successful partnership structure, such as transparency and effective flow of information across the partners, respect and alliance throughout. However, to maintain and secure the collaboration long-term funding is warranted. A few examples of this long-term and strong governmental collaboration in Sweden exist. Through this collaboration, nature conservation is carried out at regional and local levels so that European-level nature conservation commitments are met, and participants gain a wide range of benefits that can support them in finding future work.

Health and Safety requirements in Forest Stewardship Council (FSC) standards

T4.34 Work and employment in the forest sector: challenges and opportunities

Paul Opanga[1]
Marion Karmann[2]
[1] FSC International, Labour Issues Manager
[2] FSC International, Adenauerallee 134, 53113 Bonn, Germany

Abstract: The 2019 'ILO Report for Discussion at the Sectoral Meeting on Promoting Decent Work and Safety and Health in Forestry' highlights that the sector has relatively high accidental rates with notable differences between and within regions. Some Europe countries report that one in eight forestry workers suffer an accident every year, while others report less than one accident in 200 forestry workers / year. FSC certification requires that certified forest management operations "shall maintain or enhance the social and economic wellbeing of workers" (FSC Principle 2 of 10). One of the six criteria under Principle 2 requires that Health and Safety (H&S) practices are implemented, which meet or exceed the ILO Code of Practice recommendations. Regular office audits and consultations with forest workers have to be undertaken by auditors, and workers have to receive regular job specific H&S trainings, and the use of personal protective equipment appropriate to their tasks and use of personal protective equipment is enforced. Beside H&S, workers wellbeing is enhanced through FSC Principle 2 criteria which addresses decent work deficits in areas such as upholding the fundamental rights at work, promoting gender equality, wages paid meet or exceed minimum wages, workers have job specific trainings and mechanisms for resolving grievances and for providing fair compensation are established. In some cases, FSC requirements for risk assessments and better signage of work zones has improved public safety.

Review on research papers show that overall, FSC has proven to be a powerful tool for improving H&S while strengthening workers' rights and working conditions in certified operations. In addition, based on FSC internal analysis of public forest management certification reports, we will show how certification has led to improvement of H&S legislations in some countries, including the provision of better equipment and training, use of safety procedures, and the reliance on properly qualified forest workers. We will also show how and when the research community can efficiently engage in the development of further improved criteria and indicators for working conditions and workers' H&S and safety consciousness.

Is employment in the forest sector automatically a green job? A systematic literature review

T4.34 Work and employment in the forest sector: challenges and opportunities

Emilin Joma da Silva[1]
Jörg Schweinle[1]
[1] Thünen Institute of Forestry

Abstract: Employment in environmentally friendly and green economies are potentially green jobs. However, these jobs can only be called "green" if they provide good and decent work. The forest sector performs essential environmental services and manages vital natural resources, therefore is a green economy. But clear evidence about the quality of these jobs is lacking. Is employment in the forest sector automatically a green job? To answer this question, a systematic literature review was carried out, following the Reporting standards for Systematic Evidence Synthesis (ROSES). Science Direct and Google Scholar (first 100 search results) were the search engines utilized to capture topic-related literature written in English, German, Spanish and Portuguese. Only studies reporting employment in the forest sector and green jobs in the American and pan-European regions were considered. After a systematic search, two additional "inclusion criteria" were applied to select the final literature sample. One question aimed to identify (1) if there are indicators to recognize green jobs in the forest sector. Another question sought evidence (2) if there are incentives to foster green jobs in the forest sector. Only the literature fulfilling at least one of the inclusion criteria was considered in this review study.

A total of 43 documents were systematically reviewed and showed that the forest sector has great potential to provide green jobs. An emerging forest sector with cross-sectoral enterprises has provided good jobs in alternative forest-related economies. However, there is no clear evidence that employment in the traditional or emerging forest sector is automatically a green job. At the present moment, no indicators for identifying or assessing forest-related green jobs' quality are available. Forest certification was appointed as a "shade" of green for forestry jobs, because it follows labour standards, ensuring minimal working conditions. It was observed, that political actions aiming at developing rural employment or improving working conditions created jobs in the forest sector. However, no information about the quality of created jobs was available. In conclusion, it is highly recommended to collect data on job quality to design solutions that guarantee increasingly forest-related green jobs.

Mass redundancies in state-owned forest management - is there an impact on private forestry?

T4.34 Work and employment in the forest sector: challenges and opportunities

Meelis Teder[1]

[1] Estonian University of Life Sciences, Chair of Forest and Land Management and Wood Processing Technologies, Estonia.

Abstract: Estonia is a high forest cover country (53 %, 2.3 million ha) with even public-private ownership share at 51:49. Within last 30 years, reforms of state forest management (in 2008 and 2013) led to mass staff reductions.

Parliamentary elections in 2007 led to re-structuring of the State Forest Management Centre (RMK) in 2008. The main objectives of the re-structuring were to create a more efficient organization and to decrease staff numbers. The entire restructuring process and associated discussions have been highly controversial and emotional. Staff reductions caused 193 forestry specialists and administrative staff had to leave the organization: 140 made redundant, 50 retired, and 3 found other jobs.

Forest management was again re-structured in 2013, when RMK merged the responsibilities of local forest area managers and forest surveyors. As a result, another 23 qualified foresters were dismissed, because they did not hold a certificate of approved forest surveyor as required by the Forest Act.

The presentation introduces the results of a longitudinal study related to the 2013 reductions. The first survey was conducted a few days before the terminations in 2013, where foresters involved were mainly interested in finding alternative jobs in state-related institutions. Only a few foresters intended to establish their own companies or to find an occupation in private forestry. The study also analyses the opinions of colleagues of the foresters made redundant, concerning the potential of finding jobs elsewhere in forestry, of being self-employed, or other options.

Four years after the redundancy in 2017, all the former forest area managers were questioned. The aim was to find what they were doing 4 years after leaving; did they stay in the forest sector or move to other sectors, was there a desire to work in the private sector or to be an entrepreneur, how long did they stayed unemployed, did they participate in any educational programs, would they have done anything differently given knowledge of past layoffs (e.g., 2013) and the likelihood of more in 2017. The final survey is planned to be carried out in 2023, 10 years after redundancy, to find out the long-term impact of redundancies.

Navigating societal transformations: insights from work organisations in the Austrian forestry sector

T4.34 Work and employment in the forest sector: challenges and opportunities

Barbara Öllerer[1]
Elias Andersson[2], Maria Johansson[3], Alice Ludvig[1]
[1] University of Natural Resources and Life Sciences, Vienna (BOKU)
[2] Swedish University of Agricultural Sciences
[3] Umeå University

Abstract: The Austrian forestry sector, like many other national forestry sectors around the globe, has a long tradition of facing societal transformations, and is currently facing them in a more rapid way. These societal transformations include the effects of the climate crisis, urbanisation, migration movements, and social insecurities. Additionally, the public opinion is shifting towards the protection of forests. In turn, this influences the balance of prioritising environmental issues in relation to production in forestry.

As a consequence, work organisations in the forestry sector face the challenge of having to adapt to these new conditions. The aim of this study is to investigate how practices regarding hiring, promoting and valuing the work of their employees are carried out in light of the transformations the sector is facing. By doing so, this study adds to the understanding of how the societal and discursive transformations are understood by the organisations. Additionally, a more comprehensive ambition in this study is to explore whether these shifts have had an influence on gender equality and diversity strategies and measures, both already in place and newly introduced.

This study is based on a series of interviews with representatives of management and human resources of organisations in the Austrian forestry sector as well as a qualitative analysis of policy documents and mission statements of those organisations.

When traditional forestry is challenged, it might shape work, organisations and strategies in different ways. Looking at work organisations, the study connects the basis for their actions, and use of different tools, with their perception of the changes "needed" and their own understanding of the organisations. It additionally looks into the prevalent work identities and into who is impacted by the adaptations of the organisations, and discusses how this relates to potential power relations.

Promoting gender equality and decent work: Cases from the Mekong region's small-scale forest sector

T4.34 Work and employment in the forest sector: challenges and opportunities

Thomas Colonna[1]
Ratchada Arpornsilp[1]
[1] European Forest Institute

Abstract: The European Forest Institute (EFI) has worked with close to 400 wood-based household businesses in Lao PDR, Myanmar, Thailand and Viet Nam. The main objective of the work is testing solutions to challenges that smallholders and MSMEs face to participate in legal and sustainable timber supply chains. EFI has been working directly with smallholder tree growers, furniture business owners and workers as well as local and national authorities, industry associations, financial institutions, vocational training schools and academia.

EFI has been training micro and small wood processors and tree growers on key technical topics ranging from continuous improvement and occupational health and safety to complying with laws and regulations and improving silvicultural practices. EFI is using a variety of strategies and approaches to support smallholders and MSMEs such as technical workshops, customized coaching, study tours to larger enterprises, on-the-ground engagement of local authorities, policy makers and financial institutions, the establishment of associations, etc.

EFI has been coaching women-led enterprises and strengthening the role of women in tree growing communities and wood-based micro and small businesses. EFI is integrating gender aspects into technical trainings for private sector actors and conducting multistakeholder trainings and workshops on gender. This has generated interest among MSMEs and in some cases empowered women to engage more strongly in the businesses. It has also generated interest among the authorities and industry associations who are now more willing to promote gender equality in the forest sector.

EFI's presentation will share lessons from these strategies distilled from direct observations and reflections in working with tree growers, MSMEs and partners. It will discuss approaches and methods to promoting equality and women's economic empowerment in the small-scale forest sector and improving working conditions and occupational health and safety in wood processing workshops. Finally, the presentation will discuss obstacles and incentives to formalization.

Social sustainability in the forest-based bioeconomy: Challenges from micro-entrepeneurs' perspectives in Finland

T4.34 Work and employment in the forest sector: challenges and opportunities

Jukka Luhas[1]
Mirja Mikkilä[2]
[1] Department of Sustainability Science, LUT School of Energy Systems, LUT-University, Finland
[2] University of Helsinki, Department of Forest Sciences, Faculty of Agriculture and Forestry, Finland

Abstract: In the face of increasing environmental challenges and socio-economic pressures, forest-based businesses play an important role in creating well-being in rural areas. At the same time, social sustainability issues, such as poor working conditions, challenges in time management and dissatisfaction, have raised in various forest-based sectors. To increase understanding of such issues, collective action framework has been applied to explain complex interactions of socio-ecological systems. The collective action refers to the actions of a group of people whose goal is to improve their state and achieve a common objective through cooperation and joint benefits.

We investigate social sustainability through the lens of forest-based entrepreneurs in two different regions in South-East and North Finland. A thematic content analysis was employed to analyze qualitative data from forestry, wood transportation, tourism, natural products and heating sector. The results not only increase understanding of incumbent collective action between entrepreneurs, but also present novel practices to enhance social sustainability. In addition, differences between the regions in terms of cooperation and raised social sustainability issues are derived.

Intensive cooperation among diverse forest-based businesses exemplifies collective action and is greatly linked with social sustainability. The relationships of workers and collaborative partnerships between small entrepreneurs and organizations forms a social foundation for forest-based bioeconomy in Finland. More accessible open data provided by forest-related organizations, such as The Finnish Forest Centre, same-sector, and cross-sectoral partnerships are seen as an opportunity to strengthen social sustainability of people involved in forest-based businesses. Collective action framework offers relevant approach to analyze causalities of social sustainability in the context of forest-based bioeconomy.

Soft Skills Training Curriculum for Liberia's Forest Sector Workforce

T4.34 Work and employment in the forest sector: challenges and opportunities

Philip P. Norrington Jr[1]
Janet Lolemeh[1], Elizabeth King[2], Jesse Abrams[2], Troy Bowman[3], Rashidah Farid[4], Johnson Fromayan[5], Joel Gamys[1], Arnold Hill[6], Kris Irwin[2], Mulbah Kortimai[5], Adanta Lymas[6], Catherine Machalaba[7, 8], Layli Maparyan[9], Albertha Mulbah[5], BK Robertson[2, 10]
[1] Forestry Training Institute, Liberia
[2] University of Georgia, U.S.A.
[3] Alabama Agricultural and Mechanical University, U.S.A.
[4] Tuskegee University, U.S.A.
[5] University of Liberia
[6] William R. Tolbert Baptist University, Liberia
[7] Conservation Works, Liberia
[8] EcoHealth Alliance, U.S.A.
[9] Wellesley College, U.S.A.
[10] Alabama State University, U.S.A.

Abstract: Liberia is a biodiversity hotspot and aspiring leader in community, commercial, conservation, and climate/carbon forestry, as well as One Health coordination. However, the forestry workforce faces major challenges, including poor working conditions, gender biases, and lack of sufficient coordination with other sectors. Integrating soft skills into forestry education will ensure a prepared and resilient workforce. Soft skills are personal, social, communication, and higher order thinking competencies that enable people to work more effectively. Through a collaboration between several Liberian and U.S. institutes of higher education (IHEs), we are building a model national curriculum to provide soft skills training for Liberian forestry students. Our team conducted several forms of assessments of existing training strengths, needs, and priorities for different soft skills. These included (a) interviews and conversations with key informants from government, NGOs, and IHE faculty and administration; (b) semi-structured interviews with leaders and residents in forest- dwelling communities across Liberia; (c) qualitative and quantitative elicitation workshops with faculty and students at University of Liberia and the Forestry Training Institute of Liberia; (d) in-class observations, (e) desk research, and (f) a synthesis Working Group with representatives from multiple sectors. Our assessments found that, while the term "soft skills" was unfamiliar, the underlying concepts were both familiar and widely recognized as critical training needs for Liberia's forestry sector. All stakeholder groups emphasized needs for soft skills to improve national progress in the areas of community forestry, forest conservation, and sustainable livelihoods. The workshops and Working Group found that training modules should be embedded in multiple contexts: forestry classes, training events, and real-world practical contexts. The curriculum rollout process entails presenting a draft curriculum to all stakeholders for review and revision, with a full model in December 2023. Addressing the current challenges and future aspirations for Liberia's forests and people requires an inclusive workforce with strong competencies in leadership, teamwork, cultural sensitivity, communication, conflict resolution, systems thinking, and strategic innovation. Creating a national model soft skills curriculum will facilitate Liberia's IHEs in implementing evidence-based training to build those capacities and ensure the longevity and recognition of the sector's contributions

The establishment of Indigenous forestry cooperative to manage the forestry

T4.34 Work and employment in the forest sector: challenges and opportunities

Mei-Chih Yeh[1]
Chung-chih Sun[2], Wei-Ling Kuo[2], Chun-Kai Huang[2], Hsueh-Che Ho[2], Cheng-Hsien Lee[2]
[1] Providence University
[2] Nantou Forestry District Office of Taiwan

Abstract: For the current forestry rejuvenation, it's crucial to develop the value of numerous enterpries in Taiwan's public and private forests. The "Forestry Sustainability and Diversification Guidance Program" was introduced in 2018, and the Forestry Bureau declared it to be "the first year of domestic timber" since 2016. Through the cooperation of expert teams and forestry experts, diversity and friendliness are both essential values to direct forest owners and cooperatives. The majority of the afforestation, maintenance, and management work in Nantou Forest District Office of Taiwan is carried out by contracted manufacturers. Most of the jobs were done by the indigenous people with little wages and the contractors own the actual profits. So, it is important to improve the current operation and management status and provide economic benefits for indigenous people to prevent being exploited by outsourced manufacturers and to encourage indigenous people to manage their own forests and to develop the forest sector. The best stragegy to assist indigenous people to organize and obtain the forest management contract from Nantou Forest District Office is to help them to establish forestry cooperatives. Everyone is the boss in forestry cooperatives, so it will improve the economic conditions of local indigenous people. The purposes of this study is to (1) investigate the indigenous people who are willing to establish forestry cooperatives within the juristiction. (2) Guiding them to establish forestry cooperatives , and assisting in the planning of follow-up operation. (3) Train local people to participate in cooperative operation. (4) Arrange a field trip to exchange experience of peer cooperatives. Literature review, cases study, in-depth and focus group interview were used to establish indigenous forestry cooperative. Finally, the indigenous forestry cooperative was established on May, 2023.

Towards a safer and healthier working environment in forestry

T4.34 Work and employment in the forest sector: challenges and opportunities

Waltteri Katajamäki[1]
[1] International Labour Organization

Abstract: Forests provide livelihoods, food and a range of environmental services for populations around the world, including for the at least 33 million people employed in forestry. Despite efforts and some improvements over the past decades, forestry remains a dangerous sector for its workers, who face numerous occupational safety and health risks and hazards. While many of those relate to "traditional" aspects such as use of machines and tools, falling trees, working in remote and isolated locations, and natural and biological hazards, there are changing and new safety considerations in forestry work, impacted by trends in the world of work, such as technological developments, climate and environmental change, and demographic shifts, among others.

In 2022 the International Labour Organization (ILO) included "safe and healthy working environment" in the framework of the fundamental principles and rights at work. This means that all ILO Member States, even if they have not ratified the now fundamental Occupational Safety and Health Convention, 1981 (No. 155) and the Promotional Framework for Occupational Safety and Health Convention, 2006 (No. 187), have an obligation arising from the very fact of membership in the ILO to respect, promote and realize the principles concerning the fundamental right to a safe and healthy working environment.

This paper looks at the opportunities and challenges for promoting safety and health and decent work in forestry in the changing world of work. It will assess the implications of the elevation of safe and healthy working environment as a fundamental right at work to forestry and discuss specific safety challenges for workers in the informal economy, women, and young people, among others. It builds on the joint FAO-ILO-UNECE paper on "Occupational safety and health in the future of forestry work" and is further guided by the ILO's work on the topic, including the process of updating the Code of practice on safety and health in forestry work.

Understanding Diversity in the U.S. Forest Sector: An Analysis of Employee Data

T4.34 Work and employment in the forest sector: challenges and opportunities

Jaana Korhonen[1, 2]
Rajat Panwar[3], Jesse Henderson[2], Zakiya Leggett[4], Arvind Bhuta[5], Bruno Kanieski Da Silva[6], Katie Fernholz[7]
[1] Oak Ridge Institute for Science and Education (ORISE), USA

[4] College of Natural Resources, North Carolina State University, USA
[5] USDA Forest Service, National Headquarters, State, Private & Tribal Forestry Cooperative Forestry, USA
[6] College of Forest Resources , Mississippi State University, USA
[7] Dovetail Partners, Inc., USA

Abstract: Understanding diversity is crucial for sustainability transitions, as employees play a pivotal role in shaping these transitions. Consequently, it becomes essential to examine the participation and potential influence of employees in determining future pathways. While employee data is collected by various organizations to assess risks, impacts, and interdependencies related to representation and well-being, data accessibility remains limited, hindering the establishment of standards beyond individual entities. Furthermore, identifying the producers and users of such data poses challenges due to their scattered and heterogeneous nature.

We explored the diversity of the U.S. forest industry and its sectors based on the North American Industry Classification System (NAICS) to better understand how employee diversity could impact sustainability transitions and identify any opportunities or challenges related to our work. The sectors we analyzed included the forestry and logging, wood products manufacturing, and paper manufacturing sectors.

By focusing on race/ethnicity, gender, age, native- and foreign-born status, and immigration within specific occupations, we highlight the current status and trends on diversity in these sectors and provide evidence on the current state of diversity. We discuss the implications of our findings for achieving the United Nation’s Sustainable Development Goals (SDGs) and informing research and industrial practices. We also provide insight on the implications of diversity and societal vulnerabilities, while also addressing the ethical considerations of existing monitoring systems from an environmental justice perspective.

Who will do the work in the future? : The current status of self-employed forestry contractors in Japan.

T4.34 Work and employment in the forest sector: challenges and opportunities

Akie Kawasaki[1]

[1] Faculty of Agriculture, Ehime University

Abstract: Although forestry has begun to be known as a growth industry since the 2010s, many problems remain, such as low profitability, working conditions, and occupational injuries. Forestry Agency has held education and support policies for newly employed workers since 2003 to compensate for labor shortages. However, self-employed contractors are not captured even in the statistics.

Therefore the questionnaire research was conducted in West Japan from February to August 2023 to clarify their working conditions and safety measures. As a result, 550 questionnaires have been sent or handed out through forestry self-employed workers' organizations for workers' accident insurance, and 194 were responded to by the end of May; the questionnaire sheet is still collecting. The survey items include years of experience, previous jobs, the scope of work, machinery, client, and safety.

As a result, the median age of respondents is 64 years old, and only 6% of respondents are under 40. Compared with the national aging population rate, self-employed forestry contractors are tremendously aging, the over-65 years old rate in Japan is 28.9% in 2021, and the rate of respondents is 49.5%. Regarding occupational safety, respondents' casualty rate during the past year was 16%, and 5% were hospitalized for more than four days. However, the casualty rate per thousand people of employed workers in forestry in 2021 is 24.7, and it can be said that self-employed workers have more than six times the risk of occupational accidents as employed workers. About 60% of fatal occupational injuries in forestry happened during chainsaw work. Although the Occupational Health and Safety Regulations have required wearing chainsaw protective pants since 2019, 16% of respondents still don't wear protective pants. Chainsaw protective boots are known as high protection, but they are not required. Only 11% of respondents use those, most of whom wear spiky tabi: Japanese split-toed heavy cloth boots or rubber boots, and 47% wear them without tiptoe protections.

In conclusion, many firms rely on the labor of self-employed contractors. However, their problems are grim as no able to replace generations and should be solved by policy support.

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Machine Learning alternatives to assess individual tree mortality: a performance comparison

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Aitor Vázquez-Veloso[1]
Astor Toraño Caicoya[2], Peter Biber[2], Enno Uhl[2, 3], Hans Pretzsch[2], Felipe Bravo[1]

[3] Bavarian State Institute of Forestry, Hans-Carl-von-Carlowitz-Platz 1, 85354 Freising, Germany

Abstract: Tree mortality is an important process in forest dynamics and a key component of growth simulations, but the complexity of the effects affecting it makes that process hard to predict. One of the common techniques applied to that field is Logistic binomial Regression (LR), but the increase in the computing power of the last decades promoted a higher popularity of using Machine Learning (ML) techniques, which started to be applied to different forest modelling topics, including the prediction of tree mortality. However, a comparison between them to know their classification ability in that field is lacking. In this work, we compare the performance of the Logistic Regression (LR) as a reference approach to six different ML techniques (Decision Trees, Random Forest, Naive Bayes, K Nearest Neighbor, Support Vector Machine and Artificial Neural Networks) to estimate the individual tree mortality probability. We selected *Picea abies* pure stands established under different plantation and silviculture treatments, comprising 97 permanent plots located at 8 different study areas in Bavaria (Southern Germany). Each tree was studied individually in its neighborhood, and features concerning tree and stand sizes, vigour, growth, competition, density and climate were selected as candidates due to their importance to explain tree mortality. Different feature combinations were used to develop LR and ML models, highlighting the ones which provide better classifications from each technique. Their performance was studied through different metrics (Area Under Precision/Recall Curve, Matthews Correlation Coefficient, Cohen's Kappa Coefficient...) appropriated to deal with imbalanced data sets (8.87% mean mortality rate). Preliminary results demonstrate the potential of ML to assess tree mortality, showing comparable performances to the obtained with LR. Among them, Random Forest showed the
best overall performance. However, even in the cases when ML techniques can provide better predictions, difficulties in their biological interpretation and longer training periods must be considered when those techniques are pretended to be used. When ML techniques don't outperform LR, the interpretation difficulties make those methods less useful.

Aboveground biomass prediction of arid shrub-dominated community based on airborne LiDAR through parametric and nonparametric methods

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

DONGBO XIE[1]

[2] Tribhuwan Univeristy

Abstract: Aboveground biomass (AGB) of shrub community in desert is a basic quantitative characteristic of desert ecosystem and important index to measure ecosystem productivity and monitor desertification. Accurate and efficient method of predicting AGB of shrub community is essential for studying the spatial patterns and ecological functions of the desert region. Even though there are several reports on the AGB prediction of desert shrub community using remote sensing data, the applicability and accuracy of airborne LiDAR data and prediction methods have not been well studied. We first extracted the elevation, density and intensity variables based on the airborne LiDAR, and then sample plot-level AGB prediction models were constructed using the parametric regression (nonlinear regression) and nonparametric methods (Random Forest, Support Vector Machine, K-Nearest Neighbor, Gradient Boosting Machine, and Multivariate adaptive regression splines). We evaluated accuracies of all the AGB prediction models we developed based on the fit statistics. Results showed that:1) the elevation, density and intensity variables effectively predicted AGB of the desert shrub community at sample plot-level, 2) the kappa coefficient of nonlinear mixed-effects (NLME) model obtained was 0.6977 with improvement by 13% due to random effects included into the model, and 3) the nonparametric model, such as Support Vector Machine showed the best fit statistics (R2=0.8992), which is 28% higher than NLME-model, and effectively reduced the heteroscedasticity. The AGB prediction model presented in this paper, which is based on the airborne LiDAR data and machine learning algorithm, will provide a valuable tool to the managers and researchers for evaluating desert ecosystem productivity and monitoring desertification.

Assessing biotic and abiotic effects on tree species richness in uneven aged and mixed forests using machine learning approaches

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Sahar Heidari[1]
Mahmoud Bayat[1], Pete Bettinger[2]

Abstract: Forest ecosystems play multiple important roles in meeting the habitat needs of different organisms and providing a variety of services to humans. Biodiversity is one of the structural features in dynamic and complex forest ecosystems. One of the most challenging issues in assessing forest ecosystems is understanding the relationship between biodiversity and environmental factors. The aim of this study was to investigate the effect of biotic and abiotic factors on tree diversity of Hyrcanian forests in northern Iran. For this purpose, we analyzed tree diversity in 8 forest sites in different locations from east to west of the Caspian Sea. 15,988 trees were measured in 655 circular permanent sample plots (0.1 ha). A combination of machine learning methods was used for modeling and investigating the relationship between tree diversity and biotic and abiotic factors. Machine learning models included generalized additive models (GAMs), support vector machine (SVM), random forest (RF) and K-nearest–neighbor (KNN). To determine the most important factors related to tree diversity we used from variables such as the average diameter at breast height (DBH) in the plot, basal area in largest trees (BAL), basal area (BA), number of trees per hectare, tree species, slope, aspect and elevation. A comparison of RMSEs, relative RMSEs, and the coefficients of determination of the different methods, showed that the random forest (RF) method resulted in the best models among all those tested. Based on the results of the RF method, elevation, BA and BAL were recognized as the most influential factors defining variation of tree diversity

Discrimination of leaves in a multi-layered Mediterranean forest through machine learning algorithms

Abstract: Terrestrial Laser Scanning (TLS) systems precisely characterize standing trees with millimetric resolution. To accurately calculate the leaf area index (LAI), a crucial indicator of trees' photosynthetic activity, using TLS point clouds, it is important to distinguish between timber and leaf components. This study aims to evaluate the performance of six machine learning algorithms in discriminating timber and leaf points using TLS point clouds, with a specific focus on eight Mediterranean tree species. The findings revealed that random forests, deep learning, gradient boosting machine, and stacked ensemble algorithms achieved the highest accuracies, with the maximum accuracy reaching 0.96. The machine learning models demonstrated accurate discrimination, supported by their AUC values, with the highest accuracy reaching 0.99. The observed and predicted data showed moderate to high agreement, with average Kappa values ranging from 0.67 to 0.76. The accuracy of timber-leaf discrimination varied across species, with Italian maple, European Beech, Hazel, and Small-leaf lime achieving an average overall accuracy exceeding 0.90. Various factors influenced the contrasting response patterns among tree species, including bark and leaf traits, bark defects, lianas, forest structure, occlusion caused by small trees or shrubs on large branches, reduced accuracy of laser beams in intermediate and overstory layers (particularly for tall trees ranging from 6 to 30.7 meters in height), and the presence of dense stems (672 trees per hectare). Nevertheless, the best machine learning models exhibited reasonable computation times of 8 to 37 seconds for discriminating timber and leaf points from 2 million data points. Future studies are encouraged to utilize the obtained leaf area estimates to derive LAI for individual trees of each species.

Estimating canopy cover of natural forests using airborne laser scanning (ALS) data: A case from Alabama, USA

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

CAN VATANDAŞLAR[1, 2]
TAEYOON LEE[1], ALICIA PEDUZZI[1], **PETE BETTINGER**[1], KRISTA MERRY[1], JONATHAN STOBER[3]
[1] University of Georgia, Warnell School of Forestry and Natural Resources, Athens GA 30602, U.S.A.
[2] Artvin Coruh University, Faculty of Forestry, Dept. of Forest Engineering, Artvin 08000, Türkiye
[3] U.S. Forest Service, Talladega National Forest, Heflin AL 36264, U.S.A.

Abstract: Canopy cover (i.e., crown closure) is defined as the area of tree crowns, projected vertically from a horizontal plane, as a fraction of the total ground area of a forest stand. It is a valuable forest attribute used in forest management planning, especially for estimating growing stock, stratifying large forest expanses into homogeneous stands, and evaluating the necessity of thinning operations, among other purposes. Canopy cover can be measured by using a tape or densiometer from the ground perspective and by sampling or other assessment methods that use optical data such as aerial photography and satellite imagery. However, three-dimensional LiDAR (light detection and ranging) point clouds have recently gained popularity and are increasingly being used instead of, or in conjunction with, optical data in forestry research. While many studies have focused on deriving various canopy metrics from LiDAR data, typically based on the ratio of LiDAR returns above a specified height threshold, these metrics are primarily related to canopy density rather than the specific definition of canopy cover stated above. Therefore, the objective of the present study was to develop a simple workflow for estimating the canopy cover ratio of stands in a federal forest in Alabama based solely on airborne laser scanning (ALS) data collected between 2020 and 2021. The accuracy of the approach was evaluated using visual assessments (NAIP orthophotos) and field data from 255 sample plots. The results suggest that the canopy cover ratio of pure and mixed plots could be estimated with a root mean square error (RMSE) of 14%. The correlation coefficient (Pearson's r) between the observed and estimated ratios was 0.77. Whereas the canopy cover estimates for pure conifer plots tended to be slightly underestimated, canopy cover estimates for broadleaved plots were virtually unbiased, despite the ALS data being collected during the leaf-off season. As this project is still ongoing, stand-level estimates and a canopy cover map of the entire study area will be provided at the conference. The findings of this study may serve a blueprint for researchers and practitioners working with LiDAR data in their everyday efforts related to natural resources management.

Impact Assessment of Forestry Machines on Mountain Forests using Deep Learning to Develop a Severity Index based on Wheel Rut Depth and Erosion Risk

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Alberto Udali[1]
Bruce Talbot[2], Gunta Grube[1], Davide Imperiali[1], Stefano Grigolato[1]
[1] Università degli Studi di Padova, Department of Land, Agriculture, Environment and Forestry, Italy
[2] Stellenbosch University, Department of Forest and Wood Science, South Africa

Abstract: Mountainous regions are prone to large-scale disturbance events such as wildfires, landslides, and windstorms, which can significantly impact forest ecosystems. Forestry machines, like harvesters and forwarders, are crucial for post-disturbance forest management and recovery. However, their passage can lead to additional surface disturbance enhancing soil compaction and erosion, further aggravating ecological vulnerability.

This study aims to assess the impact of forestry machines and salvage logging operations in mountain areas following large disturbance events, with a specific emphasis on developing a severity index based on wheel rut depth and the exposure to potential erosion risks. The methodology integrates LiDAR data for pre-event analysis, close-range photogrammetry from drones for the post-event scenario, and deep learning techniques for accurate wheel rut detection and depth estimation.

To quantify the impacts, LiDAR data will be used to reconstruct pre-event forest structure and topography. Close-range photogrammetry from drones, along with deep learning approaches, will enable the identification and measurement of wheel ruts accurately in the post-event scenario. Convolutional neural network (CNN) models will be trained using a large dataset of drone images to automatically detect and classify wheel ruts, providing a quantitative measure of soil compaction and disturbance severity.

Additionally, a simple hydrological model will be employed, incorporating parameters such as slope, soil type, vegetation cover, and topography to evaluate erosion risk in the affected areas. By integrating the severity index based on wheel rut depth and erosion risk exposure, a comprehensive assessment of the impact of forestry machines and salvage logging operations will be achieved with respect to changes in the micro-topography.

This study will contribute to understanding the ecological consequences of post-disturbance forest management in mountainous regions. The severity index, derived using a deep learning approach for wheel rut depth estimation, will serve as a valuable tool for assessing the extent of disturbance caused by forestry machines. Moreover, the incorporation of a hydrological model identifies areas at high risk of erosion due to machine passage, aiding in the development of sustainable management strategies to mitigate environmental degradation.

Integrating high- and low-frequency forest monitoring data into AI models for climate sensitive tree growth

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Anita Zolles[1, 2]
Silvio Schüler[1], Anahid Naghibzadeh-Jalali[3]
[1] Austrian Research Centre for Forests, Vienna
[2] University of Natural Resources and Life Sciences, Vienna
[3] Austrian Institue of Technology, Vienna

Abstract: Traditional statistical modeling approaches are limited in capturing the complexities of tree growth and its response to the increasing occurrence of climate extreme events. Moreover, the increasing availability of tree monitoring data in high temporal and spatial resolution requires new modeling approaches.

The present project employs a combination of AI and traditional statistical models, such as Long Short-Term Memory (LSTM) and Generalized Additive Models (GAMs), to develop a comprehensive modeling approach for tree growth. LSTM models are utilized to capture temporal dependencies and patterns in tree growth data, while GAMs provide interpretability and account for non-linear relationships between growth and climate variables.

The project utilizes detailed long-term datasets from the ICP forests monitoring network. Hourly single tree growth data enable the analysis of physiological processes and interactions with climate variables, while periodic stand characteristics provide insights into long-term development and carbon sequestration. Terrestrial laser scanning (TLS), along with satellite-derived parameters, are integrated into the models to capture high- and low-frequency features, especially individual competition factors. Our analysis aims to identify growth parameters and should aid the further development of monitoring setups. By combining AI techniques with explainable error analysis, we strive to enhance our understanding of tree growth and optimize forest ecosystems' resilience in the face of changing climate conditions.

Linked Open Data: a tool for foresters on their artificial intelligence journey

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

[2] Group of Intelligent and Cooperative Systems, Universidad de Valladolid, Spain

Abstract: By opening forest data and facilitating their use we promote forest management transparency, support the participation of different stakeholder profiles in decision making processes, and increase productivity in the forest sector, and promote the awareness of society on forest ecosystems and forest resources. Semantic technologies are part of the symbolic artificial intelligence (AI) and are particularly adequate to organize information, facilitate interoperatibility, search and expert systems. On the base of specially developed ontologies and Linked Open Data (LOD), our group developed Forest Explorer (https://forestexplorer.gsic.uva.es) that it is a web based tool that allows users to access dendrometric and land use data for forests in Spain and Portugal. The data in Forest Explorer comes from the National Forest Inventories and forest maps from Portugal, IFN6 (Inventário Florestal Nacional) and COS (Carta de Uso e Ocupação do Solo de Portugal Continental) and Spain, IFN3 (tercer Inventario Forestal Nacional) and MFE50 (Mapa Forestal Nacional). These resources have been converted to RDF and annotated with a dedicated forest ontology. Since Portuguese IFN6 was only partially disclosed, the data from Spain are more extensive and detailed than the Portuguese data. Forest Explorer caters to a diverse user base, ranging from lay users to professional foresters, each with different requirements and objectives. Forest Explorer offers raw dendrometric data at plot and tree level, providing controls to filtering by location, forest cover and species composition. This information can be used by professional foresters to inform their decision-making and support sustainable management alternatives, opening opportunities to insight on current and forecast species composition distribution, feeding forest simulators (as SIMANFOR: www.simanfor.es), and allowing users forecast forest stand dynamic and the impact of management actions and climate change. Forest Explorer offers the opportunity to access dendrometric data that can combine with other data sources to train, validate, and test AI algorithms.

Machine Learning for landscape level forest inventory: extract 3D attributes from 2D data

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Bogdan Strimbu[1]
John Sessions[1], Robert Schriver[1]
[1] Oregon State University

Abstract: Modern forest inventory records not only the dimensions of individual trees but also their location. Positioning trees from georeferenced data is a simple task irrespective of the type of data (i.e., 2D or 3D), but extraction of relevant tree attributes depends on the available information, as various heights require 3D data. Because the ubiquity of 2D representation of the Earth's surface, it is desirable to estimate tree height from orthophotos. Therefore, in this study, we aim at positioning and estimating the size of individual trees using high-resolution imagery. We selected as study areas two regions from Wheeler County, Oregon, USA, each of approximately 1600 ha. The dominating species in the area are western juniper (*Juniperus occidentalis* Hook.) and ponderosa pine (P*inus ponderosa* Douglas ex C.Lawson). We executed the forest inventory in two stages, each using a dedicated neural network. First, we identify individual trees by segmenting high-resolution multispectral images using a Faster Region-based Convolutional Neural Network, and second, we compute the tree heights from a canopy height model created using a Generative Adversarial Network. The Generated Adversarial Network was trained using lidar-derived digital elevation models. We compare our method with the multiscale watershed segmentation algorithm of Wang et al. (2004) applied to the generated canopy height model and the original imagery. The multiscale watershed segmentation algorithm exhibited a precision of at most 75% and recall of 81% (precision in this case was just 53%), with the smallest omission error of 22%. Our implementation of the Faster Region-based Convolutional Neural Network algorithm identified the trees with a precision of 91%, a recall of 73%, and an omission error of just 7%. The heights supplied by the Generative Adversarial Network were not significantly different from the values derived from lidar. Our results show that accurate spatial explicit maps of the trees can be obtained from 2D products, orthophotos and digital elevation models.

Machine Learning of Tree Height-Diameter Relationships – Data Dimension Perspectives on Selecting an Appropriate Modelling Approach

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Jari Vauhkonen[1]
Lauri Mehtätalo[2]
[1] University of Eastern Finland, School of Forest Sciences, Finland
[2] Natural Resources Institute Finland (Luke), Bioeconomy and environment unit, Finland

Abstract: Various machine learning algorithms have been applied to regression and classification of tree and stand parameters over the last decades. We claim that performance comparisons between methods could be considered more successful if they qualitatively considered the fitness of the selected machine learning method to the available amount and type of data in addition to model fitting and accuracy statistics in an application. To demonstrate this, we evaluate the learning process of tree height-diameter relationships based on linear and nonlinear regression, mixed effects, nearest neighbor, random forest, and fully connected and convolutional neural networks in settings with varying data availability.

Height-diameter modeling is a well known and well studied problem. Due to the measurement of trees within plots and plots within stands, the data are nested with a hierarchical error structure. A general recommendation is to use a mixed effects modeling approach to deal with the hierarchical errors, but also because in a practical case the parameters associated with the random effects are unknown and need to be predicted. The ability of the algorithms to predict the random stand effects, or to calibrate the predictions with a limited number of observations, would have resulted in a comparative evaluation taking into account all the possibilities of the modeling methods in a practical situation.

We use a total of 299 permanent plots measured at three time points, additional data from about 2,000 plots from one time point, and various related geospatial data from a test area in Central Finland. We observe the learning of tree height-diameter in different situations and evaluate the implications for the derivation of volume from diameter and height using different strategies. By testing different extents and selectively selected data, we evaluate the transferability of the model through different calibration and transfer learning approaches. While the height-diameter relationship can be learned by all approaches with fundamentally similar population accuracy, the mixed-effects modeling approaches offer undisputed advantages due to their calibration capabilities using Best Linear Unbiased Prediction. We discuss the strengths and limitations of the different approaches and the implications for stand, holding, and regional decision making with different objectives.

Machine learning prediction of tree species diversity using forest structure and environmental factors: A case study from the Hyrcanian Forest of Iran

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Hamed Asadi[1]
Esmaeil Valizadeh[1], Abolfazl Jaafari[2], Mahya Tafazoli[1]
[1] Department of Forest Sciences and Engineering, Faculty of Natural Resources, Sari Agricultural Sciences and Natural Resources University, Sari 4844174111, Iran.
[2] Research Institute of Forests and Rangelands, Agricultural Research, Education and Extension Organization (AREEO), Tehran 1496813111, Iran.

Abstract: The Hyrcanian Forest is an ecologically important region with diverse flora, but its tree diversity has been significantly impacted by human activities. To address this issue, we conducted a study using three machine learning methods, i.e., linear regression (LR), random forest (RF), support vector machine (SVM), to assess and predict tree species diversity within the forest. To do so, we collected an extensive dataset of forest structure and environmental factors from 2725 sample plots located throughout the forest. The Shannon-Wiener diversity index was used to quantify the tree species diversity for each plot. We found that basal area, tree density, and height of trees were the most important predictors of tree diversity, followed by diameter at breast height, elevation, slope, and aspect. We measured the performance of the models using the coefficient of determination (R^2), root mean square error (RMSE), and percent of relative error index (PREI), and found RF as the best-performing model in both the training (RMSE = 0.143, R^2 = 0.94, PREI = -0.088) and validation (RMSE = 0.146, R^2 = 0.94, PREI = -0.094) phases. RF was able to generalize effectively to new data without losing much accuracy or explanatory power. SVM demonstrated a moderate performance training (training phase: RMSE = 0.230, R^2 = 0.57, PREI = -0.178) and (validation phase: RMSE = 0.365, R^2 = 0.34, PREI = -0.207) among the models, while LR performed the worst (training phase: RMSE = 0.406, R^2 = 0.13, PREI = -0.195) and (validation phase: RMSE = 0.414, R^2 = 0.11, PREI = -0.357). These findings have broad applications beyond this specific region and can contribute to promoting sustainable land use practices and conservation efforts in other ecosystems facing similar challenges.

Mapping forests matching to sites by linking potential productivity with distribution suitability based on machine learning in northeast China

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Xiangdong Lei[1]
dan liu[1], wenqiang gao[1], liyong fu[1]
[1] Institute of Forest Resource Information Techniques, Chinese Academy of Forestry, Beijing 100091

Abstract: Matching tree species with sites is a basic principle in forest management. This matching was conventionally achieved through site quality evaluation based on site index by tree species. Developing site index model through empirical growth model is necessary for this. In this study, a novel methodology was developed for matching tree species (mixture) with sites, which produced a happy tree index (HTI) combing potential productivity with distribution suitability using machine learning algorithms and multiple environment variables including soil, topology and climate. The data were from 2825 sample plots of national forest inventory in northeast China, 1km resolution climate and 250m resolution soil database. Potential site productivity (maximum annual volume increment) was produced for 13 tree species (mixture) through stand growth model and optimization algorithms. Distribution suitability for 13 tree species (mixture) was produced from assemble species distribution models. HTI for all plots was firstly attained and then trained by random forest for generalization at large scale. All models showed good generation capacity with R^2 larger than 0.70. Based on the trained model, HTI for all grids across the region was generated with the input as soil, topology and climate variables for all tree species (mixture). Our study provided useful tools for mapping forests matching to sites which is important for afforestation, degraded forest restoration and forest management decision-making. The advantages and challenges for using machine learning at large scale with multiple variables were discussed.

Modeling Height—Diameter Relationship Using Artificial Neural Network for Durango Pine species in Mexico

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Geronimo Quinonez-Barraza[1]
Yuduan Ou[2]
[1] National Institute of Forestry, Agricultural and Livestock Research (Mexico)
[2] College of Coastal Agricultural Siences, Guangdong Ocean University

Abstract: The relationship between tree height (*h*) and diameter at breast height (*dbh*) is important for forest management and planning. Various approaches have been used to study the height-diameter (*h—dbh*) relationship across different species worldwide. Nonlinear mixed effect modeling (NLMEM) has been widely utilized, and recently, the resilient backpropagation artificial neural network (RBPANN) approach has gained attention for modeling this relationship. In this study, both NLMEM and RBPANN approaches were employed to model the *h—dbh* relationship for Durango pine species (Pinus durangensis Martínez) in a mixed-species forest in Mexico. The dataset consisted of 1,000 randomly selected plots (11,472 measurements) from 14,390 temporary forest inventory plots. The dataset was divided randomly into two parts, with 50% allocated for training and 50% for testing. To analyze the dataset, a cluster analysis was performed using the *k*-means clustering method, grouping the data into 10 clusters. Plot variables such as density, basal area, mean *dbh*, mean height, quadratic mean diameter, altitude, and aspect were considered in the clustering process. The RBPANN approach was applied using tangent hyperbolicus (RBPANN-tanh) and logistic function (RBPANN-logistic) for the cross product of the covariate or neurons, along with the weights for the ANN analysis. For both the training and testing stages, 10 classical statistics, including RMSE, R2, AIC, BIC, and logLik, were computed to evaluate the performance of the approaches in modeling the *h—dbh* relationship. The results showed that the ANN approach outperformed the NLMEM approach in both training and testing. Thus, the ANN method was found to be more effective for modeling the *h—dbh* relationship for Durango pine species in the mixed-species forest of Mexico.

Modeling productivity–diversity relationship using artificial neural networks and parametric models in typical uneven-aged and mixed forests

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Mahmoud Bayat[1]
Sahar Heidari[1], Pete Bettinger[2]
[1] Research Institute of Forests and Rangelands, Agricultural Research, Education and Extension Organization (AREEO)
[2] Warnell School of Forestry and Natural Resources, University of Georgia, Athens, GA 30602, USA

Abstract: The relative importance of different biotic and abiotic variables in determining productivity remains unclear for many forest ecosystems around the world. This article investigates the productivity–diversity relationship in typical uneven-aged and mixed forests in northern Iran. Using a large dataset from 258 forest monitoring permanent sample plots distributed across uneven-aged and mixed forests in northern Iran, we tested the relationship between tree species diversity and forest productivity and examined whether several biotic and abiotic variables (i.e., solar radiation, topographic wetness index, wind velocity, seasonal air temperature, basal area (BA), tree density, basal area in largest trees (BAL)) had an effect on productivity. In our study, productivity was defined as the mean annual increment of the stem volume of a forest stand in m3ha-1yr-1. Plot estimates of tree volume growth are based on averaged plot measurements of volume increment over a 9-year growing period. We investigated relationships between productivity and tree species diversity using a parametric model, i.e., multiple linear regression, and two artificial neural network models, i.e., multilayer perceptron (MLP) and radial basis function (RBF) networks. According to a sensitivity analysis, diversity had significant and positive effects on productivity in species-rich broadleaved forests (approximately 31%), but the effects of biotic and abiotic variables were also important (29% and 40% respectively). The artificial neural network based on the MLP was found to be superior for modeling productivity–diversity relationships.

Real-time detection of trees and obstacles in complex forest environments using 3D depth cameras and machine learning

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Gunta Grube[1]
Alberto Udali[1], Bruce Talbot[2], Stefano Grigolato[1]
[1] University of Padova, Department of Land, Environment, Agriculture and Forestry, Italy
[2] Stellenbosch University, Department of Forestry and Wood Science, South Africa

Abstract: Accurate monitoring and efficient forest resource management are essential for sustainable forestry practices. Recent technological progress has significantly transformed numerous facets of forest management, offering opportunities to enhance inventory management and optimize planning processes. By leveraging these advancements, it becomes feasible to streamline operations, ensure resource efficiency, and promote environmentally conscious practices within the forestry sector.

This study focuses on developing a fundamental methodology that utilizes a 3D depth camera, real-time object detection, and deep learning techniques to detect trees and machine obstacles in complex forest environments, enabling more efficient forest management practices. Implementing a tree and obstacle detection and localization system holds the potential for significant benefits, including improved planning, enhanced situational awareness for forest machine operators, and valuable positional data crucial in facilitating informed decision-making processes by precisely pinpointing the positions of trees and primary machine obstacles. Therefore, this study intends to implement a system prototype that automatically locates trees and main machine obstacles based on accessible hardware and standard software infrastructure.

This work describes and evaluates an automatic tree and object detection and localization system based on ZED 2i stereo camera sensing, capable of capturing high-resolution color and depth maps. We employ the NVIDIA Jetson Orin AGX computer as the computational platform for camera control and data analysis to facilitate seamless integration and processing. As a key component of our system, we utilize the YOLO (You Only Look Once) object detection algorithm, a deep-learning approach that enables efficient and accurate detection and localization of objects of interest. By leveraging YOLO object detection, we can derive precise object positions in 3D space, further enhancing the capabilities of our object detection and localization system.

To validate the effectiveness and performance of our methodology, comprehensive field trials will be conducted, involving manual labeling and precise positioning of trees and machine obstacles.

Regeneration in a Complex Forest: What Can We Learn From, and About, Machine Learning?

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Mark Ducey[1]
[1] University of New Hampshire

Abstract: Forests in the northeastern United States are structurally complex and species diverse, and management relies on natural regeneration. However, concerns over adequate regeneration are chronic and widespread. We used data from the U.S. Forest Service, Forest Inventory and Analysis program, along with Random Forest (RF) and Mixed Effects Random Forest (MERF) machine learning, to examine the predictability of regeneration using a series of biotic and abiotic predictor variables. Regeneration was represented using a suite of community-level traits: abundance, average shade tolerance, proportion conifers, and proportion in primary economic species. We also evaluated multiple techniques for variable selection. RF and MERF showed very similar predictive ability, but MERF provided more accurate projections of prediction errors when compared against reserved validation data. Variable selection was far more sensitive to the choice of selection technique, than to the underlying model. Regeneration attributes remained difficult to predict, even with a large set of available predictors; however, expert selection informed by RF or MERF results led to a parsimonious model that retained substantial predictive ability along with interpretability.

Testing the accuracy of personal laser scanning data and different processing methods for individual tree attributes estimates in European beech forests

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Ivan Balenović[1]
Andro Kokeza[1], Luka Jurjević[2], Fran Domazetović[3], Ivan Marić[3], Ante Šiljeg[3], Krunoslav Indir[1]
[1] Croatian Forest Research Institute, Jastrebarsko, Croatia
[2] Geo Unit Ltd., Zadar, Croatia
[3] University of Zadar, Department of Geography, Zadar, Croatia

Abstract: Rapid progress in sensor miniaturization resulted in the development of lightweight and highly mobile personal laser scanning (PLS) systems that may be carried or held by person. The emergence and availability of new generation PLS systems with considerably improved features (e.g., scanning range and rate, measurement accuracy) of LiDAR sensor resulted recently in initial research on the possibility of its application in forest inventory, primarily for the estimation of the main tree attributes. The main goal of this research is to test the accuracy of three different methods of processing PLS point clouds for the individual tree attributes estimation. These methods are supervised automatic, unsupervised automatic, and semi-automatic. The research was conducted in twelve circular sample plots (500 m^2) distributed in two study areas of Central Croatia, i.e., in European beech (*Fagus sylvatica* L.) middle-aged and older forest stands. Considering their ecological, social and economic value, they are among the most important tree species in Europe. Sample plots were scanned using a GeoSLAM Horizon scanner, while three different processing methods were designed using the algorithms and procedures enabled by LiDAR360 software. The obtained results of tree detection, tree positions, diameter at breast height (dbh) and tree height for each PLS processing method were compared to ground reference data, i.e., estimates obtained from detailed field measurements and terrestrial laser scanning (TLS) data. TLS data were collected using a Faro FOCUS S70 scanner and multi-scan approach. As expected, the semi-automatic PLS processing method, which requires the most manual work, provides the results of the highest accuracies for all observed variables which are closely comparable to TLS estimates. The unsupervised automatic method provides the least accurate estimates, mostly due to a greater rate of non-segmented or incorrectly segmented smaller trees with dbh<20 cm. Supervised automatic method provides results of considerably higher accuracies than unsupervised method regarding the tree detection but compared to semi-automatic method the results of considerably lower accuracies for tree height estimates, especially in more dense sample plots with overlapped tree crowns.

The potential of artificial intelligence in forest growth and yield modelling

T5.1 Artificial Intelligence in Forest Biometry: from predictions to understanding

Clara Antón Fernández[1, 2]
[1] Norwegian Institute of Bioeconomy Research (NIBIO)
[2] University of Valladolid (Spain)

Abstract: Artificial intelligence (AI) has transformational potential and promises to revolutionize almost every aspect of our life, but the revolution has not reached yet forest growth and yield modelling (FGYM). What are the niches within FGYM with the greatest potential to benefit from AI? What are the potential benefits? What is needed to fully benefit from the transformational potential of AI? In this talk I present an exploration of the potential applications of AI in the context of forest growth and yield. I will discuss the challenges and opportunities associated with implementing AI technologies in FGYM, including data availability, model interpretability, and the need for interdisciplinary collaboration.

T5.2 Artificial Intelligence in Forest Management – Opportunities, Challenges and Social Consequences

Causal understanding of the deep learning processes of convolutional neural networks by learning predefined features of digital terrain models

T5.2 Artificial Intelligence in Forest Management – Opportunities, Challenges and Social Consequences

Jari Vauhkonen[1, 2]
Alireza Hamedianfar[2, 3], Cheikh Mohamedou[2], Mikko Niemi[1, 2]
[1] University of Eastern Finland, School of Forest Sciences, Finland
[2] University of Helsinki, Department of Forest Sciences, Finland
[3] Geological Survey of Finland GTK, Information solutions unit, Finland

Abstract: Artificial intelligence could potentially augment decision making to the extent that autonomous machines and systems learn from observations and experience and reconfigure themselves when new components or information are introduced. However, deep learning applications in forestry are in the intermediate stages of achieving this overarching goal. One limitation to the adoption of these algorithms may be the excessive amount of specific terminology and concepts that an operator needs to understand in order to optimally implement these methods in practice.

For convolutional neural networks (CNNs), choices regarding the architecture and hyperparameters of the training process, as well as data augmentation (using synthetic data based on transformations) and transfer learning (using a limited local sample to calibrate a large pre-trained network) can effectively contribute to the predictive accuracy, efficiency and training time of the model, also depending on the available training data. CNNs may need to be contextually optimized for each application, where we identify challenges related to (1) obtaining sufficient amounts of representative and labeled training data, (2) difficulties in selecting an appropriate architecture and hyper-parameterization among many methodological choices, and (3) susceptibility to overlearning of the training data and consequent risks related to the generalizability of the predictions, which can, however, be reduced by appropriate choices on the above.

To provide guidance on appropriate method and parameter choices, we propose learning terrain micro- and macrotextural features from digital terrain models (DTMs) as a possible CNN training testbed. The simplest features, such as slope and aspect, are computed primarily by applying local filters to the DTM and should be learned by CNNs with a reasonable amount of iterations and data, depending on how well e.g. CNN filters match the initial choices. More complex features, such as terrain morphological features, flow accumulation, and wetness indices, depend on pixel neighborhoods and flow direction and distribution from the watershed, and thus require more complex CNN training. Since all these features can be uniquely defined from the DTM, their learning provides an excellent demonstration of the required training data, associated learning processes, and transfer learning. We discuss these implications more generally with respect to forestry.

Digital literacy among individual forest owners in Sweden – Is it associated with sustainable management?

T5.2 Artificial Intelligence in Forest Management – Opportunities, Challenges and Social Consequences

Adan L. Martinez-Cruz[1]
Daniel Martey Junior Mensah[2], Camilla Widmark[1]
[1] Swedish University of Agricultural Science (SLU), Forest Economics, Sweden
[2] Swedish University of Agricultural Science (SLU), Forest Resource Management, Sweden

Abstract: Digital literacy is envisioned as a booster of sustainability. In the forest sector, digital literate owners are expected to become instrumental in spreading sustainable management. For instance, they can better incorporate up-to-date information readily available on-line into their management plans, or take advantage of ever evolving Artificial Intelligence tools. These type of owners would therefore be able to take informed actions to counteract climate conditions. To measure digital literacy for individual forest owners, we adapted a previous study, initially aimed to estimate Americans' digital awareness in utilising electronic devices to achieve online learning, to individual forest owners in Sweden. Using Horrigan's work as a baseline, we defined digital literacy through three components: a) *Digital skills*, one's ability to access online information; b) *Trust*, one's self-perception to separate trustworthy data from inaccurate news and c) *Use*, one's potential to take educated decisions about forest management using online information. In the survey, we dedicated two questions to *digital skills*, one question to *trus*t and another one to *use*. Logistic models' estimations were used to determine the association between digital literacy and sustainable forest management. Due to the fact that sustainable forest management as a concept presents its own "thorns", we asked forest owners a question about forest management practices engaged on their property and from their answers we elaborated our sustainability index. Through gathering and analysis of answers provided by a nationally-representative sample of individual forest owners in Sweden, this paper documents that i) only 10% of forest owners are digital literate; and ii) digital literacy is associated with a higher likelihood of observing sustainable management practices but only among individual owners of age 66 to 76 years old. These owners, in general, reside in rural areas, report higher education levels, and use their property for non-commercial purposes. A limitation of findings reported in this manuscript is that we relied on self-reported information from forest owners to develop our indexes. We discuss implications in terms of how we can increase digital literacy among forest owners and how its association with sustainable management can be strengthened.

Exploring the effects of abiotic drivers on the classification of leaf phenology groups in a tropical forest using machine learning

T5.2 Artificial Intelligence in Forest Management – Opportunities, Challenges and Social Consequences

Alice Rodrigues[1]
Andreza Neri[1], Lhoraynne Gomes[1], Pedro Villa[2]
[1] Laboratory of Ecology and Evolution of Plants - LEEP, Department of Plant Biology, Postgraduate Program in Botany - Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil
[2] Department of Biological Sciences, Postgraduate Program in Botany - Universidade Federal de Feira de Santana, Feira de Santana, Bahia, Brazil

Abstract: The vegetation distribution is largely determined by the environmental drivers and stand age. Predicting future vegetation changes in response to abiotic drivers is crucial to identify and understand patterns and processes in tropical forests. Machine learning (ML) has been used by different ecological and environmental researchers to model forest types and ecosystem services classification. Thus, in this study we employed three main machine learning algorithms (Random Forest, Support Vector Machine and classification and regression tree) to predict the association of the abiotic factors and stand age for the classification of tree leaf phenology groups (evergreen, deciduous, and semideciduous) in an Atlantic tropical forest, in southeast of Brazil. Especially, we used ML models with the climate data (climatological water deficit, CWD), soil data (sum of basic exchangeable cations (SB) and exchangeable acidity potential (HAl)) and topographic data (elevation, slope and convexity) during tropical late-secondary forest succession to predict the classification of functional leaf phenology groups. The data were obtained through a long-term forest inventory (1980-2020) in a Atlantic forest. The prediction of leaf functional groups classification based on multiple abiotic predictors using the three different machine learning-based classification algorithms showed higher accuracy and suitable Kappa using the Random Forest (A = 0.753, K = 0.629) compared to the classification and regression tree (A= 0.470, K= 0.648) and Support Vector Machines (A= 0.460, K= 0.640) algorithms. Using random forest, it was observed that the most influential predictor in the classification of functional groups was topography and soil properties. Specifically, elevation shows a high explanatory contribution in the three functional groups followed by soil properties such as SB and HAL. Our results showed that topography, mainly elevation, is a important driver for leaf phenology group classification in a tropical forests. The prediction of functional group classification can be the basis for the identification of key species to be used during ecological restoration and for defining environmental policies and forest management strategies under different topography and soil-dependent conditions in the Atlantic forest. Furthermore, the use of ML expands traditional data analysis and offering fast processing and allowing significant advances in data description and predictive modeling.

Forest Owners' Perspective on Machine Learning in Forestry: Uncovering the "Tree-mendous" Influence of Context with Q-Methodology

T5.2 Artificial Intelligence in Forest Management – Opportunities, Challenges and Social Consequences

Joakim Wising[1]
William Lidberg[2], Camilla Sandström[1]
[1] Umeå University (UmU)
[2] Swedish University of Agricultural Science (SLU)

Abstract: The application of machine learning in forestry has gained considerable attention in recent years due to its potential to enhance decision-making processes and promote sustainable forest management. However, understanding the perceptions of individual forest owners towards the use of machine learning in this domain is crucial for successful adoption and integration of such technologies. Previous research has suggested that perceptions of machine learning applications are conflated with opinions about the context – implying that perceptions of what are appropriate applications is largely shaped by one's relation to the social context. Social context refers to the set of social circumstances that shape an individual's experience, actions, and interaction within a particular social setting.

Based on Q-methodology and naturalistically derived Q-statements the aim of this study is to explore the diverse viewpoints held by individual forest owners regarding the use of machine learning and forest management in Sweden.

The study involved a purposive sample of forest owners from various geographic locations within Sweden, reflecting a range of demographic characteristics and forest management practices. Q-methodology, a systematic approach for exploring subjective opinions and perspectives, was employed to identify the underlying factors influencing forest owners' perceptions. Participants were asked to rank a set of statements representing different attitudes towards machine learning in forestry administration and forestry administration in general, according to their level of agreement/disagreement. The statements were derived from several purposefully sampled semi-structured interviews across Sweden.

The findings confirm previous findings that social context is important in shaping perceptions, but that the concept has been underspecified in previous research. Context has been used analogously to "area of application" rather than as a collection of potential factors which shape the perceived appropriateness of application. Through employing Q-methodology with statements regarding both context and technology use – the paper suggests a more granular way to understand how context and perceptions of technology-use go hand-in-hand.

This study highlights the importance of considering individual forest owners' perceptions and attitudes when implementing machine learning solutions in forestry administration. These insights can assist policymakers and technology developers in tailoring interventions that address the concerns and expectations of forest owners.

Intelligent management of forest ecosystem based on multi-source information

T5.2 Artificial Intelligence in Forest Management – Opportunities, Challenges and Social Consequences

Prof. Zuomin WEN[1]
Prof. Liu LYU[1]
[1] College of Economics and Management, Nanjing Forestry University, China

Abstract: Ecosystem Management reflects human behavior of utilizing and protecting natural resources scientifically and sensibly. Sustainable development relies on renewable resources, especially the rational use of biological resources. Hence, ecosystem management is an important approach to the sustainable development. The paper aims to study wisdom management of forest ecosystems comprehensively. The ecological data in the study area been obtained by remote sensing and other wireless sensors. Through analyzing the multi-source data, the paper discussed the adaptive management model of forest ecosystem based on multi-agent system theory. The paper also constructed the aggregation and segmentation algorithm of forest ecosystem in flexible scales and calculated the dynamics of uneven-aged forests providing ecological services for developing a strategy model of optimizing algorithms taking multi-agent into account. On this basis, the paper tried to draw up a multi-sector social accounting matrix. After examining parameter and analyzing variance of the data on the social matrix, a multi-sector model of ecological economic system would been developed to illustrate various impacts of ecosystem management on the economy in the same area.

Key words: Intelligent management; forest ecosystem; multi-source information

T5.3 Assessing forest sustainability through operations research

A behavior-based robust decision making approach for managing forest under risk and uncertainty

T5.3 Assessing forest sustainability through operations research

Rasoul Yousefpour[1]

[1] Institute of Forestry and Conservation, John H. Daniels Faculty of Architecture, Landscape, and Design, University of Toronto, 33 Willcocks St, Toronto, ON M5S 3B3, Canada

Abstract: Forest management in times of climate change asks not only for integration of adaptation and mitigation strategies but also taking into account multiple risks affecting forest processes and functions. Moreover, climate change is challenging forest decision processes due to larger fluctuations in the severity and frequency of biotic and abiotic disturbances. Thereby, forest processes are subject to uncertainty because of the dynamics of natural systems and inherent deep uncertainty of future climate change represented by IPCC as a set of plausible scenarios. As the expectations about forest management outcomes in the future are built based on the dynamics of forest ecosystems and the timing of management interventions over planning horizon, novel decision-making approaches are essential to deal with these challenges. Robust decision-making (RDM) provides a unique opportunity to optimize the forest outcomes under deep uncertainty. RDM trades nominal optimality for robustness under worst conditions subject to a set of climate change scenarios, management options, and forest conditions. However, it is essential as well to integrate the risk and uncertainty attitudes of decision-makers in the robust decision-making process. Therefore, a set of robust decision-making approaches are investigated to assess the effects of risk and uncertainty aversion on final decisions. The outcomes confrms the sensitivity of RDM to risk and uncertainty behaviors and concludes that it is essential to communicate the effects with forest owners and decision-makers.

Automatic detection of forest management units as a basis to optimally coordinate planning, operations, controlling and assessing sustainability

T5.3 Assessing forest sustainability through operations research

Leo Bont[1]
Clemens Blattert[1], Lioba Rath[1], Janine Schweier[1]
[1] Swiss Federal Research Institute WSL, Zürcherstrasse 111, 8903 Birmensdorf, Switzerland

Abstract: Forest management in Central Europe provides numerous ecosystem services in addition to the provision of wood as a raw material. Managing these forests sustainably thus requires an efficient planning for management objectives (ecosystem services) and execution of harvesting operations. To consider planning and forest operations jointly and having an efficient controlling, it is essential to subdivide the forest area into smaller forest management units (FMU). The aim of FMUs is to have forest entities that can be managed and planned independently of each other; meaning each FMU should have a self-contained fine access into the forest and should be homogenous in terms of operational harvest methods and management objectives.

For an efficient and sustainable forest management and its assessment, it is particularly important to have well-chosen and meaningful boundaries between neighbouring FMUs. However, the demarcation of the FMUs is challenging, especially in steep terrain harvested by cable yarders. The planning of the layout and installation of the cable roads is usually very time consuming and associated with high costs.

We will present a spatial optimization model (Mixed Integer Linear Programming) that automatically identifies FMUs. The optimization pursues three goals: BWEs should be as compact, spatially contiguous areas as possible (objective 1), within each FMU forest management should be technically and operationally coordinated (objective 2), and the area should have as homogeneous properties as possible, such as the harvesting method used, the ecosystem service provided, or the administrative affiliation (objective 3).

The model was developed and successfully tested in close cooperation with the Forest Service of Grisons in the Swiss Alps. The model allows to generate different FMU layout variants in a short time that can easily be compared. The generated solutions can afterwards be reviewed by local experts and adopted, or slightly modified if necessary. The use of this method enables a transparent and efficient demarcation of FMUs considering multiple forest management planning goals and operational criteria at the same time.

Balancing biodiversity and ecosystem services in forestry under changing climate - Insights from a Swedish case study

T5.3 Assessing forest sustainability through operations research

Johanna Lundström[1]
Karin Öhman[1], Adam Felton[2], Eva-Maria Nordström[1], Daniel Mensah[1]
[1] Department of Forest Resource Management, Swedish University of Agricultural Sciences
[2] Department of Southern Swedish Forest Research Centre, Swedish University of Agricultural Sciences

Abstract: Forests play a crucial role in providing both biodiversity conservation and essential ecosystem services to society. However, the management of forests to address multiple objectives is a complex task, particularly in light of climate change, which places additional uncertainties in the way of informed decision making. In Sweden, intensive forest management has traditionally prioritized wood production as the primary ecosystem service. This has resulted in large areas of relatively homogeneous production forests with limited quantities of key features typically found in more natural forests, such as dead wood and old trees, vital for maintaining biodiversity. Furthermore, features associated with other ecosystem services such as recreation and carbon sequestration is often overlooked, leading to suboptimal management practices with regard to these services.

Here we assessed the implications for biodiversity and various ecosystem services resulting from the adoption of different forest management strategies within the framework of the Swedish SPARC project. The consequences were identified by quantifying conflicts and synergies between biodiversity conservation and ecosystem services in different future scenarios, considering various climatic projections.

Utilizing data from the Swedish National Forest Inventory, simulations of forest development were performed using the forest decision support system Heureka. A multi-objective optimization approach was applied to identify conflicts and synergies, between different indicators within each management strategy and climate scenario.

The results of this study revealed complex relationships between biodiversity conservation, ecosystem services, climate change, and forest management strategies. While some management alternatives show conflicts between biodiversity and ecosystem services, others demonstrate potential synergies. Thus, trade-offs are needed when deciding future forest management.

Our study contributes to the advancement of understanding regarding how multiple goals in forestry can be achieved by balancing biodiversity conservation and ecosystem services in the face of climate change. By quantifying conflicts and synergies through trade-off analyses, this study provides valuable insights for identifying effective combinations of management strategies that promote sustainable forest management in the face of ongoing environmental changes.

Bridging the gap between models of forest dynamics and decision support systems in forestry

T5.3 Assessing forest sustainability through operations research

Olalla Díaz-Yáñez[1]
Harald Bugmann[1], Verena C. Griess[1]
[1] Department of Environmental Systems Science. Institute of Terrestrial Ecosystems, ETH Zurich, Zurich, Switzerland

Abstract: Forests provide multiple ecosystem services crucial for humankind. Changes in environmental conditions caused by climate change, natural disturbances, and shifting societal needs jeopardize the provision of forest ecosystem services. Thus - more than ever – tools are needed to (1) reduce the uncertainty of forest growth projections considering climate change and risks, and (2) efficiently assess sustainable management alternatives.

Models of forest dynamics (MFDs) are essential tools to project future forest trajectories but have not often been integrated into Decisions Support Systems (DSSs) for forest management. DSSs and MFDs represent tree demography to some extent, but their necessary inputs, risks, and management considerations differ considerably. In general, MFDs include rather complex formulations of ecological processes. Some MFDs have management modules, but obtaining results with optimal management strategies for more complicated models remains challenging. DDSs commonly use much simpler models of forest demography that predict yield considering a more varied set of management strategies and often include the possibility of finding optimal solutions by applying mathematical optimization approaches. DDSs in forest management are gradually moving towards a more general, causal-oriented approach in which other relevant aspects, such as climate change, are being considered.

We review how MFDs and DSSs assess forest dynamics by considering management, risk, and climate change. More specifically, we evaluate 1) how climate change, risk, forest management, and optimization techniques are considered, 2) how flexible management is represented concerning the formulations of forest dynamics, risk, and environmental change, and 3) current gaps and research recommendations for these tools.

We base our assessment on 40 MFDs and DSSs that represent tree demography and have been used in the last 20 years to assess the implications of climate change, risk from natural disturbances, and/or forest management. MFDs and DSSs are classified according to variables representing their approach to modeling forest dynamics and how they consider risk, climate change, and management. We analyze each of these aspects and variables concerning their flexibility and complexity. Ultimately, we provide recommendations for a way forward related to flexible forest management under risk considering changing environmental conditions for implementation in the context of forest operations research.

Developing a Forest Ecosystem Management Decision Support System (FEMDSS) for Enhanced Adaptability and Generality

T5.3 Assessing forest sustainability through operations research

Silvana Nobre[1]
Marc McDill[2], Luiz Rodriguez[3], Luis Diaz-Balteiro[1]
[1] Research Group "Economics for a Sustainable Environment", Technical University of Madrid, Spain – ETS Ingenieros de Montes, Ciudad Universitaria 28040 Madrid, Spain
[2] Department of Ecosystem Science and Management, Pennsylvania State University, University Park, PA, USA
[3] Department of Forest Sciences, University of São Paulo, São Paulo, Brazil

Abstract: Developing a comprehensive Forest Ecosystem Management Decision Support System (FEMDSS) is time-consuming and expensive, often spanning several years or even decades. Even though efforts have been made to generalize and share knowledge and resources, given the complexity, researchers have focused on developing FEMDSS tailored to specific forest contexts, models, and methods. However, to address the evolving climate change challenges through nature-based solutions, modern FEMDSS must transcend conventional applications. A modern decision support system should be embedded within a Multicriteria Decision Analysis framework and designed to be inclusive, allowing researchers, forest managers, and practitioners from diverse regions, countries, and forest contexts to utilize it effectively. Therefore, FEMDSS's resulting plans could encompass all aspects of a multifunctional forest while considering financial viability.

In this study, we introduce the initial two modules of the Romero® FEMDSS, namely *iGen*, and *iMath*, which were conceptualized in a cutting-edge technological environment. Both modules are Python packages designed to function as components of local solutions, utilizing SQL databases for the Rule-base, initial forest state, and scenario results. The iGen module contains an engine that generates management alternatives, allowing forest managers to describe their forests using variables, rules, formulas, functions, and procedures. They can define possible interventions, their temporal progression, and how they change in the initial forest state. Outputs can be related to yields, income, costs, or other ecosystem services.

The iMath module allows users to specify the accounting variables and their calculation methods using variables from the preceding module. These accounting variables can subsequently be employed as constraints or objectives within a linear programming model (LP or MIP). Notably, the FEMDSS is not limited to, adapted to, or focused on any particular region, landscape, forest condition, projection method, or yield function. Instead, it aims to maximize generality, enabling it to address various Forest Ecosystem Management Problems.

This presentation demonstrates the flexibility, adaptability, and generality of the developed FEMDSS, highlighting the *iGen* and *iMath* modules. By showcasing these components, we contribute to the discourse on forest ecosystem management, providing a powerful decision-support tool for researchers and practitioners across diverse contexts and locations.

Joint analysis of forestry and factories using linear and nonlinear programming methods

T5.3 Assessing forest sustainability through operations research

Juha Lappi[1]
[1] Norwegian University of Life Sciences (NMBU)

Abstract: The open source software Jlp22 available at github.com/juhalappi/Jlp22 provides many methods for analyzing forestry data. The most interesting may be the linear programming functions which provide a flexible interface and an efficient algorithm for forest management planning problems. Jlp22 is a completely rewritten successor of the J software which was the successor of JLP software used in the Finnish Mela planning system. J provided possibilities to include factories in the analysis. Jlp22 will provide more advanced methods for analyzing transportation of logs to sawmills, chips from sawmills to pulp mills, pulp wood from forest to pulp mills and import and export of timber. The data structures and functions have been developed for nonlinear programming and piecewise linear functions. Ecological constraints and objectives can be included in different spatial scales. The utilization of parallel computation in supercomputers is under development. A book will describe the mathematics of the applied optimization methods and show how the interaction between forestry and industry can be analyzed from the view point of forest owners, independent saw mills, companies having both saw and pulp mills and government. The carbon and climate change can be included in the analyses when proper data and models will be available. Uncertainties in growth and price trends will also be considered.

Spatial configuration at landscape level for reducing spruce bark beetle susceptibility: a mathematical modelling approach

T5.3 Assessing forest sustainability through operations research

Teresa Lopez-Andujar Fustel[1]
Karin Öhman[1], Mikael Rönnqvist[2]
[1] Swedish University of Agricultural Sciences, Department of Forest Resource Management, Sweden
[2] Université Laval, Département de génie mécanique, Canada

Abstract: Spruce bark beetle (Ips typographus L.) is considered a significant threat to European forests often resulting in extensive tree mortality and economic losses. Forest management planning, using operations research, can be a valuable tool to address this problem by understanding which are the factors that contribute the most to susceptibility and finding ways to address them in the long term. In this study we adopted a landscape approach to generate new spatial configurations promoting less prone conditions to spruce bark beetle susceptibility. We simulated forest development alternatives and implemented the heuristic method simulated annealing to optimize the spatial configuration of harvest activities at landscape level. The objective is to optimize harvest activities to achieve forest conditions for lower overall susceptibility to spruce bark beetle at landscape level while achieving the largest possible financial value. Our mathematical model consists of three parts describing the development of spruce bark beetle susceptibility of the forest, and a fourth part accounting for financial value, 1) total spruce bark beetle susceptibility at landscape level, 2) distance between areas with high susceptibility, 3) size of areas with high susceptibility, and 4) net present value estimations for each management possibility. The proposed model is evaluated in a case study for Asa forest property located in southern Sweden and comprised by more than 700 forest stands and for a 50-year planning horizon. Preliminary results indicate that the model is functional and contribute to a forest with lower susceptibility against bark beetle damage. The evaluation of these results provides valuable insights into optimizing forest landscapes to reduce spruce bark beetle susceptibility.

Sustainable forest landscape planning under climate change: an interactive multi-scenario multiobjective robust approach

T5.3 Assessing forest sustainability through operations research

Babooshka Shavazipour[1]
Dmitry Podkopaev[2], Kaisa Miettinen[1]
[1] University of Jyvaskyla, Faculty of Information Technology, P.O. Box 35 (Agora), FI-40014 University of Jyvaskyla, Finland
[2] Systems Research Institute, Polish Academy of Sciences, Newelska 6, 01-447 Warsaw, Poland

Abstract: Forest landscape planning involves complex decision-making processes that encompass high dimensionality, conflicting objectives, and uncertainties from various sources. To effectively tackle these challenges, decision-makers require appropriate decision support tools. While some uncertainties, such as those arising from climate change, cannot be adequately addressed using probabilistic models, they can still be described as a set of plausible future outcomes known as scenarios. In situations where decision-makers lack information or consensus regarding the likelihood of these scenarios occurring, a condition referred to as deep uncertainty, support is needed to identify robust decisions that perform well across a broad spectrum of scenarios. Balancing tradeoffs among conflicting objectives and the uncertainties presented by various scenarios becomes crucial in this context.

We propose a novel interactive approach to address key challenges in real decision-making situations in forest management. These challenges include dealing with deep uncertainty from multiple sources and conflicts between sustainability objectives such as timber revenue, carbon storage, and biodiversity. Unlike previous approaches, the proposed approach enables decision-makers to explore various aspects of forest planning and assess objective conflicts in different future scenarios. This provides deeper insights and helps avoiding extreme losses by considering the unknown future. The interactive nature of the approach reduces complexity and cognitive load, providing a more conducive environment for decision-makers to learn about problem limitations and augment the data available with their domain expertise leading to better decisions. indeed, the tool supports finding the best balance among conflicting objectives and across scenarios. The benefit of analyzing multiple plausible future scenarios is to gain realistic insights into consequences, understand overall robustness, and ensure the robustness of the chosen management strategy to climate change and other uncertainties. We demonstrate the practicality of our proposed approach as a decision support tool through a case study of forest landscape planning with a 50-year planning horizon. It has four objectives and twelve scenarios (including climate change scenarios), showcasing the efficacy of our approach in aiding decision-makers in their complex decision-making processes.

The ease, or difficulty, of addressing forest sustainability through operations research

T5.3 Assessing forest sustainability through operations research

Pete Bettinger[1]
Çan Vatandaşlar[2], Krista Merry[1], Alba Rocio Gutierrez Garzon[3], Kevin Boston[4], Taeyoon Lee[1], Joshua Uzu[1]
[1] University of Georgia
[2] Artvin Çoruh University
[3] Independent researcher
[4] Cal Poly Humboldt

Abstract: In a perfect world, the ability to consider socio-economic and environmental conditions through operations research methods employed to develop forest plans can help society assess the potential outcomes of the forests we manage. The language employed in forest plans today often suggests sustainability will be achieved by following certain courses of action. However, the metrics employed to measure sustainability, and the functional relationships that link management actions (as represented by formal decision variables in an operations research context) to sustainability metrics are often unclear. Further, concepts regarding what is, and is not, sustainable change as our knowledge of forest systems evolves. The objective of this presentation is to illustrate the outcomes from a survey where forest planners were asked how easy or difficult it would be to incorporate real-world statements of forest sustainability into an operations research framework. Results suggest that statements regarding the sustainability of provisioning ecosystem services may be easier to confirm through operations research processes, while statements regarding the sustainability of cultural, regulating, and supporting ecosystem services may be much more difficult to confirm. Insight is provided into challenges regarding the development of the data and the functional relationships necessary to sincerely assess forest sustainability through operations research. Commentary is provided on the potential disconnect between vague statements regarding forest sustainability and the ability to prove it through mathematical modeling, and whether certain aspects of forest sustainability have been generalized to such an extent that their meaning may no longer be of value.

Tradeoffs among Wildfire Protection & Other Ecosystem Services in a Forest Management Problem with Harvest Area Constraint: A Pareto Frontier Approach

T5.3 Assessing forest sustainability through operations research

Dagm Abate[1, 2]
Susete Marques[1], Vladimir Bushenkov[3], Jose Riffo[4], Andres Weintraub[4], Miguel Constantino[5], Constantino Lagoa[6], Jose G. Borges[1]

Abstract: Forest management has broadened its scope to consider various ecosystem services, including fire protection, beyond timber production. Given the need to balance multiple ecosystem services and understand their trade-offs amidst regulatory constraints such as harvest area and timber flow over a planning period, our research applied a Pareto frontier approach for a large mixed-integer forest management problem. With this method, we analyzed trade-offs between fire-related ecosystem services (using fire resistance indicators as a proxy) and other services such as biodiversity, erosion prevention, and carbon sequestration. The resulting interactive decision maps effectively depict these trade-offs while ensuring that harvest area and timber flow constraints are not violated. We applied this approach to a forest landscape in Northwestern Portugal, yielding promising initial results that enhance our understanding of ecosystem service trade-offs in spatially optimized forest management. This paper also highlights the challenges encountered during the study and discusses potential enhancements to our methodology for future applications.

Keywords: Wildfire protection, Ecosystem Services, Trade-offs, Pareto Frontier, Spatial Constraint, Optimization

T5.4 Between synergies and conflicts: public and private forest governance initiatives in the context of turbulent times

A Decade of REDD+ in Nepal: Status and Way Forward

T5.4 Between synergies and conflicts: public and private forest governance initiatives in the context of turbulent times

Shankar Adhikari[1]

[1] REDD Implementation Centre, Ministry of Forests and Environment, Kathmandu, Nepal.

Abstract: REDD+ is a climate change mitigation strategy aiming at reducing emissions from deforestation and forest degradation in the developing countries, and the role of conservation, sustainable management of forests, and enhancement of forest carbon stocks. This paper provides a general overview of the REDD+ readiness activities to get prepared for REDD+ implementation in Nepal. Readiness activities over the past decade have been focused on the development of National REDD+ strategy, capacity building and establishment of institutional arrangements. Although most of the readiness activities have been carried out, some additional activities, including strengthening national forest monitoring system and updating forest reference level are still ongoing. A participatory and inclusive approach involving and engaging stakeholders in the REDD+ process is adopted in Nepal. After more than a decade of REDD+ readiness, Nepal has already entered into REDD+ implementation phase. Emission reduction payment agreement with the forest carbon partnership facility (FCPF) of the World Bank in 2021 has paved the way for REDD+ implementation phase. During the implementation phase, Nepal is now implementing emission reduction program at the subnational level in 13 districts of the Tarai Arc Landscape. Seven emission reduction program interventions ranging from localized and improved community-based forest management, through private sector engagement in the forestry sector and alternative energy promotion, to integrated land-use planning is being carried out in the field. Furthermore, Nepal is also working with another emission reductions program in three Provinces including Gandaki, Bagmati and Lumbini provinces under the Lowering Emissions by Accelerating Forest Finance (LEAF) Coalition. With these programs in place, Nepal will be eligible to receive result-based payments for emission reductions that will ultimately contribute to forest based climate mitigation and adaptation at the grassroot level.

Decolonial environmental justice in forest landscape restoration

T5.4 Between synergies and conflicts: public and private forest governance initiatives in the context of turbulent times

Sabaheta Ramcilovik-Suominen[1]
Susan Chomba[2], **Anne Larson**[3], Fergus Sinclair[3]
[1] Natural Resources Institute Finland, Luke
[2] World Resources Institute
[3] Centre for International Forest Research - World Agroforestry (CIFOR-ICRAF)

Abstract: Chapter accepted and forthcoming in: Restoring forests and trees for sustainable development - Policies, practices, impacts and ways forward. Editors: Pia Katila, Carol J. Pierce Colfer, Wil de Jong, Glenn Galloway, Pablo Pacheco, Georg Winkel. Oxford University Press."

This presentation focuses on gender transformative approaches and environmental justice in international landscape restoration initiatives. We depart from the three-dimensional environmental justice framework to draw from decolonial, indigenous and gender justice perspectives, placing particular attention to human-nature binaries, epistemic justice, relational ontology, self-determination, and self-governance. We highlight the embeddedness of the current international landscape restoration efforts within the (neo)colonial and neoliberal natural protection efforts, risking similar injustices, violence and forms of oppression, including epistemic and political denial and oppression, ignorance and/or erasure of local people's histories, agency, their sense of belonging and ways of knowing, as well as weakening of their rights and access over their territories and livelihoods. Some of the major barriers to effective, just and equitable landscape restoration include: (i) prioritization of global over local knowledge systems, logics and politics in global landscape restoration; (ii) targeting of small-scale drivers of land degradation over large-scale and more profitable ones; (iii) offshoring burdens of global landscape restoration on the local people's shoulders; and (iv) reliance on state authority and institutional structures and bypassing of customary and indigenous authorities and legal systems. We conclude by proposing a set of questions and conditions for policy makers and scholars to contemplate and reflect upon when designing and analysing landscape Restoration projects and activities.

Implications and Policy Insights of the EU Supply Chain Due Diligence for the Korean Forestry Sector

T5.4 Between synergies and conflicts: public and private forest governance initiatives in the context of turbulent times

Sujeong Ju[1]
Inkook Kay[2], Hee Han[1]
[1] Department of of Agriculture, Forestry and Bioresources, Seoul National University, Republic of Korea
[2] Graduate School of Public Administration, Korea University, Republic of Korea

Abstract: This study conducts a comprehensive analysis of the implications and policy insights arising from the EU supply chain due diligence directive for South Korea's domestic forest policy sector. It focuses on examining market-related due diligence obligations and legislation pertaining to the forest sector, particularly in relation to supply chain due diligence. Additionally, the study investigates various guidelines and discussions that have influenced the formulation of OECD guidelines, with a specific emphasis on the Draft OECD-FAO Handbook on Deforestation, Forest Degradation, and Due Diligence in Agricultural Supply Chains. By comparing the findings of this analysis with the current forest policies and regulatory landscape in South Korea, the study aims to understand the response of the Korean forest sector and consider potential legislative implications. Notably, certain limitations within Korea's existing systems, including the Act on the Sustainable Use of Timbers' framework for promoting legal timber trade, are revealed through this research.

Preferences of private forest owners regarding membership in the forest owners association (FOA)

T5.4 Between synergies and conflicts: public and private forest governance initiatives in the context of turbulent times

Emilia Wysocka-Fijorek[1]
Piotr Gołos[1]
[1] Forest Research Institute

Abstract: The purpose of this study is to determine the preferences of private forest owners regarding membership in the Forest Owners Association (FOA) - a case study for Poland. The intended goal was achieved by directly surveying a nationally representative sample of Polish farmers who own forests. The surveyed forest owners were offered to choose one of the four defined models of forest association organization in Poland, with the fifth option being to make their own proposal. The obtained distribution of preferences was analyzed using two log-linear models. They made it possible to explain the differences in the frequency of respondents' statements on the proposed models of forest association organization in relation to selected content variables (answers to three closed questions of the survey) and variables from respondents' statements (age, gender, and education). The survey was conducted on a representative large, nationwide random sample of forest landowners who are farmers (1003 questionnaires). The computer-assisted personal interview (CAPI) method was used, with a standardised interview questionnaire containing 16 factual questions and a survey metric. This publication provides the results that allow to indicate the preferred form of organization of associations in Poland, as well as the results of a random typology of a representative sample of forest owners (farmers) based on the preferred form of organization of associations, taking into account aspects of management of wood raw materials, as well as social variables of owners (gender, age and education). Owners of private forests in Poland agree to organize into FOAs. The preferred form of FOA depends, among other things, on the purpose of the harvested wood, the willingness to sell it, and the gender, age, and education of the forest owner. The financial situation of the owner, on the other hand, does not play a role. Based on the conducted analyzes, it can be concluded that the most beneficial solution would be to establish an association of owners in a community, working together at the district (poviat) level in Poland, which would allow forest owners to take various initiatives at the commune (local) level, including the joint sale of wood.

Reflections on forest policies in turbulent times: Hydra and Chloris worldviews

T5.4 Between synergies and conflicts: public and private forest governance initiatives in the context of turbulent times

Bas Arts[1]
[1] Wageningen University & Research

Abstract: We live in turbulent times of multi-crises: climate change, biodiversity loss, deforestation, geopolitical conflict, increasing poverty. As a consequence, demands for and pressures on forest resources are tremendously increasing. At the same time, while many expect that forest policies might make some difference in addressing these crises, various scholars consider this position as very naive and even contra-productive, because these policies are part of the problem, not part of the solution. Although such worries and ciriticism are justified, we have to be careful not to become fully caught in a 'dystopic discourse' from which we cannot escape. Terms like crises, catastrophies, fragmentation, conflict, incoherence, marginalization, power asymmetries, etc. are all taking central stage, thus funeling our worldviews into ever darker tunnels with no light at the end. Many youngsters are even getting depressed of the world they are born in recently. So, maybe we have the obligation to show that another world is possible, and partly in the making, without becoming too naive and techno-optimistic. Maybe we also have the obligation to use or add alternative terms - like challenges, diversity, alternative practices, cooperation, success - in addressing the multi-crises, or show the dialectics between contradictory concepts. In this paper, the worldviews of Hydra (dystopic) and Chloris (utopic) will be presented, after which I will analyse how these relate in a dialectic way, are to be linked to forest policies, and how both are - at least in my view - legitimate positions. With the aim to bring at least some light at the end of the tunnel...

Synergies and conflicts in dynamic dialogues for shared forest governance between the Cree nation and the Quebec state in Eeyou Itschee, Canada.

T5.4 Between synergies and conflicts: public and private forest governance initiatives in the context of turbulent times

François-Xavier Cyr[1]
Stephen Wyatt[2], Martin Hebert[1]
[1] Université Laval, Canada
[2] Université de Moncton, Canada

Abstract: Forest governance, long seen as either a state or private role, is increasingly recognised as a shared responsibility involving a variety of actors, from the local to the international. In *Eeyou Itschee*, traditional Cree territories in north-eastern Canada, new forest governance initiatives engage the Cree, the Quebec provincial government, private forestry companies, non-Cree communities, and the broader national society. We analysed the dialogue between the two key actors, the Cree and the Quebec state, since 2002 as they developed a new forest governance framework to accommodate multiple and often conflicting goals. In common with many modern states, Quebec has a strong centralized framework of policy and legislation for managing forests, that is not easily reconciled with the Cree's own values, knowledge, and aspirations, nor with their expectation for a redistribution of power in respect of their traditional rights.

In this poster we present key findings about the nature of this relationship, seeing it as a series of dynamic dialogues, themselves assemblages of practices and processes. We identify five clusters of practices that are used in differing ways in multiple processes, and with varying outcomes: distinct representations of the landscape; trickling-down of policy debates into "technical" issues; competing knowledge systems; a bureaucratic logic; and the role of gaps and bridges in collaboration. This can best be understood as a tapestry, where threads of varying colours represent different practices intersecting in different patterns or designs. The Quebec state, with greater resources and power, has more influence over these patterns and designs, although the Cree have made significant progress towards their own goals and Quebec has not obtained all it wants. This presentation shows that the distinction between synergy and conflict is not always clear and that the design and implementation of policies that respect the positions of parties is a challenging process.

Synergies or conflicts between international forest-related governance initiatives? Setting the scene

T5.4 Between synergies and conflicts: public and private forest governance initiatives in the context of turbulent times

Lukas Giessen[1]
[1] TU Dresden

Abstract:
This contribution to the round table will discuss international forest governance regimes based on my experience in political studies and tropical forestry
This contribution aims to take stock of recent and emerging forest governance initiatives at international scales, which have emerged as a response to various challenges and crises. In particular, it addresses forest-focused as well as forest-related public and private initiatives from climate change, biodiversity, indigenous rights, ecosystem restoration and bioeconomy policy realms. In a round table format, this contribution discusses the extent to which these initiatives and their policy instruments converge or contradict in their goals, theories of change, and expected effects on the ground. It will elaborate to what extent these initiatives might contribute to problem- and crises-solving, or on the contrary, will only remain symbolic entities. Their further potential impacts will be scrutinized, including on e.g. forest ecosystem service supply, trade and market organization as well as the relation between priced vs. non-priced services.

The forestry sector in turbulent times: towards a 're-concentration' of governance centers and capacities?

T5.4 Between synergies and conflicts: public and private forest governance initiatives in the context of turbulent times

Davide Pettenella[1]
Aynur Mammadova[1], Mauro Masiero[1], **Laura Secco**[1], Todora Rogelja[1]
[1] TESAF Dept. - Univ. of Padova - Italy

Abstract: Policymakers have recently introduced strong normative frameworks and new policy tools to support a transition toward a climate-neutral and just society, and numerous private and market initiatives were and are being developed. However, new and forthcoming policies (e.g., EU Green Deal, Sustainable Development Goals, Bonn Challenge on Forest and Landscape Restoration, New York Declaration on Forests, REDD+, EU Deforestation Regulation, US Forest Act, and others) have contradictory goals with respect to the increase of forest coverage, use of forests for biomass production to support bioeconomy, biodiversity protection, and carbon sequestration. Contrasting demands are affecting the use of forest resources, increasing the risks of conflicts over ownership, management, access, and land use rights. The implementation of the new policy instruments will have large implications for individuals and organizations, markets (e.g., shifting trade patterns), and societies (e.g., raising inequalities), and beyond. If not designed and implemented carefully, this can lead to conflicting requirements of different policy instruments themselves, as well as among policy instruments and private sector and civil society initiatives. These new policy instruments should also carefully consider their potential impact on small producers, indigenous and traditional communities, thus avoiding replicating the power patterns that have put them in unfavourable and marginalized positions. Finally, the stakeholders living in and managing forests should be closely engaged in the process of the design and implementation of policy instruments, to avoid sentiments of new colonialism, and thus achieve 'true' participation and deliberation.

For all these reasons, a 're-concentration' of governance centres and capacities is much needed soon. But how are the new forest-policy discourses practicable considering our turbulent times and the need to balance environmental protection and decarbonisation with the associated increase in biomass production? How can power be redistributed to support a "just, sustainable, and green" society, considering the emergence of new needs and technologies? The paper will reflect on all these driving forces, suggesting principles and priorities for policy action.

The Impact of Environmental Regulations on the Power Dynamics of Third-Party Environmental Standards: The Case of the European Environment

T5.4 Between synergies and conflicts: public and private forest governance initiatives in the context of turbulent times

Aynur Mammadova[1]
Luiz Henrique Cosimo[1], Mauro Masiero[1], Todora Rogelja[1], Davide Pettenella[1], Laura Secco[1], Jelle Behagel[2], Verina Ingram[2]
[1] University of Padova
[2] Wageningen University & Research

Abstract: In recent years, regulatory actions have increased at the European Union (EU) level on different issues in response to public requests for an increased EU commitment to a greener and a just future. The growing number of environmental regulations shows the growing ambition of the EU as an environmental regulator and an important player in global quality standards of environmental performance. However, the governance implications of these new legislative acts individually and in relation with each other have not yet been studied.

An example is provided by the European Regulation on Deforestation-Free Products (EUDR) approved in 2023, whose requirements for due diligence and control for cattle, cocoa, coffee, palm oil, soya, natural rubber and wood products entering the EU market are becoming stricter than those of private standards in the relevant sectors. These changes influence the position and power of Voluntary Sustainability Standards (VSS) enacted since the 1990s, with the aim of primarily filling policy and regulatory gaps, that also influenced the landscapes and governance regimes in origin countries. It is not clear whether these VSS will adapt to the new policy and governance arrangements, remain relevant or simply disintegrate. Despite the generally welcoming attitude of private standards towards the new Regulation, the nested interests of various stakeholders in VSS suggest that the transition might be challenging and costly. This research seeks to explore the changes in power dynamics in Europe surrounding the topic of sustainable and deforestation-free forest management and agriculture. First, we take the EUDR as a case study and compare its criteria and requirements with those of prominent private standards in each of the commodity sectors. Second, to understand the narratives of adaptation, we present the discourse analysis of the public documents as well as of the interviews with the representatives of VSS. Our preliminary conclusions indicate that private standards and related enterprises will still play an important role in sustainable forest management and commodity markets, but their role is increasingly contested by origin states. Significant changes in their criteria and requirements are necessary to maintain the relevance in view of the newly adopted EU regulation.

The Wood Solution—Creating a high-value timber industry in the Global South

T5.4 Between synergies and conflicts: public and private forest governance initiatives in the context of turbulent times

Rosa Goodman[1]
Berty van Hensbergen[2], Klas Bengtsson[2], Aaron Kaplan[2]
[1] Swedish University of Agricultural Sciences
[2] Eco-Innovation Foundation

Abstract: There is a serious disparity between high-value bio-economy solutions proposed in the global North (ie, CLT and mass timber buildings) and those proposed in the Global South (ie, beekeeping and other non-timber forest products). Given the dominant paradigm of tropical forestry, it is understandable that many environmentally and socially-conscientious people and organizations have shied away from engaging with timber production in tropical countries with developing economies. However, another model of management is possible for natural tropical forests—if we change the industry outside of the forests. Not only is it possible, it is necessary to transform the tropical timber industry or we will lose the immeasurably valuable natural tropical forests to more profitable land uses.

We theorize that the unsustainable nature of tropical forests begins with the market for large, standard dimensional timber, primarily for export. This model relies on harvesting the largest, best formed trees of a few well-known species from nearly pristine forests and degraded them with each harvest. Very little value is added in country; and it requires little transparency, so illegal logging is rampant. However, with an integrated and adapted industry, this trajectory can be transformed. If the final products are known in advance, it becomes possible to harvest timber from forests that would otherwise be deemed degraded and restore them through active management. This is made possible through adaptive small- and medium-scale timber processing systems—the often-ignored link between forests and forest products.

To be implemented at scale, this model needs to be genuinely enticing to rural and regional entrepreneurs and forest managers. Our analysis shows that over 3 times more value can be created with an integrated system across the value chain. Forests could gain 10 times their value, through increased productivity and timber quality. Operating margins in the local sawmills can increase nearly 28 times with an optimal mix of products and markets. Mass timber building is completely possible in tropical environments. Tapping into the $US10 trillion year^{-1} construction and engineering industry[87] could serve as a massive market driver for large-scale forest restoration and management and the creation of a new, regenerative industry.

Transnational timber legality and deforestation policy changes in the EU, UK, USA and China, and their implications on tropical countries

T5.4 Between synergies and conflicts: public and private forest governance initiatives in the context of turbulent times

Metodi Sotirov[1]
[1] University of Freiburg, Germany

Abstract: In my talk, I will present policy science results on the development and implementation of the transnational Forest Law Enforcement, Governance, and Trade (FLEGT) and new set of deforestation free regulations. I will show both stabilty and changes in the rules governing legality and sustainability, and point out both trade-offs and synergies between a range of regulations in the EU, UK, USA and China. I will conclude with offering a summary on the implications of the variety of transnational regulatory standards for market leackage and distortions on the global markets.

Voluntary carbon market in land use in the sector - development, demand and measures in Finland

T5.4 Between synergies and conflicts: public and private forest governance initiatives in the context of turbulent times

Jani Laturi[1]
Laura Aalto[1], Sari Forsman-Hugg[1], Paula Horne[1], Anna Laine[2], Pekka Kinnunen[1], Olli Korhonen[1], Päivi Kujala[1], Kirsi Noro[1], Iris Mäntylä[2], Matti Valonen[1]
[1] Pellervo economic research PTT
[2] Gaia Consulting

Abstract: It is predicted that voluntary carbon markets will experience significant growth in the future due to companies' carbon neutrality goals and increased awareness of climate crisis. Voluntary carbon markets offer companies the opportunity to offset emissions of their operations that cannot be otherwise reduced in the short term.

This report examines potential mitigation activities in agriculture and forestry in Finland. The report also evaluates factors related to the demand and supply of carbon credits, the impact of legislation on voluntary carbon markets, and the implications of voluntary carbon market growth on the forest and agricultural value chains. The report also addresses consumers' and companies' perspectives on purchasing and using carbon credits, as well as landowners' and farmers' willingness to participate in voluntary carbon markets. The findings of the report are based on a literature analysis, expert and company interviews, and a consumer survey.

The results indicate that consumers may perceive carbon offsetting as greenwashing, and there is significant uncertainty surrounding voluntary carbon markets. Consumers' attitudes towards voluntary carbon markets and offsets influence the actions of companies and the demand for mitigation outcomes. There are challenges in demonstrating the additionality and permanence of mitigation outcomes for domestic projects, particularly concerning mitigation activities that increase raw material production. While companies value domestic mitigation activities, the lack of standardization and the issue of double counting of mitigation outcomes restrict their purchasing.

Creating a voluntary carbon market that simultaneously serves the goals of consumers, companies, producers, and society is challenging. The objectives of stakeholders in voluntary carbon markets are partially conflicting. Although reaching compromises is not mandatory as participation in the markets is voluntary, finding compromises is crucial for market development and climate change mitigation. Thus, the voluntary carbon markets can grow, and more carbon dioxide can be absorbed from the atmosphere.

T5.5 Climate Action in Forest Education

EduFire Toolkit: A new teaching resource for secondary schools in a world with a changing climate and growing risk of wildfire.

T5.5 Climate Action in Forest Education

Renata Martins Pacheco[1]
Catarina Sequeira[1], Iryna Skulska[1], Helena Ballart[2], Núria Prat[2], Jordi Vendrell[2], Guillem Canaleta[2], David Martin[2], Laura Gracia[2], Míriam Arenas[3], Clàudia Torrens Flores[3], Finian Joyce[4], Israel Rodriguez[3], Maria Cifre-Sabater[3], , Conceição Colaço[1]
[1] Center for Applied Ecology Prof. Baeta Neves - University of Lisbon
[2] Pau Costa Foundation
[3] Open University of Catalonia
[4] Leitrim County Council

Abstract: In the context of a changing climate, wildfires are among the most critical social, economic, and environmental challenges that many societies are experiencing worldwide. Information and education are essential to increase community preparedness and to properly manage forest ecosystems and landscapes, increasing their wildfire-resilience.

Having identified this educational need, the Pau Costa Foundation (Spain) joined efforts with the Open University of Catalonia (Spain), Leitrim County Council (Ireland), and the School of Agronomy of the University of Lisbon (Portugal) to address this need through an Erasmus+ project. The EduFire Toolkit (Educational Toolkit for Secondary Schools in Wildfires and the Climate Change Context) is a set of multidisciplinary educational resources that address the socioeconomic and environmental complexities related to wildfires. This toolkit follows a Project-based Learning (PBL) approach and comprises activities that promote school community engagement. It targets secondary school teachers and students (ages 12-16) and provides educational material and activities dealing with real and local issues related to climate change and wildfire risk reduction or its mitigation.

The EduFire Toolkit content encompasses multiple disciplines and European educational competencies, addressing fire, wildfire, culture, and climate change concepts. Challenges with various activities demonstrate how these issues are interrelated and promote student participation and engagement. The PBL approach stimulates students to gain knowledge and skills by developing challenges that deal with real-life problems. All the materials and resources developed by this project will be open-access. These materials can be used to complement existing teaching materials, facilitating schools in addressing the issue of climate change with an emphasis on wildfire risks.

The final EduFire Toolkit content will result from a collaborative effort between the four project partners, teachers, students, and local communities. An extensive literature review on wildfire educational materials available online was conducted and was combined with every partner's technical expertise. Finally, an Advisory Board composed of education and wildfires specialists worldwide will review all the content created before pilot tests are conducted in each partner country, and final adjustments are made. The EduFire Toolkit will help our next generations to become more aware of climate change impacts and increase their wildfire preparedness.

Broadening forestry education to tackle the climate crisis

T5.5 Climate Action in Forest Education
Rocio Danica Condor Golec[1]
Anssi Pekkarinen[1]
[1] Food and Agriculture Organization of the United Nations (FAO)

Abstract: Transparency helps build mutual trust and accountability and encourages countries to increase their climate ambition over time. Boosting the transparency of forest data for climate action will be vital to supporting the enhanced transparency framework (ETF) under the Paris Agreement. The Food and Agriculture Organization of the United Nations work towards enhancing and strengthening the capacity of developing countries to collect, analyze and disseminate forest-related data to meet the ETF.

To date, raising awareness of the evolving climate landscape – particularly, the transparency-related aspects of the Paris Agreement – has been supported by the Capacity-building Initiative for Transparency (CBIT) trust fund. The FAO and the Global Environment Facility (GEF) have collaborated on the project, Building global capacity to increase transparency in the forest sector (CBIT-Forest), to make forest data more transparent, accessible and available, in line with the ETF requirements.

Since 2020, the FAO Sub-Commission of the International Forestry Students' Association (IFSA) and the FAO Forestry Division (NFO) have collaborated to ensure students and young professionals can access educational transparency-related material. For example, the self-paced eLearning courses and the three editions of the massive open online courses, all in multiple languages. This has allowed more equitable access to forest and transparency-related knowledge with almost 40% participation of women in the online courses. More recently, a series of IFSA-FAO webinars organized on "Forests and Climate Transparency" has shared knowledge resulting from the forest and transparency case studies of Asia, Africa and Latin America regions.

It is crucial to make transparency-related efforts and knowledge visible and inform students and young professionals. This knowledge will empower them to help adapt local knowledge and practices to a changing world.

Emerging opportunities for forestry education through strengthening climate change curricula

T5.5 Climate Action in Forest Education

Regan Pairojmahakij[1]
David Ganz[1]
[1] RECOFTC

Abstract: Climate change is the global challenge of our era and is an existential threat. In a survey in the United Kingdom earlier this year, about a third of young people are scared, sad or pessimistic about climate change, with more than a quarter feeling overwhelmed. Given that the youth of today stand to suffer the worst effects of climate change in coming decades, this makes sense. This deep rooted and evidence backed source of concern can serve as a powerful trigger for action and for mobilizing a growing cohort of activists, scientists, advocates and voters. At the same time, there is a disconnect between the sense of urgency being experienced by global youth around climate change and the relevance and emphasis being placed on climate change in international educational curricula. While climate change and the science around it is moving rapidly, curricula and educational programs are updating materials to reflect climate realities at a much slower pace. For FAO in 2020, RECOFTC undertook a regional assessment of forest education in Asia Pacific. The findings based on extensive surveys concluded that 'forest jobs have an image problem' and that forestry education could be considered to be suffering from a growing gap with contemporary interests of students and youth, including direct exposure to forests, inclusion and gender sensitivity, and generally failing to incorporate critical issues of the time such as climate change. This panel presentation will outline some of these challenges and the role that embedding climate change more meaningfully within more adaptive curricula development processes could contribute to significantly revitalizing the forestry education sector.

Global Virtual Seminar in the MSc EF programme – A joint effort of six European universities to include SDGs and climate education in the curriculum

T5.5 Climate Action in Forest Education

Marjoriitta Möttönen[1]
Lucian Curtu[2], Meriem Fournier[3], Heinrich Spiecker[4], Timo Tokola[1], Harald Vacik[5], Cristina Vega Garcia[6]
[1] University of Eastern Finland
[2] Transilvania University of Braşov
[3] AgroParisTech
[4] University of Freiburg
[5] University of Natural Resources and Life Sciences, Vienna
[6] University of Lleida

Abstract: MSc in European Forestry (MSc EF) is an accredited double-degree Erasmus+: Erasmus Mundus MSc programme jointly organised by six universities: University of Eastern Finland, AgroParisTech, University of Freiburg, University of Lleida, University of Natural Resources and Life Sciences Vienna, and Transilvania University of Braşov. All partner universities collaborate intensively in the programme delivery by offering joint study modules in addition to their existing curricula. In addition, Associated Partner universities in Brazil, Canada and China and Associated Industrial and Scientific Partners contribute to the programme delivery. The aim of the programme is to provide academic education in the field of sustainable resource management with special emphasis on bioeconomy and climate change knowledge. Global Virtual Seminar (3 ECTS) is one of the jointly organised courses included in the curriculum to complement climate action education for students of the programme. It is introduced here as an example of good practise on how to involve several universities in organising a joint course, how to include SDGs and climate education in the curriculum and how to provide students coming from different cultural backgrounds with good skills in project management, time management and communication in a digital, online environment. After this course, students will have a global view about the SDGs with a special focus on the chosen topics and have improved their knowledge and resources to tackle climate change. In addition, Keynote Talks by experts from the Associated Partners in the final seminar provide feedback for each student project and bring additional value by highlighting the importance of evaluating SDG's in a global context. The project work within multicultural groups and lasting for the whole academic year improves students' project management, teamwork, critical thinking, leadership, data management, communication and time management skills and teaches them responsibility to carry out long-term projects which are the skills that are very much appreciated in the working life. In addition, they will be familiar with the SDGs and recognize the factors and strategies that can be used in tackling climate change and in working to preserve our environment.

IFSA TreE-Learning - Climate education for all!

T5.5 Climate Action in Forest Education

Jair Granados-Chacón[1, 2]
[1] International Forestry Students' Association (IFSA)
[2] Instituto Tecnológico de Costa Rica, School of Forest Engineering, Costa Rica

Abstract: With the increasing threat and importance of climate change, many sectors, including forestry will need to undergo significant transitions to adapt. This will require a competent and well-trained workforce to face the climate-related challenges of the future. Currently, the topic is not well addressed in higher education curricula and the resources available are very limited. The TreE-Learning platform provides an innovative alternative to fill this gap and complement climate-related education in forestry studies.

During the period 2023/2024, we created three learning modules focusing on climate-related topics for the purposes of the TreE-Learning platform:

1. Wood Energy and forestry By-Products Potential. The module provides extensive information on renewable energy and forest by-products as a source of energy to combat climate change.
2. Soil Health and Land Recovery. This module focuses on the potential of agroforestry systems to restore soils and increase their productivity and carbon sequestration.
3. Forestry on Peatlands. Provides insights on practical forest management applications to achieve sustainable timber production in peatlands.

The results presented will include the number of students who have taken the modules, the regional and gender diversity of the students, and their feedback on how the modules contributed to their existing knowledge and formal education.

School forest Carolinum: where the next generation shapes the forest of the future

T5.5 Climate Action in Forest Education

Alexa Beaucamp[1, 2, 3]

Abstract: While the young generation will be strongly confronted with the consequences of climate change, education curricula still do not sufficiently incorporate knowledge about mitigation and adaptation strategies. Besides the need for well-structured educational material within forestry degrees in the tertiary education, there is a strong lack of climate and forest related knowledge transfer within secondary education curricula as well. Education programmes are needed to counteract the resulting stigmatised images of the forestry sector, the increasing disconnection of young people with the natural environment (Aruguete et al., 2020) and to prepare young adults how to address future environmental challenges effectively (Bradley, et al., 1999).

The pilot project School Forest Carolinum aims to address the above-mentioned problem and actively integrates students into the sustainable management of existing forest stands, open sites and lakes (overall around 2500 hectares) in Northern Germany. The programme focuses on the interrelations between forests and climate change and uses an approach based on citizen science, stewardship and interdisciplinarity. This does not only encourage students to develop a strong feeling of responsibility for "their school forest", but it also promotes a project-based, scientifically-oriented educational approach to enhance students' knowledge and awareness about the various interconnections of forests and climate change. While more recent forest school projects also involve the planting of trees to combate climate change (Schröer and Sauerwein, 2014), our project extends this form of climate action to a *long-term climate change mitigation and adaptation project* with students. Informed by forests and climate science, students will support i.a. the transformation of pine monocultures into more climate-resilient mixed forests in cooperation with practitioners and scientists. This responds to the issue that environmental education programmes often do not adequately address the complexity and interrelation of specific environmental problems and do not offer concrete opportunities for participants to become active (Hudson, 2001; Davis, 2003). As an innovative and new interpretation of forest schools, the project also contributes to global aspirations of more sustainable forest management. This presents a prospect important for policy makers and other stakeholders, striving for collective climate action and coherent education programmes for students of all ages.

The European Regulation on Deforestation-free Products: The importance of Education and Training of experts in the Implementation of the Regulation

T5.5 Climate Action in Forest Education

Jacopo Giacomoni[1]
Aynur Mammadova[2], Colm O'Driscoll[1], Nicola Andrighetto[1], Elena Massarenti[1], Helena Leonel Ferreira[1], Sofia Marzolo[1], Todora Rogelja[2], Mauro Masiero[2], Davide Pettenella[2], Laura Secco[2], Metodi Sotirov[3], Jelle Behagel[4]

[4] Wageningen University - Department of Environmental Sciences - Netherlands

Abstract: Within the framework of the Green Deal the European Union is developing a broad range of regulatory and policy initiatives on environmental and sustainability issues. However, new regulations challenge present and future practitioners within targeted sectors putting them in need of specific guidance to cope with normative requirements. To facilitate a green transition, a fair access to green skills across vocational education and training systems is needed. In the EU, training uptake has been increasing, but is still considerably below the target for 60% of the adult population to participate in training each year by 2030, as set by the European Pillar of Social Right Action Plan.

The European Regulation on Deforestation-free Products approved in 2023 provides the latest example of a regulatory instrument for enforcing sustainable forest management. The new Regulation implies overcoming new challenges and investments into preparing professionals and practitioners who can properly understand the requirements and support the process of its enactment. The training of new experts will be crucial in supporting the public and private sectors in preparation, adaptation, and application of the best available tools for the compliance with this Regulation. This will need to involve education and training of students and professionals, as they will need knowledge, skills, and entrepreneurial mindsets on the adaptation of existing practices, as well as promotion, development, and implementation of emerging solutions from policy, research, and practice. With this in mind, the Erasmus+ project Innovation Alliance for Training Programmes for Deforestation-free Supply chains in Europe (EMMA4EU) responds to the emerging needs for new green, transversal, resilience and digital skills and qualifications in international education and training curricula to meet emerging professional needs for deforestation-free economies and sustainable development. We will present how the project aims to fill the identified gap by studying the training, awareness and knowledge needs, and developing a specialised training program for the relevant stakeholders, within its lifetime 2023-2026, and share preliminary results emerging from the early phases of project implementation.

Tranformative learning for climate action in forest education

T5.5 Climate Action in Forest Education

Steve Makungwa[1]
Michael Kleine[2], Janice Burns[2]
[1] Centre for Appplied Systems Analysis (CASA)
[2] International Union of Forest Research Organizations (IUFRO)

Abstract: Climate action is transdisciplinary in nature. There is a growing need for transdisciplinarity learning in forest education in order to develop professionals that can integrate knowledge and skills from multiple disciplines to address problems around climate change that cannot be tackled effectively by a single discipline. The advantage is significant as students get to develop a diverse set of skills and perspectives, as well as the ability to work across disciplinary boundaries to address complex problems of climate change. The gradutaes are, therefore, well-positioned to pursue careers in a variety of fields that require an understanding of multiple disciplines, including climate action. How does a curriculum that produces such professionals look like? A case of Malawi.

T5.6 Continuing Challenges and Novel Solutions: Adapting Growth and Yield Modelling to the Global Change Paradigm

A climate-sensitivity study of hybrid poplar plantations

T5.6 Continuing Challenges and Novel Solutions: Adapting Growth and Yield Modelling to the Global Change Paradigm

Ning Liu[1, 2]
Jan Van den Bulcke[1], Xiaohua Su[2], Qinjun Huang[2], Joris Van Acker[1]
[1] UGent-Woodlab, Laboratory of Wood Technology, Ghent University
[2] Research Institute of Forestry, Chinese Academy of Forestry

Abstract: Poplars (*Populus spp.*) are one of the most important fast-growing timber species in the temperate world, and their sensitivity to climate is of great interest to breeders. However, breeders often select by genotype and environment interaction, and rarely carry out large-scale 'climate-growth' modeling. Most of the current research on climate sensitivity is carried out in the field of ecology, and the modeling object is more of a tree species, which is difficult to accurately reach the species Section or clone level. Unlike natural forests, poplar plantations have little variation in age, planting density, tree genetics, etc., and can better focus on climate response.

The poplar plantations in this study are distributed in typical climatic zones of China and Europe, including 14 Köppen-climate types in temperate and subtropical zones. The experimental materials were poplars of the *Sect. Aigeiros, Sect. Populus* and *Sect. Tacamahaca* that were more than 10 years old. After drilling the wood core at each site, X-ray scanning is used with equipment from Woodlab and UGCT of Ghent University. The annual growth of tree rings is correlated with historical meteorological data. The sampling will be completed in China by October 2023 and in Europe by summer 2024. At the same time, soil data, survival rate and other plantation parameters are quantified and added to the model. Climate-sensitive analysis are used in linear mixed models or Bayesian models. It is the intention based on modelling to predict poplar timber production in 2050 can be predicted using future climate predictions.

A New Approach for Modeling Stand Height Development

T5.6 Continuing Challenges and Novel Solutions: Adapting Growth and Yield Modelling to the Global Change Paradigm

Jan Schick[1]
Matthias Albert[1], Matthias Schmidt[1]
[1] Northwest German Forest Research Institute, Department of Forest Growth, Germany

Abstract: Climate Change leads to rapidly shifting environmental conditions, which influences the future suitability of currently established tree species. When determining the optimal composition of tree species for different management goals, stand height growth is one of the driving factors. Though it's is most prominent in economic analyses, it can also be used to assess carbon storage or, as auxiliary variable, for windfall risk.

Losing site consistency implies, that future stand growth potential changes, as well. This calls for management tools, which can estimate stand growth in a changing environment. We present a new approach for statistical, site-sensitive models, to estimate stand height at any age under a broad range of environmental conditions for several species, including European beech, Norway spruce and Scots pine.

Our models are based on a growth curve, i.e. a modified, linearized Korf function, such that all obtained predictions follow a biologically plausible pattern. The data we use for parameterization is a unique novelty, a combination of state-space and space-for-time data, i.e. research plots and inventories from several sources. From this data, we can derive both a longitudinally feasible pattern as well as plausible model effects over a broad range of environmental conditions.

As dynamic environmental variables, we consider temperature, precipitation and nitrogen deposition. These are calculated as a weighted mean of sums for the annually determined vegetation period. As weights, we use species specific growth functions. Moreover, we use soil characteristics and location as static variables.

To combine the longitudinal characteristics with a broad amplitude of covariates, a two step approach is necessary: First, we derive the basic shape of the Korf function from the state-space data with a mixed model. Then, we use this shape in a generalized additive model (GAM) with the full data to estimate effects for the continuous and categorical covariates. Thus, we are able to dynamically predict stand height for the whole stand life under changing conditions, without the need for initial height measurements.

In the presentation we will show characteristics and traits of the novel data set, the models themselves and applications.

A Novel Construction Principle for Yield Tables – combining recent observations and growth simulation data

T5.6 Continuing Challenges and Novel Solutions: Adapting Growth and Yield Modelling to the Global Change Paradigm

Matthias Albert[1]
Jürgen Nagel[1], Matthias Schmidt[1], Ralf-Volker Nagel[1], Hermann Spellmann[1]
[1] Northwest German Forest Research Institute

Abstract: Yield tables are still a useful tool for forest planning in many parts of the world, in many cases even without alternative planning instruments. But many of the presently used yield tables are outdated looking at the underlying growth dynamics or silvicultural management concepts. The empirical data foundation to construct yield tables traditionally relies on long-term experimental research plots.

However, observations from experimental plots measured in periods of the far past cannot be used to derive the common yield table attributes as changing site conditions due to climate change, depositions etc. result in shifts of growth dynamics. On the other hand, using only recent data as a consequence will result in a heavily reduced data set not being sufficient to derive a yield table in most cases. This issue is exacerbated looking at the prerequisite to have balanced data over site index and age.

Therefore, we developed a novel construction principle for yield tables combining recent empirical research plot data with growth simulations using a single-tree growth simulator. The empirical data ensures realistic starting values for the simulator. Applying growth simulation provides growth data at the current increment level and widens the data set as each simulation stand is projected for a 30-year time period. The new yield tables are derived for Sessile and Pedunculate oak, European beech, Norway spruce, Douglas-fir and Scots pine. They are valid for northwestern Germany. However, the new construction principle can be applied universally to other species and world regions.

Although the resulting yield tables are not sensitive to future climate change they can be applied for their primary use, i.e. giving decision support in forest planning for the next 10 to 20 years. Envisaged future updates of the yield tables ensures adaptation to changing climate.

Climate Sensitive Mortality and Growth Modelling in Québec

T5.6 Continuing Challenges and Novel Solutions: Adapting Growth and Yield Modelling to the Global Change Paradigm

Christina Howard[1]
Bianca Eskelson[1], Mathieu Fortin[2]
[1] The University of British Columbia - Department of Forest Resources Management – Faculty of Forestry
[2] Canadian Wood Fibre Centre – Canadian Forest Service - Natural Resources Canada

Abstract: Evaluating and implementing forest management strategies relies on forest managers having accurate and reliable climate-sensitive forecasts of where particular tree species are likely to survive and grow. However, current operational growth models are not fully climate-sensitive or only consider a limited number of species. My research focusses on modelling mortality rates for 29 individual species and 4 species groups in Québec, Canada, using 190,475 non-overlapping intervals measured over the period 1970-2018 in about 12,000 permanent sample plots.

Individual tree mortality was predicted with a generalized linear model (GLM) based on a complementary log-log (CLL) link function. Tree and plot-level variables along with disturbance variables were tested as potential variables in reference models. Enhanced models were built to include climate variables and were compared to the reference models in order to quantify the improvement in the model fit. These models of mortality will be used as a component to build a climate-sensitive individual-tree growth simulator for Québec.

Effects of functional traits on tree growth rates - now we know

T5.6 Continuing Challenges and Novel Solutions: Adapting Growth and Yield Modelling to the Global Change Paradigm

[2] Leiden University, Institute of Environmental Sciences (CML), Netherlands
[3] Université de Sherbrooke, Department of Biology, Canada

Abstract:
Ensuring the sustainability of goods and services provided by forest ecosystems in the face of global change implies understanding the mechanisms underlying tree growth and being able to predict their relative influence across taxa and biogeographic environments. Functional ecology suggests that mechanisms affecting resource acquisition operate through differences between individuals that can be estimated from their functional traits. However, previous attempts to link traits to the individual growth rates of trees have shown that the most commonly accessible traits only explain a small portion of their growth. Furthermore, these small effects are inconsistent across studies and environments. In our study, we tested the relationship between the height growth rate of 35 tree species and 6 functional traits (specific leaf area, wood density, seed mass, leaf dry matter content, leaf nitrogen content, and photosynthetic capacity). Trees were planted in monoculture plots in common garden experiments, minimizing the influence of biotic and abiotic factors across seven sites of the IDENT network of experimental plots in North America and Europe. The individual height growth of each tree species was calculated considering several time intervals following planting over an 8-year period. Species-specific functional traits were identified by generating averages of individual values from the TRY database and the literature. Bayesian generalized mixed models were parameterized to predict growth as a function of the traits. Our results showed that functional traits have a slightly greater effect in the early years of growth, and those occupying a distinctly more important role in the first years of growth are subsequently replaced over time. Moreover, the magnitude of the effects exerted by these traits varies markedly between deciduous and evergreen species. We argue that the wide variation in the values of certain traits between deciduous and evergreen trees can mitigate the effects of traits on growth and highlight the importance of assessing trait effects for these two groups separately. Our results provide forest managers with reliable trait effects that will be useful for better predicting and managing the performance of planted and managed forests in tackling global change.

Empirical growth modelling in the Swiss National Forest Inventory: developments, achievements and challenges

T5.6 Continuing Challenges and Novel Solutions: Adapting Growth and Yield Modelling to the Global Change Paradigm

Brigitte Rohner[1]
Marco Ferretti[1], Jeanne Portier[1], Golo Stadelmann[1], Roman Flury[1], Esther Thürig[1]
[1] Swiss Federal Institute for Forest, Snow and Landscape Research, WSL

Abstract: Understanding tree growth dynamics is crucial in economic, ecological, and socio-political contexts and has implications for forest development scenario analyses and management strategies. Traditional empirical models for basal area increment (BAI) typically rely on basic tree, stand, and site information, assuming constant environmental conditions. Recognizing the urgency to incorporate (a) effects of environmental change and (b) more complex stand dynamics, the BAI modelling based on forty years of Swiss National Forest Inventory (NFI) data has undergone a variety of advancements over the recent years.

Regarding environmental change, initial efforts focused on incorporating temperature, drought, and N-deposition effects into empirical BAI models using a space-for-time substitution approach. We specifically optimized the definition of climatic variables by complementing NFI with tree-ring data. Findings indicated that using mean values of temperature and precipitation rather than extremes and considering whole-year or spring information, rather than vegetation periods, is advisable for capturing climatic effects on decennial BAI measured in the NFI. Further model developments specifically involved interactions, particularly between drought and N-deposition. Additionally, while studying the effects of the severe 2018 drought on a sub-selection of NFI plots, we found that compared to decennial intervals between inventories, annual remeasurements improved the quantification of drought effects on growth.

Regarding more complex stand dynamics, we found that mixed forests can promote BAI compared to monospecific stands, depending upon stand, topographic, climatic, and soil conditions. Furthermore, by combining NFI data collected on plots smaller than typical forest stands with growth and yield data, growth partitioning was investigated, i.e., the relative contribution of differently sized trees to total stand growth. Currently, our research makes use of the long-term nature of NFI data, which provides a unique opportunity to study temporal growth trends at regional and national scales, providing crucial insights into global change effects.

Our research revealed the great potential of NFI data for empirically modelling growth dynamics, as well as pathways to complement NFI with other data sources for further improvement of targeted growth-related research.

Environmental filtering of forest inventory data to incorporate climate response in site-based carbon capture models

T5.6 Continuing Challenges and Novel Solutions: Adapting Growth and Yield Modelling to the Global Change Paradigm

Koen Kramer[1, 2]
Marco Van der Heijden[1], Ysbrand Galama[1], Veronica Nooijen[1]
[1] Land Life Company
[2] Wageningen University and Research

Abstract: Reforestation projects are increasingly funded by parties aiming to compensate for their CO2 emissions. These projects are paid for *ex-ante* based on the projected CO2 capture over a 40-year period. Accurate projection of the carbon capture of the potential reforestation of a site is thus of key importance for decision making on the financial viability of the project.

We developed a multi-species carbon capture model which is data-driven and globally applicable for site-level decision making on reforestation. The structure of our model is based on IPPC higher-tier approaches, expanded with competition for space between the tree species. The accuracy of this model is determined by calibrating the model to growth and yield data considered to be representative for the future growth conditions of the site. This is attained in a 3-stage process:

1) filtering national forest inventory data (NFI-data). We compiled both NFI-data (currently: US, Canada, Australia, Iberia, Iceland), and environmental data (among others: current and projected climate, soil type, elevation, elevation). NFI plots, containing the same species as planted, are selected if they fall within preselected ranges in the environmental data and distance to the planting site,

2) calibrating site-specific model parameters to the filtered NFI-data. We developed a user-interface allowing the user to select state-variables and several goodness-of-fit statistics to find the best model fit to the filtered data. The outcome of this step are optimal parameters and a covariance matrix on the variability and correlation structure between the model parameters,

3) applying the model and reporting its outcome. The optimal model parameters and the covariance matrix is used to arrive at a distribution of projections, representing the mean and uncertainty ranges of the output.

Climate response is thus implicitly accounted for based on selection of NFI plots that have grown in the expected future climate of the planting site. This approach thus avoids the explicit modeling of climate-growth relationships which requires the estimation of many parameters. The constraint of the method is thus that it relies on the availability of growth data that can be considered as representative for the future growing conditions of the planting site.

Integration of climate drivers into tree mortality modelling in Nova Scotia, Canada.

T5.6 Continuing Challenges and Novel Solutions: Adapting Growth and Yield Modelling to the Global Change Paradigm

Jamie Ring[1, 2]
Bianca Eskelson[1], Ignacio Barbeito[1], Mathieu Fortin[3]
[1] Department of Forest Resources Management, Faculty of Forestry, The University of British Columbia
[2] Nova Scotia Department of Natural Resources and Renewables
[3] Canadian Wood Fibre Centre, Canadian Forest Service, Natural Resources Canada

Abstract: Empirical individual tree growth and yield models for the Acadian forest region are an important tool used in strategic, tactical, and operational forest management planning. Climate normals are a component of two Acadian forest site productivity models, used as inputs to two commonly used growth and yield models in the region (Forest Vegetation Simulator - Acadian Variant and Open Stand Model). The use of climate normals in a single sub-model (site productivity) within a model composed of many sub-models (diameter increment, height increment, mortality, and recruitment) presents several limitations. Under a changing climate, these climate normals used as inputs become invalid for future growth projections. The site productivity sub-models can be re-developed using projected climate normals from various representative concentration pathway scenarios, however this methods lacks the ability to deal with temporal changes in climate during model simulations. An evaluation of Forest Vegetation Simulator - Acadian Variant and Open Stand Model predictive accuracy was completed with permanent sample plot data from 1965 to 2022 in Nova Scotia, Canada. This evaluation assessed the predictive accuracy of the sub-models used within these two growth and yield models, and overall (net growth) model predictive accuracy. The permanent sample plot dataset and historical climate data were used to develop a mortality model that directly includes climate variables, providing the ability to incorporate temporal changes in climate into mortality predictions during simulations with these two growth and yield models commonly used to make forest management decisions.

Machine Learning Forest Simulator (MLFS): R package for data-driven assessment of the future state of forests

T5.6 Continuing Challenges and Novel Solutions: Adapting Growth and Yield Modelling to the Global Change Paradigm

Jernej Jevšenak[1, 2]
Domen Arnič[3, 4], Luka Krajnc[5], Peter Prislan[3], Mitja Skudnik[1, 4]
[1] Slovenian Forestry Institute, Department for Forest and Landscape Planning and Monitoring, Slovenia
[2] Technical University of Munich, School of Life Sciences, Germany
[3] Slovenian Forestry Institute, Department for Forest Technique and Economics, Slovenia
[4] University of Ljubljana, Biotechnical Faculty, Department of Forestry and Renewable Forest Resources, Slovenia
[5] Slovenian Forestry Institute, Department of Forest Yield and Silviculture, Slovenia

Abstract: The Machine Learning Forest Simulator (MLFS) is the first fully data-driven model of forest dynamics. It is an easy-to-use and freely available tool applicable to all forest ecosystems, from even-aged monocultures to mixed forests with diverse vertical structures. The MLFS (v0.4.2) is available as an R package and can be downloaded from the Comprehensive R Archive Network (CRAN). It is a model system consisting of five sub-models for 1) calculation of tree and crown heights, 2) prediction of radial increments, 3) mortality of individual trees, 4) recruitment and 5) simulation of timber harvest. Thus, the newly developed model system requires forest inventory field plots data from at least two inventory periods and does not need to be manually parameterized. The main task for the users is to prepare the inventory data correctly and define the simulation assumptions, including climate, disturbances, mortality and harvesting rates. In the first step of a simulation, MLFS checks the input data for possible inconsistencies, calculates tree and crown heights, tree volumes, and competition and stand variables, and divides the data into independent training data sets needed to calibrate specific sub-models that are then applied sequentially during the simulation. At the end of each simulation step, dead and harvested trees are removed, and all other trees are made the subject of the next simulation step. We tested the MLFS with the latest national forest inventory data from Slovenia and simulated different mortality, harvesting, and climate scenarios. We show a wide range of possible applications and input settings that result in different growing stocks, yields, and forest structures. MLFS produces reasonable long-term simulations that can be used as forest management or decision support tools, for understanding the future national greenhouse gas emission trends, and for scientific purposes related to understanding forest dynamics from multiple perspectives.

Mixed-effects height prediction model for Juniperus procera Hochst. ex Endl. tree from Dry Afromontane Forest in Ethiopia

T5.6 Continuing Challenges and Novel Solutions: Adapting Growth and Yield Modelling to the Global Change Paradigm

Mindaye Teshome Legese[1, 2]

Abstract: The height of a tree is an essential variable to determine the aboveground biomass, volume, site productivity, and vertical structure in a forest stand. However, measuring the total height of trees is challenging. This study aimed to develop an accurate height prediction model for *Juniperus procera* Hochst. ex Endl. trees using a nonlinear mixed-effects modeling approach. We recorded 1215 pairs of height-diameter measurements from 101 randomly established plots in Chilimo Afromontane Forest in Ethiopia. The most appropriate base model was chosen after comparing fifteen nonlinear models. We included the sample plot as a random effect in nonlinear mixed-effect models. The effect of adding various stand variables on the model's ability to predict height was then assessed. The best sampling alternative and methods for calibration were determined by comparing various sampling alternatives using an independent data set. The bias, root mean square error (RMSE), and Akaike information criterion (AIC) was computed and used as the model evaluation criteria. Our findings revealed that the Michaelis-Menten model best represented the height-diameter allometry of *J. procera* trees and was selected as a base model. The best mixed-effects model improved the height prediction performance with the RMSE and bias values of 2.692 and 0.043, respectively. The addition of the quadratic mean diameter and stem density slightly improved the prediction performance of the model. However, the best-mixed effects model captures the largest proportion of between-plot variability in height-diameter allometry and provides the best plot-level prediction. The best-mixed effects model's fixed effect can be used to predict the mean height of *J. procera* trees for a given diameter. The calibration response revealed that the systematic selection of the three largest diameter trees in a plot was the best sampling alternative to estimate the random effects and predict the height of *J. procera* trees from new plots. Generally, the height-diameter model developed in this study will help forestry practitioners and researchers reduce data collection efforts and improve decision-making regarding stand volume and biomass estimation in Afromontane forests in Ethiopia and elsewhere.

Transferable Climate Sensitive Growth and Yield Models: Improving Projections for Interior Spruce in British Columbia

T5.6 Continuing Challenges and Novel Solutions: Adapting Growth and Yield Modelling to the Global Change Paradigm

Liam Gilson[1]
Bianca Eskelson[1]
[1] University of British Columbia

Abstract: The goal of many climate sensitive growth and yield models in practice is to estimate future conditions under climate change, often requiring predictions in settings outside the available training data. Using the example of interior spruce (Picea engelmannii x glauca) in British Columbia, Canada, we examined the potential of several techniques to improve the ability of climate sensitive models to extrapolate to future climatic settings. These methods include novel combinations of data sources, such as data drawn from multiple ranges, and novel model selection techniques. Existing provenance trials have been previously proposed as a source of climate response data in commercial tree species, but typically lack wide climatic coverage. In this project, we combined provenance trials from multiple native and exotic planted ranges of interior spruce with permanent sample plot data, to cover a wider range of climatic and stand conditions. We additionally utilized model selection techniques inspired by research in causal statistics to identify the climatic and edaphic variables best suited to prediction in uncertain future conditions.

Tree height, crown and slenderness ratio mixed-effects seemingly unrelated models for the Transylvanian region

T5.6 Continuing Challenges and Novel Solutions: Adapting Growth and Yield Modelling to the Global Change Paradigm

[2] Department of Forest Monitoring, "Marin Drăcea" Romanian National Institute for Research and Development in Forestry, 128 Eroilor Blvd., 077190 Voluntari, Ilfov, Romania
[3] Department of Forest Engineering, Forest Management Planning and Terrestrial Measurements, Faculty of Silviculture and Forest Engineering, "Transilvania" University, 1 Ludwig van Beethoven Str., 500123 Braşov, Romania

Abstract: Tree height estimation plays a pivotal role in individual tree growth and yield models. It serves as a fundamental step that enables the computation of other essential variables, such as crown ratio and tree slenderness, which are important for predicting individual tree growth. The conventional approach involves developing separate models for each of these variables and using height as a predictor in the crown ratio and tree slenderness ratio models. However, an alternative approach is to establish a connection between these three models, and one way to achieve this is through simultaneous fitting. By employing simultaneous fitting, the interrelationships among height, crown ratio, and tree slenderness can be effectively captured, enhancing the accuracy and coherence of the growth and yield modelling process.

The aim of this study is to develop height-diameter, crown ratio, and slenderness ratio models specifically applicable to the Transylvania region. Spanning from 2020 to 2022, the study involved the measurement of over 24,000 trees on a systematic grid of plots covering the southern part of Transylvania in Romania. Height-diameter relationships, crown ratio models, and slenderness models were established for the most prominent tree species. The selection of functions was based on the cross-correlation power of their coefficients while in order to account for the hierarchical structure of the data, the models were fitted simultaneously using mixed-effects seemingly unrelated regression.

These developed models incorporate both stand-level and tree-level variables, taking into consideration the competition effect and they can be readily employed by forestry practitioners and growth modellers. A notable advantage of these models is their ability to cross-calibrate the random effect when new observations are available. This feature reduces fieldwork time and simplifies the calibration process of an entire growth model, as only a few tree heights are needed. The study highlights the benefits of employing a mixed-effects seemingly unrelated framework and demonstrates the cross-model calibration of one of the functions when new observations arise.

Abstract: The presence of instream wood, including trees, logs, and branches, is a critical component of healthy riparian ecosystems. Instream wood provides habitat for fish, promotes nutrient cycling, and helps to stabilize the stream channel. Mapping instream wood features is essential for managing and restoring riparian ecosystems. Airborne laser scanning (ALS) and more recently mobile laser scanning (MLS) have emerged as valuable tools for mapping instream wood features due to their ability to provide high-resolution data—both from above and below the tree canopy. ALS and MLS use laser pulses to capture the 3D structure of the forest canopy and the ground surface. ALS is typically acquired from a fixed-wing or helicopter platform, while MLS is acquired from the ground, often using a handheld or backpack-based platform.

We present a framework for the integration of ALS and MLS for mapping instream wood features in two forested watersheds across nine different stream reaches in British Columbia, Canada. Both watersheds have extensive harvesting histories beginning in the 1920s, with areas of both second growth and old growth currently present. Primary inputs of large wood to stream channels result from windthrow and mass wasting events. Historically, riparian harvesting and cross-stream yarding also contributed wood to stream systems.

Our mapping framework consists of three key steps to detect instream wood features from laser scanning point clouds 1) point cloud filtering, 2) skeletonization, and 3) validation protocols. Using ALS data, we found that our methodology was able to detect instream wood features with moderate overall accuracy ranging from 37–87%. Further, logjams were delineated with 87% accuracy and individual instream wood features with 49%. We then examined which laser scanning metrics, environmental characteristics, and instream wood properties (i.e. length, width, submerged depth) influence the detection accuracy. Our results indicate that the number of returns classified as ground, absolute scan angle, wood orientation, and submerged depth of wood have significant effect on detection accuracy.

Overall, the use of ALS and MLS for mapping instream wood features represents a significant advancement in providing information for improved forest management and planning in forested watersheds.

Dead tree dynamic monitoring with the use of multitemporal ALS and CIR data

T5.7 Deadwood mapping based on remote sensing – Methods and applications, progress and perspectives.

Abstract: Climate change often causes extreme weather conditions that have a huge impact on forest vitality. Floods, extreme winds, fires, and hailstorms of insects, for example, cause trees to die. Monitoring the dynamics of dead wood occurring in the forest with a highly dynamic process and an extensive area requires access to a dense time series of remote sensing data to add value and actually support the Forest Service's operations.

In the Polish part of Białowieża Forest, monitoring of dead trees was conducted for eight years from 2015 to 2022. In the activities, we used multi-temporal airborne laser scanning data and mainly aerial CIR data. These data were acquired at different points in the growing season and allowed us to map the condition and detection of individual trees.

The monitoring results indicated that during this period several million trees died, and the share of spruce in the stands of the Bialowieza Forest decreased by more than half. The highest spruce mortality was recorded in the Białowieża Forest District, whereas the lowest was in the Białowieża National Park. The analyses carried out showed that the more open, older (over approx. 90 years old) spruce stands were the most susceptible to dieback in the initial phase of the outbreak. As a result of the thermal conditions in 2015, which were highly favourable to the spread of the European spruce bark beetle, more spruce stands died in the forest in subsequent years. Areas with young trees less than 90 years old proved to be the most resistant to the pest.

The fusion of ALS and CIR data enabled precise monitoring tree mortality process. It also supported practical management decisions in the Bialowieża Forest area, and increased the safety of people visiting it.

Detecting tree mortality and vitality in temperate forests using aerial RGB and RGBI imagery and deep learning

T5.7 Deadwood mapping based on remote sensing – Methods and applications, progress and perspectives.

Abstract: In the last years, concerns about climate change risks to global forest health are rising due to increasing tree mortality as a result of anthropogenic climate extremes such as drought and windthrows and consequently pathogens and insects' infestations. To better understand mortality processes and quantify trends sufficient data for long-term monitoring is required. Tree mortality monitoring is a challenging task that typically requires extensive and costly field surveys. However, new perspectives are given by the advent of computer vision methods and the availability of high-resolution remote sensing data.

Here, we developed a highly automated, straight-forward approach to detect tree vitality and mortality covering the heterogeneous forest ecosystems in Switzerland using the object detection algorithm YOLOv7 and countrywide freely available RGB and RGBI aerial imagery. As reference data over 10,000 individual trees were labeled dead, heavily damaged, and slightly damaged using aerial image interpretation.

Validation with an independent test data set revealed that higher accuracies were obtained for dead trees than the other vitality classes, i.e., around 20% of the heavily and slightly damaged trees were misclassified as dead trees. In some cases, roads or open forest ground were misclassified as dead trees. A comparison of the model's performance based on RGB and RGBI imagery revealed a slightly higher dead tree detection for RGB images (F1-score = 0.76) than for RGBI (F1-score = 0.73). Together with the CNN models, we present a dataset of more than 10,000 individually labeled trees that can be used for further studies on tree vitality.

This work advances our current tree vitality and mortality inventory by providing a highly automated and reliable approach for identifying and geolocating individual tree health in heterogeneous forests over large areas using the available CNN framework. It also shows the potential of the single usage of RGB imagery and that the near-infrared is not a must-have. Thus, the presented CNNs models and approach are compatible with low-cost UAV systems that are applicable to a wide range of users. This can serve as a basis for planning, and targeted management actions for more resilient forests.

Evaluating the effectiveness of retention forestry for bats using remote-sensing-based forest structure variables

T5.7 Deadwood mapping based on remote sensing – Methods and applications, progress and perspectives.

Abstract: Retention forestry, i.e. retaining groups of trees or small stands from harvesting, is an important conservation instrument for enhancing structural complexity and biodiversity in multifunctional forests. However, in contrast to local scale effects, its large-scale effectiveness is largely unknown, as this requires area-wide and sufficiently precise information on the target structures such as old trees and standing deadwood, as well as on associated species' habitats. Bats are particularly sensitive to forest structural characteristics and are therefore target organisms of most retention programs. To assess their response to retention efforts, we here compared key habitat structures and overall habitat suitability for bats across forest areas with and without retention, using forest structure variables derived from remote sensing along with topographic, climatic and land-cover variables and a multi-scale modelling approach. Based on acoustic data from 135 1-hectare plots across the Black Forest, Germany, we calibrated area-wide species distribution models for 9 bat species or bat species groups thereby identifying the best-performing scale (50 – 1000m radius) for each predictor and species(-group). Forest structure variables explained 38.3% of bat habitat selection, with forest height heterogeneity and the percentage area with standing dead trees performing best, mostly at small spatial scales (50 - 100m). Especially standing deadwood was identified as a limited resource for most of the investigated species. Their habitat suitability increased steeply at low deadwood levels and showed optima that by far exceeded the average amounts of deadwood in the study area. To assess the benefit of retention forestry for bats, we finally compared forests with and without retention measures. Forests with retention showed higher values of all bat-relevant structural variables, resulting in higher predicted habitat suitability for all dependent bat species(-groups). The results highlight the positive effects of retention programmes, and the value of remote sensing for evaluating the effectiveness of conservation instruments that aim at enhancing key forest structures for biodiversity.

Satellite Time Series Analysis for Near Real-Time Mapping of Deadwood and an Estimation of its Causes

T5.7 Deadwood mapping based on remote sensing – Methods and applications, progress and perspectives.

Janik Deutscher[1]
Martin Puhm[1], Andreas Wimmer[1], Manuela Hirschmugl[2]
[1] Joanneum Research, Institute for Digital Technologies, Graz, Austria
[2] University of Graz, Institute of Geography and Regional Science, Graz, Austria

Abstract: Deadwood mapping from remote sensing data is currently done at various scales: from terrestrial laserscanning on a local scale to airborne applications on a regional scale to large area mapping based on satellite data on a national scale. Our project focuses on the latter and builds on time series data from Sentinel-2. We have developed an automated system, which is able to map forest disturbances in near real-time, i.e. with an observed time lag of 15 – 30 days depending on location. This is possible through the smart integration of a Kalman filter in modeling of the spectral reflectance over time. Our approach produces useful results even in areas with a distinct phenology (deciduous tree shares) and in mountainous environments, where other methods fail or return very erroneous results. However, the availability of cloud-free observations is still a pre-condition for mapping any disturbances and longer time lags occur regionally if cloud or snow conditions are unfavorable.

The accuracy of our disturbance detection varies per year (due to weather conditions and thus image availability) and region. For Germany, the annual change maps derived from the NRT workflow show an overall accuracy of 99.1 ± 0.1 % over multiple study areas and years. The overall user's accuracy for the disturbance class was 83.8 ± 2 % and the overall producer's accuracy was 83.6 ± 3.3 %.

The time series behavior not only indicates the disturbance itself, but also gives important information on the underlying disturbance cause. Storm damage occurs very fast, while drought-induced dieback, often associated with bark beetle attacks, shows a longer deteriorating trend, which the time series data depicts. In combination with the specific spectral signatures of areas affected by different disturbance agents, it is also possible to distinguish red and grey attack stages for bark beetle infested forest stands.

The system runs both on DIASes and on desktop computers and has been developed in the frame of various research projects (AlpMon, BEAT IT!, FNEWs). It is currently running on test sites in Germany and in a wall-to-wall application in Austria (ESA FCM, ESA GTIF). A wall-to-wall roll-out for Germany is currently in preparation.

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

dataDriven: A Google Earth Engine and R tool for design-based data-driven mapping and per-pixel error estimation

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Abstract: Accurate information about forest ecosystems is critical for conservation, resource management, land use planning, understanding ecosystem services, advancing research and education, making informed decisions and supporting sustainable practices.
The value of remote sensing in providing such information has been a topic of historical discussion. Although remote sensing has made enormous progress in recent decades, several limitations persist, leading many researchers and authorities to favor ground data acquisition. This is because although map products derived from remotely sensed data are increasingly available, reliable quality indicators and uncertainty estimates may be lacking. Consequently, clearer and more transparent validation and uncertainty estimation of maps remain a major challenge in forest remote sensing. Here we present dataDriven (https://github.com/saveriofrancini/dataDriven), an open access tool that exploits cloud computing features (google earth engine) and high-level programming language (R) to make users able to easily produce maps of environmental attributes and maps of the associated per-pixel error within a specific area of interest. This tool uses a data-driven design-based approach and relies on Sentinel-2 remote sensing data as auxiliary information, avoiding the need for extensive modeling associated with model-based approaches. Also, reference data are needed and must be available for a sample selected by simple random sampling, one per stratum stratified sampling, or systematic sampling. A unique aspect of our tool is the generation of both the attribute map and the corresponding map of estimated precision. This allows users to make informed assessments of the attributes being investigated.

A design-based critical look at k-NN spatial interpolation

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

[3] Research Centre for Forestry and Wood – CREA (Italy)

Abstract: Mapping the spatial pattern of natural and environmental resources is essential for monitoring and management. Many spatial prediction methods have been developed that allow maps of the survey variable to be constructed based on a selected sample of units. Among them, the k-nearest neighbour (k-NN) technique has been widely adopted for a long time. Many applications of the k-NN method are related to the coupling of field data and satellite data for the mapping of forest and environmental attributes, also due to the increasing availability of freely accessible remote sensed data. Despite its popularity, most papers are of an applicative nature while only few are of a methodological nature.

Only recently, the asymptotic properties of k-NN predictors have been investigated by the authors in a design-based framework such that the statistical properties derive only from the probabilistic sampling schemes adopted to perform the surveys. More precisely, consistency of k-NN predictor has been proven when neighbours are determined in the geographic space, while consistency could be precluded when neighbours are defined only in the space of auxiliary variables, i.e. neglecting the geographical location.

A simulation study based on a real population of pixels partitioning a forest area is implemented to investigate the finite sample performance of k-NN predictors and, in particular, whether the exploitation of auxiliary information provides relevant increases in the precision of the predictors versus that achieved considering only the geographic space.

Furthermore, the simulation study aims to compare the performance of k-NN exploiting auxiliary information with that of alternative model-assisted predictors, which are obtained by considering auxiliary variables as covariates in a prediction model and the prediction errors are interpolated defining neighbours in geographic space.

Finally, some applications of k-NN and model-assisted predictions are presented.

A partnership to operationalize small area estimation within a national forest inventory

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Steve Prisley[1]
George Gaines[2], Holly Munro[1], Gretchen Moisen[2]
[1] National Council for Air and Stream Improvement, US
[2] USDA Forest Service

Abstract: The Forest Inventory and Analysis (FIA) program of the United States Department of Agriculture Forest Service (USFS) is responsible for the national forest inventory in the United States. The program uses a combination of remotely sensed data and over 140,000 field plots to gather data on tree and forest attributes. Portions (panels) of the field plots are measured annually, with complete remeasurement taking from 5 years in the east to 10 years in the west. Approximately one field plot is measured per 2,400 hectares, resulting in a sample that provides reliable estimates with specified precision at the regional and national levels. However, the broad array of forest sector users who depend on FIA data have repeatedly called for efforts to enhance the precision of smaller domain estimates using FIA data to assist in carboning reporting, wood supply analysis, and assessing resource sustainability. Thus, the US Congress has directed additional funding to USFS Research and Development to address these needs. Challenged by disjoint research efforts producing sometimes conflicting results, the FIA program responded by initiating a Partnership for Small Area Estimation to unify its research and development efforts. Coordinated funding now supports small area estimation approaches that combine field inventory data with remotely sensed and other auxiliary data to enhance the precision of key parameters such as forest area, biomass, and carbon stock changes. This Partnership brings together a diverse range of stakeholders across industry, academia, government, and non-profit organizations, and their collective expertise is directed towards developing innovative approaches and computer applications that deliver valuable information products to the public. This presentation will describe the Partnership's origins, structure, and the process by which it is mobilizing research and technology to develop credible and accessible small area estimates through the national forest inventory of the US.

A separable bootstrap variance estimation algorithm for hierarchical model-based inference of forest aboveground biomass using data from NASA's GEDI and Landsat mission

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Abstract: Hierarchical model-based (HMB) statistical method have been developed in response to demands for efficiently utilising multiple data sources, such as field and earth observation data, for assessing forest conditions. The method is currently employed in connection with NASA's Global Ecosystem Dynamics Investigation (GEDI) mission for global assessment of aboveground biomass and the associated uncertainty at a resolution of 1-km grid cells. This study focuses on uncertainty assessment using a bootstrapping procedure that separates the problem into parts, thus substantially reducing the time required for computations, which may otherwise make bootstrapping less attractive in this context.

The bootstrap procedure we propose is based on a theoretical decomposition of the variances into two parts based on a conditioning approach known as the law of total variance. Through this decomposition, each variance component can be estimated separately and simultaneously through bootstrapping. The variance components are (i) the variance conditional on the predictions obtained from the second model, i.e., the variance due to the first prediction step propagated through the second step, and (ii) the variance conditional on the first prediction model, i.e., the variance due to the second prediction step. The separable algorithm not only leads to less time-consuming bootstrap variance estimation but also allows a combination of bootstrap methods with analytical methods.

Airborne LiDAR Reveals the Wood Density of Central African Forests

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Arthur Vander Linden[1]
Jean-François Bastin[1], Sassan Saatchi[2, 3]
[1] TERRA Research Center, Biodiversity Landscape, University of Liège (ULiège)
[2] Jet Propulsion Laboratory, California Institute of Technology ; 4800 Oak Grove Drive, Pasadena, CA 91109 USA
[3] Institute of Environment and Sustainability, Center for Tropical Research, University of California (Los Angeles, USA)

Abstract: Wood density is a key parameter for understanding the forest functioning and to quantify the amount of carbon stored in trees and forests. This fundamental functional trait is associated to physiological, structural, and defensive trade-offs of trees, and reflects the ecological processes that shape forest communities and their responses to environmental and historical drivers. As of today, there is a lack of adapted remote sensing approaches to depict this key determinant of carbon stocks, remaining the missing link for accurate mapping of AGB. Here we show that structural patterns of forest canopy, which can be readily captured by airborne LiDAR remote sensing, serve as reliable predictors of forest wood density. Our study reveals a strong relation between LiDAR-based canopy metrics, such as the sizes frequency-distribution and the proportion of gaps, and the successional stage of tropical forests, which determine the average wood density of the ecosystem. This result demonstrates that complex ecological processes are reflected in the canopy of the forest, and that LiDAR remote sensing is well suited to intercept this structure. We anticipate that our assay will be a breakthrough in achieving accurate largescale estimates of aboveground biomass (AGB) through remote sensing. Furthermore, as wood density is a key functional trait of trees, this methodology paves the way for future studies on the macroecological functioning of tropical forests.

AN APPROACH TO SILVOPASTORAL LANDSCAPE PLANNING IN THE BRAZILIAN CERRADO USING THE POTENTIAL FOR CONSERVATION USE INDICATOR

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Lucas Abreu Kerkoff[1]
Carlos Moreira Miquelino Eleto Torres[1], Felipe Correa Ribeiro[1], Eraldo Aparecido Trondoli Matricardi[2], Melanie Feurer[3], Aldicir Osni Scariot[4], Dietrich Darr[5], Eleydiane Maria Gomes Vale[5]

[4] Embrapa Recursos Genéticos e Biotecnologia
[5] Hochschule Rhein-Waal, Sustainable Food Systems Research Centre

Abstract: Environmental Zoning (EZ) is considered a useful process for planning socioeconomic and conservation activities from a landscape perspective. Among the scalable and objective methods for integrating EZ, the Potential for Conservation Use (PCU) stands out. In this study, the PCU is calculated as an indicator based on relevant components expected to affect silvopastoral potential. The thorough evaluation of extensive regions is crucial for developing cohesive action plans, mitigating conflicts, and promoting effective public policies, especially in the Brazilian Cerrado. The intersection of ecological significance and agricultural activities in the region necessitates tailored approaches to ensure sustainable land management and biodiversity conservation. This study assesses the land suitability for silvopastoral purposes in the Brazilian Cerrado considering soil, vegetation, and ecosystem services supply. The PCU was computed using a script in Google Earth Engine, incorporating three sets of layer information: [I] soil class and terrain slope, [II] natural conservation areas, carbon storage, annual water yield, and habitat quality, and [III] a combination of [I] and [II]. Soil classes with favorable drainage, clayey texture and fertile values received higher scores, as did the flatter reliefs that were deemed more suitable for economic activities. The second set considered a higher percentage of natural conservation zones as conducive to biodiversity and successful reforestation, indicated by lower scores. Carbon storage, annual water yield and habitat quality were factors influencing agricultural or grazing aptitude. The variables were weighted using the Analytic Hierarchy Process to assess their individual effects on the PCU score. The PCU classification distinguishes the land potential for conventional agricultural activities (PCU ≥ 3) and underscores its importance for biodiversity conservation in the context of the Cerrado and its silvopastoral systems. Silvopastoral systems, known for their capacity to maintain biodiversity, can be key areas for biodiversity conservation, as reflected by a PCU score below the threshold of 3. We hypothesize that the PCU approach, integrated with environmental zoning, can improve sustainable landscape planning by offering insights into land suitability for tailored purposes. We expect that the results can contribute to a broader understanding of sustainable land management and support evidence-based decision-making processes in biodiverse landscapes.

An improved method for mapping understory bamboo from Gaofen-1 imagery

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Shuping Hu[1]
[1] CHINESE ACADEMY OF FORESTRY

Abstract: Obtaining the distribution of understory bamboo is an important task for monitoring giant pandas and their habitats. Mapping understory bamboo distribution is significant to understand the spatial distribution pattern of giant pandas' habitats, and to assess habitat suitability, habitat fragmentation and ecological carrying capacity. In this study, we extracted the spectral features, texture features, vegetation indices and topographic features of coniferous forests, mixed coniferous and broad-leaved forests, and deciduous broad-leaved forests in Baishuijiang National Nature Reserve, China. A regression decision tree was used to calculate the importance values of the classification features, and the features with the top 15 importance values were selected to participate in the modeling. After reorganizing the classification features with the help of Gradient Boosting Decision Tree, a deep neural network model was applied to predict the spatial distribution of understory bamboo. The results show that the method has an accuracy of 89.56%, a recall of 93.37% and an F1 value of 0.90 for predicting the distribution of understory bamboo. The regression decision tree can effectively screen out the characteristic variables affecting the distribution of understory bamboo and weaken the influence of factors unrelated to the distribution of understory bamboo. The deep neural network framework combined with the gradient boosting decision tree can extract the spatial distribution of understory bamboo and promote the application of remote sensing images in monitoring the distribution of giant panda staple food bamboo.

Analyzing Forest Fragmentation Patterns through Vegetation Indices: A Study in the Tuchola Forest, Poland

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Sanjana Dutt[1]
Mieczysław Kunz[1]
[1] Nicolaus Copernicus University, Toruń, Poland.

Abstract: This study aims to determine the optimal vegetation index (VI) for analyzing forest landscape fragmentation in northern Poland, with a specific focus on the Tuchola Forest. Utilizing Sentinel-2 images over the comprehensive summer period of 2019, our analysis leverages an extended suite of vegetation indices – NDVI, DVI, RVI, PVI, IPVI, WDVI, TNDVI, GNDVI, GEMI, ARVI, NDI45, MTCI, MCARI, REIP, S2REP, IRECI, PSSRa, SAVI, MSAVI, EVI, LAI – selected for their sensitivity to various plant parameters such as structure, growth condition, canopy closure, and understorey contribution.

To assess forest fragmentation, this research employs the Foreground Area Density (FAD), which measures the degree of fragmentation from Guidos Toolbox, analyzing forest cover across five observational scales and categorizing it into six fragmentation classes: Intact, Interior, Dominant, Transitional, Patchy, and Rare. This methodology facilitates a detailed examination of fragmentation patterns and their variability with observation scale.

Correlation analyses, employing Pearson's r for linear relationships and Spearman's rho for non-linear ones, were conducted to identify which vegetation indices most closely reflect changes in forest fragmentation. This dual analytical approach ensures a comprehensive understanding of how specific VIs correlate with the extent and nature of forest fragmentation.

By leveraging a broad array of vegetation indices and a sophisticated fragmentation analysis framework, the research offers profound insights into the intricate relationship between vegetation dynamics and landscape fragmentation. These insights are instrumental for developing more refined strategies for vegetation monitoring and forest management, ultimately contributing to the enhancement of forest ecosystem resilience and sustainability in the face of climatic challenges. This study underscores the importance of tailored, multi-scale analyses in informing effective forest conservation and management practices.

Application of Videogrammetry in Volumetric Measurement of Forest Structure Characteristics and Silviculture

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Aiding Kornejady[1]
Saeid Shabani[1], Davoud Davoudi Moghaddam[2]
[1] Research Department of Natural Resources, Golestan Agricultural and Natural Resources Research and Education Center, AREEO, Gorgan, Iran.
[2] Department of Watershed Management, Agriculture and Natural Resources Faculty, Lorestan University, Khorramabad, Iran.

Abstract: The scientific community in recent decades was endowed with an advanced form of forest assessment and monitoring availed by high-tech remote sensing tools and techniques. However, the choices on which apparatus or technique to opt for would be narrowed down to a handful as it is dictated mainly by the study goal, extent, required detail and precision, budget, and time. Meanwhile, measurement of what appears to exist underneath the dense forest canopy is one of the main challenges that most radar and optical satellites fail to resolve. Instead, alternative techniques such as mobile laser scanning (MLS) have recently been investigated and proved promising for a broad spectrum of forest assessment endeavors. As helpful as they look, the MLS applications can also be problematic once the budget excels in importance, among other rivaling criteria. Hence, we tested videogrammetry, a subgroup of close-range photogrammetry, in different parts of the Caspian Hyrcanian forests, in pursuit of attaining high-resolution topography of the forest surface (e.g., terrain, 1st order stream tributaries, and artificial designs such as dams, walls, and excavation pits) and volumetric measurement of forest structural complexity and silviculture (type mapping, disease and pest detection such as gummosis, burls, galls, and tumors). By doing so, different photogrammetry products such as dense point cloud, high-quality mesh, texture, and 3D models were generated and rescaled. The results revealed that videogrammetry (extracting frames from videos) could compensate for the small areal coverage and occlusion of standard photogrammetry shoots (photography) due to the agile movement of the camera and the high frame rate obtained from high-definition videos. On the other hand, the surveyor is strictly advised to adhere to the basic photogrammetry rules such as camera settings (ISO, shutter speed, focus, lenses, diaphragm, depth of field) and following nested spiral/circular patterns rather than camera panning and 360 movements. Moreover, the mixture of photography (single shots) and video-oriented frame as an integrated photogrammetry technique would recompense the blurred photos due to motion blur and camera shake during the exposure time.

Assessing the transferability of nationwide forest attribute models to different spatial resolutions using airborne laser scanning data in Norway

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Zsofia Koma[1]
Johannes Breidenbach[1]
[1] Norwegian Institute for Bioeconomy (NIBIO), Norway

Abstract: Fine-scale, spatially explicit forest resource maps are essential for monitoring sustainable forest management practices. Such maps, based on the combination of National Forest Inventory (NFI) and remote sensing datasets, have a long tradition to characterize timber volume, biomass, basal area, and Lorey's height and other forest attributes in the Nordic countries. For instance, the Norwegian Forest Resource Map (SR16) is currently produced using mixed effect regression models at 16 m resolution with predictor variables based on Airborne Laser Scanning (ALS). The spatial resolution of these maps was set according to the NFI plot size. This, however, limits their applicability in various local-scale forest management applications.We therefore investigated whether the spatial resolution (i.e. pixe size) of forest attribute maps can be reduced while utilizing models fit on original scale. We processed ALS datasets at various spatial resolutions (1, 5, 10, and 16 m) to assess the transferability of nationwide models using independent field validation data from two geographically separated regions in Norway. Our initial results show that the prediction accuracy of the main forest attributes is not substantially affected by the spatial resolution of the ALS-based predictor variables. This suggests that the nationwide models are robust and transferable to a finer spatial scale. The result of this study is an important step towards harmonizing forest attribute maps across countries to match their spatial resolutions for European-scale forest monitoring.

Can GEDI accurately model vertical structure and Above-Ground biomass along rainfall and fire disturbance gradients?

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Hermane Diesse[1]
John Godlee[2], Nichola Knox[3], Kyle Dexter[4], Olivia Haikali[1], Dav Ebengo[5], Oluibukun Ajayi[1], Vera De Cauwer[1]
[1] Namibia University of Science and Technology

[5] Université Clermont Auvergne, CNRS, MSH

Abstract: Miombo woodland covers large parts of eastern and southern African. Miombo woodland faces deforestation, which affected 17.0% of the wooded area from 2007 to 2010 and resulted in an almost 55% loss of woody biomass. Despite this human pressure, Miombo woodland still plays an important role for the human population and provides several products and services such as timber and non-timber forest products, fuelwood, construction timber, and tangible services (regulation of climate, carbon storage and maintenance of biodiversity). Stand structure is fundamental to maintaining the capacity of the forest to provide these products and services.

Traditionally, monitoring of forest structure and above-ground biomass (AGB) has been achieved through in situ field methods. These methods however, are costly, laborious, and difficult to apply at larger spatial scales. In this research we investigate the vertical structure of Miombo woodland along a rainfall and fire disturbance gradients, integrating *in-situ* and remote sensing data, to develop models that will enable scaling from local to regional scales. We focus on the use of Light Detection and Ranging (LiDAR) data, specifically the Global Ecosystem Dynamics Investigation (GEDI) full-waveform LiDAR due to its coverage (+/- 51.6 degrees latitude) and its capability to penetrate the canopy layer. This gives LiDAR the ability to measure vertical structure parameters and to produce detailed 3D point clouds illustrating the vertical structure of woodland vegetation.

This research used data collected in 12 sample plots in Namibia and the Democratic Republic of Congo: (a) to evaluate the potential of GEDI to estimate the vertical structure of forest Miombo woodland stands; (b) to describe the vertical structure of Miombo woodland and to understand if these characteristics differ along the rainfall and fire disturbance gradients.

Comparison of different methods to estimate canopy openness using close-range sensing and field surveys in temperate rainforests

Abstract: To estimate and monitor canopy gaps and fragmentation, which could be triggered by natural or anthropogenic disturbances, there are several alternatives, such as direct field measurement or through remote sensing applications related to canopy openness or vegetational indices. In this study, we compared two field survey techniques and four remote sensing methods, using a close-range approach to estimate canopy openness over four categories of forest disturbance: none, low, medium, and high. The method was applied to 12 forest stands, with three repetitions in each category. The remote sensing methods consisted of using an unmanned aerial vehicle (UAV) based on photogrammetry principles that produced 3D point clouds. These point clouds were further processed to estimate canopy openness and detect forest disturbances in *Araucaria*-*Nothofagus* forests. The two field instruments used were the Canopy-Scope (CS) and Hemispherical Photography (HP). Although the four remote sensing analysed spatially the 3D point clouds from the canopy to map estimated canopy openness values over the area. The results show a correlation between the two field methods of R^2 0.58 when all the observations were included, which means they were not separated by category. However, when the observations were divided by the category of forest disturbance levels, the R^2 between CS and HP was not significant for the category "none" but increased in value and significance at higher disturbance categories. The best remote sensing method consisted of a direct estimation of canopy openness from the point clouds using a software developed ad-hoc for this work. This method has a R^2 of 0.68 without grouping by forest disturbance categories and increased to 0.90 over the "high" category, but with a lower and non-significant correlation in the lower category. Our finding suggests that results using a 180° field of view (FOV) to simulate HP from point clouds can distinguish the four forest disturbance categories and, therefore, can be a useful tool to determine canopy openness in remote areas, which is linked directly to forest fragmentation.

Data assimilation – a tool for making use of big data to improve forest stand information

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Abstract: Data assimilation (DA) has been used for a long time in fields such as meteorology. It is currently considered an interesting option in forestry due to the large amounts of remotely sensed (RS) data available for predicting forest characteristics. With DA, new information can be merged with existing information, such as predictions from a previous time point updated with a growth model. Thus, old information is not discarded when new information becomes available but is used to the extent motivated by its accuracy. With ever-increasing amounts of RS data, it is important to evaluate not only how to make assessments and growth updates through DA but also how to best utilize large amounts of RS data within single years.

Within the Norwegian SmartForest program, the first large-scale application of DA in Norway has been initiated. DA is being applied between 1998 and 2022 in an approximately 900-ha forest area in Våler municipality in southeastern Norway. By utilizing data from previous time periods, we will be able to improve the estimates for 2022 compared to using information from this year only. However, applying DA in practice is far from trivial. During the presentation, we will report results on evaluating whether building separate models for each RS dataset and applying composite estimation or merging all data into a single model through principles of partial least squares regression and random forest non-parametric regression yields the best results in terms of prediction accuracy. The RS data were acquired in 2022 and included ALS point clouds, digital aerial photogrammetric point clouds, and Sentinel-2 spectral data. Alongside comparing prediction accuracies, we conducted a qualitative assessment to discern the practical advantages and disadvantage of each method in integrating them into a multi-temporal data DA system.

DETECTING FLORISTIC DIVERSITY OF FORESTS IN RESTORATION USING REMOTE SENSING AND MACHINE LEARNING

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Gustavo Rossi[1]
Angelica Resende[1], Thiago Silva[2], Catherine Torres[3], Pedro Brancalion[1]
[1] University of São Paulo
[2] University of Stirling
[3] São Paulo State University

Abstract: Forest restoration is considered one of the best options to mitigate the effects of climate change and reduce biodiversity loss. Several forest restoration techniques were developed in the State of São Paulo, playing a crucial role in the protection of the Atlantic Forest. However, the methods for monitoring the success of restoration mostly depend on field trips to analyze different factors, such as diversity and floristic composition, a time-consuming and costly process. With the use of remote sensing techniques, we can reduce the cost of monitoring by increasing the spatial and temporal scale and combining different sensors to detect various vegetation characteristics. The Sentinel 1, Sentinel 2 and the Planet satellite constellations image in different bands of the electromagnetic spectrum, ranging from visible to microwave , detecting different aspects of the water content and vegetation composition and structure. In addition, images derived from LiDAR sensor data, which is capable of providing a 3D view of forests, are useful for estimating different structural variables, which can be related to floristic variables. This project used remote sensing images (Sentinel 1, Sentinel 2, Planet and LiDAR), combined with forest inventory data obtained in the field (Newfor project - #FAPESP 2018/18416-2) and Machine Learning techniques to analyze the diversity and floristic composition of semideciduous seasonal forests under restoration in São Paulo state. By doing so, it was possible to identify wich Remote Sensing variables have the highest correlation to floristic parameters, allowing for a more precise monitoring of forest in restoration remotely. The highest correlation found was between the LiDAR data (Canopy Height Model) and the Menhinick diversity index (0.5). As for the Satellites, the Sentinel 2 Red, RedEdge and SWIR bands had some correlation with the Simpson index, specially in the rainy season, however, the values were still low (0.3 - 0.4), indicating the need to combine different variables and use higher spatial and spectral resolution satellites to obtain higher correlation values.

Determining the optimum mesh size for evaluating site productivity for Cryptomeria japonica using airborne laser scanning data

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Keiko Nagashima[1]
Kota Ueoka[1]
[1] Graduate School of Life and Environmental Science, Kyoto Prefectural University

Abstract: Airborne laser scanning (ALS) data at a fine mesh size are being widely used to analyze site conditions to evaluate site productivity. However, the optimum mesh size for evaluating site productivity remains unknown. In this study, the optimum mesh size was determined by analyzing the relationship between site conditions derived from ALS data and height growth data obtained from the long-term monitoring of an experimental *Cryptomeria japonica* site. We assumed that (1) based on the optimum mesh size, the site conditions should demonstrate the lowest mean standard deviation of height at a given age, which is an indicator of site productivity, and (2) site productivity class derived from site conditions of an appropriate mesh size has the smallest numbers of trees whose actual height growth curve differed from the growth curve of the site productivity class. Four digital elevation models with different mesh sizes (1.0, 2.5, 5.0, and 10 m) were calculated using the ALS data and used for developing maps of slope type, topographical type, soil deposition type, and slope location. Trees with the same site conditions were combined to calculate the average and standard deviation of tree height at the ages of 30 and 45 years based on the long-term monitoring data. The mean standard deviation for the 5.0-m mesh size was the lowest (1.97 m), followed by that for 1.0 m (1.99 m), 2.5 m (2.00 m), and 10 m (2.14 m) at 45 years. Site conditions were also classified into site productivity classes based on the average height data. Subsequently, the height growth curves of productivity classes and the actual height growth curve were compared for each tree and the number of contradicted trees were measured. The contradicted tree number for the 5.0 m mesh size was the lowest (19), while it was 28, 22, and 37 for 1.0, 2.5, and 10 m, respectively. Thus, the appropriate mesh size for evaluating site productivity of *C. japonica* was concluded as 5.0 m, which might provide accurate evaluation of site productivity that influences the profitability of forestry and the future forest management regime.

Development of a single-tree extraction method for broadleaf trees using Air Borne Laser Scan data

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Hiromi Shiota[1]
[1] Kyoto Prefectural University

Abstract: In general, tree analysis using Airborne Laser Scan (ALS) data is suitable for extracting coniferous trees with relatively well-defined topped edges, while broadleaf trees with flat topped edges are less likely to be used for tree analysis.

In this study, we verified whether it is possible to extract broadleaf trees using tree height information obtained from ALS data, relative laser reflection intensity, and aerial photographs taken at the same time as the survey.

Method：

1. Generate Digital Canopy Height Model (DCHM) from tree height information to reproduce the tree canopy shape by the slope angle and contour lines around the tree canopy
2. Extract the canopy surface by using relative ALS reflection intensity and contour lines of the reflection intensity map
3. Extraction of tree tops from DCHM
4. Assuming that the ALS reflections are from near-infrared radiation, calculate pseudo-NDVI

These were overlaid on the GIS and the degree of agreement between the data was verified.

Main result:

Visually, the data were found to be consistent with each of the tree canopy shapes, and the data were found to be visually usable without any consistency problems.

Conclusions:

Although the shape of the trees could be visually confirmed, it would be necessary to confirm the trees by field survey and verify data consistency by merging data in the GIS.

Extraction of dendrometric parameters from UAV LiDAR data with a focus on the treeline ecotone

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Alex Šrollerů[1]
Markéta Potůčková[1], Václav Treml[2]
[1] Charles University, Faculty of Science, Department of Applied Geoinformatics and Cartography, Czech Republic
[2] Charles University, Faculty of Science, Department of Physical Geography and Geoecology, Czech Republic

Abstract: Rare and endangered species thrive significantly in treeless ecosystems at higher altitudes. However, they are affected by the movement of the treeline to higher elevations. The trend has been documented in numerous alpine regions, especially those with a very limited extent; for example, in Krkonoše (50.75N, 15.58E), a mountain range located in the north-western part of Czechia and covered by protected arctic-alpine tundra.

In 2018 and 2021, dendrometric data was collected using traditional inventory methods on permanent monitoring plots. The areas cover the entire gradient of the treeline ecotone and consist of Picea abies, Sorbus aucuparia, and Betula pendula stands. New and dead wood and seedling survival were recorded. Based on the analysis of the changes in vegetation structure, the dynamics of the upper treeline were assessed. A different rate of biomass growth and canopy cover in parts of the treeline ecotone was detected. The lower parts of the ecotone are characterized by a more intensive height, radial, and crown area increase. Higher areas have the smallest height increase and most symptoms of non-temperature stress.

Traditional forest inventory is rather time-consuming and expensive, limited to selected locations. Remote sensing provides a suitable alternative or support for ground measurements. UAV LiDAR data with high point density represents a versatile tool, particularly suitable for smaller to medium-sized areas, less accessible locations, or when data must be acquired repeatedly at shorter time intervals. According to the results of the literature search, its use in heterogeneous forest environments and for understory vegetation remains a challenging topic.

Throughout the summer months of 2023, new dendrometric measurements will be collected along with high-density LiDAR point clouds from a Riegl miniVUX-1 UAV laser scanner equipped with the APX-15 UAV GNSS/IMU and mounted on a hexacopter DJI M600. Data will be acquired throughout two gradients in the treeline ecotone. Results of individual tree detection and subsequent dendrometric parameter extraction from UAV LiDAR data will be presented, with the aim of effective continuing of the monitoring on permanent plots and assessing the dynamics of the treeline ecotone.

Forest condition assessment – A benchmarking study in Germany

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Abstract: With a continuous assessment of forest condition since the 1980s, Europe takes a keen interest in its forests. It is therefore no surprise that the increasing hot drought frequency and the unprecedented post-2018 forest decline in Central Europe spiked a range of new remotely sensed products to assess its health. They could not be further away from the ground-based assessment of the previous 30 years which aim to directly quantify canopy condition (e.g. percentage of leaf loss), while remotely sensed products provide information on the spectral reflectance which can be considered an indirect measure of canopy condition. However, the information on crown condition is based on the ground assessments of ICP Forests. Therefore, the term might not be ticking the box when presenting remote sensing derived indices. It is thus our aim to define the wording being aware of the differences caused by the change from ground assessment to airborne or spaceborne analysis.

However, the opportunities for high temporal resolution and a gapless spatial cover are fulfilled with a variety of remote sensing products. Here we present a selection of German forest monitoring products derived from satellite-borne remote sensing products, i.e. Sentinel, Landsat and MODIS. The products are compared among each other based on ground-truthed, and thus well-documented changes in forest condition (e.g. defoliation, forest fire, wind-throw). The comparison aims at documentation of the various products, the definition of the methods and terms, as well as the start of a discussion to improve the respective algorithms within a benchmarking process. This process covers two parts: firstly, the presentation and discussion of the currently available products with a focus on the influence of resolution, forest mask, reference year or period, time of detection, and indices used. Secondly, the provision of more detailed information on the specific potentials to map forest disturbance (e.g. storm, forest fires) and the underlying algorithms, discussing aspects of phenological phases, thresholds, and variance.

Besides identifying potentials for product-specific improvements, the study aims at improving their applicability for various users, especially those with little working knowledge in remote sensing.

Global forest management intensity data set

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Dmitry Schepaschenko[1]
Myroslava Lesiv[1], Steffen Fritz[1]
[1] International Institute for Applied Systems Analysis (IIASA)

Abstract: Spatially explicit information on forest (and trees) management intensity is critical for understanding the status of forests, planning sustainable forest management, restoration and conservation activities, assessing wood and biomass supply potential, among others. Here, we present a reference data set and a globally consistent forest management map with high spatial detail on the most prevalent forest management classes such as intact forests, managed forests with natural regeneration, planted forests, plantation forest (rotation up to 15 years), oil palm plantations, and agroforestry. We developed the reference dataset of 226 K unique locations through a series of expert and crowdsourcing campaigns using Geo-Wiki (https://www.geowiki.org/) tool for visual interpretation of very high resolution imagery and vegetation indices. We then combined the reference samples with time series from PROBA-V satellite imagery to create a global wall-to-wall map of forest management at a 100 m resolution for the year 2015, with forest management class accuracies ranging from 58% to 80%. The data set is peer-revied and published (Lesiv, Schepaschenko et al., 2022) in Scientific Data journal and Zenodo. A revised and further developed data set for the year 2020 is expected by the time of IUFRO congress 2024.

Hierarchical hybrid estimation of boreal forest biomass using ICESat-2 data

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Petri Varvia[1]
Svetlana Saarela[2], Matti Maltamo[1], Petteri Packalen[3], Terje Gobakken[2], Erik Næsset[2], Göran Ståhl[4], Lauri Korhonen[1]
[1] University of Eastern Finland, School of Forest Sciences, Finland
[2] Norwegian University of Life Sciences, Faculty of Environmental Sciences and Natural Resource Management, Norway
[3] Natural Resources Institute Finland, Finland
[4] Swedish University of Agricultural Sciences, Faculty of Forest Sciences, Sweden

Abstract: The ICESat-2, launched in 2018, carries a photon-counting spaceborne lidar that provides strip samples of points over the terrain. While primarily designed for snow and ice monitoring, ICESat-2 has been shown to also provide relatively accurate canopy height measurements. There has also been a high interest in using ICESat-2 to predict forest above-ground biomass (AGB). Due to ICESat-2 using a polar orbit, it provides good spatial and temporal coverage of boreal forests. The aim of this study is to test ICESat-2 data in hierarchical hybrid estimation of boreal forest AGB.

The data consist of two adjacent study areas of circa 50 x 50 km in eastern Finland, near Valtimo and Nurmes, respectively. The areas are mostly forested, with Scots pine (*Pinus sylvestris*) as the dominant species, followed by Norway spruce (*Picea abies*) and birches (*Betula* spp.). The study areas have field plots, wall-to-wall airborne laser scanning (ALS) data and Sentinel-2 images captured in the summer of 2019 and 2020, respectively. On Valtimo area, we have ICESat-2 data from years 2018 and 2019, and on Nurmes, from the year 2020.

The modeling chain is as follows: 1) predict allometric AGB on Valtimo field plots, 2) build a model for predicting proxy AGB using ALS and Sentinel-2 data, 3) predict proxy AGB on the ICESat-2 tracks in Valtimo, 4) build a model for predicting AGB using the ICESat-2 data and proxy AGB, 5) use the Valtimo ICESat-2 model to predict AGB on Nurmes ICESat-2 tracks. Finally, the ICESat-2 AGB predictions in Nurmes area are used in a hybrid inference setting to estimate the average AGB. Uncertainty is propagated through the whole model hierarchy. For validation, we have a separate ALS and Sentinel-2 based AGB model trained in Nurmes area, which is used in hierarchical model-based estimation.

The preliminary result for the ICESat-2 hybrid inference for the average AGB in the Nurmes area was 63.2 ± 1.9 Mg/ha (2.9%). The reference estimate using local ALS and Sentinel-2 data in Nurmes was 63.9 ± 0.6 Mg/ha (1.0%). The preliminary validation results support the use of ICESat-2 data for estimation of boreal forest biomass.

High-resolution tree height mapping from GEDI data: the case study of Mediterranean forests

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Abstract: Structural information related to forests, such as tree heights, diameter, and density, is crucial in quantifying biomass and carbon stock and managing forest ecosystems in light of climate and land use changes. NASA's Global Ecosystem Dynamics Investigation mission (GEDI mission) has provided valuable data on canopy heights worldwide since late 2018. However, the GEDI mission's satellite footprints do not offer detailed spatial data on tree heights. In this study, we present an approach for mapping canopy heights at a resolution of 10 meters by combining GEDI data with Sentinel-1, Sentinel-2, and topographic variables (elevation, slope, and aspect). Three machine learning techniques—Random Forest (RF), Gradient Boosting (GB), and Classification and Regression Trees (CART)—were tested. The study focused on two Mediterranean forests in Italy, one characterized by a conifer stand and the other by a multilayer mixed-species stand. The complete GEDI data collected over the study area was used, with the dataset divided into training (70%) and testing (30%) subsets to evaluate prediction accuracy. We compared the GEDI canopy height map with Airborne Laser Scanning (ALS) data to assess the performance using a pixel-by-pixel analysis. The RF algorithm exhibited the highest accuracy (adjusted R-squared: adj. $R2 = 0.90$; root mean squared error: $RMSE = 3.09$) compared to GB (adj. $R2 = 0.83$; $RMSE = 3.93$) and CART (adj. $R2 = 0.84$; $RMSE = 3.16$). Across all algorithms, the comparison between GEDI canopy heights and ALS data showed moderate agreement, with adj. R2 values ranging from 0.27 ($RMSE = 5.23$) to 0.48 ($RMSE = 4.58$) for pure stands and weak agreement, with adj. R2 values ranging from 0.06 ($RMSE = 6.87$) to 0.14 ($RMSE = 5.59$), for the multilayer mixed-species stand. The proposed approach will contribute to forest monitoring initiatives, especially in inaccessible or remote forests worldwide.

Improving Aboveground Biomass Estimation methods through Multi-Sensor Data and Prediction Modeling Correlated with Ground-Based Information

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Stefan Leca[1]
Gheorghe Raul Radu[1], Albert Ciceu[2], Ionut Silviu Pascu[1], Alexandru Claudiu Dobre[1], Bogdan Apostol[1], Serban Chivulescu[1], Luminita Mărmureanu[1], Ovidiu Badea[1, 3]

[3] Faculty of Silviculture and Forest Engineering, "Transilvania" University of Brașov, 500123 Brașov, Brașov, Romania

Abstract: The European Union's current climate policies aim to position Europe as the first continent to achieve climate neutrality by 2050. This ambitious objective places significant responsibility on the forest sector to contribute to the overall reduction of greenhouse gas (GHG) emissions. Accurate aboveground biomass (AGB) estimation is particularly crucial for carbon stock assessment and sustainable land management practices. In recent years, integrating multi-sensor data synergy and prediction modeling techniques has shown promise in improving AGB estimation. This study accentuates the potential of utilizing synergistic data from multiple sensors and developing prediction models correlated with ground-based data to improve AGB estimation.

Diverse remote sensing data types, both airborne and satellite, such as optical, radar, and LiDAR, were used to assess vegetation structure and composition across a heterogeneous topographic region spanning 15,000 ha^{-1}. Ground-based data, such as field measurements of forest inventory, were collected concurrently with remote sensing data to establish a robust correlation between AGB and the sensor data. Ground measurement data involved over 24 000 trees on a systematic grid network of 450 plots of 1000 m^2, each located in the Southern Carpathian temperate mixed broadleaves-coniferous forest ranging from 500m to 1650m above sea level (ASL). Several random forests (RF) regression models were trained using a subset of the data, and their performances were evaluated using cross-validation techniques. The prediction models were then applied to the entire dataset to estimate AGB at the landscape scale. The study aims to analyze the most valid combination of sensors for a comprehensive characterization of vegetation structure and, finally, to predict AGB accurately.

The prediction models developed using the integrated data achieved high accuracy in estimating AGB, as indicated by low root mean square error (RMSE) and a high coefficient of determination values (R^2). The study also highlighted the importance of ground-based data in the modeling process. The correlation analysis between the remote sensing data and ground-based measurements provided insights into the relationships between sensor-derived variables and AGB. This information facilitated the development of more robust and reliable prediction models, resulting in improved AGB estimation accuracy.

Integrating Radar and Multispectral Data with Machine Learning for Accurate Fuel Models in Forest Fire Management

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

[3] Departamento de Ingeniería Forestal, Universidad de Córdoba, Córdoba, España
[4] Centro de Investigaciones Aplicadas al Desarrollo Agroforestal, IDAF, Córdoba, España

Abstract: The increasing frequency of megafires in Mediterranean areas underscores the critical need for updated fuel models to mitigate the impacts of these wildfires. Climate change has heightened the risk of forest fires. This was evident in the summer of 2017 when a single fire engulfed approximately 180,000 hectares of agricultural and forest systems in the Maule Region (Chile) within a matter of days. The recurrent occurrence of such destructive wildfires necessitates the development of tools and strategies to effectively prevent and manage their consequences. This study aims to develop accurate and precise fuel models for effective forest fire management. The integration of radar and multispectral imagery plays a vital role in obtaining reliable fuel models. Strategic project sites, ranging from 500 to 1,000 hectares, were carefully selected to capture maximum variability in fuel models. A combination of synthetic aperture radar (SAR) and high-resolution satellite imagery was analyzed to derive both structural and spectral information. Post-processing of the sensor data resulted in various outputs, including forest metrics (40 in total), high-precision topographic models, and spectral resolutions depicting the forest reality. Machine learning techniques, including several algorithms, were employed to analyze the metrics and predict fuel models. Among them, the Random Forests algorithm consistently produced the best results in terms of accuracy and performance. The study yielded compelling results, with 12 fuel models achieving area under the curve (AUC) values ranging from 0.4412 to 1. Accuracy scores varied from 0.774 to 0.7763, with kappa coefficients ranging between 0.717 and 0.7402. These metrics provide quantitative evidence of the robustness and reliability of the developed fuel models. This study demonstrates the effectiveness of integrating radar and multispectral data, coupled with machine learning techniques such as Random Forests, in obtaining updated and precise fuel models. These enhanced models will enable more efficient management of forest fires, facilitating strategic decision-making and the implementation of preventive measures to protect ecosystems and ensure the safety of affected communities. The findings have significant implications for forest fire management, where the threat of megafires necessitates accurate and reliable fuel models for effective response and mitigation strategies.

Integration of remote sensing techniques in national environmental monitoring

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Anna Allard[1]
Sven Adler[1]
[1] Swedish University of Agricultural Sciences, Department of Forest Resource Management, Section of Landscape Analysis, Umea, Sweden

Abstract: This presentation will focus on the constant development that is taking place within a national environmental monitoring programme to make several different technology applications more efficient, be it for the sampling of aerial photo inventories, for modelling of potential habitats or for using neural networks to model parts of the inventories or develop image recognition.

The sampling strategy developed within the programme for targeted environmental monitoring allows for large-area searches without adding large costs for field inventory, due to the employment of several phases in the scheme. The data collected utilises the whole chain of geographical scales, from satellite images through aerial photos, drone images and to quality variables collected in the field. Collection of detailed field data makes up the decision basis for recording the actual nature type but also has great value as input data for models and algorithms, as well as constituting next year´s ground truth and in-house education on mid-level data collection from aerial photos and drones.

The National Inventories of Landscapes in Sweden, (the NILS programme) is a monitoring programme functioning as an umbrella for several target inventories on the national level. Commissioned by the Swedish Environmental Protection Agency, the monitoring is target-based for habitats with insufficient data from other monitoring programmes to provide sufficient data for national reporting according the EU Habitat Directive, or Annex-1 habitats, completing the overall national knowledge of the targets. Current targets are deciduous forest, hardwood deciduous forest, grasslands, raised bogs, several seashore habitats and the entire mountainous area of the Scandes Mountain range.

Mapping of deforestation and forest degradation in Vietnam using Sentinel-1/2 images

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Phùng Văn Khoa[1]
Marius Rüetschi[2], Langning Huo[3], Nguyen Ba Long[1], Henrik Jan Persson[3]
[1] Vietnam National Forestry University
[2] Swiss Federal Institute for Forest Snow and Landscape Research (WSL)
[3] Swedish University of Agricultural Sciences (SLU)

Abstract: About 85%of the natural forest in Vietnam is regenerated and secondary forest. These forests are under very high pressure due to land conversion to agriculture and other land types. Furthermore, substantial illegal cutting and burning occurs in remote forest areas that are not easily detected by the forest rangers. As result, the forest can be cut for a long time without being detected. Hence, remote sensing constitutes an attractive alternative to monitor large areas timely, especially solutions based on free satellite images.

In this study, we investigate approaches to use satellite images to identify and monitor deforestation and forest degradation in the Central Highlands of Vietnam. The active forest management and short rotation periods in Vietnam can make it challenging to distinguish between permitted and illegal forest cuttings. The fast regrowth is furthermore quickly eliminating traces of illegal cuttings. Therefore, it is of high importance to develop methods that allow continuous monitoring and rapid identification of forest-degraded areas. The region is frequently covered by clouds, which makes dense acquisitions of optical data difficult. Therefore, SAR imagery constitute a good complement, which however has lower spatial resolution and is sensitive to the hilly terrain in Vietnam. We have developed a workflow in Google Earth Engine (GEE) to pre-process and extract time series of Sentinel-1 synthetic aperture radar (SAR) images and Sentinel-2 optical multispectral images. The optical images were used to compute the normalized difference vegetation index (NDVI) and distance-red-swir (DRS). The Sentinel-1 backscatter and the vegetation index data were analyzed and compared with more than 200 reference areas spread across southern Vietnam, located in different forest types. The references consisted of field reference data and high-resolution Planet imagery, which were visually interpreted and used for delineation. The forest degradations are mostly clearly visible, while the analyses will continue during 2023 to clarify and quantify the effects in different forest types and regions.

The main result of this study is a procedure to apply GEE for mapping the deforestation and forest degradation in the Central Highlands of Vietnam, which can be applied for many other inland forests in the country.

Mapping surface fuels in three-dimensional space using terrestrial laser scanning and RGB image mosaics

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Miriam Herrmann[1]
Fabian Ewald Fassnacht[1]
[1] Institute of Geographical Sciences, Remote Sensing and Geoinformatics, Freie Universität Berlin

Abstract: Changing weather patterns due to climate change can result in increasingly dry summers in formerly not fire prone forest systems in central and northern Europe. A prerequisite for fire occurrence is the presence of burnable materials, that is fuels. Fuels can be classified according to their vertical position: ground fuels (humus, tuff), surface fuels (shrubs, woody debris, logs) and canopy fuels (tree canopies). Much research using remote sensing technology has focused on canopy fuels. In contrast, remote sensing research on surface fuels has been scarce as established optical remote sensing approaches from satellite or UAV platforms are hardly able to collect information from below the canopy.

In a new research project, we aim on increasing our understanding of small-area spatial patterns of surface fuels and develop alternatives for traditional field sampling methods for forest fuels. For this, fuels are mapped using 3D and RGB data and results are compared to traditional field sampling methods.

We use a) a terrestrial laser scanner for the acquisition of 3D point clouds and b) under canopy RGB image mosaics for a continuous representation of the forest floor and the understory. For reference, traditional field sampling is carried out in subplots. Sampling will take place in pine forests in Brandenburg, Germany, during summer 2023.

The research objectives are a) to create a detailed continuous map of different surface fuels using deep learning and the RGB image mosaics to b) explore the capacities of remote sensing methods compared to traditional, time-consuming, and potentially subjective field sampling and c) relate patterns detected by remote sensing to fire behavior models and ecological processes.

At the IUFRO conference we will present the developed methodical workflow and first results from the field campaign.

Methods to reduce the design-bias of model-based predictors based on remotely sensed data

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Göran Ståhl[1]
[1] Swedish University of Agricultural Sciences

Abstract: The choice of framework for statistical inference is important when utilizing remotely sensed data for mapping and estimating forest characteristics. This choice is sometimes delibe-rate, but often it follows indirectly from the methods applied to make predictions. For example, large-area mapping and estimation of biomass has emerged as a very important field of applying remotely sensed data, where parametric or non-parametric regres-sion models are typically applied. Such approaches provide approximately model-unbiased biomass predictions for individual population units (often grid-cells in maps), conditional on the input data. Thus, implicitly a model-base inference approach is adopted. However, if we instead adopt a design-based perspective, it can be shown that model-based predictors are design-biased, and that typically there is a trend in the design-bias implying that small true values are overestimated and large true values are under-estimated. This has important negative implications in many fields of application where wall-to-wall information from remotely sensed data are used for the decision-making. In this presentation, different approaches to reduce the design-bias of model-based predictors will be proposed and compared. The presentation will focus on estimation and prediction at the level of individual population units, but also demon-strate the effects when such estimates are aggregated to domains and population totals.

Modeling forest attributes using public LiDAR of Aleppo pine (Pinus halepensis Mill.) forests in a Mediterranean island context.

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Vicent Agustí Ribas Costa[1, 2]
Rachel Cook[1], Aitor Gastón González[2]
[1] Department of Forestry & Environmental Resources, NC State University, Raleigh, NC 27695, USA
[2] ECOGESFOR Research Group, Departamento de Sistemas y Recursos Naturales, ETSI Montes, Forestal y del Medio Natural, Universidad Politécnica de Madrid, José Antonio Novais 10, 28040 Madrid, Spain

Abstract: Mediterranean forests, especially naturally regenerated Aleppo pine (*Pinus halepensis* Mill.) ones, have a crucial role in climate change. Despite being threatened due to temperature increase and precipitation decrease, intensifying the desertification risk and wildfire potential, these forests are key in climate change mitigation, as they are extremely adaptative and can provide valuable information like carbon or timber stocks. However, quantifying these forests' attributes and productivity should be done first. Although National Forest Inventories are an acceptable approach, continuous cover maps of Mediterranean forest stand attributes are still lacking, as these efforts are normally done for more productive species. In this work, we use the low-density public Spanish PNOA LiDAR flights to model forest attributes (i.e., dominant height, above-ground biomass, volume, tree density, and basal area) in the context of naturally regenerated Mediterranean forests of Aleppo pine, abandoned and unmanaged since mid-XXth century. We compared two different methodologies: area-based and individual tree detection, with the ultimate goal of generating continuous maps for these variables. We trained and validated the models with ground forest inventory data and found that the two approaches yielded similar results in terms of goodness of fit and error. For the latest version of the methodology, area-based approach models yielded $R^2 \sim 0.7$, RRMSE ~ 1.5 m, and RRMSE ~ 12% for dominant height and $R^2 \sim 0.7$, RMSE ~ 25.6 Mg ha^{-1}, and RRMSE ~ 30% for above ground biomass; whereas the individual tree detection models yielded $R^2 \sim 0.7$, RRMSE ~ 1.5 m, and RRMSE ~ 12% for dominant height and $R^2 \sim 0.5$, RMSE ~ 30.3 Mg ha^{-1}, and RRMSE ~ 38% for above ground biomass. Due to the higher computational power of the latter and no significant increase in quality relative to the former, we encourage the use of area-based approach for large-scale mapping. We believe these models, and their corresponding maps, will be a great asset for policymakers and different stakeholders not only for the region they have been created for but also for similar environments of unmanaged Aleppo pine forests throughout the Mediterranean basin.

Reconstruction of the evolution of afforestation and abandoned agricultural lands using retrospective geosimulation

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

[3] Department of Land Use Planning and Geomatics, Faculty of Engineering, Agriculture Academy, Vytautas Magnus university, Universiteto str. 10, Akademija, Kaunas district, Lithuania

Abstract: Natural forest regeneration on non-forest land in Lithuania is only recognized as a forest after it reaches the age of twenty years. If these areas are not properly inventoried and registered, they may be treated as abandoned agricultural land. Consequently, this can lead to legal sanctions or a decision of landowners to clear large areas leading to the removal of young trees. This study aims to investigate the potential of timely inventory of afforestation on agricultural land by employing a combination of advanced spatial analysis, artificial intelligence, and remote sensing techniques. We hypothesized that the improvement of abandoned land identification in Lithuania depends on mapping and specifying trees outside currently registered forest lands. Primarily, we mapped and specified areas covered by woody vegetation using remotely sensed data based on airborne laser scanning (ALS) and aerial imaging. A combination of individual tree detection and area-based approaches in processing the ALS data resulted in most promising solution for mapping the objects of interest. Spectral information from optical images increased the accuracy of estimations. Then, we improved the characterization of mapped objects by reconstructing their historical development using simulation models based on machine learning and deep learning approaches. All available auxiliary historical geographic information was used to facilitate the identification of afforestation on non-forest lands and the abandonment of agricultural lands. Alongside mapping areas grown with woody vegetation, we managed to achieve better understanding of factors behind abandonment of agricultural lands and clearing out potential new forests. We suggest our approaches to be used also for wall-to-wall land-use change mapping in the past or future in accordance with forthcoming EU legal acts for the LULUCF sector within the frames of greenhouse gas management efforts.

Remote sensing of functional complex networks for the forests of the northern hemisphere

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Hugo De LAME[1, 2, 3]

[2] Université du Québec en Outaouais, Institut des Sciences de la Forêt Tempérée, Canada
[3] Fonds National de la Recherche Scientifique, Belgium

Abstract: Forest ecosystems play major roles e.g. in climate change mitigation by storing and capturing vast amounts of atmospheric carbon, in the water cycle and in the sheltering of biodiversity. Yet, they are increasingly threatened by climate change and the related increases in temperature, severe droughts, pest invasions and wildfires. Innovative theories in forest ecology suggest that, in order to be resilient to external forcings, forest ecosystems should present a wide range of functional traits coupled with an organization at the landscape level under the form of a functional complex network. However, this theory has yet to be confirmed in practice and validated at different spatial scales and for different regions of the world.

In this context, the case of northern forest ecosystems is particularly concerning, notably due to the long history of silvicultural practices that focused mostly on timber production which led to current poorly resilient ecosystems. Consequently, I develop here a research project that tests the functional complex network theory for these northern forest ecosystems, building innovative approaches from innovative remote sensing technologies, i.e. airborne and spaceborne LiDAR. Using a multiscale framework, I (i) identify key airborne LiDAR metrics characterizing key functional traits in similar yet contrasted forest plots from Wallonia and Quebec at the stand level; then (ii) identify key landscape properties enabling functional connectivity between forest patches from the combination of LiDAR and spectral data at the landscape level; and finally I map (iii) the current and (iv) potential state of the functional networks at the biome level to localize and qualify key functional gaps where we should act upon to make our forest ecosystems resilient, either through an adaptation of silvicultural practices or through ecosystem restoration.

Remote sensing-based assessment of relationships between native Oak tree structure and wind damage in the UK following Storm Arwen

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Kate Halstead[1]

[3] Action Oak, Haslemere, UK
[4] Forest Research, Northern Research Station, Roslin, EH25 9SY, UK

Abstract: Oak trees are an essential component of the UK's treescape, yet, in recent years, their population has declined due to several threats. Extreme storm events have been identified as a significant abiotic threat to the health of native Oak, causing severe damage and mortality. Due to climate change, storm events are increasing in intensity and occurring in regions that were once unaffected. The UK Winter 2021/22 storm season was particularly damaging regarding event occurrence and intensity. Storm Arwen caused extensive damage to Oak in the North of England and Scotland. Extreme windspeeds came from an unusual North-Easterly direction. As the predominant UK wind direction is from the South-West, the root plates of many Oak may not have been adapted, contributing to windthrow.

The research aims to profile the consequences of Winter 2021/2022 extreme storm events upon the health of the UK's native Oak population, studying Oak in different settings such as woodland, parkland and field margins. The unique wind direction of Storm Arwen presented an opportunity to study the interrelationships between Oak health and strong wind in the North-East of England.

Novel remote sensing techniques are incorporated into the project. A GeoSLAM ZEB Horizon laser scanner, and DJI Matrice RTK quadcopter drone, mounted with a LiDAR sensor, were used to create high-resolution 3D models of the structure and canopy of the damaged Oak. Analysis of the structure, using the ITSMe R package (extracted parameters include DBH, tree height, crown area and tree volume), will help determine the extent to which local wind strength and direction were responsible for storm damage. At each site, a GeoSLAM ZEB Horizon scanner has also been used to derive the amount of carbon lost from the canopy and stored in deadwood. This is significant, as Oak has the potential to store more carbon than any other native UK tree species.

An understanding of which factors contribute to damage during extreme storms will provide national stakeholders with suggestions to alleviate stresses and aid Oak management practices. The research has the potential to be applied to other species of storm damaged trees, both nationally and internationally.

Satellite data reveal differential tree species recovery to unprecedented 2018 drought

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Abstract: Rising global temperatures together with the increase in drought frequency, intensity, and duration are affecting the productivity, phenology, regeneration, and mortality of forest ecosystems. Species-specific responses to drier conditions are likely to be influenced by their functional traits and local site conditions. Yet knowing which species are affected by drought and where is often a difficult monitoring task.

Here, we analyzed forest recovery from drought using an extensive network of field-based inventories and remote sensing data. We compiled forest health indicators based on field-based canopy condition and vegetation indices derived from Sentinel-2 satellite data (Normalised Difference Vegetation Index (NDVI) and Normalised Difference Water Index (NDWI)). We quantify the drought response of more than 10,000 individual trees of 11 tree species in Switzerland, across ten biogeographical regions. We calculated NDVI and NDWI changes between 2017 and 2021 to capture tree species' health before, during, and after the 2018 drought.

Preliminary results show that all species had high vitality prior to the 2018 summer drought and were significantly affected by the drought, except for *Pinus cembra*. While most species recovered significantly within one year of the drought, *Quercus petrea* only recovered two years later. Pre-drought vitality was not regained in most cases within the next three years after the 2018 drought, except for *Betula pendula, Populus nigra,* and *Pinus sylvestris*. Factors influencing tree recovery were the prevailing climatic conditions in the ten biogeographical regions and species-specific drought coping strategies.

Our results demonstrate the suitability of satellite-based quantification and monitoring of drought-induced tree species damage and recovery at high spatial resolution across large areas. Knowing which species are most affected and how they recover from extreme droughts will help us develop adaptive management strategies and understand processes that improve the adaptive capacity of forests to new climatic conditions. Coupled with tree species recognition models, this approach can serve as a basis for more automatic monitoring of forest health.

Seeing sick trees from the air or space: Opportunities and challenges in forest health assessments from remote sensing

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Abstract: Forest mortality rates are increasing globally. Tree mortality is the fastest way to lose carbon and biodiversity from intact forests. Increasing our capacity to detect forest health issues when they are limited in spatial extent, while there may still be time to mitigate them remains one of our best hopes for limiting tree mortality. Early detection of tree mortality events and tree decline through remotely sensed products provides an avenue for biodiversity conservation and carbon sequestration. Mortality events most often occur at the scale of the individual or a small group of trees in a forest. Our ability to detect shifts in tree mortality and determine the causal factors responsible is defined by the intensity, scale, and frequency of our observations. Currently, most observations are too coarse in spatial scale and too infrequent in time to determine causal factors of mortality or how they vary across space and time and lack detail of why a tree died. We aim to fill this knowledge gap. Our objective is to address this challenge and build scalable models of tree mortality with underlying factors associated with tree death.

To evaluate causal factors and detectability of mortality from remote sensing, we collected three years of annual tree health data across five spatially mapped ForestGEO plots for over 60,000 trees. We also accessed repeated airborne remote sensing data (lidar, RGB, and hyperspectral) collected by the National Ecological Observatory Network (NEON) at all plots and their surrounding landscape. We also acquired very high-resolution data from UAV collections to leverage both spectral and spatial information about different tree health status conditions. Our field surveys have found a wide range of species-specific mortality rates and an even wider assortment of factors associated with tree death often with species-specific syndromes. We have found that the species that are experiencing the highest mortality have compound causal agents corresponding to an accumulation of problems that ultimately kill the tree. We will present our results on connecting remote sensing data to tree health censuses with advanced algorithms to provide insights into how we might detect forest health threats in the future.

Spectral behavior variables are key indicators for mapping and discriminating restoration methods in secondary forest areas in the Atlantic Forest

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Abstract: Forest ecosystem restoration is crucial for biodiversity preservation and mitigating the impacts of climate change. However, accurately mapping and differentiating restoration methods in secondary forest areas pose challenges for researchers. In this study, we utilized comprehensive datasets to investigate actively restored and naturally regenerated secondary forest areas in the Atlantic Forest of São Paulo State, Brazil. Our first dataset examined landscape context, including variables such as slope, proximity to watercourses, and statistical analysis of primary vegetation within a 300-meter buffer around each restoration area. We also evaluated the current spectral behavior using four vegetation indices during rainy and dry periods. Furthermore, we analyzed the historical spectral behavior of vegetation using various indicators, including trend, magnitude, anomalies, seasonality, mean NDVI, and interannual variation, derived from time series data of each study area. Principal Component Analysis revealed that the combination of current and historical spectral behavior variables explained 65% of the restoration and regeneration areas across the first three principal components. Context variables, on the other hand, contributed only 6% and were limited to the fourth principal component. These findings emphasize the crucial role of vegetation spectral behavior characteristics in distinguishing restoration methods. To validate our method, we trained four classifiers using machine learning algorithms: XGBoost, Gradient Boosting, Bagging Classifier, and Linear Discriminant Analysis. The XGBoost classifier achieved an impressive accuracy of 88%, while the other algorithms also yielded promising results with an accuracy of 84%. Our results demonstrate the feasibility of using current and historical spectral behavior variables to differentiate actively restored and naturally regenerated secondary forest areas. This method's accuracy is essential for guiding effective restoration strategies and ensuring proper monitoring of these areas, thus guaranteeing the persistence and sustainability of young forests. The study represents a significant advancement in forest restoration monitoring, offering a comprehensive and accurate approach to distinguish restoration methods in the Atlantic Forest's secondary forest areas. The acquired results are of paramount significance in improving the management of degraded landscapes, promoting biodiversity conservation, and advancing environmental sustainability. Furthermore, it provides an opportunity to model the potential for natural regeneration by removing active restoration plots.

Synergistic Forest Carbon Estimation using Spaceborne Active and Passive Remote Sensing Data

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Yong Pang[1]
Tao Yu[1], Wen Jia[1]
[1] Chinese Acaemy of Forestry

Abstract: The enhancement of forest carbon sink is an effective approach to achieve carbon neutrality goals. The forest carbon sink contributes over 80% sink amount over terrestrial ecosystem. Accurate measurement of forest carbon stock can provide scientific support for achieving carbon neutrality goals. However, due to complex terrain and long-term human activities, the fragmentation and spatial heterogeneity of forest patches bring significant challenges to accurately estimating carbon stocks. Through the complementary advantages of the active and passive optical remote sensing payloads, the first Terrestrial Ecosystem Carbon Inventory Satellite in China, called "Goumang" was lunched on Aug. 4, 2022. This satellite provides 5 beams full waveform LiDAR together with 5 angle multiple spectral cameras, which provides the forest carbon storage synergistic estimation based on active LiDAR and passive multi-angle optical. The forest carbon stock measurement system at the footprint level of spaceborne LiDAR will be developed using a big dataset and new LiDAR biomass indices. Then we built a forest bidirectional reflectance reconstruction method which couples kernel-driven models and multi-angle observation data. Then build forest structure characteristic parameter inversion models by the integration of angular and spectral information. The developed system of forest carbon stock synergistic estimation method using active and passive data based on deep learning framework was tested in the north and south of China.

The new generation of multi-layer fuel load modeling in tropical savannas from space

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Abstract: Quantifying fuel load over large areas is crucial for effective integrated fire management in fire-prone regions, aiming to preserve carbon stock, biodiversity, and ecosystem functioning. It also plays a vital role in understanding global climate regulation as a potential carbon sink or source. The NASA's Global Ecosystem Dynamics Investigation (GEDI) full waveform lidar sensor holds great potential in addressing this need. However, its capability for estimating fuel load has not yet been evaluated. In this study, we developed a novel framework and tested machine learning models to predict multi-layer fuel load in the Brazilian tropical savanna (Cerrado), using GEDI simulated and on-orbit data. For GEDI data simulation, we conducted lidar flights using an unnamed aerial vehicle (UAV) over selected sample plots representing distinct Cerrado vegetation formations, including grassland, savanna, and forest. Field measurements were taken to determine the load of surface, herbaceous, shrubs and small trees, woody fuels, and the total fuel load. Subsequently, GEDI-like full-waveforms were simulated from the high-density UAV-lidar 3-D point clouds. We calculated vegetation structure metrics from these on-orbit and simulated waveforms and correlated them with field-derived fuel load components using Random Forest (RF) models. Overall, the RF models demonstrated better performance for woody fuels and total fuel loads ($R2 > 0.71$ and 0.79, respectively). Although performance for components in the lower stratum varied from moderate to low, the results remained reliable. This framework can be extended to other fire-prone regions where accurate measurements of fuel components are necessary. We anticipate that this study will contribute to the broader application of spaceborne lidar for integrated fire management and support carbon monitoring initiatives in tropical savannas worldwide.

Abstract: In this work, an ensemble of machine learning algorithms was trained using stratified sampling to extract values from an existing European-scale biomass map from 2018 to estimate an updated version for 2020. The strata are necessary to ensure that the full range of biomass values is represented. The sampled values from 2018 were distributed over areas that did not suffer forest loss according to the "Global Forest Change" forest cover/loss/gain map derived from Landsat time-series. We trained the algorithm using a total of 49 features obtained from bioclimate, land cover, tree cover, and tree height map, in addition to annual composites of maximum values of vegetation indices per pixel (EVI and NDVI) from Sentinel-2 imagery, and radar backscatter median annual values from Sentinel-1 products. Except for the bioclimate maps, all other features represent the 2020 conditions. The model divided Europe into 19 tiles to limit variability due to the differences in bioclimatic zones. The result is a raster with ~100 m cell resolution depicting estimated biomass (Mg ha^{-1}). The rationale of this method is that, in an ideal situation, training should be done with ground-

measured data. However, rarely a significant number of large forest plots (~1 ha) are available with biomass estimates for the year of interest, and be representative of the extremely varied biomass conditions of Europe. Therefore, we used existing biomass data for the training needs. These data have a larger error compared to ground measurements, but the very high number of samples that we can use allows the machine learning ensemble to minimize the error effect. Overall, results produced using validation data over Europe report a root mean square error (RMSE) of 37 Mg ha^{-1}, and a mean absolute error (MAE) of 24.7 Mg ha^{-1}. Regarding single tiles, the largest RMSE was 55.3 Mg ha^{-1} from the tile depicting the Alpine region and the western part of Eastern Europe, which can be explained by the very high actual variance of biomass values in the region.

USE OF EARTH OBSERVATION DATA TO ASSESS AND MAP LAND COVER CHANGES IN MT. ELGON FOREST BETWEEN THE YEAR 2010 AND 2016

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Edward Juma[1]
[1] Directorate of resource Surveys and Remote Sensing

Abstract: Mt. Elgon is one of the major forests found in Lake Victoria catchment. The forest catchment serves the rift valley drainage system where rivers emanating from it are a source of water to downstream. The forest supports Kenya's economy by sustaining agriculture, manufacturing, horticulture, tourism and energy sectors. Despite the significance, the forest underwent degradation affecting its capability in providing both economic and ecological services. The study assessed and mapped land cover changes within the gazetted forest boundary and in 5 km buffer zone created around the forest; mapped the extent and distribution of the land cover types from 2010 to 2016; and established major threats facing the forest. Satellite images were used to generate land cover maps and the questionnaire survey conducted to collect socio-economic data. The approach of mapping was based on classification scheme proposed by the Intergovernmental Panel on Climate Change (IPCC), which was domesticated to seven classes namely; Forestland, Annual Cropland, Perennial Cropland, Open Grassland, Wooded Grassland, Open Water and Settlements. The generated maps were validated and compared to determine areas that experienced changes. Results indicated that forestland decreased by 6% within gazetted forest boundary. The rest of the land cover also decreased a part from annual cropland which increased significantly. In the 5 km buffer zone, forestland and wooded grassland increased by 1% and 24% respectively, while perennial cropland decreased significantly. The loss of 3,137ha of forest cover within the gazetted forest boundary over a 6-year study period was equivalent to a loss of 523ha of forest per year. Major threats facing the forest were established as: encroachment by farms and settlements; unsustainable harvesting of forest products; excisions and abuse of Plantation Establishment for Livelihood Improvement Scheme (PELIS). Based on these findings, there is need to reverse the negative trend in forest cover through the following measures: stop further excisions and survey the forest to update the boundary; stop forest encroachment and remove people who live or farm in the forest; strictly implement policies guiding PELIS; rehabilitate and restore the mapped degraded areas; and sensitize locals on tree planting in private farms adjacent to forest.

Using multi-level sampling and model-assisted estimation to support forest inventory in interior Alaska, USA

T5.8 Developments in complex remote sensing-assisted forest surveys to support monitoring and assessment of forest ecosystems

Hans-Erik Andersen[1]
Göran Ståhl[2], Bruce Cook[3]
[1] USDA Forest Service Pacific Northwest Research Station
[2] Department of Forest Resource Management, Swedish University of Agricultural Sciences, Umeå, Sweden
[3] NASA Goddard Space Flight Center

Abstract: In 2016, the US Forest Service Forest Inventory and Analysis program (the national forest inventory of the USA) initiated the first systematic, comprehensive inventory of the boreal forests of interior Alaska in the modern era. This forests of this region, which represent approximately one-fifth of all US forestland (~46 million hectares), are extremely remote and costly to inventory using the conventional FIA sampling design. Through a partnership with NASA Goddard Space Flight Center, a cost-effective design was developed and implemented in interior Alaska which leverages high-resolution, multi-sensor G-LiHT (Goddard-Lidar- Hyperspectral-Thermal) airborne remote sensing data flown in a strip sampling mode and covering every FIA plot established on a relatively sparse grid (1 plot per 12,000 ha). G-LiHT provides detailed, high-resolution measurements of forest structure (e.g. biomass/carbon), vegetation composition (e.g. forest type), and condition (e.g. mortality). A model-assisted estimation framework was developed that integrates G-LiHT-derived measurements (obtained as a strip sample) with field measurements to provide precise, and unbiased, estimators of important inventory attributes, including totals (e.g. total live tree carbon), areas (e.g. total area of black spruce forests), and domain-level averages (e.g. average live tree carbon per hectare in black spruce forests). Here we present the model-assisted estimators used in this inventory, as well as an assessment of the statistical properties of these estimators (bias, coverage probability) obtained via simulation.

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Combined terrestrial and digital mapping for area-wide maps, modelling soil properties and link re-mote sensing data with classical site surveys.

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Marcus Wilhelmy
Klaus Klebinder[1]
[1] Bundesforschungszentrum für Wald (BFW) Abteilung Wildbachprozesse und Hydrologie, Innsbruck, Austria

Abstract: In many forest areas especially near the timberline there is a lack of spatial covering data about soil properties. To handle large areas in a reasonable time and with manageable manpower, soil development and soil properties are spatially covering modelled.

So-called substrate maps have established themselves as an important predictor for modelling physical properties such as permeability and pore volume and chemical soil properties such as the potential of cation release (K^+, Ca^{2+}, Mg^{2+}). These maps consist of polygons whose homogeneity is defined primarily by the sedimentological process essential in them, the gen-type, the genetical types of abrasion and accumulation which are responsible for the substrate, the matter in about 1 to 1,5 m beneath the surface.

Terrestrial mapping of corridors, mainly using forestry roads, provides important data about physical and mineral chemical properties of substrate. These hard data result directly from the field surveys or from results of analysed samples (x-ray diffraction, grain size distribution, mineral petrographical analyses).

Along the maped corridors, the location of polygon boundaries represent the change of gen-type or substrate properties. These boundaries can be defined to within a few metres. In this way, a full-surface pattern of directly adjacent polygons along the terrestric corridors is created.

This corridor-network is digitally supplemented to form an area-wide map. This work is also done manually according to the same rules as along the terrestrial corridors.

The result is an area-wide map of the quantitatively classified substrate. According to the different data basis for terrestrial corridors and referenced classified areas in between, the attribute information sharpness is applied. For the classified substrate, quantitative data for nutrient supply and water balance can be derived.

Through this combination of terrestrial mapping and modelling, the properties of large areas can be represented in relatively high resolution in a reasonable amount of time and with a manageable amount of manpower.

These maps are an essential predictor for spatial modelling of soil properties such as nutrients and water and also provide a useful link between remote sensing data and terrestrial point information.

Cost-efficient mapping of a site-based forest ecosystem classification using machine learning

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

William H MacKenzie
Genevieve Perkins[1]
[1] Ninox Consulting, Smithers, British Columbia, Canada

Abstract: Ecosystem maps are an important tool for managing natural landscapes. Existing ecosystem mapping (EM) of the site-based biogeoclimatic ecosystem classification system use expert models or air photo interpretation, which are confounded by high cost, subjectivity, poor updateability and require expensive independent field verification to assess map accuracy. A data-driven, machine learning approach to EM has the potential to address these limitations, however, the high cost of training data acquisition has limited its application in practice. We outline a scalable, cost-efficient sample design that places line-intercept transects using cost-constrained conditioned Latin hypercube sampling of ecologically relevant landscape-level predictors. Ecosystem units, which reflect site conditions, are identified primarily by indicator species assisted by topographic and soils factors. Our hierarchical sample design provides spatially distinct units for 1) training data, in the construction of machine-learning ecosystem models, and 2) appropriately scaled experimental unit for statistical map accuracy evaluation. We produce accuracy statistics from a repeated leave-one-out model build and assessment. Mean accuracy with variance are reported for a suite of metrics that reflect proportional and spatially-explicit accuracy, a 'theta' metric to adjust for imbalanced map unit abundance, and fuzzy set scoring. The appropriate metric can be selected for different applications of EM.

We applied this methodology to sample, build and evaluate a stand-level ecosystem map in a 50 000 ha area of low boreal and subalpine forest using a Random Forests learner and a standard suite of predictor covariates derived from LiDAR. The sample design successfully sampled both important stand-level predictor distribution and a representative set of ecosystem map units, while reducing sample costs by an order of magnitude compared to single point sampling. Machine-learning models trained with optimally rebalanced training data from as few as 30 sample transects, representing 3-4 crew-days of effort, produced a stand-level forest ecosystem map with 85% +/- 10% agreement on map unit proportions and 75% +/- 10% spatial accuracy where fuzzy membership scores and 5m corrections for spatial misregistration are applied. This cost-effective method can be adapted to other inventories requiring intensive field sampling will allow implementation of comprehensive and reliable ecosystem mapping program.

Developing soil moisture maps at high spatiotemporal resolution for forest management and nature conservation: a study in a boreal forest landscape

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Francesco Zignol[1, 2]
Anneli Ågren[1], William Lidberg[1]
[1] Department of Forest Ecology and Management, Swedish University of Agricultural Sciences, Umeå
[2] Bolin Centre for Climate Research, Stockholm

Abstract: Digital soil moisture maps are valuable tools to practitioners, stakeholders and researchers for planning forest management and promoting nature conservation. However, mapping soil moisture at both high spatial and temporal resolutions is challenging, especially over spatially extensive geographic regions. By focusing on the Krycklan catchment in the boreal region of northern Sweden as a pilot study area, we propose a novel procedure that combines LIDAR-derived terrain and vegetation indices, reanalysis climatological data and in-situ field measurements within a machine-learning (ML) framework to develop daily soil moisture maps at 2-meter resolution. First, we explored the ability of numerous potential climatic, topographic and vegetation-related variables from different sources and with different spatial and temporal resolutions to predict soil moisture data recorded at about 90 sites across the study area over the snow-free seasons of 2022-2023. Second, these in-situ measurements of soil moisture served as a means to train and validate three ML models using (i) only field data, (ii) only remote sensing data, and (iii) a combination of both as predictors. The resulting maps reproduced well the spatiotemporal variability of soil moisture in the study area, with the second type of ML models performing only slightly worse than the other two. We argue that these dynamic soil moisture maps at high spatial resolution could provide valuable information for practical forest management and the methodological framework that relies exclusively on remote sensing data could be extended to the scale of Sweden.

Digital soil mapping and modelling of forest soils in Europe

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Laura Poggio[1]
Luis Calisto[1], Giulio Genova[1], Niels Batjes[1]
[1] ISRIC - World Soil Information

Abstract: Forest soils are important providers of ecosystem services, underpinning economic sustainability. The health and sustainability of forest ecosystems depend on the health and functioning of forest soils. Their conservation and management are essential for the well-being of both natural ecosystems and human societies. It is fundamental to have up to date spatial information on forest soils for continental coverage in Europe for various stakeholders. In this work, carried out in the framework of the EU H2020 project on 'Holistic management practices, modelling and monitoring for European Forest soils' (HoliSoils), we will present two key aspects: 1) how forest soil datasets from different sources were integrated and harmonised, and 2) how these data were used to map soil properties of forest soils at continental scale. The soil data were processed following updated Extract Transform Load (ETL) procedures developed for WoSIS (ISRIC - World Soil Information Service). For the mapping, we used an approach featuring model tuning, covariates selection and regression random forest to map key soil properties at a resolution of 100 m and assess the spatial uncertainty for each pixel. The work shows the importance of quality-assessed, harmonised data when mapping and modelling across countries at continental scale to support decision making towards climate and sustainability goals.

Efficient sampling approach for digital soil mapping in mountainous forests of Japan

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Naoyuki Yamashita[1]
Yasuhiro Ohnuki[1], Takuma Watakabe[1]
[1] Forestry and Forest Products Research Institute

Abstract: Digital soil mapping (DSM) has developed rapidly in recent years in line with the development of machine learning, and there has been a growing focus on the approach for site selection to improve mapping accuracy (sampling for DSM). However, most studies have been conducted on less undulating areas, including farmland. Few studies have been conducted on mountainous forests with difficulty reaching target points due to bushes, steep slopes, and a lack of forestry roads. Thus, the more efficient sampling that enables accurate mapping at fewer points is necessary for reducing survey costs in Japan, where mountainous forests cover 75% of the national land area. This study focused on mapping soil thickness and compared the methods to determine the appropriate sampling for DSM in mountainous forests. The study area (ca. 120 ha) is in mountainous and hilly terrain, contains ca. 30 first-order drainage basins, and is mainly planted with *Cryptomeria japonica*. We measured soil thickness using a soil strength probe at 80 points each by covariate space coverage sampling (CSC) as the sampling for mapping and by traditional spatial coverage sampling (SC). CSC determines the sampling point using spatial covariates that are expected to be related to soil properties by k-means. Several topographic factors, such as slope, TWI, and TPI, were used for CSC. Finally, using random forest, DSM was conducted by both sampling sets and compared their accuracy. To test the sensitivity to the number of training points, DSM using 90%, 80%...10% of the total points are compared in both models. As a result, the accuracy of CSC was significantly higher than that of SC for all sampling points. The difference was more in smaller sample sizes. The predicted map by CSC was almost similar in spatial pattern to the map by all 160 points. Thus, CSC would be cost-efficient sampling for DSM in mountainous forests, where the topographic factor is strongly correlated with soil properties. Meanwhile, more efficient soil surveys would be possible if the distance from the roads or the location of bushes were considered in the CSC.

Fine-grained Soil Particles Prediction Based on GeoAI and LiDAR for Precision Harvesting Applications

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Omid Abdi[1]
Ville Laamanen[1], Jori Uusitalo[1], Veli-Pekka Kivinen[1]
[1] Department of Forest Sciences, University of Helsinki

Abstract: In precision harvesting, it is important for foresters to understand the soil-bearing capacity in order to take appropriate measures to minimize soil compaction, preserve soil structure, and ensure that the soil is suitable for use by harvesters or forwarders. Fine-grained soils play a particularly crucial role in determining soil-bearing capacity, as they tend to be more sensitive to compaction and deformation than coarse-grained soils. Creating accurate and detailed maps of soil particles in forested areas is a complex and challenging task due to the significant variability in soil properties and the difficulty in accessing and sampling the soil. However, recent advances in technology, such as deep learning-based approaches and remote sensing data, offer promising solutions to this problem.

In this study, we developed a fully connected neural network (FCNN) approach that utilizes high-density LiDAR data derivatives to estimate the values of fine-grained soils. Our soil samples were collected from 47 forest stands located in southern Finland. We determined the distribution of grain sizes of the soil samples using the laser diffraction method. To create the target map of soil particles within each forest stand, we used geostatistical models. The predictors' layers, such as geomorphological and forest features, were derived from LiDAR metrics. These data were used to create training and testing datasets. After tuning the architectures and hyperparameters, we trained our FCNN using the training dataset and evaluated its performance using the testing dataset.

We anticipate that our model will produce promising results, with the potential to significantly improve the accuracy of the prediction of fine-grained soil particles in the forest environment. This could have important implications for the prediction of soil disturbances induced by harvesters, as well as the prediction of soil-bearing capacity. While our study is still ongoing and we have not yet obtained final results, we believe that our GeoAI-based approach has significant potential for advancing soil studies. We look forward to sharing our findings with the research community at the conference.

High-Resolution Map on Base Saturation: an Essential Tool for Forest Management in Austria

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

[4] Institute of Silviculture, Department of Forest and Soil Sciences, University of Natural Resources and Life Sciences (BOKU), Vienna

Abstract: Understanding soil nutrient status and its spatial distribution is crucial for effective forest management, especially in the face of climate change. This study focuses on the development and significance of a high-resolution base saturation map based on nutrient classes for a forest area of 1 million hectares in a complex topographic and geological environment in the federal state of Styria, Austria. This study emphasizes the importance of such a map in light of existing data limitations and future challenges posed by climate change.

In a first step, pedotransfer functions were developed using laboratory analysis of soil chemical parameters from 400 soil pits in 4 depth layers. In order to expand the dataset and enhance coverage, an additional 1400 assessment plots were characterized solely by field descriptive soil assessment. This dataset of 1800 assessment plots served as the basis for subsequent analyses. In a next step, a combination of base saturation, soil pH and mineralogical composition was identified as robust parameters for defining soil nutrient classes in form of base saturation types.

Different digital soil mapping techniques, including Random Forest and Artificial Neural Networks, were then utilized to generate projections based on the expanded dataset. These techniques enabled the development of a high-resolution base saturation map that captures the spatial variability of base saturation types and thus soil chemical parameters.

The validation of this modeling approach was conducted by comparing the model outputs with the presence of tree species at the forest sites, average tree species growth, and plant sociological communities. Results demonstrated a strong correlation between the base saturation map and tree species distribution, highlighting the model's accuracy in capturing important ecological relationships. Furthermore, the growth of tree species aligned closely with the predicted nutrient classes, validating the utility of the map for assessing growth potential.

The map serves as a valuable tool for forest planners, enabling them to identify areas of specific interest and subsequently develop targeted interventions and adaptive management strategies (e.g. tree species selection), addressing current and future challenges in respect to nutrient status.

Mapping carbon stocks in forest litter considering vegetation, topography, climate, and soil parent material factors

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Kimihiro Kida[1]

[3] Forestry and Forest Products Research Institute, Research Planning Department, Japan

Abstract: The forest litter is a carbon pool on forest floor and also a major source of soil organic carbon. Then, geographic information on litter layers is important for climate change research and understanding the global and regional carbon cycle via forested areas. Since litter layer observation using remote sensing approaches is unreasonable at a present and complex decomposition and accumulation process of litter layer are affected by vegetation, topography, climate, etc., factors, this information is limited. Therefore, to generate the reliable geographic data about litter layers in the forest area of Japan (*ca*. 250000 km^2), we try to predict carbon stocks in litter layer with a digital soil mapping approach at a 10m grid resolution. This study conducts a random forest modeling using 2462 sites litter carbon stock data investigated since 2006 until 2010 as training data. Initial trial of random forest modeling of this study is based on vegetation, topography, and climate factors, according to the computing flow of previous study for forest soil carbon prediction using same investigation data (Yamashita et al. 2022). The random forest modeling for carbon stocks in litter layers indicates that dominant tree species of forest might be effective vegetation factor as differed from previous study about prediction of soil carbon stocks in Japanese forest area. Although this study improved accuracy of prediction for carbon stocks in litter layers, we need more consideration of selection explanatory factors to improve accuracy reaching to same level as compared to previous soil carbon prediction. This study was supported by JSPS KAKENHI Grant Number JP22H02400.

Mapping Multiple Soil Properties Using Artificial Neural Networks: Creating Coherent Soil Datasets

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Tobias Huber[1]
Reinhard Fromm[1], Michael Englisch[2], Josef Gadermaier[3], Klaus Katzensteiner[3], David Keßler[2], Harald Vacik[3], Klaus Klebinder[1]

[3] Department of Forest and Soil Sciences, University of Natural Resources and Life Sciences, Vienna, Austria

Abstract: Mapping multiple soil properties is essential for soil-related ecological modeling, including the prediction of tree species suitability. In this study, we propose an approach that utilizes artificial neural networks (ANN) to simultaneously map soil properties, ensuring the generation of a coherent and plausible dataset. Our aim is to enhance the compatibility and plausibility of the predicted dataset by considering the interdependencies among different soil properties. To achieve this, we employed ANN to model individual soil properties while incorporating independent covariates such as climatic, morphometric, geological, and remote-sensing information. Our approach aimed to maintain the accuracy of the predictions by considering the relationships among soil properties and their interplay with the covariates. By leveraging the collective information from the dataset, we aimed to maintain a balanced representation of the soil properties. In addition, we implemented a topically clustered strategy, grouping target variables based on specific themes such as hydrological or nutrient-related properties. This enhances the quality and accuracy of the predicted values by capturing the interdependencies among certain soil properties within each cluster. To evaluate the effectiveness of our methodology, we compared the results obtained to both random forest and ANN predictions fitted for single soil properties. Through comparative qualitative analysis of predicted soil properties, we evaluated the agreement and consistency of the mapped properties, taking into account their interdependencies. The findings demonstrate the capability of our approach to produce accurate and reliable maps of multiple soil properties by employing ANN and considering interdependencies. These maps provide valuable insights into the spatial variability and distribution patterns of soil properties, actively supporting soil-related ecological modeling for mapping tree species suitability in the context of sustainable forest management.

Mapping the productivity of forest sites across the Canadian landscape to predict which species to plant where in a changing climate

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

David Paré[1]
Luc Guindon[1], Francis Manka[1]
[1] Natural Resources Canada, Canadian Forest Service, Québec, QC, Canada

Abstract: Long-term tree growth depends on the complex interaction between site, soil, climate, and biological factors. Forest inventories provide abundant plot-based information on tree growth, but often lack essential information on soil chemical and physical properties. To overcome this problem, we used digital maps of soil properties, terrain, and climate variables to predict groundplot site index, a measure of site productivity for four major Canadian tree species. The models predicted different optimal growing conditions for each species and revealed interactions between climate and edaphic variables. For example, species that performed well in a cold climate perform better with a warmer climate as long as they remain under the same edaphic conditions. However, above certain climatic thresholds they become less competitive with other species and their presence is limited to sites of lesser quality. Digital mapping of soil and site conditions is crucial to understand how the complex interplay between edaphic, climatic, and biological factors drive forest productivity. The results of this study will be useful to predict the suitability of the plantation of different tree species to edaphic conditions in a changing climate and to better know what to plant where.

Mapping understory vegetation density using airborne and mobile laser scanning

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Ana De Lera Garrido[1]
Stefano Puliti[1], Maciej Wielgosz[1], Marius Hauglin[1]
[1] Norwegian Institute of Bioeconomy Research

Abstract: Understory vegetation plays a vital role in characterizing forest sites, wildlife habitat, and fuel load, and it is a necessary metric for simulating fire behavior or understanding forest competition dynamics. Traditionally understory vegetation has been characterized through field vegetation surveys which are time-consuming and limited in spatial coverage. To address this challenge, we propose a digital mapping approach combining data from airborne laser scanning (ALS) and mobile laser scanning (MLS), which can provide understory vegetation information at a larger scale.

The aim of this study was to map the understory vegetation density employing ALS and MLS technologies. Ground reference data were acquired using MLS, with a voxel-based analysis to characterize the understory vegetation structure. After excluding the trunks of the trees using semantic segmentation, we calculate understory vegetation density at different heights (surface from 0 to 0.3 m, near-surface from 0.3 to 0.7 m, and elevated from 0.7 to 2 m) by dividing the 3D point cloud into 10 cm voxels and determining the proportion of voxels containing laser echoes.

We then construct predictive models that relate the understory vegetation density of each height layer to ALS metrics. New ALS metrics related to ground points were tested in addition to the standard height and density metrics from different parts of the point cloud. Linear regression prediction models were developed for each understory layer using the ALS metrics as input variables. The accuracy of the models was evaluated through leave-one-out cross-validation by calculating the relative root mean square error and mean deviation. Finally, a wall-to-wall map of understory vegetation density was generated for each layer.

Preliminary results show promising potential for predicting understory vegetation using ALS data, with R2 values of 0.20, 0.41, and 0.47 for modeling understory vegetation density in the surface, near-surface and elevated layers, respectively.

Abstract: Accurately estimating forest biomass and carbon fluxes in extensive areas is critical for supporting sustainable forest management. In this study, the filed data and corresponding airborne laser scanning (ALS) data collected form 1086 sample plots distributed over the Guangxi between 2017 and 2019 were used to developed species-specific above-ground biomass(AGB) estimation models for other broadleaved forests, *Cunninghamia lanceolata* forests (*C. lanceolata* forests), *Eucalyptus grandis*×*Eucalyptus urophylla* forests (*E. grandis* forests), and *Pinus massoniana* forests(*P. massoniana* forests). There are three types of ALS instruments were employed to obtain the ALS data corresponding to our sample plots and the wall-to-wall ALS data. Therefore, Guangxi was partitioned into three distinct study areas, distinguished by the type of ALS instrument employed, wherein we subsequently developed species-specific AGB estimation models tailored to the forests within each respective study area. Then, a forest type distribution map with a resolution of 50m * 50m, derived from an aerial orthophoto image with a resolution of 0.2m * 0.2m, for validating and determining the forest type assigned to each grid cell within the rasterized wall-to-wall ALS dataset. Final, we generated a spatially-continuous map with a resolution of 20m * 20m of AGB by inputting the forest type and corresponding ALS metrics in each grid cell in the rasterized wall-to-wall ALS data to species-specific estimation models. The total AGB of other broadleaved forest, *C. lanceolata* forest, *E. grandis* ×*E.urophylla* forest, and *P. massoniana* forest in Guangxi in 2018 was $24433.07*10^4$t, $15291.22*10^4$t, $10993.97 *10^4$t and $18535.51*10^4$t, respectively. This article presents a method for acquiring a spatially continuous distribution map of AGB specific to different forests in the region of Guangxi, China. In subsequent research, a direct attempt could be made to determine the forest types of each grid cell in the rasterized ALS dataset , utilizing both the ALS and sample plot data.

Merging soil moisture forecasts and rolling resistance data by a forest harvester for predicting site trafficability and soil damages

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Aura Salmivaara[1]
Petra Virjonen[2], Eero Holmström[1], Sampo Kulju[1], Jari Ala-Ilomäki[1], Paavo Nevalainen[2], Jukka Heikkonen[2], Samuli Launiainen[1]
[1] Natural Resources Institute Finland
[2] University of Turku

Abstract: Mechanized forest harvesting operations with heavy machinery can lead to significant soil rutting. To avoid soil damages, reliable knowledge on site and time-specific trafficability and soil strength is needed. Factors influencing soil strength, such as soil texture, organic matter and clay content, bulk density, stoniness, and root system, have considerable spatial variability. These static or slowly varying site characteristics then determine how dynamic environmental conditions, e.g. weather patterns, drive the temporal variability of soil strength. While rather accurate spatial data on topography and above ground vegetation are available, the other landscape attributes influencing soil bearing capacity have much more coarse data resolution. More detailed understanding of the temporal variation in trafficability is crucial particularly due to climate change that might change the duration and timing of frost periods when trafficability is on sufficient level. Collection of detailed data on soil state and site trafficability is slow and expensive with traditional methods. We propose that utilizing the Arcnet-channel data from forest vehicles provides an useful data source and proxy for trafficability by informing about soil bearing capacity. In our project TRAM, funded by the Research Council of Finland, we have collected Arcnet data from a forest harvester and forwarder under normal forest operations. The data allows computing the rolling resistance based on engine power used, machine characteristics and local slope. We characterize and interpret the rolling resistance variability in typical forest landscapes in Southern Finland using the extensive machine data and open geospatial datasets. We explore how accurately rolling resistance can be predicted with machine-learning models using spatial data and high-resolution soil moisture predictions using a distributed hydrological model. We consider how the rolling resistance variability correlates with observed soil rutting derived from drone-based photogrammetry. We focus on 11 sites in Southern Finland harvested during spring and summer of 2021 under varying hydrometeorological conditions.

Potential for Using Machine Learning to Improve the Swedish National Soil Surface Deposit Map

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Yiqi Lin[1]
William Lidberg[1], Cecilia Karlsson[2], Anneli M. Ågren[1]
[1] Swedish University of Agricultural Sciences
[2] The Geological Survey of Sweden

Abstract: In the age of precision forestry, accurate and detailed soil information is crucial for optimizing forest management practices and forestry logistics. Soil classification provides a foundation for understanding key soil characteristics such as texture, nutrient content, water-holding capacity, pH, and other essential physical and chemical properties important for forest management. However, soil maps such as Sweden's current quaternary deposit maps suffer from limited high-quality coverage areas, rendering them impractical for hands-on use in some cases. This limitation arises partly due to the dense forest canopy prevalent in boreal regions, which poses challenges for traditional mapping techniques that rely on visual interpretation or direct field observations.

To address this issue, this study focuses on leveraging insights from field sampling data from the Swedish forest soil inventory and quantitatively assessing the effectiveness of incorporating indices calculated from the LiDAR-derived digital elevation model (DEM) and satellite imagery as input for machine learning models. Furthermore, the study aims to determine the optimal model for spatial prediction of soil classes, which will be deployed to generate a map of soil surface deposits at 2-m resolution for the entire country. Additionally, we will estimate the uncertainties associated with each soil class and discuss the advantages and limitations of this approach. The quality of the conventional maps at various scales and the machine learning-based surface deposits map are evaluated against a subset of the field observations. Preliminary results indicate that integrating field data with machine learning improves the identification of most soil types. We are confident that the machine learning-generated map can effectively complement the existing conventional soil maps in Sweden, but expert geological and pedological knowledge is still required when identifying certain sorted sediment types. The improved soil surface deposits map will serve as a decision support tool for future precision forest management, facilitating key tasks such as site-index determination, tree selection, and soil trafficability assessment, among others.

Predicting forest water status under climate change scenarios: A case study in Central Europe

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

[4] Institute of Wood Technology and Renewable Materials, University of Natural Resources and Life Sciences BOKU, Vienna, Austria

Abstract: Soils play a major role in the hydrological response of ecosystems. Spatially explicit forest soil attributes are however largely missing in Austria. Therefore, we developed a framework to map soil hydraulic properties and drought stress indices for a forest area of 1 million hectares at a spatial resolution of 10 m x 10 m. We aim to assess water budgets of forest site units for the past 40 years and for two climate scenarios until the end of this century.

Our approach combines various data sources: high-resolution digital terrain information, properties of the parent material for soil formation (sub-solum geological substrate) at polygon level, vegetation properties derived from remote sensing, downscaled high resolution climate data and point information (site and soil description of 1800 plots, analyses of physical soil properties of forest floor of five geometric mineral soil horizons of 400 pits).

Soil properties were upscaled with digital soil mapping techniques like Artificial Neural Networks. The water balance for 1,800 surveyed forest plots in the study area was modelled with the lumped 1-D- hydrological model LWFBrook90R. Hydrological soil characteristics for the parameterization of the model were derived from pedotransfer-functions. We simulated changes in soil water content, matrix potential, and transpiration deficit as an indicator of stress for a ‘generic’ forest stand. Combining this output with soil and topoclimate information we assessed the site-specific water supply which was then upscaled for the whole study area.

To validate the models, we compared their outputs with dendrochronological records available for all plots as well as vegetation indices from the ground-vegetation and site indices derived from stand properties. Dendrochronology provides valuable information on past growth patterns and can help us assess the models' ability to describe physiologically relevant information.

Overall, the development of the water balance framework is a promising tool for assessing the impacts of climate change on forest ecosystems. We could show possible impacts on the water balance in a future climate for different scenarios and were also able to identify areas which might be susceptible to future droughts.

Site Mapping based on the Correlation of Site and Soil Properties to Eucalyptus Plantation Productivity

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Kirti Bajpai[1]
Iswandi -[1], Paulo Rossin Pessotti[1], Marda Deta[1]
[1] APRIL Fiber Research and Developement

Abstract: This study assessed the utility of an object-oriented approach to obtain accurate correlation of site characteristics and soil properties to *Eucalyptus* clonal plantation productivity. The objectives were to characterize the soil physical and chemical properties and correlate them with two *Eucalyptus* clones productivity at age 42 months as well as to understand the most influential factors of site and soil on *Eucalyptus* productivity. We have built a model to predict productivity of *Eucalyptus* clonal plantations presented as digital maps. In the study, we characterized the site and soil spatially including clay content, soil CEC, organic carbon, pH, total nitrogen, extractable P, and exchangeable cations (Aluminum, Hydrogen, Potassium, Calcium and Magnesium). The most influential site characteristics and soil properties on *Eucalyptus* productivity were identified by using Global Boosting Model (GBM). Soil fertility status was divided into three clusters (high, adequate, and low) by K-Means cluster analysis. *Eucalyptus* clonal plantation productivity spatially has a high variation indicated by Universal Kriging Interpolation and Inverse Distance Weight (IDW) with high actual and predicted productivity correlations (R^2 of 0.9 for both method and clonal). The most relative influential factors of site and soil characteristics on *Eucalyptus* productivity variation at age 42 months old were clone variety (78% relative influence of R-square 0.73) where each clone showed different responses to site characteristics and soil physical and chemical properties. This study suggests that the current available soil data from soil survey can be used to predict site potential productivity for specific clones, however, data distribution (soil and growth) may affect the error; clone is main relative contributor in productivity variation and analysis; the genetic deployment plays an important role in productivity; Soil C-org, pH, P bray variation contributed to clonal productivity variation in most of the estates, so any operation must take care the soil for long term sustainable productivity.

[5] Büro für Wald- und Wildökologie, regionale Landnutzung und Umweltplanung, Wildschönau-Auffach, Austria

Abstract: Spatiotemporal modeling is an efficient approach for predicting abiotic factors such as soil moisture and surface temperature – both affecting plant growth. This modeling technique holds great promise for supporting sustainable forest management, e.g. by the accurate prediction of forest yield.

In our study, we utilized time-series of ERA5-Land retrievals, and static information given by topographic indices, and soil maps to model the annual growth of mature stands in the Northern Calcareous Alps. To capture growth patterns over a span of 30 years, we conducted a forest inventory and analyzed annual growth with dendrochronological methods based on image analysis techniques. Multiple linear models and machine learning models were employed, followed by a feature selection process to identify the most influential predictor variables. These reduced models were then validated using 10-fold cross validation.

Our spatiotemporal modeling approach successfully predicted tree growth with a high level of accuracy. The final model incorporated static variables representing topography and soil information, as well as dynamic variables derived from ERA5-Land retrievals. These retrievals indicate significant temporal variations of forest growth over the observed time period.

Our findings demonstrate that by leveraging data from diverse sources, including ERA5-Land retrievals, topographic indices, and soil maps, we can effectively predict tree growth. This information can be utilized to enhance forest inventory and inform forest management practices. Particularly in the face of changing environmental conditions, a dynamic approach that incorporates mid-term weather anomalies to forecast forest growth holds increasing value.

The integration of levels of extent and scale in tree species distribution models of Abies alba (Mill.) and Fagus sylvatica (L.) in mountain forests

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Alois Simon[1, 2]

Abstract: Mountain forests in the European Alps cover the distribution margins of several tree species and therefore are particularly well-suited to reveal soil-climate effects on the shaping of these margins. Combining different scales and extents are essential in species distribution models when it comes to the investigation of the environmental niche of species. The study focuses on two levels of spatial extent, on the one hand the continental level of Europe, and on the other hand the regional level of the federal state of Tyrol in Austria. The potential occurrence of the two investigated tree species, *Abies alba* and *Fagus sylvatica,* was modelled with Deep Neural Networks. In the process, we observed a strong imbalance of absence and presence records at the continental level and evaluated different methods to address this issue. The potential predictor variables for species distribution modelling were grouped into climatological, soil, and topographical information. The combination of the different levels of scale and extent was implemented by using the outputs of the continental model as a predictor variable in the regional model. The binary classification of the 30% test dataset showed a True Skill Statistic of 0.73 to 0.76 for the regional level and 0.5 to 0.74 for the continental level, with slightly higher values for *F. sylvatica* than for *A. alba*. For both species and extent levels, the climatological predictor group showed the greatest contribution (81 to 96 %) to the models' predictive power. At the regional level, climate was followed by the soil and the topographical predictor groups. At the continental level however, topography showed stronger effects than soil information. In most cases, the consideration of soil information along climatological gradients led to an increase in the occurrence probability at the climatic distribution margins. There is evidence that edaphic conditions are more important in determining the inner Alpine distribution margins for *F. sylvatica* than for *A. alba*. To improve species distribution models at the regional level, e.g. in the Alpine area, a focus on soil information is proposed. In general, models which combine continental and regional data are preferable.

Topographically high-resolution mapping of catchment-scale soil carbon dioxide and methane fluxes

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Shoji Hashimoto[1]
Tadashi Sakata[1], Naoyuki Yamashita[1], Taiki Mori[2], Tomoaki Morishita[3], Shigehiro Ishizuka[1]

[3] Tohoku Research Center, Forestry and Forest Products Research Institute

Abstract: Soil-to-atmospheric CO_2 and CH_4 fluxes in forest soils play crucial roles in the global greenhouse gas cycles. Soil CO_2 flux is a major carbon flux in forest ecosystems, while soil CH_4 uptake flux in upland forest soils represents the only significant biological sink of CH_4 in the global methane budget. To estimate catchment, country, and global-scale soil GHG fluxes, upscaling of observed GHG fluxes from field measurements is necessary. In this study, we upscaled observed soil CO_2 and CH_4 fluxes within a forest catchment using a digital elevation model (DEM) and machine learning techniques, and examined the spatio-temporal distribution of each gas flux within the catchment. The study was conducted in a 2.5 ha mountain watershed in Hitachi Ohta City, Ibaraki, Japan. Monthly measurements of soil CO_2 and CH_4 fluxes were taken at 10 different topographic positions in the catchment. The fluxes were upscaled using a Random Forest model with topographic and climatic covariates. The methane flux was predominantly influenced by the topographic index, while the CO_2 flux was primarily controlled by the climatic index. By employing machine learning analysis with the DEM-derived covariates and climatic covariates, we visualized the spatio-temporal distribution of CO_2 and CH_4 fluxes within the catchment. The generated map revealed lower CH_4 fluxes in the valleys and slightly lower fluxes in hilly areas. The valley consistently exhibited low CH_4 fluxes throughout the year, with predominantly uptake fluxes but occasional emission fluxes predicted. In contrast, CO_2 fluxes were slightly lower along the valleys and demonstrated clear seasonality, while CH_4 fluxes showed less pronounced seasonal patterns. The total catchment flux estimates based on the predicted maps often differed from those based on simple catchment means, indicating that the upscaling scheme considering topographic variability is useful for accurate estimation of catchment-scale fluxes.

Utilising spatially explicit site information for mapping tree species suitability: The role of digitally mapped soil data

T5.9 Digital (soil) mapping as a suitable approach to generate spatial forest site and biodiversity data at different scales

Michael Kessler[1]
Harald Vacik[1], Manfred J. Lexer[1]
[1] University of Natural Resources and Life Sciences, Vienna, Department of Forest- and Soil Sciences, Institute of Silviculture, Peter-Jordan-Straße 82/II, 1190 Vienna, Austria

Abstract: Tree species selection is an important strategic decision in forest management, especially in the context of adapting forests to climate change. However, uncertainty in future climatic conditions makes tree species selection a complex task. Therefore, tree species suitability models have been developed to support forest managers. These tools provide spatially explicit information on the suitability of tree species, considering the dynamic nature of site factors over time as well. In general, such models are based on the concept of the fundamental niche, i.e. tree species suitability is derived from the ecophysiological characteristics of tree species regarding nutrient and water supply as well as the thermal conditions. These site factors are represented by a set of climate and soil variables and need to be provided with a high spatial resolution in order to create spatially explicit tree species suitability maps.

In this contribution we introduce a static expert model that has been developed to map the suitability of 18 European tree species in Austrian forests. We demonstrate its use by mapping the suitability of tree species under current and projected future climatic conditions, and evaluate the sensitivity of the model towards input variables, with particular focus on the effects of uncertainty in soil-related variables. This focus is motivated by the wide-spread use of digitally mapped soil data.

The results highlight the general relevance of soil data for modelling tree species suitability and underline the importance of the quality of digital soil mapping techniques for creating spatially explicit data sets on tree species suitability.

T5.10 Digitalization for sustainable forest management

A New Approach for Feeding Multispectral Imagery into Deep Learning Improved Classification of Seedlings

T5.10 Digitalization for sustainable forest management

Abstract: Accurate information about tree species is critical in management of forests, particularly in seedling (regenerating) forest stands. When remote sensing techniques are utilized to inventory the seedling stands where the tree crowns are often small and with lesser foliage cover, the spectral admixture of understory reflectance with seedling canopy occurs, which challenges the tree species classification process. To moderate the admixture issue, we proposed an image pre-processing step based on canopy threshold (C_{th}) to be applied on input tensors made of drone-based multispectral images, before training the convolutional neural network (CNN) and random forest (RF) classifiers. The aim of this research is to explore capabilities of CNN in classification of seedlings of Scots pines (*Pinus sylvestris* L.), Norway spruces (*Picea Abies* (L.) H. Karst.) and birches (Betula sp.) from other seedling species in south boreal seedling stands in Evo, Finland. Hence, this research focuses on 1) improving classification of seedlings utilizing the proposed strategy, 2) comparing the performance of the two classifiers (CNN and RF), and 3) improving classification of seedlings by adding vegetation indexes in the CNN classifier.

The classification of 5417 field-mapped seedlings from 75 forest plots revealed that applying the proposed method improved the overall accuracy (OA) of seedlings species classification from 75.7% to 78.5% on the C_{th}-affected subset of the test dataset using CNN method (2). CNN yielded more accurate OA (79.3%) compared to RF (68.3% pp; 2). Additionally, combining vegetation indexes with multispectral data improved the OA from 75.1% to 79.3% in CNN (3). Further investigation uncovered that shorter seedlings and tensors with higher number of C_{th}-affected pixels have negatively affected the classification of seedling. Based on the results obtained in this study, the proposed pre-processing step can be considered in the species classification of seedlings in operational forest inventorying using operational multispectral consumer-grade drones.

Airborne laser scanning application in operational forestry in Poland - good practices and challenges

T5.10 Digitalization for sustainable forest management

[2] Department of Forest Management Planning, Dendrometry and Forest Economics, Institute of Forest Sciences, Warsaw University of Life Sciences (SGGW), 159 Nowoursynowska St., Warsaw 02-776, Poland

Abstract: LiDAR technology makes it possible to accurately determine the biometric characteristics of trees as well as many stand variables. Airborne laser scanning has been used for more than 20 years to determine forest characteristics, whether based on the detection of individual trees or an area-based approach.

In Poland, work has been ongoing for almost 20 years to integrate airborne laser scanning data into practical forest management, which is carried out every 10 years. In recent years, it has been possible to develop and practically test a method for estimating growing stock volume (GSV) at the stand level using ALS data and permanent sample plots. This method is currently being implemented in forestry practice and is to be approved as an alternative in the preparation of forest management plans in state forests.

The presentation will demonstrate the process of implementing ALS solutions in forestry practice using a dedicated ALSgator application. The application consists of two modules - the control module and the stand variable prediction module. Within the control module, it is possible to check many parameters of the ordered point cloud and the aerial orthophoto and to check whether the data meet the requirements. The stand characteristics estimation module allows the determination of the following stand level characteristics: GSV, basal area of all trees, DBH of all trees, DBH of the 100 thickest trees per hectare, the number of trees per hectare, the top height of the 100 thickest trees per hectare, the average height of all trees, the average height of the first layer trees.

Furthermore, we will present the experiences and challenges in the practical application of ALS from the perspective of the Polish forestry sector.

Assessing Change Detection Algorithms for Monitoring PEFC forest certification: Towards Sustainable Management and Certification Compliance

T5.10 Digitalization for sustainable forest management

Isabel González[1]
Jéssica Esteban[1], Marta Salvador[2], Iyan Teijido-Murias[3], José Luis Tomé[1]
[1] Agresta S. Coop
[2] PEFC Spain
[3] SMartForest Group, Oviedo University

Abstract: In this study we evaluate the effectiveness of change detection algorithms in identifying changes in forest cover within different provinces in Spain.

These algorithms leverage a data-driven approach to identify and quantify the occurring changes by analyzing multi-temporal satellite imagery datasets. In the second phase, we classify the changes to differentiate between changes caused by forest fires, clear-cutting, and thinning using machine learning methods. The results aim to highlight the accuracy and robustness of these algorithms for detecting forest changes with high spatial and temporal resolution.

The ability of these algorithms to provide consistent and objective assessments enables internal auditors and the certification body to focus audits on areas where changes have occurred and thus better assess compliance with PEFC's certification standards and regulations. Furthermore, the automated nature of the algorithms enhances efficiency, reducing the manual effort required for monitoring and auditing processes. The findings from this study will contribute to improve the transparency and accountability of PEFC forest certification.

Moreover, by employing a change detection tool for analysis, stakeholders can obtain valuable insights into the dynamics of certified forests, facilitating informed decision-making and policy development. This research underscores the importance of data-driven approaches in supporting effective forest management and the sustainable use of forest resources.

The study is part of the project "GO Bosques 3.0: Digitalization and remote sensing of sustainable use, biodiversity, and resilience of Spanish forests",

Automatic assignment of forest inventory plots to municipalities using Linked Open Data

T5.10 Digitalization for sustainable forest management

Natalia Crespo-Lera[1, 2]
Guillermo Vega-Gorgojo[1, 2], José M. Giménez-García[2], Felipe Bravo[1], Irene Ruano[1]
[1] Sustainable Forest Management Research Institute, University of Valladolid, Spain
[2] Group of Intelligent and Cooperative Systems, University of Valladolid, Spain

Abstract: There is a growing demand in modern forestry to openly publish, share, and interconnect forestry information with other forestry and cross-domain data. National Forest Inventories (NFIs) serve as important databases supporting research, management, monitoring and conservation efforts for forest ecosystems. However, data interoperability between NFIs and other data sources often presents a significant challenge.

Semantic Web technologies offer promising solutions for addressing this problem through the publication of Linked Open Data (LOD). LOD encourages best practices for publishing open data on the Web, promoting interconnectivity between data sources. The W3C standardizes the formats and protocols for publishing LOD, including RDF, a standard model for data interchange on the Web, and SPARQL, a query language for RDF data. Besides, the OGC developed GeoSPARQL for representing and querying geospatial linked data.

In the EU project CrossForest (https://crossforest.eu/) we have published in LOD format an integrated repository of NFIs and land cover maps from Spain and Portugal, henceforth the CrossForest dataset.

We present here the work done to enhance the CrossForest dataset with official Spanish municipality data. By integrating administrative boundaries with plots location, CrossForest dataset increases their applicability in forest assessment and planning. Furthermore, this integration holds significant importance in Spain, since municipalities serve as the fundamental territorial division with jurisdiction over public forest management. Although the Spanish NFIs include municipality data, it is both incomplete and inaccurate.

To tackle this issue, we have converted the municipal entities and their geometries, provided by the Spanish National Geographic Institute, into LOD and matched them to the plots they contain comparing GeoSPARQL and a GIS. The enriched CrossForest dataset is publicly available through a SPARQL endpoint: https://crossforest.gsic.uva.es/sparql and on GitHub: https://github.com/Cross-Forest.

The integration of municipality data as LOD provides the foundation for extracting new information and conducting statistical analyses at geographical level as municipalities or counties (by aggregating municipalities). This offers valuable insights that contribute to effective forest management and informed decision-making. By leveraging this dataset, we were able to generate a series of maps that showcase the dominant species within each Spanish municipality, based on metrics such as basal area and tree density.

Characterizing structural changes in boreal forests by combining terrestrial and airborne laser scanning point clouds

T5.10 Digitalization for sustainable forest management

[3] Department of Photogrammetry and Remote Sensing, Finnish Geospatial Research Institute, National Land Survey of Finland, Finland

Abstract: Point cloud-based observations of trees and tree communities enable non-destructive solutions to monitor their spatiotemporal structure and thus provide information of trees' physio-ecological functionalities and the dynamics of tree communities.

Terrestrial laser scanning (TLS) has been widely utilized for detailed 3D reconstruction and characterization of trees and tree communities. The resulting point clouds enable measurements with millimeter-level accuracy. However, when used alone, the TLS point clouds have a limited capacity to characterize the vertical forest structure and upper parts of trees crowns may remain occluded. Simultaneously, aerial point clouds have been widely used to characterize the vertical structure of trees with especially detailed view on the upper canopy structure.

Aerial point clouds have already been used for change detection of forests for decades, whereas tree growth and structural changes in forests have lately been investigated with multi-temporal TLS point clouds. Considering the certain limitations but also promising results of the earlier research, this study will be among the first to present a method, which uses fusion of terrestrial and airborne laser scanning (ALS) point clouds to improve the estimation accuracy of increment in tree height and tree crown volume.

Data from 2555 trees on 22 sample plots (32 m x 32 m) located in boreal forests of Evo in southern Finland was used. Both ALS and TLS point clouds were acquired in year 2014 and 2021 to create two date data that enabled characterization of spatiotemporal structure of trees and tree communities.

Benefits of using the multi-sensorial approach was assessed by comparing the respective tree characterization performance to that of methods utilizing TLS or ALS point clouds only. The results show that correlation between tree height estimates and reference measurements increased, whereas bias and RMSE decreased, when multi-sensorial approach was utilized instead of using only TLS point clouds for estimation. This indicates improvement in accuracy of characterizing changes in the structure of trees. The findings and experiences obtained in this study will be useful in justifying future data acquisition campaigns aiming at providing valuable information about trees and tree communities in space and time for purposes of sustainable forest management.

Combining laser data and aerial imagery in preparation for nationwide tree species classification

T5.10 Digitalization for sustainable forest management

Christoffer Axelsson[1]
Johan Holmgren[1], Henrik J. Persson[1], Eva Lindberg[1]
[1] Department of Forest Resource Management, Swedish University of Agricultural Sciences (SLU), Sweden

Abstract: The third phase of the Swedish national laser scanning is planned to start in 2024 and will have a higher point density than the previous phases. The denser point cloud can be used to map tree species at the level of individual tree crown segments. As part of the Mistra Digital Forest programme task 1.1, we use airborne laser scanning data combined with multispectral aerial imagery to classify tree species at the Asa test site in southern Sweden. The goal is to develop a methodology that can be applied nationwide and assess the classification accuracy for different point densities. The point density of the next national laser scanning is currently yet to be determined. Here, we evaluate how the classification accuracy changes with point densities varying between 5 and 20 points per square meter. This is accomplished by thinning out a denser point cloud. We also investigate the added benefit of combining the laser data with aerial imagery, and how the aerial imagery should be processed for optimal results. As expected, the results show that the overall accuracy decreases with decreasing point density. The aerial imagery was better for identifying deciduous trees than the laserdata, and was thereby an important complement. The positive contribution of the aerial imagery was consistent for both higher and lower point densities.

Deep learning-based tree species identification using high-density airborne laser scanning and forest harvester data

T5.10 Digitalization for sustainable forest management

Raul de Paula Pires[1]
Christoffer Axelsson[1], Eva Lindberg[1], Henrik Jan Persson[1], Kenneth Olofsson[1], Johan Holmgren[1]
[1] Swedish University of Agricultural Sciences

Abstract: Tree species composition is one of the most relevant features to consider in forest assessments at varying scales. Such information is essential for societies as there is increased pressure to use more wood-based materials instead of fossil fuels and plastic. According to Yu et al. (2017), species-specific size distribution of the trees is the optimum output from the mapping process requested by forest companies. Hence, in this study we evaluate methods for identifying tree species based on 3D branch structure and intensity values obtained from high-density dual-wavelength airborne laser scanning (ALS). The ALS data was collected in 19 stands in Hällefors, southern Sweden from a helicopter. The resulting point cloud had an average point density of > 500 points/m^2. After ALS data collection, the stands were harvested and the harvester production reports (HPR) were used as reference data for the identification of tree species. Such files contain detailed information on each harvested tree's tapering, location, and species, making them an excellent reference data source for forest modelling at individual tree-level. The preliminary workflow involves segmenting tree crowns using the three-dimensional segmentation method by Holmgren et al. (2022), generating images from the segmented tree crowns from different angles, and training artificial intelligence (AI) models with such images. By using the proposed workflow, we aim to demonstrate the effectiveness of using three-dimensional branch structure and intensity values obtained from ALS as an input for AI models of tree species identification. Finally, this study's results will contribute to development of precision forestry by enabling tree-level species-specific assessments of the forest state.

Developing multispectral and hyperspectral drone imagery to early identification of infestations of European spruce bark beetle

T5.10 Digitalization for sustainable forest management

Langning Huo[1]
Henrik Persson[1], Jonas Bohlin[1], Eva Lindberg[1]
[1] Department of Forest Resource Management, Swedish University of Agriculture Sciences, Sweden

Abstract: With the aggravation of global warming, the outbreaks of forest pests happen more frequently and damage huge amounts of forests. Detecting and removing trunk-boring infestations from the forest at an early stage (green attack) is important to avoid spreading. By using remote sensing techniques, forest mortality can be efficiently detected and mapped; however, achieving early detection of the infestation is still challenging because the spectral changes are subtle.

This study assessed the detectability of the green attacks by the European spruce bark beetle (*Ips typographus*, L.) using multispectral and hyperspectral drone images. The scientific questions and objectives are (1) testing whether trees were under stress before the infestation (predisposition) and whether the stress can be sensed by multispectral and hyperspectral sensors mounted on drones, (2) quantifying the detectability of the attacked trees with different duration of infestations, and (3) developing methods of using multispectral and hyperspectral drone images for early detection, and comparing their performance.

The study area is Remningstorp in southern Sweden. We are monitoring spruce trees in 24 plots from 4 spruce-dominant stands by weekly health inventory from April to October. Pheromone bags are attached to the center tree in each plot to attract bark beetles and induce an attack. Sensors are mounted on 32 trees to monitor the sap flow throughout the season, indicating the potential water stress before and during the infestation. Bi-weekly multispectral and hyperspectral images are acquired, covering healthy and early to late stages of infestations. The images will be processed and the spectral signatures of trees will be analyzed. A methodology for early detection using drone imagery will be proposed, and the scientific question will be answered on how early the infestations can be detected by drone images.

Digitalization of the forest road maintenance by implementing sensor technologies and AI

T5.10 Digitalization for sustainable forest management

Felipe De Miguel-Díez[1, 2]
Ferréol Berendt[2], Ina Ehrhardt[3], Tobias Cremer[2]
[1] University of Freiburg, Chair of Forest Operations, Germany
[2] Eberswalde University for Sustainable Development, Chair of Forest Utilization and Timber Markets, Germany
[3] Fraunhofer Institute for Factory Operation and Automation IFF

Abstract: Forest roads are essential infrastructures in the forest management, since they provide access to the forest areas and are the basis for forest operations, fire protection and recreation. The ideal maintenance management of these infrastructures plays a key role to ensure the optimal use of those activities. Traditionally, the evaluation of the state of forest roads has been conducted visually by the forest owners on-site. Thus, this method is susceptible to misinterpretation due to its subjectivity. Consequently, the use of new technologies such as sensor technology-based devices and AI is currently being implemented in order to automate the assessment processes of the forest road maintenance and offer the stakeholders a digital visualization of the forest roads and their current maintenance state. The succesful implementation of these systems can provide the stakeholders a powerful tool for different objectives such as navigation or development of efficient maintenance plans.

Notably, several issues related to the implementation of such systems are currently unresolved, for instance, the diverse requirements concerning the forest road maintenance state according to each stakeholder, the parameters (for instance, trafficabiliy or construction material) to be included in the digital data, the used technologies or the capabilities of the stakeholders to participate in related subprocesses such as data collection. Therefore, a qualitative social study, which consisted of 30 semi-structured interviews and several workshops with a wide range of stakeholders, was conducted in Germany. In this framework, relevant information was collected to resolve the mentioned issues as well as determine possible implications of the implementation of such systems, especially, the development of data-driven business models that might provide further revenues to the involved stakeholders.

This presentation will firstly offer an overview of the diverse requirements concerning the forest roads maintenance state depending on each stakeholder. Secondly, different innovative possibilities to evaluate the state of forest roads using sensor technologies and machine learning will be shown, in particular, the output of using those technologies: the digital data as well as the possible applications. Finally, perspectives of using these technologies and their implications in the forestry will be demonstrated.

EDAPHOCLIMATIC BASED SPECIES DISTRIBUTION MODEL FOR PORTUGAL: PINUS PINEA & QUERCUS SUBER MIXED FORESTS

T5.10 Digitalization for sustainable forest management

David Lloberas Lafuente[1]
Alexandra Correia[1], Antonio Monteiro[2]
[1] INIAV - Instituto Nacional de Investigação Agrária e Veterinária
[2] IGOT / UL - Instituto de Geografia e Ordenamento do Território / Universidade de Lisboa

Abstract: The challenges that climate change imposes to forest production in the Mediterranean region require a new way of thinking forest planning. It becomes necessary to explore silviculture alternatives that guarantee species resilience to climate variability but, most importantly, that are able to maintain the productive sustainability function of many Mediterranean forests which many rural populations depend on. Mixtures are becoming an important topic for managers due to the potential to enhance ecosystem services in comparison to monospecific formations. Knowing were it is ecologically viable to install such formations was the objective of this study taking as examples the mixtures of *Quercus suber* (cork oak) and *Pinus pinea* (stone pine).
Probabilistic species distribution models (SDM) built on the current presence/absence were created with the aim of i) identifying the influence of a series of climatic and soil-related determining variables on the distribution of species; and ii) estimating the suitability of the Portuguese territories for the eventual presence of those two species together. The models, based on Generalized Linear Model (GLM) and Random Forests, were calibrated in the South of Portugal and, once validated, have been applied to the rest of the country.
In this regard, the models focus solely on the abiotic component of distribution and confirm the significant anthropogenic disturbance in the current occupation, upon which the modeling of potential distribution is based.
The results show that the most significant edaphoclimatic variable for both species is soil texture, specifically the percentage of sand. Meanwhile, maximum temperature and continentality are more relevant in the models for stone pine, while precipitation is more influential for cork oak. There is limited scientific consensus on the determinants of the distribution of these two species, highlighting the need for a better understanding of the impact of variables on both in order to increase the explanatory power of the models in the Mediterranean region.

eForestry - digitalisation of forestry in Slovenia

T5.10 Digitalization for sustainable forest management

Miha Varga[1]
Gregor Danev[1], Aleš Poljanec[1]
[1] Slovenia Forest Service

Abstract: Forestry in Slovenia has a long tradition of following close-to-nature, multi-objective and sustainable principles, which are embedded into forest management system on national level. Due to increasing social and climate change challenges in managing forest ecosystems and the need for harmonization of various interests, effective control over forest ecosystems as well as a modern digital tool to support decision-making about the future forest management is needed. Thus, Slovenia Forest Service, together with Ministry of Agriculture, Forestry and Food and Forestry Institute of Slovenia is working on a project to digitalise the key public forestry services including forest inventories and monitoring, forest management planning, supporting implementation of planned measures, and controlling use of forest resources, changes in the forest as well as forest health status. The focus of the project is to insure modern field and office equipment in combination with modern spatial information system that will support the most demanding spatial analysis and forest management processes with the main task to simplify, optimise and upgrade public forestry service in Slovenia. With the set-up of the new E-forest apps, the owners and managers of forests will have better insight into the history of forest development and new decision tools supporting participative decision-making. The innovative eForestry tools will be presented and further discussed.

Estimating Effects of Operator Assistant System Based on Mobile Laser Scanning in Cutting of Thinning Stands

T5.10 Digitalization for sustainable forest management

Johannes Pohjala[1]
Ville Kankare[1], Juha Hyyppä[2], Kalle Kärhä[1]
[1] University of Eastern Finland (UEF), School of Forest Sciences, P.O. Box 111, FI-80101 Joensuu, Finland
[2] Finnish Geospatial Research Institute (FGI), Department of Remote Sensing and Photogrammetry, Vuorimiehentie 5, FI-02150 Espoo, Finland

Abstract: Thinning work is very challenging for harvester operators due to the need for several quick repetitive decisions regarding tree selection and bucking. Harvester operators must monitor thinning intensity, the width of strip roads and the distance between strip roads and issues related to biodiversity. Advanced Driver Assistance Systems (ADASs) in cars and traffic have been the subject of comprehensive research and development efforts for a long time. Similar technological inventions can also be utilized in the field of forestry. PONSSE Plc. has introduced Thinning Density Assistant concept based on Lidar technology. This system can automatically monitor the density of remaining trees and the distance between strip roads on site. In addition, the harvester operator can use the tree map on a separate screen in the cabin of the harvester. However, the effects of the system on thinning productivity or quality are unknown. As part of a dissertation, three studies investigated the effects of the harvester operator guiding in thinning work. The studies aimed to find and identify the impacts of such systems on cutting productivity, harvesting quality and workload of the operators. The productivity was determined using a comparative time study using video records and machine data. The assessment of harvesting quality was measured using the density of remaining trees, the number of defective trees, the width of strip roads, and the distance between strip roads. The first study clarified the effect of the prior tree marking on cutting productivity, thinning intensity and tree selection in a field study. The prior tree marking increased cutting productivity by 2.7–2.8%. The second study investigated the benefits and weaknesses of Ponsse's Thinning Density Assistant concept on real-world thinning sites. The third study specifically focused on evaluating the same system in a harvester simulator environment, which enabled the participation of novice operators in the study, as well as experienced ones. In conclusion: The specifically designed ADASs for forestry will become more common in forest machines during the next years. The research-based findings are essential to support the product development of these novel systems.

Estimating wood quality attributes from dense airborne lidar point clouds.

T5.10 Digitalization for sustainable forest management

Nicolas Cattaneo[1]
Stefano Puliti[1], Carolin Fischer[1], Rasmus Astrup[1]
[1] Norwegian Institute for Bioeconomy Research (NIBIO), Division of Forest and Forest Resources, Høgskoleveien 8, 1433 Ås, Norway.

Abstract: Point clouds from laser scanning are a standard data source in forest research, but the lack of clear and robust workflows has limited the translation of experimental knowledge into operational tools. We present a novel machine learning-based workflow that uses individual-tree point clouds from drone laser scanning to predict wood quality parameters. Unlike object reconstruction methods, our approach is based on simple metrics computed on vertical slices that summarize information of point distances, angles, and geometric attributes of the empty space between and around the points. Our models use these slice metrics as predictors and achieve high accuracy for predicting diameter of the largest branch per whorl (DLBw) and stem diameter at different heights (DSi) from survey-grade drone laser scans. We show that our models are also robust and accurate when tested on suboptimal versions of the data generated by reductions in the number of points or emulations of suboptimal segmentation scenarios. Our approach provides a simple, clear, and scalable solution that can be adapted to different situations and has the potential to revolutionize forest management and monitoring

FLORESTA DB: A SOFTWARE PLATFORM FOR FOREST RESEARCH FROM IN FIELD COLLECTION TO INVENTORY AND ANALYSIS

T5.10 Digitalization for sustainable forest management

Abdullah Almsaeed[1]

[4] Independent
[5] University of Kentucky, Lexington, KY, USA

Abstract: Forest research projects frequently involve collecting digital data and/or physical samples from forest trees, followed by laboratory analysis. Outdated methods such as pencil and paper or spreadsheets are prone to errors, can slow collection efforts, and do not manage data for the full research life cycle. We have developed FlorestaDB as a flexible and innovative system to manage forest tree research collections and provide a powerful set of software applications to support research from the field to the final data analysis. It includes a mobile app for in field collection for multiple collectors with barcode scanning and GPS location services. The mobile app is available for Apple and Android platforms, and works out of cellular range by saving data locally to the phone for later upload. It is currently available in Chinese, English, French, and Spanish, and contains infrastructure to support translation to additional languages. The FlorestaDB web application offers the ability to manage project participants, collaboratively plan expeditions, store permit documents, track samples during shipping, and maintain a record of physical sample inventories. As data analysis results are produced, they can be attached to the tree records and sample inventory. We are currently building support for wood anatomy, isotope, DNA and mass spectrometry analysis. FlorestaDB manages research projects separately and privately. Each project's data is accessible via an interactive website and map and through comprehensive reporting capabilities, generating summaries by location, species, expeditions, etc. With a focus on managing user permissions and digital security, all data is protected and private to the group that generated it. We have been operating for over 4 years with 2 member organizations, which manage over 300 users, 10,000 tree observations, and 37,000 physical samples from 47 different countries. While member organizations are focused on collecting physical tree samples to create a reference database to combat timber fraud, FlorestaDB has matured into a stable and well tested platform and is now open to partnering with additional organizations and use cases.

Four years of deep learning for forest monitoring and management in a nutshell

T5.10 Digitalization for sustainable forest management

Stefano Puliti[1]
Maciej Wielgosz[1], Johannes Rahlf[1], Rasmus Astrup[1]
[1] Norwegian Institute of Bioeconomy Research (NIBIO), Høgskoleveien 8, 1430 Ås Norway

Abstract: Deep learning has emerged as a state-of-the-art technique for handling large and complex forest sensor data, accelerating innovation and digitalization in the field. This abstract summarizes four years of SmartForest's research and development in deep learning for forestry and highlights its deployment in real-world scenarios along the forest value chain. Our focus lies on the image, video, and point cloud-based models that have revolutionized forest monitoring and management.

Image-based deep learning models were developed to classify tree species, detect forest disturbances, measure tree growth, assess wood quality, and enable traceability. Utilizing LiDAR point cloud data, deep learning techniques were applied for semantic and instance segmentation of individual trees, thus enabing the creation of detailed 3D forest structure maps, facilitating improved forest inventory management and precise timber yield and wood quality predictions.

The deployment of these deep learning models in real-world scenarios has been integrated into SmartForest's ForestSens cloud platform. This platform empowers forestry professionals with data-driven decision-making capabilities, enabling remote monitoring, identification of critical areas, optimization of harvesting operations, and evaluation of management practices for sustainability.

Importantly, the scalability and generalizability of the deep learning models were achieved through transfer learning and domain adaptation techniques. This ensures their effectiveness across different geographical regions and forest types, expanding their applicability worldwide.

The research presented in this abstract demonstrates the transformative potential of deep learning in forestry. By leveraging image and point cloud data, our models offer valuable insights into forest resources and their dynamics, supporting sustainable management and preservation of this critical ecosystem. Integration of deep learning into the forest value chain represents a significant step towards digitization and intelligence in forestry, fostering innovation and resilience in the face of environmental challenges.

Overall, our work highlights the significant advancements made in deep learning for forest monitoring and management, underscoring its potential for revolutionizing the field and contributing to the sustainable management of forest resources.

GoForward moving forward: updated decision support tool for efficient forwarding in harvest operations

T5.10 Digitalization for sustainable forest management

Linnea Hansson[1]
Anders Rowell[1], Patrik Flisberg[1], Mikael Rönnqvist[2], Petrus Jönsson[1]
[1] Skogforsk, the forestry research institute of Sweden
[2] Laval University, Canada

Abstract: Efficient forwarding is essential for achieving high productivity in harvest operations. GoForward is a decision support tool developed for optimizing forwarding in cut-to-length harvest operations by efficient co-loading of different wood assortments. The tool utilized the harvester production data and tracking to optimize the forwarding routes, loading, and unloading at the landing.

The first prototype of the decision support tool (published in 2022) indicated potential for efficient forwarding. However, when the suggested routes were compared with the actual forwarding routes, it was evident that the forwarder operators were using shortcuts compared to the harvester routes. Hence, the possibility to suggest shortcuts needed to be incorporated in the decision support tool. Another important improvement was to upgrade the two-dimensional model to three dimensions by including a digital elevation model for trafficability calculations and depth-to-water maps for identifying areas sensitive to driving where less wood should be transported.

In the present study, we have developed and tested a new version of GoForward on several clearcuts in northern Sweden. The new version includes a shortcut possibility and geospatial data such as slope and depth-to water maps. To facilitate field implementation, the adoption of machine data following StanForD 4.0 is proposed, which includes precise tracking of individual log positions. This facilitates real-time field tests of GoForward, as precision is improved compared to the previous version were the approximated log position was calculated from the harvester position when felling the tree.

A decision support tool for forwarding operations is high on the wish list of forwarder operators and with the suggested updates, the tool starts getting ready for trials in practical forestry. When implemented, the goal is to increase efficiency in forwarding operations, especially for new operators, and contributing to more sustainable forest management practices.

Hot Wheels: Assessing Soil Response to Fully Mechanized Timber Harvesting

T5.10 Digitalization for sustainable forest management

Abstract: The increasing demand for wood, driven by the bio-economy, is leading to the increased use of fully mechanized timber harvesting systems. These ground-based harvesting systems typically have a large impact on the soil. This study investigates the impact of fully mechanized winch-assisted harvesting systems on sustainability criteria such as soil deformation and soil properties during late thinning in two beech stands on Stagnic Cambisol on Flysch. It is motivated by the need for more precise data to plan future harvesting operations on sensitive soils. A sample of 27 skid trails with an average slope of 35 % were scanned in April 2023. A mobile laser scanning system (GeoSLAM ZEB Horizon) with a simultaneous localization and mapping (SLAM) algorithm was used to generate a 3D point cloud and collect high-resolution data on soil deformation and soil properties in the study area. To our knowledge, this is the first study to use the SLAM algorithm to assess displaced soil volume on skid trails. The effects of harvesting with and without tracks, slope gradient, and number of forwarder passes on the soil will be compared and analyzed. We hypothesize that fully mechanized harvesting systems have a significant impact on soil deformation and soil properties of a Stagnic Cambisol on Flysch. We expect these effects to vary depending on the use of bogie tracks and soil conditions (e.g., moisture content) during logging operations. We anticipate that the results will highlight the need for careful selection of vehicle equipment, route planning, and timing to reduce the likelihood of rutting in fully mechanized harvesting operations. The study contributes to a better understanding of the impact of modern harvesting machinery on soil properties. It provides data to guide future sustainable harvesting operations on sensitive soils under expected future climate conditions.

How to make the most of digitalization in forest management - a global forest company perspective

T5.10 Digitalization for sustainable forest management

Erik Willen[1]
Antti Kaartinen[1]
[1] Stora Enso AB

Abstract: Most forest companies are eager to get on top of the opportunities offered by digitalization in the forestry sector. New digital data collection by handheld devices, remote sensing and forest machines, in combination with traditional field data, forms the foundation to feed artificicial intelligence to provide operational decision support and open for more automated data handling also taking the cloud processing capacities in consideration. Global forest companies also have the unique possibility to learn from digital evolution in different continents to try to capture values for the digital forestry. Stora Enso will share some of their efforts in digitalization of the operational forest management and keeping forest data up to date. We will also describe how we work in co-operation with the research community in order to shorten time from research to implementation.

Identifying cultural remains using airborne laser scanning

T5.10 Digitalization for sustainable forest management

Henrik Jan Persson[1]
Sima Mohtashami[1], Daniel Löwenborg[2], Maria Nordström[1]
[1] Skogforsk
[2] Uppsala Universitet

Abstract: Swedish forestry is highly mechanized with harvesters and forwarders doing the main parts of harvesting. The requirements are yet high to carry out forest operations without causing unnecessary damages to the surrounding forest and the environment. One challenge in Swedish operational forestry is the insufficient knowledge of the location of cultural remains in forested areas. They are often hidden under the vegetation and may not always be discovered before harvest. The legal consequences can yet be significant if the presence of such remains is ignored and they are damaged by forest machines. There is a national public database available with the currently known remains, which are inventoried by professionals (archeologists). However, the forest companies often have considerably more remains in their own maps because of new findings in the forest, which can however not be added to public databases without first being assessed by professionals. Another challenge includes remains not yet found. The work in this study aims to address both these aspects, by 1) proposing a complementary database structure containing more and other information about cultural remains in forests, and 2) by developing automatic methods for identification of remains using remote sensing. In the past five years, several projects have been completed that have started this process, by identifying, e.g., charcoal production sites, using convolutional neural networks (CNNs). One of the focuses of our study is to develop automatic classification methods for house foundations. The use of CNNs has proven efficient for classification tasks, although larger amounts of reference data are needed. Hence, our study investigates the possible use of various image classification methods, including several machine learning and deep learning methods. The study area is located in Dalarna, central Sweden, where airborne laser scanning (ALS) data as well as different field references are available. The work does also investigate the impact of laser point density, pre-processing to intermediate products, and the possibly added value with other existing open-source data.

Locating high-value broadleaf trees from the sky: unmanned aerial vehicle (UAV) aerial images analysis with deep learning

T5.10 Digitalization for sustainable forest management

Nyo Me Htun[1]
Toshiaki Owari[2], Satoshi Tsuyuki[1], Takuya Hiroshima[1]
[1] Department of Global Agricultural Sciences, Graduate School of Agricultural and Life Sciences, The University of Tokyo, Japan
[2] The University of Tokyo Hokkaido Forest, Graduate School of Agricultural and Life Sciences, The University of Tokyo, Japan

Abstract: High-value timber species are extremely demanded throughout the world, for their timber products with high commercial value. They are also important structural components in forest ecosystems. Such trees with economic and ecological importance are usually distributed at very low densities. Therefore, acquiring accurate location of these trees within a forest is critical for forest management practices. Traditional acquisition work for individually locating high-value trees is time consuming and labour-intensive. Here, recent technological developments integrating unmanned aerial vehicle (UAV) imagery and deep learning provides an efficient method for mapping forest attributes with the advantage of greater positional accuracy. In this study, we explored the applicability of high-resolution UAV imagery and a deep learning classification algorithm to locate high-value deciduous broadleaf trees of Japanese oak (*Quercus crispula*) in an uneven-aged mixed conifer-broadleaf forest in Hokkaido, northern Japan. UAV images were collected by using DJI Matrice 300 RTK UAV. The UAV flights were conducted in September and October 2022 before and after changing the colour of the leaves of Japanese oak to identify the suitable timing of UAV image collection. Our data analysis applied object segmentation scheme via semantic segmentation and watershed separation algorithm. We analysed the RGB information of UAV images through a ResU-Net model (U-Net model with backbone ResNet101), which has demonstrated state-of-the-art performance on multiple object segmentation tasks. Our results showed that the F1-score of the model trained using October UAV dataset was higher than that of the model trained using September UAV dataset. Our case study revealed that the integration of UAV imagery with the ResU-Net model was applicable to predict the location of Japanese oak with a reliable accuracy. It also suggested to use UAV images taken after changing the colour of the leaves for identifying Japanese oak trees through deep learning technology. Moreover, our findings highlight a potential methodology to offer transferable solutions to manage high-value timber species in other regions.

Looking backwards at countrywide forest cover using Unet and alpha shape

T5.10 Digitalization for sustainable forest management

Abstract: Forest ecosystems play an essential role in climate regulation and carbon sequestration. Therefore, information on forest cover and its changes over time is a key input for assessing a variety forest services. Usually, forest changes are estimated by comparing forest cover maps of two different time periods. Modern remote sensing techniques provide a variety of methods to derive forest cover maps. But there is limited availability of high-resolution remote sensing data to obtain forest cover from the last century. Historical black&white (B&W) aerial imagery is a valuable but currently little exploited data source for deriving past forest maps. And it is challenging to derive past forest cover maps using historical B&W imagery due to the fact that only one band of information is available and the images had different geometric and radiometric qualities.

In this study, we assess forest cover maps of 1980s using available B&W historical images over the entire country of Switzerland. We first developed a BWForest-Unet model based on semantic segmentation to generate a tree/non-tree map. The model uses the 2019 orthoimages converted to B&W and trees are labelled based on the 2019 countrywide canopy height model (CHM). Since the historical B&W images have more severe distortions than the modern ones, image augmentations such as thickness, local elasticity, squeezing, scratching, and grid were performed to simulate the historical image quality on the 2019 training samples. After training the model, the 1980 tree cover map was obtained by prediction from the historical B&W images.

Subsequently, a forest cover map is derived from the tree cover map by applying an alpha shape algorithm that generates bounding polygons around a set of points. The forest/non-forest polygons of 1980s are generated from alpha shape follow the criteria defined by the national forest inventory based on tree height and canopy cover. The study shows that semantic segmentation using Unet combined with the alpha shape approach is an efficient method to map forest cover over the past century at a countrywide scale.

Mapping of structures for biodiversity in boreal forest in Sweden from airborne laser scanning data and Sentinel-2 satellite images

T5.10 Digitalization for sustainable forest management

Eva Lindberg[1]
Langning Huo[1], Mats Nilsson[1], Jörgen Sjögren[2]
[1] Swedish University of Agricultural Sciences, Department of Forest Resource Management, Sweden
[2] Swedish University of Agricultural Sciences, Department of Wildlife, Fish, and Environmental Studies, Sweden

Abstract: Sustainable forest management is dependent on accurate geospatial information about the state of the forest. Size-related forest variables such as stem volume and tree height can be estimated with high accuracy from airborne laser scanning (ALS) data and surface models from matching of aerial images. However, there is a lack of methods for mapping information relevant for forest biodiversity. Planning and management of forest resources require such information both at a nationwide scale and in more detail for smaller areas.

New technologies offer opportunities to do this. Airborne laser scanning (ALS) data enables analysis of the structure of tree canopies and other vegetation. High-resolution ALS data offers the potential to identify individual trees and estimate their species and status (i.e., dead or living). The Sentinel-2 satellites provide multispectral images at short time intervals, making it possible to exploit phenological differences to map tree species. An important question is which type of information is most relevant for forest biodiversity because the habitats differ between different forest types and different forest-dwelling species have different habitat needs.

The aim of this study is to develop new methods to map and monitor forest biodiversity in boreal forest in mid-Sweden by deriving biodiversity indicators from RS data, in particular ALS data. The indicators include stand age, tree species, vertical and horizontal structure, and amount of dead wood. The analysis is done at landscape scale (i.e., approximately 300x300 km) from data with nationwide coverage. The indicators are validated with information on Natura 2000 habitats and with a dataset consisting of key substrates and structures for biodiversity. Finally, we present models to estimate the species richness in different species groups with statistics derived from the spatial distribution of the indicators in an area around the field plots as explanatory variables.

Mobile Application for Citizen Engagement in Forest Management

T5.10 Digitalization for sustainable forest management

Sokratis Nifakos[1]

[2] University of Borås
[3] Institute of Informatics, Slovak Academy of Sciences

Abstract: Digitalization has surfaced as a propitious instrument for attaining sustainable forest management amidst the era of rapid technological progress. Within the SILVANUS H2020 Green Deal Project, our focus lies in investigating the roles of the citizens in forest management as well as examining how digital solutions can enhance their awareness, foster changes in their attitudes and behaviours concerning wildfires, and facilitate their participation in fire prevention and rehabilitation endeavours. The solution we propose introduces a novel application for citizen engagement that is aiming to provide citizens with up-to-date information, ensure their safety, and establish seamless communication with emergency responders. The Citizen Engagement App (CEA) aspires to become an important digital channel for forest fire management by pursuing the following goals:

1. Consolidate fragmented information and data from authorised sources for instance from firefighters, authorities and first responders as well as tools related to wildfire management into a unified, user-friendly application.
2. Establish a dependable communication channel between citizens and authorities/firefighters through diverse information-sharing functionalities.
3. Enhance situational awareness and actively involve citizens in fire prevention and rehabilitation initiatives.
4. Advocate for the innovative measures undertaken by the SILVANUS project.

The initial version of CEA is currently undergoing an internal testing phase for Android phones and contains a set of different educational and situational awareness modules for citizens. Within these modules, we have developed the modules for Guidelines and Safe Practices that were either integrated into a digital format from diverse authorised sources or crafted by SILVANUS' Citizen Engagement Program (CEP). The application also includes an interactive map showcasing reported fire locations accompanied by a Fire Reporting module enabling users to to relay their precise location, along with pertinent information about the forest fire (photos or videos), and textual description or voice recording. In addition, several pilot tests have been arranged for the SILVANUS Project, where the users will evaluate the functionality of CEA. Future improvements include real-time notifications of fires, analytics and warnings regarding high fire risk in the user's area, emergency indicators, additional educational content and news-sharing features, ensuring a bidirectional communication between wildfire management professionals and citizens.

Multi-Species Expert System for Supporting the Refloresta-SP Programme: An Essential Component of São Paulo's Climate Action Plan

T5.10 Digitalization for sustainable forest management

Silvana Nobre[1]
Natalia Guerin[2], Maria Jose Zakia[3], Helena von Glehn[4]
[1] Research Group "Economics for a Sustainable Environment", Technical University of Madrid, Spain – ETS Ingenieros de Montes, Ciudad Universitaria 28040 Madrid, Spain
[2] Brazil Project Manager - WeForest (www.weforest.org) - Cantersteen 47, 1000 Brussels, Belgium
[3] Forest Science – UNESP Botucatu - Sao Paulo State University, Brazil
[4] Secretariat of Environment, Infrastructure, and Logistics of Sao Paulo – Brazil

Abstract: The Refloresta-SP Programme, an essential aspect of São Paulo's climate action plan, aims to restore 1,500,000 hectares of native forest vegetation by 2050. The program's objective is to ensure an equitable distribution of vegetation across the state, moving away from the current concentration in the coastal region. It targets primarily degraded areas and municipalities with limited native vegetation cover. It also aims to enhance vegetation recovery in areas with cover ranging from 10% to 30%, striving for a 30% native vegetation cover. This ecological target is crucial for sustainability, ecosystem services provision, and biodiversity conservation.
Over the past 12 years, the Secretariat of Infrastructure and Environment has developed an expert system to support these goals. This system integrates cutting-edge knowledge from over 40 scientists affiliated with universities and research institutions across the state. It encompasses a comprehensive knowledge base, including species adaptability, silviculture practices, region-specific costs, production tables, and growth and yield curves for wood and non-wood products. The expert system employs simulation techniques to generate species compositions that adhere to Brazilian forest regulations, ecological considerations, and economic parameters. Notably, the system incorporates nearly 200 species adapted to the state's unique ecological contexts, striking a balance between ecosystem services and economic feasibility. By considering the characteristics of the 62 microregions defined by Phyto physiognomies and ecological regions, the system generates approximately 5,000 cash flows and corresponding multi-species establishment and management plans. Policymakers utilize this knowledge base to tailor incentives based on the specific characteristics of regions.

Additionally, an internet-based application accessible through web browsers and mobile devices assists landowners in obtaining personalized recommendations, presenting the best 3 to 5 options aligned with their preferences and their land's conditions.

This presentation aims to provide a comprehensive overview of the expert system's structure, operational framework, and tangible outcomes achieved thus far. By shedding light on the inner workings of this expert system, we contribute to the broader discourse on sustainable forest management and climate action planning. Furthermore, we highlight the significance of the expert system in simplifying the realization of a multi-species structure, emphasizing its role in meeting climate and bioeconomy targets.

Open data, models, and software for machine automation

T5.10 Digitalization for sustainable forest management
Arvid Fälldin[1]

[1] Umeå University
[2] Swedish University of Agricultural Sciences
[3] Skogforsk - the Forestry Research Institute of Sweden

Abstract: We create partially annotated datasets from field measurements for developing models and algorithms for perception and control of forest machines using artificial intelligence, simulation, and experiments on physical testbeds. The datasets, algorithms, and trained models for object identification, 3D perception, and motion planning and control will be made publicly available through data and code-sharing repositories.

The data is recorded using forest machines and other equipment with suitable sensors operating in the forest environment. The data include the machine and crane tip position at high resolution, and event time logs (StanForD) while the vehicle operates in high-resolution laser-scanned forest areas. For annotation, the plan is to use both CAN-bus data and audiovisual data from operators that are willing to participate in the research. Also, by fusing visual perception with operator tree characteristics input or decision, we aim to develop a method for auto-annotation, facilitating a rapid increase in labeled training data for computer vision. In other activities, images of tree plants and bark are collected.

Research questions include, how to automate the process of creating annotated datasets and train models for identifying and positioning forestry objects, such as plants, tree species, logs, terrain obstacles, and do 3D reconstruction for motion planning and control? How large and varied datasets are required for the models to handle the variability in forests, weather, light conditions, etc.? Would additional synthetic data increase model inference accuracy?

In part we focus on forwarders traversing terrain, avoiding obstacles, and loading or unloading logs, with consideration for efficiency, safety, and environmental impact. We explore how to auto-generate and calibrate forestry machine simulators and automation scenario descriptions using the data recorded in the field. The demonstrated automation solutions serve as proofs-of-concept and references, important for developing commercial prototypes and for understanding what future research should focus on.

Operational assessment of forest growth using airborne laser scanning data acquired on the national level.

T5.10 Digitalization for sustainable forest management

Jörgen Wallerman[1]
Alex Appiah Mensah[1], Mats Nilsson[1], Carl Vigren[1], Emma Sandström[1], Mikael Egberth[1], Jonas Jonzén[1], Peder Axensten[1], Kenneth Nyström[1], Liselott Nilsson[2], Göran Ståhl[1]
[1] Swedish University of Agricultural Sciences, Umeå, Sweden
[2] Swedish Forest Agency, Skellefteå, Sweden

Abstract: Accurate assessments of forest growth are crucial for responsible management of the forest resource, to meet the broad range of challenges the society is facing today. The forest has potential to provide renewable and essential materials, bio-based energy, mitigate climate change by large-scale sequestration of atmospheric carbon, and is also an ecosystem with potentially very high biodiversity. Knowledge about the rate of change (growth), not only as large-area summary statistics, but also as spatially explicit maps with very high resolution, is expected necessary to provide full benefits from digitalization of the forestry in view of current challenges. Today, precision forestry is developing fast and will change the scale of forestry data capture from stand-level to the single tree-level. As one example, this development will most likely revolutionize management planning of the continuous cover forestry gaining popularity today.

The fast development of remote sensing provides today more data about current and past forest states than ever before. Especially, three-dimensional airborne laser scanning data about tree canopies have proven essential for forest monitoring and management planning. In Scandinavia, there are often time-series of such data available on the national level, providing new possibilities to operationally assess and model forest growth with higher spatial accuracy and improved errors compared to traditional growth models. Time-series of 3D data are measurements of the actual changes in forest state, summarizing growth, mortality, as well as silvicultural activities. This, in contrast to traditional growth models often relying on site index assessments only.

This paper reports ongoing activities in the Mistra Digital Forest project, a PhD project financed by the Knut & Alice Wallenbergs foundation, as well as the national forest mapping of Sweden by SLU and the Swedish Forest Agency. Here, new models of forest growth, models powered by time series of 3D tree canopy data in combination with hydrological maps, all acquired using airborne laser, are presented. The new potentials of assessing competition, mortality, and silvicultural treatments as measured by changes in, and the structure of, the forest canopies are explored to construct models applicable for raster mapping as well as on the single tree level.

Optimal tree selection in forest thinning for economic, carbon sink, biodiversity, and scenic beauty benefits

T5.10 Digitalization for sustainable forest management

Mikko T. Niemi[1, 2]
Jari Vauhkonen[1, 2], Omid Abdi[1], Ville Laamanen[1], Jori Uusitalo[1]
[1] Department of Forest Sciences, University of Helsinki, Latokartanonkaari 7, Helsinki 00014, Finland
[2] School of Forest Sciences, University of Eastern Finland, Yliopistokatu 7, Joensuu 80101, Finland

Abstract: Thinning is the selective removal of trees to provide the remaining trees with more growing space and growth resources such as water and soil nutrients. Tree selection plays a key role in forest productivity, carbon sinks, biodiversity, and scenic beauty. For example, retaining deciduous trees can increase forest biodiversity and resilience, but it can also reduce the net income of forest owners.

The selection of harvested vs. retained trees and the placement of retention trees has typically been left to the harvester operator, who makes decisions based on his subjective opinion and experience. However, the increasing quality and availability of individual tree inventory data would allow for optimized tree selection considering multiple ecosystem services. Our vision is that the pre-planned tree selection can guide the operator's decisions, but the operator is still responsible for e.g. evaluating the quality of the remaining trees and modifying the tree selection if necessary.

To rationalize these decisions, we formulate the problem as numerical multicriteria priority functions to optimize tree selection for economic benefits, carbon sink, biodiversity, and scenic beauty. Harvesting priority is evaluated across tree, plot, and stand scales, and tree harvesting decisions are made by weighting multiple decision criteria based on the preferences of the decision maker in heuristic optimization. The spatial pattern of the remaining trees, as measured by the Clark-Evans index, limits the possible solutions, so the growth space must be used comprehensively.

This study presents the procedure for tree-level multi-criteria optimization in thinning-stage forest stands. Further studies can also use forest soil data and terrain characteristics in the optimization phase to consider different growth potentials within thinning stands. In general, this research supports precision forestry, where decisions are made at a very local scale, and aims to facilitate the demanding work of harvester operators.

Optimized extraction routes and roadside storage location to maximize efficiency and minimize environmental impact in forest operations

T5.10 Digitalization for sustainable forest management

Mikael Frisk[1]
Erik Rönnqvist[1], Patrik Flisberg[1], David Bredström[1], Mikael Rönnqvist[1]
[1] Creative Optimization Sweden AB

Abstract: In recent years, the development towards increasingly high-resolution LIDAR data has enabled a detailed description of terrain, soil, and forest density. In addition, so-called depth-to-water maps measuring the soil wetness can be computed. This information has provided an excellent basis for better planning of a standard two-machine system (harvester and forwarder) before felling so that efficient operations (e.g., low average extraction distance) can be done while simultaneously reduce the risk of soil damage. However, manual planning with all information is very difficult and there is a need for advanced optimization models and methods to consider all information while finding solutions quick. Optimized solutions lead to less environmental impact in several ways, partly less impact on the soil, partly less emissions thanks to reduced energy consumption.

Timbertrail is a decision support tool for planning optimized extraction routes. It is also a very successful example of where research has quickly led to implementation with wide practical use in forestry. Timbertrail is used to plan in detail where the harvesting machines should drive in order not to risk any soil damage. As a further development of Timbertrail, a new service, Log Landing, has been developed with the aim of optimizing where the roadside storage should be placed to provide the most optimal forwarding as possible. Based on detailed information (e.g., houses, road crossings, power lines, terrain obstacles, and heritage areas) about the area along nearby roads and combined with results from Timbertrail, an optimization model provides suggestions for optimal locations where the piles should be placed.

With our models for creating extraction routes and the placement of log piles, we demonstrate how advanced optimization models can be used together with high-resolution data to streamline forest operations and reduce environmental impact. In our presentation, we show how decision support tools are used in practical operation in different parts of the world. We also illustrate how they can be used on a strategic level together with information on the annual variation of rainfall, to create a basis for when different harvest areas are best suited to be harvested to minimize the risk of soil damage.

OPTIVEG: Improving operational and environmental efficiency of forest operations by the development of a machine allocation digital platform

T5.10 Digitalization for sustainable forest management

Pedro Marques[1]
Salvador Posser de Andrade[2], Reinaldo Gomes[3], **Pedro Britto**[4], David Almeida[1]

[4] ForestWise

Abstract: In Portugal, wildfires are a recurrent and increasing issue. Networks of fuel breaks are a measure to slow the progression of fires. The maintenance of these lanes requires a great input of machinery and manpower, however, in Portugal, forest operation are have an inferior productivity and environmental performance than in other European countries. One of the reasons for this problem is the common mismatch between the equipment used and the specific conditions of the site to intervene – such as vegetation and stand characteristics, slope and other characteristics. The mismatch is in part, due to communication difficulties between the service provider and the forest manager, but also due to the lack of easily accessible technical information on the suitability of different types of equipment under different conditions.

The OPTIVEG project - Optimization of Sustainable Planning for Vegetation Management Operations - of the Transform Agenda – Agenda for the digital transformation of the Portuguese forest sector in a resilient, low-carbon economy, financed under the Portuguese Recovery and Resilience Plan - aims to develop a technological solution to support the process of allocating the most suitable equipment to the operations.

Teams working on the vegetation management of the areas managed by REN – Redes Energéticas Nacionais – the Portuguese transmission system operator are accompanied to collect data of the performance of different machinery working under different conditions. Productivity was measured through time studies and in-build machinery sensors. Vegetation characterization is done with LiDAR and imported to a geo-referenced database. The model is being developed, with established Key Performance Indicator related with site and vegetation characteristics as well as machinery categories. Several social, economic and environmental indicator of operational performance were selected as indicators for operational productivity. An algorithm is being developed by INESC TEC - Institute for Systems and Computer Engineering, Technology and Science to automate the machine selection process. At the end this project will deliver an online platform, where forest managers and decision-makers could receive an output with the most suitable equipment along with estimated costs, productivity, and greenhouse gas emissions, associated with intervening a particular area, for a set of predetermined mechanical alternatives.

Pinus pinea plantations monitoring using unmanned aerial vehicles derived data

T5.10 Digitalization for sustainable forest management

Abstract: Stone pine (*Pinus pinea* L.) is a Mediterranean species, with high plasticity and low genetic variability. Even though its edible seeds, the pine nuts, are the most expensive nut in the world, it is mainly harvested from natural forests and there are no intensive management techniques. Recently, more than 4,000 ha have been planted in Chile, increasing the demand for technological solutions to obtain field data to guide this crop management, information traditionally field-measured analogically. The use of remote sensing in forest plantations surveys has shown to be a novel alternative for the estimation of dasometric variables through the processing of images captured by Unmanned Aerial Vehicles (UAV), having been studied in the species in Turkey, Italy, Portugal and Spain. This study aims to validate the use of the Light Detection and Ranging (LiDAR) technology for monitoring stone pine plantations in central Chile. The study was performed on two plantations of 13 and 30 years-old. In both sites, trees were identified and georeferenced. Flights were carried out with a UAV equipped with a LiDAR sensor. At the same time, each tree was field-measured for height, DBH and crown diameter. Canopy Height Model (CHM) was obtained from the LíDAR point cloud. From the CHM, values of height, diameter and crown surface of each tree were estimated, and later used to adjust dasometric models, using the field-measured data as a dependent variable. A third of data was used to generate the training dataset and the remaining 70% for validation. Height, stem diameter and crown prediction models were significant with R^2 values greater than 0.8 in both plantations, showing the applicability of this technology to stone pine plantations with different age, size, spacing and slope.

Predicting forest road trafficability using GIS and Remote Sensing based variables

T5.10 Digitalization for sustainable forest management

Timo Tokola[1]
Ville Karjalainen[1], Tomi Karjalainen[1]
[1] University of Eastern Finland, School of Forest Sciences

Abstract: Mills wish to maintain a year-round continuous flow of fresh roundwood, which is a major challenge during low bearing capacity seasons in Finland, as there are few forest roads in the current network that are suitable for year-round use by heavy-duty vehicles. Since manual determination of forest road conditions is laborious and slow, it is vital to develop faster methods for identifying the properties of these roads using already available or easily accessible data in order to assist route planning and the targeting of road maintenance measures.

This paper describe. how the bearing capacity of forest roads can be predicted using such properties which can be easily measured in the field or extracted using remote sensing data, together with Open GIS variables. The trafficability prediction is very demanding task. The prediction results indicated that operational road width is the most significant variable when assessing the bearing capacity. LiDAR data, various Gamma ray sensors, and falling weight deflectometer measurements were used to understand the quality of the road.

Recent advances in the mapping of wood quality with laser scanning at industrially relevant scales

T5.10 Digitalization for sustainable forest management

[3] Swedish University of Agriculture, Department of Forest Sciences

Abstract: We present recent advances in wood quality mapping using fusions of dense airborne laser scanning (ALS), and static and mobile terrestrial laser scanning (TLS and MLS, respectively) with industrial references. Studies spanning several areas with Norway spruce (*Picea abies* H. Karst.) and Scots pine (*Pinus sylvestris* L.) – dominated, mature boreal forest stands in Southern Finland and Sweden are revisited and discussed. The state-of-the-art laser scanning techniques enable the extraction of features that indicate wood quality at variable scales, e.g., crown geometry variables, branching information, stem taper, competition indicators, and stand variables. With such data, we show how wood quality attributes such as knottiness, ring width, and wood density can be predicted to individual trees over entire stands, with respect to the industrial references. We have evaluated the accuracies of the wood quality maps with over 500 sample trees that were tracked from the forest to sawmills. We discuss how the wood quality maps could be used to enhance operational wood procurement planning, and log-breakdown optimization. Our studies also provide insights to the traceability-problem of tree stems from forest to factory, to enable automated identification of corresponding logs along the production chain. The digitalization of wood procurement planning based on industrial data, laser scanners mounted on harvesters and within- and above-canopy flying drones, and nationwide ALS data can facilitate more precise and flexible decision-making regarding the optimal use of wood with various qualities, and the distribution to the most appropriate end-use.

Smart forest inventory using samples of dense airborne laser scanning

T5.10 Digitalization for sustainable forest management

Henrik Jan Persson[1]
Kenneth Olofsson[1], Ritwika Mukhopaday[1], Christoffer Axelsson[1], Johan Holmgren[1]
[1] Swedish University of Agricultural Sciences

Abstract: As part of the Mistra Digital Forest Programme 2023-2026, task 1.2, we have developed multi-stage inventory methods. A central part of the approach consists of samples of dense airborne laser scanning (ALS) data, to provide cost efficient estimates of traditional and new forest variables. The ALS data are acquired with about 500 pts/m2 and are used to segment single trees as well as branches and damages. The reference data are collected with harvesters, terrestrial laser scanners (TLS), and field inventories. The other phases include both TLS and wall-to-wall data from ALS of lower resolution, as well as satellite images. This project focus on developing methods for the new variables (e.g., trunk crooks, stem quality, tree species, stem profile etc.), efficient airborne inventory designs, and the propagation of errors across the phases. The overall framework has already proven more efficient than traditional field inventories for, e.g., estimation of stem volume (Persson et al. 2022), and this work extends to more variables and an improved understanding on the uncertainties related to this framework.

Persson, H.J., Olofsson, K., Holmgren, J. 2022. Two-phase forest inventory using very-high-resolution laser scanning. *Remote Sensing of Environment*, Vol 271.

Teaming for Excellence – a Prerequisite for Sustainable Forest Management Today: The Role of Forest 4.0

Abstract: Forest ecosystems and forestry face numerous challenges in the present day. These challenges arise from the increased use of timber and bioenergy, uncertainties brought about by climate change and efforts to mitigate it, the intricate dynamics of evolving global markets, rural depopulation, and the growing emphasis on the social values of forests. Effectively managing such a multidimensional system is only possible through the implementation of smart technologies. These technologies enable the acquisition and utilization of information on the processes occurring within and around forest ecosystems, as well as the prediction, prevention, or mitigation of potential risks. By integrating advanced digital technologies such as Artificial Intelligence (AI), the Internet of Things (IoT), blockchain, and big data analytics, which together form the components of the Forest 4.0 concept, forest management practices could potentially find a solution to these challenges. However, the successful implementation of this concept requires collaborative efforts from a diverse range of actors. This presentation aims to introduce the approach of the recently launched Horizon-Widera project Forest 4.0, which is being implemented by a team of Lithuanian and Swedish partners. The primary objective of this project is to establish a Centre of Excellence that will transform forest environment monitoring, data acquisition, and analysis, and extract value from the collected data. Lessons already learned and the challenges that lie ahead will be discussed based on the initial findings in the following research topics: IoT remote sensing and ubiquitous computing for the development of geospatial techniques; IoT monitoring and AI prediction techniques for the development of forest management systems and the detection of forest threats; crowdsourced forest-based data management and visualization; AI techniques for cognitive sensing and multi-modal signals processing in IoT-based systems for predictive analytics; development of decision support tools to assess forest management practice; life cycle assessment and bioeconomic modelling tools for the identification and justification of sustainable forest-based business model innovations. This project has received funding from the European Union's Horizon Europe research and innovation programme under grant agreement No 101059985.

The use of digital decision support tools in Swedish forestry - an overview and outlook

T5.10 Digitalization for sustainable forest management

Maria Nordström[1]
[1] Skogforsk

Abstract: Swedish forestry is currently meeting challenges like remaining competitive on the global market for forest products, continue increasing sustainability of operations and recruiting next generation's work force. To meet these challenges, forest companies and other actors are relying on the increasing use of different types of digital decision support tools tailored to the needs of forest professionals, machine operators and others. These tools are key in the transformation towards precision forestry where negative environmental impact is minimised and active forest management is creating different types of values for forest owners and the society. The increasing availability of new sources of detailed information about the forest like high-resolution remote sensing data and different types of data from forest machines will serve as a useful basis for developing such tools in combination with other types of data describing the road network, weather conditions etc and advanced statistical modelling and AI.

This study presents an overview of the current use of such digital decision support tools in Swedish forestry. What are the main drivers for the development, which applications are already being used in large scale, who are developing them and what effects have they had on operations and people using them are key questions to be discussed. The study will also provide an outlook describing probable next steps in the development and expected effects connected to the implementation of the tools.

The use of digital technologies to enhance forest operations monitoring and planning: A case study in Portugal

T5.10 Digitalization for sustainable forest management

[5] Trigger Systems

Abstract: In the digital era, sensors embedded in forest machinery can be instrumental for enhanced planning and decision support along the forest-based value chains. The combination of a multitude of sensors (e.g. GPS, GPS, humidity, temperature, movement) collect a large amount of data, in close to real time, at low cost and with high precision. The consolidation and processing of such data with adequate business analytic tools, enables to monitor over time the machinery status, operations performance and wood flows, geographically distributed. Such information can be valuable for the multiple agents of the value chain and can help to reinforce trust and transparency. Despite recent technology developments, the collection, consolidation and processing of forest operations data in not new. The StandForD2010 for data standardization and interoperability in in use for several decades, specially in Northern Europe.

In Portugal, forest machinery often has the capacity to collect and store data in the StandForD2010 format. However, this information is seldom used. In Portugal, the harvesting fleet is very diverse in terms of manufacturers and manufacturing age, therefore, compatibility issues arise, together with difficulties in the real time communication of the machineries operating in remote areas with low connectivity coverage. On the other hand, the Portuguese wood-based wood supply chains involve multiple agents, from producers, to third-party contractors and industry players, each should find value in using the data that will be provided by the sensors, as well as agree upon the conditions for sharing that data with the other players.

This research proposes an innovative solution anchored in a novel embedded device for harvesters and forwarders, developed in the logic of “one-size-fits-all”, to avoid compatibility. The information collected with StandForD standards is consolidated and processed in a prototype of a advanced planning system, combining business analytics and optimization methods with friendly graphical-user interfaces. This system enables to monitor on-time operations and also identify deviations in respect to the optimal plan. The integrated solution is being applied in the pulp and paper value chains in Portugal and the preliminary results will be presented.

Towards Digital Twin of Boreal Forests at Individual Tree Level – UNITE flagship approach

T5.10 Digitalization for sustainable forest management

[3] University of Eastern Finland

Abstract: Forest information is typically collected using different inventory techniques and the objective is to provide the fundamental information for all decision-making tasks in the society. Areas of interest are often characterized using descriptive statistics or thematic maps. Until now / At present, country-wide individual tree maps do not exist. This kind of databases and maps would support, especially wood procurement. In our presentation, we propose and demonstrate a country-level Digital Twin of forests at individual tree level. The first one billion trees have already been added to the database using the following technologies: 1) computation of individual tree information using airborne laser scanning point clouds with a point density of 5 pts/m2, 2) developed automatic field reference techniques based on above-canopy drone laser scanning that provides direct stem curve estimates, autonomous car big data and/or harvester mobile laser scanning as well as field measurements, 3) a browser-based 2D viewer for data visualization, 4) utilizing also saw-mill data to attach quality information to trees, and 5) using automated change detection to record the growth of each tree. Tree-level open data will be made available when the system develops. We have created individual tree information with the following characteristics for core tree attributes: 1) Individual tree locations (0.5 m error in the XY plane), 2) Tree height (1 m error), 3) Stem volume and biomass (30% error), 4) Stem diameter (dbh) (16% error), 5) Tree species (80% correctly classified), 6) 88% of trees bigger than 20 cm in dbh are found, and 7) 10-20% of trees with dbh about 10 cm are found. The digital twin platform is capable of visualizing multiple ecosystem services, such as improved biodiversity information, carbon sinks, berry maps and quality of forest roads. By combining individual tree information with cadastral boundaries, road & infrastructure data and other geospatial feature data, a digital twin of forests is formed, applicable to a variety of decision making tasks. Until now, we have implemented in the system improved biodiversity information, carbon sinks, berry maps, and quality of forest roads.

Which Species is this Tree? Using 3D Laser Scanning to Describe the Forest

T5.10 Digitalization for sustainable forest management

Andreas Tockner[1]
Christoph Gollob[1], Ralf Kraßnitzer[1], Sarah Witzmann[1], Tim Ritter[1], Arne Nothdurft[1]

Abstract: Measurements of individual forest trees are expensive and rarely accessible through forest inventory, but to ensure sustainable, efficient and precise harvest operations modern forest management demands detailed information. How can we visualize the tree species distribution of a forest to determine the exact wood volume per species? Person-carried laser scanning is a highly automated technology for measuring single trees in 3D point clouds. However, the complex problem of species classification has not been solved yet, due to a lack of structured data to cover the natural variety within a species. This study presents a machine learning model for classifying nine major Austrian tree species in person-carried laser scanning data. In contrast to other studies, this classification features intensity moments and measurement ratios as predictors. We set up a random forest model on more than 7.000 single tree point clouds and validated using an independent test set. The classification accuracy exceeded 90 % between conifers and deciduous trees and 80 % among all nine trees species. Reliable species predictions for individual tree point clouds increase the importance of person-carried laser scanning data for efficient forest management and lead the way to competition analysis and biodiversity assessment.

T5.11 Disturbance impacts on climate regulating services in forest ecosystems

Beyond Carbon: The Critical Need for a More Holistic View of Forests and Climate

T5.11 Disturbance impacts on climate regulating services in forest ecosystems

Kristofer Covey[1]

[1] Environmental Studies and Sciences Program, Skidmore College, 815 N Broadway, Saratoga Springs, NY 12866, USA

Abstract: Despite a large body of research showing that non-CO_2 climate forcing agents are a critical factor in the biogeochemistry of forest climate interactions, current research overwhelmingly centers on the cycling and storage of carbon (C) and its response to management. Missing, is more comprehensive consideration of other significant climate forcing agents and processes (i.e., CH_4, N_2O, black carbon, biogenic volatile organic compounds; BVOCs, transpiration, and albedo) and their dynamic responses to both localized (management, fire, land use change, infrastructure development, storms) and global (e.g., warming, drying) disturbances. This presentation reviews our current understanding of the sources, drivers, and scale of a wider suite of forest climate forcing agents and explores the demonstrated or expected impact of global and local disturbances on each agent. We highlight remaining uncertainty in non-CO_2 flux magnitudes, a lack of understanding of their responses to disturbance, and the failure to consider corresponding direct and indirect effects on regional and global climate. Given the large contribution of less-recognized agents (e.g., Amazonian trees alone emit ~3.5% of all global CH_4), a continuing focus on a single metric (i.e., C uptake and storage) is incompatible with genuine efforts to understand and manage the biogeochemistry of forests for climate mitigation.

Disturbance impacts on climate regulating services in forest ecosystems

T5.11 Disturbance impacts on climate regulating services in forest ecosystems

Dominik Thom[1]
[1] Technical University of Munich

Abstract: Climate change and increases in natural disturbance activity challenge the provisioning of ecosystem services. This is of particular importance considering that a reduction in climate regulating services (CRS) would exacerbate future climate change. Mitigating climate change relies heavily on forests, making the amplifying feedback loop of CRS reductions a formidable obstacle in limiting global temperature rise to below +2 °C. Previous research, policy, and management efforts have predominantly focused on carbon sequestration and storage, largely overlooking other crucial CRS. In this presentation, I first provide a global overview of the effects of disturbances on various CRS, that I subsequently underpin with a few case studies from Central Europe.

Disturbances exhibit diverse impacts on CRS. Carbon sequestration and storage are primarily negatively affected by disturbances, resulting in reduced biomass, gross primary production, and increased heterotrophic respiration. However, in some cases, carbon sequestration can increase in the mid- to long-term as ecosystems progress into more productive stand development phases or transition to faster-growing species. Albedo increases after disturbance as gaps usually reflect more incoming solar radiation than forests. The influence of disturbances on the latent heat flux of forests is highly dependent on temporal scales. In the short term, disturbances reduce evapotranspiration, negatively impacting latent heat flux. However, in the long term, changes in species composition might increase evapotranspiration and, thus, the latent heat flux, particularly if conifer-dominated forests transition to broadleaved-dominated ones. Similarly, the overall microclimatic buffering capacity against extreme weather events is reduced immediately after disturbances, but may recover quickly as stands develop.

Considering that disturbance activity is projected to intensify in the future, it is alarming that disturbances cause an overall reduction of CRS. Therefore, strategies to optimize CRS must incorporate adaptive measures to ensure the future stability of CRS. Yet, few studies have examined multiple CRS simultaneously and projected their future trajectories under novel climate and disturbance regimes. Addressing these knowledge gaps is imperative for the development of robust forest management strategies aiming to improve and safeguard CRS.

EVALUATION OF LAND USE/COVER CHANGE IMPACTS RESULTING FROM MINING ON ECOSYSTEM SERVICES IN BOKÉ PREFECTURE, REPUBLIC OF GUINEA

T5.11 Disturbance impacts on climate regulating services in forest ecosystems

Abdoulaye Djibril Diallo[1]
Prof. Moussa Koné[2], Dr. Jan Henning Sommer[3]
[1] Centre for Environmental Studies and Research/University of Conakry, Guinea
[2] UFR Sciences de la Nature, University Nangui Abrogoua, Abidjan
[3] Zef Centre, University of Bonn, Germany

Abstract: Land use and land cover change (LULC), especially conversion and degradation of forest land, is the key factor causing terrestrial carbon stocks decline and affecting their dynamics in ecosystems. Detecting changes in LULC is extremely important for obtaining continuous and accurate information for any type of development planning. Geographical information systems and remote sensing technologies have shown strong capabilities in detecting LULC. This study, therefore, aimed to analyse the dynamics of LULC and to assess the variation of terrestrial carbon stocks in response to mining. Remote sensing was used to map and quantify LULC changes and the Integrated Valuation of Ecosystem Services and Tradeoffs (InVEST) model to quantify and evaluate the changes in carbon storage under land use conditions in 1975 and 2020. Maps were classified based on seven LULC categories, including herbaceous wetland, forest, agricultural land, shrubland, water bodies, barren land, and Built-up/Settlement area. The results indicate that Within the period between 1975 and 2020, baren land and Bult up/Settlement related to mining have been identified as the main factors behind the alteration of land cover, which is the key factor of terrestrial carbon stocks decline in the area. Based on these findings, we recommend to science and research institutions to provide relevant policy options for better biodiversity conservation and sustainable development; to the Ministries of Environment and Mining, to integrate mine site restoration into the national environmental policy and to develop a standardised guide for ecosystem restoration in mining areas.

Even Cooler Insights: On the Power of Forests to (Water the Earth and) Cool the Planet

T5.11 Disturbance impacts on climate regulating services in forest ecosystems

David Ellison[1]
Jan Pokorny[2], Martin Wild[1]
[1] ETH Zurich
[2] ENKI

Abstract: Recent scientific innovations upend classical forest-water interaction models. The principal causal pathways by which tree, forest, and vegetation cover (TFVC) influence local and global warming/cooling are thus inadequately described. TFVC drives hydrologic cycle intensification (precipitation recycling) and the geographic extent and availability of water and water storage across the land surface. This in turn drives increased latent heat production (evapotranspiration (ET)), cloud formation, and TFVC binding of carbon from the atmosphere (carbon sequestration). Previous modeled results identify *surface albedo* and *carbon sequestration* as the principal causal pathway by which TFVC affects global warming/cooling. Surface albedo effects are presumed to overpower carbon sequestration effects toward the outer latitudes. Thus, deforestation is predicted to lead to surface cooling while increasing forest cover results in warming. Observational data, however, suggest the opposite. Land surface temperatures are influenced by the interplay of surface albedo, incoming shortwave (SW) radiation, and the partitioning of the remaining, *post-albedo*, shortwave radiation into latent and sensible heat. The avoidance of sensible heat formation on the land surface is first and foremost mediated by the presence (absence) of water and potential TFVC production of latent heat. The availability of water on terrestrial surfaces is, in turn, mediated by TFVC. Latent heat (ET) itself, however, is not directly linked to *global* cooling/warming. *Global* cooling is primarily driven by carbon sequestration and the top-of-cloud reflectivity associated with cloud formation, both by-products of TFVC driven evapotranspiration (ET), and evaporation (E) on land (and ocean) surfaces. TFVC loss reduces water storage, precipitation recycling, and downwind rainfall potential, and thus drives the reduction of both ET (latent heat) and cloud formation. Deforestation thereby powers warming (sensible heat formation) and further reduces TFVC growth (carbon sequestration). Increasing tree and forest reforestation efforts could therefore, realistically, contribute to global and surface temperature cooling.

Exploring Disturbance Dynamics: Insights from the Austrian National Forest Inventory (ANFI)

T5.11 Disturbance impacts on climate regulating services in forest ecosystems

Tammam Suliman[1]
Thomas Ledermann[1]
[1] Austrian Research Center of Forests (BFW)

Abstract: ***Context***

Climate change significantly impacts disturbance agents, abiotic and biotic, in European and Austrian forests, altering their magnitude and triggering feedback reactions in their structures, communities, and ecosystem services. Disturbances account for 16% of the annual harvest in Europe. In Austria, storms and snow damage 1-3 million cubic meters of timber annually, while bark beetle damage increased up to 3.75 million cubic meters in 2022. Implementing adaptive forest management strategies and utilizing disturbance-based growth models is crucial for effective forest management in Austria amidst these circumstances.

The objectives

The objective of this study is to develop models that illustrate the probabilities of random events such as wind, snow breakage, and bark beetle outbreaks. It includes a dedicated sub-model for wind and snow damage and explores events associated with drought and bark beetles. The study examines event probabilities, dynamics, and identifies trends, interactions, and effects among variables.

Methods

Using a dataset of 343,722 trees from 9,532 plots in the Austrian National Forest Inventory (ANFI) spanning 1981-2021, we categorized disturbance-related damages as "events." By employing approximately 20 sub-models at plot and individual-tree level, including climate data, site conditions, stand characteristics, and individual-tree attributes, we used logistic mixed-effect models to assess the likelihood of random event occurrence and explore intricate relationships.

Main results

- Stand and individual slenderness is a key variable in explaining the occurrence of random events and damage probability.
- Optimizing stand composition by reducing *Picea abies* and *Pinus Sylvestris*, and increasing Fagus sylvatica, *Quercus sp*., and *Carpinus betulus*, mitigates risk and damage intensity at the plot level.
- Interactions among wind speed, maximum stand height, snow and slenderness raise the occurrence of random events and the probability of wind and snow damage. High temperatures make the trees more susceptible to bark beetle outbreaks.

- Moderate interventions reduce tree vulnerability, while excessive interventions increase the risk of random events.

Conclusion

This study emphasizes climate change's impact on disturbance agents in European forests. By modeling random event probabilities and interactions, forest managers can optimize interventions to mitigate risks, enhance forest resilience, and adapt to changing environmental conditions.

From twisters to timber: Assessing the Effects of Tornadoes on Forests in the United States

T5.11 Disturbance impacts on climate regulating services in forest ecosystems

Holly Munro[1]
Craig Loehle[1], **Bronson Bullock**[2], Dan Johnson[2], James T. Vogt[3], Kamal Gandhi[2]
[1] National Council for Air and Stream Improvement, Inc. (NCASI)
[2] University of Georgia, Warnell School of Forestry & Natural Resources
[3] U.S. Forest Service, Southern Research Station

Abstract: Changes in climate dynamics have been forecasted worldwide, which may have significant effects on forest ecosystems. To gain deeper insights into effects of natural disturbances on forests, we conducted an analysis of tornado-related damage trends for the period 1995-2021, specifically focusing on forested ecosystems in the United States (U.S.). We documented a noteworthy pattern: while recent data collected between 1995 and the present indicate a stable or potentially declining trend in the overall number of tornadoes across the country, the southeastern U.S. has experienced an increase in both the total number of tornadoes and the extent of forest area affected, surpassing other regions over the past three decades. This points to a potential geographic shift in focused tornadic events ("tornado alley") from the midwestern U.S. to the southeastern U.S., which encompasses a larger expanse of commercial timber land (~80 million hectares across 12 states). Furthermore, we observed a 36% increase in forest area damage estimated by the total area covered by tornado tracks over the most recent two decades. These findings highlight the heightened financial implications on the wood products sector and landowners from increased tornado damage in forested areas in recent years. The outcomes of this study contribute to enhancing strategic risk assessments, guiding forest certification processes, and facilitating accurate carbon reporting. They also highlight the importance of adaptive forest management and the need for landowners to monitor and evaluate occurrence, extent, severity, and projections of the scale, frequency, and location of natural disturbances.

Impacts of efficient fuelwood consumption on carbon storage potential in mangrove ecosystems and alternative extraction sites

T5.11 Disturbance impacts on climate regulating services in forest ecosystems

Lilian Mwihaki Mugi[1]
Mark Huxham[1], James Kairo[2]
[1] Edinburgh Napier University
[2] Kenya Marine and Fisheries Research Institute

Abstract: Supplying dead wood for fuel is one of the most important ecosystem services provided by mangroves to the local communities (UNEP-Nairobi Convention and WIOMSA, 2015), but the capacity of the forests to supply dead wood sustainably is unknown, as are the impacts of dead wood removal on carbon dynamics and ecology (Stephenson *et al.*, 2011). The ecological effects of removal of fuelwood from mangrove forests and alternative source in Vanga, Kenya, was investigated following the introduction of improved cookstoves to the forest adjacent communities. Using the Before-After-Control-Intervention (BACI) method, forty households were monitored (twenty as intervention and twenty as control) for a period of 2 months, using standard kitchen performance tests. The objective of the survey was to assess the impact of the introduction of energy efficient cook stoves on the amount of fuelwood used by the forest dependent communities, and how this affects the climate egulation potential of mangrove forests in terms of carbon storage. Further, data collected on fuelwood consumption, as well as on productivity and wood extraction was used to explore the 'leakage' phenomenon, which is very poorly studied; this describes the displacement of extractive or damaging activities away from protected areas into surrounding alternative sites. Here practical guidance was produced on the likelihood of forest management schemes simply displacing damaging activities to unprotected contiguous areas.

Radiative Forcing from Pre-Industrial Land Cover Change: the Capacity of Forest Cover to Modulate Climate

T5.11 Disturbance impacts on climate regulating services in forest ecosystems

[3] University of Wisconsin- Madison

Abstract: Climate-vegetation feedbacks depend on biophysical land cover characteristics such as albedo. This measure of surface reflectance impacts the surface energy balance. However, the narrow temporal extent of direct observations of albedo make it difficult to quantify centennial to millennial scale shifts. Albedo is used to quantify terrestrial ecosystem processes; its magnitude and variability moderate terrestrial biosphere and atmosphere interactions. Networks of fossil pollen data offer an observational constraint on biophysical land cover change that extends throughout the Holocene. We reconstruct Holocene albedo and associated radiative forcing for North America. First, we estimate average monthly blue sky albedo over the 2000-2009 period from MODIS satellite reflectance data products and ERA5 atmospheric reanalysis diffuse and direct radiation. Blue sky albedo –sometimes referred to as actual albedo– represents the overall surface reflectance from combined direct and diffuse incoming radiation. Then using a spatio-temporal network of fossil pollen records and the derived blue sky albedo, we reconstruct albedo. This reconstruction is done in two steps: calibration and prediction. In the calibration step, we develop a statistical model that characterizes the relationship between modern pollen samples and seasonal albedo. In the prediction step, we apply this model to reconstruct albedo from historical pollen records. Finally, these albedo reconstructions are translated to spatio-temporal estimates of radiative forcing using a pre-industrial radiative kernel. This allows us to identify regions that have undergone land cover shifts that have resulted in warming or cooling. This work provides new insight about the nature of climate-vegetation feedbacks and ecotone shifts, and an empirical constraint on ecosystem forecasts.

Regulation and resilience：Panarchy analysis in forest ecosystem of Northeast State-owned Forest Region, China

T5.11 Disturbance impacts on climate regulating services in forest ecosystems

Dan Qiao[1]
Wantong Yuan[2]
[1] Beijing Forestry University
[2] Renmin University of China

Abstract: While COP27 proceeds in Egypt, While COP27 proceeds in Egypt, with most attempts to address global environmental issues, it is crucial to consider the significant challenges posed by climate-related changes to human livelihoods, society, and ecosystems. most attempts to take a global perspective on solutions to environmental issues. China has pledged a CO2 emissions peak before 2030 and achieves carbon neutrality before 2060. Additionally, the UN emphasizes the vital role of forest-based mitigation in averting catastrophic climate change. The Northeast State-owned Forest Region (NSFR) in China, with its vast forest resources, holds great ecological and livelihood implications for both China and global climate change issues. However, the NSFR has suffered catastrophic damage due to deforestation, leading China to implement the Natural Forest Protection Program (NFPP) and logging ban policies to restore the ecosystem. Despite these protective measures, concerns have arisen regarding the alarming state of the forest region's quality under long-term strict protection. To maintain the forest ecosystem in a stable state, effective silvicultural measures are essential, as the resilience of the forest ecosystem appears weak and unable to adapt to natural and human disturbances. Moreover, if the natural forest in the NSFR becomes a carbon source instead of serving as carbon sequestration, forest management measures need to be implemented. The fragility of the forest ecosystem may be exacerbated by climate change. To address these challenges, the concept of panarchy provides a framework in environmental science that can inform resilience thinking and adaptive approaches to forest management. Currently, the forest ecosystem in the NSFR is not progressing towards achieving high-quality forest goals. In this paper, we will discuss the adaptive cycle of the forest ecosystem in the NSFR over an extended period and propose a set of broader policy implications. Based on the application of panarchy to the NSFR, we propose a shift in focus from purely protecting the forests to ensuring their functional role in protection.

Taking the temperature of human-modified tropical forests using remote sensing

T5.11 Disturbance impacts on climate regulating services in forest ecosystems

Tommaso Jucker[1]
[1] University of Bristol

Abstract: Local-scale microclimatic conditions in forest understoreys play a key role in shaping species distributions and driving ecological processes in these ecosystems. Consequently, understanding what drives variation in forest microclimate is critical to forecasting ecosystem responses to global change, particularly in the tropics where many species already operate close to their thermal limits and rapid land-use intensification is profoundly altering local environments. Yet our ability to characterise forest microclimate at ecologically-meaningful scales remains limited, as tree cover precludes any direct measurement of understorey conditions from beyond the canopy. To address this challenge, we used airborne laser scanning to indirectly characterise fine-scale variation in microclimate across human-modified tropical forest landscapes. We established a network of microclimate sensors across one of the world's largest forest degradation experiments in Borneo, ranging from 80-m tall old-growth forests to oil palm plantations. We then used structural equation modelling to tease apart how topography and canopy structure shape variation in microclimate across the entire landscape. We found that elevation and terrain curvature primarily influenced daily mean temperatures and vapour pressure deficit, whereas canopy height had a clear dampening effect on microclimate extremes. This buffering effect was particularly pronounced on wind-exposed slopes but tended to saturate in strength once canopy height exceeded 20 m – suggesting that despite intensive logging, secondary forests remain largely thermally buffered. Nonetheless, at a landscape-scale microclimate was highly heterogeneous, with daily maximum temperatures ranging between 24.2–37.2°C. Based on this, we estimate that 15% of the landscape is currently sub-optimal for forest regeneration, a figure that we project could rise to 34% by 2100 due to regional warming alone. Together, our results emphasise how emerging remote sensing technologies such as airborne laser scanning can redefine our understanding of the microclimate ecology of tropical forests.

Abstract: Nitrogen (N) availability limits growth in most boreal forests. However, parts of the boreal zone receive significant levels of nitrogen deposition. At the same time, forests are fertilized to increase volume growth and carbon sequestration. No matter the source, increasing N in the boreal forest ecosystem will influence the resource situation for its primary producers, the plants, with possible implications for their defensive chemistry and after-effects when their litter is transformed into soil.

In a long-term experiment performed in a spruce (*Picea abies*) dominated forest landscape in Norway, we have looked at how addition of nutrients to mature forests affects chemical defense of trees and the impacts on litter decomposition, soil decomposers and soil carbon concentration.

Briefly, the phenolic defense of the current year needles of mature spruce trees was strongly lowered with increased N availability, which might imply increased vulnerability to pest organisms However, defensive chemistry in previous year needles did not differ between fertilized and non-fertilized forest, and neither that of spruce or bilberry litter or the speed of decomposition of these. On the other hand, nitrogen release increased strongly in litter from fertilized plots and a tea-bag experiment showed faster decomposition in fertilized forests. The organic soil layer of fertilized forests had a lower concentration of condensed tannins, likely due to the shift from bilberry- to grass-dominance in the ground vegetation. Fertilization also led to a less structured nematode community and the abundance of bacterivores relative to fungivores increased, indicating a more bacteria-dominated community. However, at the same time fungal biomass increased upon fertilization The C concentration in the organic soil layer was higher in fertilized plots. Our results infer that anthropogenic addition of a limiting resource for forest growth potentially change the balance between trophic levels, and as such may have cascading ecosystem effects.

AmazonFACE – A first glance on the effects of ecosystem-scale free air CO2 enrichment in the Amazon rainforest

T5.12 Experimental underpinning for projections of forest futures

Abstract: Atmospheric CO2 concentrations are still rising due to fossil fuel burning and land-use change, and have unambiguously influenced Earth's climate system and terrestrial ecosystems. Plant responses to rising atmospheric CO2 concentrations may have induced an increase in biomass and thus, increased the carbon sink in forests worldwide. Rising CO2 directly stimulates photosynthesis (the so-called CO2-fertilization effect) and tends to reduce stomatal conductance, leading to enhanced water-use efficiency, which may provide an important buffering effect for plants during adverse climate conditions. For these reasons, current global climate simulations consistently predict that tropical forests will continue to sequester more carbon in aboveground biomass. However, several lines of evidence point towards a decreasing carbon sink strength of the Amazon rainforest in the coming decades, potentially driven by nutrient limitation, droughts or other factors. Mechanistically modelling the effects of rising CO2 in the Amazon rainforest are hindered by a lack of direct observations from ecosystem scale CO2 experiments. To address these critical issues, we established a free-air CO2 enrichment (FACE) experiment in an old-growth, highly diverse, tropical forest in the Brazilian Amazon and we here present first results from the experimental plots. We discuss our main hypotheses that underpin the AmazonFACE experiment with a focus on possible effects of rising CO2 on carbon uptake and allocation, phosphorus cycling, water-use and plant-herbivore interactions, and discuss relevant ecophysiological processes, which need to be implemented in dynamic vegetation models to estimate future changes of the Amazon carbon sink.

Abstract: Anthropogenic activities have significantly altered the global nitrogen (N) cycle, with important implications for the magnitude and persistence of forests carbon sink capacity, and hence the ability of forests to continue mitigating climate change. Increasing atmospheric N input can play a crucial role in enhancing tree growth and forest productivity. However, under N excess conditions, a cascade of negative effects is expected, leading to tree growth decline, increase in soil acidification and N loss pathways. Controlled experiments manipulating N levels have been established globally since the '80s, and they are key to evaluate long-term ecosystem responses to N deposition. However, the majority of them (particularly in Europe) were conducted in conifer forests, mostly via soil N applications, often applying N doses several order magnitudes larger than ambient deposition. There is an urgent need for more realistic manipulation experiments, to provide better understanding of the complex interaction between N and carbon cycling in forests so to support informed policy decisions as well as to contribute to better representation of N cycling in dynamic global vegetation models. Here we present the AnaEE-FoR2N network, which includes 4 N manipulation experiments established between 2015 and 2017 in 3 *Fagus sylvatica* L. (Cansiglio, Cembra and Collelongo) and 1 *Quercus robur* L (Monticolo) forests in Italy. Sites were selected along climate and N deposition gradients. The experimental design across the sites includes four replicated (n=3 plots) treatments: control, soil (as single and double doses) and aerial N additions (as a single dose), the latter representing a more realistic simulation of atmopsheric N deposition. Doses applied (between 20 and 60 kg ha^{-1} yr^{-1}) are in general twice (the single dose) or three times (the double dose) higher than actual atmospheric deposition, thus, simulating expected changes in N deposition, if reactive N emissions (particularly in the NH_x forms) are not reduced. Foliar nutrients and above-ground biomass have been monitoring since the beginning of the experiment. More intensive measurements will be included starting from summer 2024, such as continuous monitoring of tree growth, transpiration, stem humidity and canopy light transmission via TreeTalkers as well as soil GHG emissions.

Atmospheric exchanges of CO2, CH4 and N2O of temperate forest soils under elevated CO2 fumigation at BIFoR-FACE

T5.12 Experimental underpinning for projections of forest futures

Abstract: Atmospheric exchanges of CO_2, CH_4 and N_2O of temperate forest soils are an important aspect of the net global warming potential and climate mitigation function of forests. However, it's unclear how these fluxes will respond to rising atmospheric CO_2 concentrations (eCO_2) in temperate forests. Increased carbon sequestration under eCO_2 and storage in biomass and soils can influence the activities of soil microbes responsible for greenhouse-gas (GHG) process dynamics and hence net emissions. Understanding the direction and magnitude of these fluxes in response to eCO_2 is critical, given that forests in northern latitudes sequester about 0.8 billion tons of CO_2 yr^{-1}, rates roughly equivalent to the net EU27 + UK emission of anthropogenic CO_2.

The Birmingham Institute of Forest Research established a Free Air Carbon Enrichment Facility (BIFoR-FACE) whereby a mature temperate forest is exposed to +150 ppm CO_2. In this abstract, the focus is on quantifying the GHG flux as influenced by eCO_2 and microclimatic conditions, whilst also partitioning heterotrophic and autotrophic contributions. The flux of CO_2 from the soil has been measured continuously within treatment (eCO_2) and ambient control (aCO_2) arrays since 2017 with capabilities to measure CH_4 and N_2O added since 2020. Initial trends from 2017 - 2020 indicated that eCO_2 arrays had a higher efflux of CO_2 relative to aCO_2 arrays by +20%. However, during 2021 and 2022, eCO_2 arrays have seen a decline in the efflux of CO_2 by -27.5% relative to aCO_2. Lower mean differences between pseudo-root exclusion and zero-exclusion chambers within the eCO_2 arrays suggests a potential decline in the heterotrophic contribution to CO_2 effluxes. Coupled with significantly lower δ13C keeling plot R^2 values from CO_2 efflux rates, this further suggests a potential shift in heterotrophic contributions. Sink potential of CH_4 and efflux of N_2O are also significantly lower under eCO_2 arrays, by -40% and -78% respectively.

Thus, with changing carbon allocation and nutrient acquisition strategies under eCO_2, potential functional changes in the microbially mediated flux dynamics could be occurring. The magnitude of these fluxes will be presented, which will have critical implications for the net global warming potential of temperate forests under increasing atmospheric CO_2.

Carbon and Soil Nutrient Cycling Responses of a Temperate Forest to Seven Years of Elevated CO2 Fumigation

T5.12 Experimental underpinning for projections of forest futures

Sami Ullah[1]
Rob MacKenzie[1]
[1] Birmingham Institute of Forest Research, University of Birmingham, United Kingdom

Abstract: Forests sequester ~18% of the global carbon dioxide (CO_2) emissions from anthropogenic sources. This "CO_2 fertilization effect" results in a predicted 67% increase in the land carbon (C) sink through enhanced CO_2 capture. The projections of the land C sink by the end of the 21st Century based on simulations of state-of-the-art Earth System Models (ESM) is highly uncertain, with a 25 to 50% reduction in the predicted land C sink when nutrient availability including nitrogen (N) is accounted for. This uncertainty emanates from poor representation of key ecosystem types, particularly mature forests, to changing nutrient supplies under eCO_2.

The Birmingham Institute of Forest Research (BIFoR) established a Free-Air CO_2 Enrichment (FACE) facility in a mature temperate forest in the UK, where fumigation of three forest plots with elevated CO_2 (+150 ppm above the ambient) was started in 2017 and continues to date. In response to CO2 fumigation, trees CO_2 uptake increased by an average of 23%, and the tree basal area increments increased by ~ 28%. Belowground C allocation via litter fall (+14%), root exudates (+40%) and fine root biomass increased. However, the litter fall N content decreased by 12% pointing towards N resorption by trees before senescence. Similarly, the soluble N to C ratios in exudates decreased corroborating the observation that trees conserved N for sustaining the growth response. Soil gross N mineralization rates were 20% higher under eCO_2. These processes sustained larger soil mineral N supply (~25 kg N ha^{-1} y^{-1}) under eCO_2 showing that the trees invested captured C for N acquisition. Whilst microbial biomass phosphorus increased in soils, a consistent treatment effect was not observed.

Overall, the forest sustained high C capture and allocation into biomass and soils. The net implications of nutrient availability for C sequestration will depend on how long upregulation of soil nutrient availability will last in meeting plant nutrient demands before manifestation of nutrient limitation, if any. The ongoing eCO_2 fumigation lasting at least until 2026 will help resolve the feedbacks between C capture and nutrient availability to enable a realistic assessment of the role of forests in climate change mitigation.

Impact of elevated CO2 and heat wave on canopy temperature and leaf heat tolerance of mature Quercus robur.

T5.12 Experimental underpinning for projections of forest futures

William Hagan Brown[1]
Sophie Fauset[1], Robert A. MacKenzie[2], Ralph Fyfe[1], Emanuel Gloor[3]
[1] University of Plymouth
[2] University of Birmingham
[3] University of Leeds

Abstract: Detailed studies to describe leaf and canopy temperature have often focused on a few species under controlled environments. Results from crop systems have reported reduced stomatal conductance under high CO_2 concentrations resulting in higher leaf temperatures. However, there is limited data on the effect of elevated CO_2 in natural ecosystems such as forests. Emerging Thermal Infrared (TIR) camera techniques to collect thermal imagery has recently proven useful for continuous monitoring of the surface temperature of natural ecosystems. In this current study, TIR was utilised to measure the canopy temperature of a mature (> 175 years) oak woodland at the Birmingham Institute of Forest Research Free Air Carbon Enrichment (BIFoR-FACE) facility at Staffordshire, Central England, during the summer of 2021 and 2022. Over the growing season, the daytime (10:00 – 15:00 hours) canopy temperature of oaks under ambient (aCO_2) and elevated (eCO_2) was higher than the air temperature. Oak leaves were further subjected to leaf heating treatments to assess the effects of high CO_2 on their heat tolerance. The canopy temperature of oaks under eCO_2 was ~ 1°C higher than those under aCO_2. The observed canopy temperature was mainly driven by microclimatic factors, which were enhanced by the interactive effect of elevated CO_2. Even though there was no difference in leaf tolerance for oaks under eCO_2 and aCO_2, there was an increase in the leaf heat tolerance of oaks after a heat wave event in July 2022. High canopy temperature deviation from air temperature impacts plant processes and ecosystem interactions, especially under eCO_2. Output from the long-term canopy temperature monitoring will be useful for validating and improving earth system models, which hitherto have utilised air temperature as a proxy for leaf or canopy temperature. Additionally, information on the leaf tolerance of species will be critical to informing policy on tree species for forest management programmes.

Legacy and resilience of a mixed beech/spruce forest under experimental drought

T5.12 Experimental underpinning for projections of forest futures

Thorsten Grams[1]
Fabian Weikl[1, 2], Hans Pretzsch[3], Thomas Rötzer[3], Karin Pritsch[2]
[1] Ecophysiology of Plants, Technical University of Munich
[2] Institute of Biochemical Plant Pathology, Helmholtz Zentrum München – German Research Center for Environmental Health
[3] Forest Growth and Yield Science, Technical University of Munich

Abstract: This paper summarises 10 years of experimental drought and subsequent recovery in a temperate mixed forest in southern Germany. The study objects are about 100 European beech (*Fagus sylvatica*) and Norway spruce (*Picea abies*) trees, each about 80 years old, growing in 12 experimental plots under monospecific or mixed interactions each (kroof.wzw.tum.de). The aim is to determine the physiological and morphological acclimation of the trees to drought and their resilience, including competitive and facilitative interactions from the rhizosphere to the stand level.

Trees were exposed to summer drought for five consecutive years, with complete exclusion of precipitation throughfall in the growing season. During the first two summers, drought stress was highest with a pre-dawn leaf water potential around -2.0 MPa, reducing physiological (e.g. leaf gas exchange, phloem transport) and morphological (e.g. root and stem growth) parameters by up to 80%. In subsequent years, leaf area acclimation in spruce reduced tree water use and thus increased soil water availability. Reduced drought stress was evident at several levels in parallel, including biomass increment, physiological responses, and mycorrhizal community composition. Overall, trees growing in mixed stands recovered better than those with monospecific interactions.

Subsequent drought release was initiated by controlled irrigation (90-100 L/m^2 of ^{2}H-labelled water over 2 days) to study the drought resilience of trees and stands over several years. During the first weeks of drought recovery, the allocation of new photoassimilates from the canopy to the rhizosphere was traced by whole-tree ^{13}C-labeling. Physiological parameters such as tree water potential or xylem sap flow recovered within hours to days, including sugar transport along the stem as an important prerequisite for restoring tree functionality. The restored canopy-rhizosphere coupling significantly promoted spruce root growth through preferential C allocation below ground, which also recovered within a few days. Other morphological parameters, such as whole-tree leaf area, recovered much more slowly and took several years. Even after 4 years, the long-term legacy of drought was still evident in the reduced water use of previously drought-stressed trees during a renewed drought period due to morphological and physiological effects.

Next Generation Experiments and Monitoring Networks for Forests Under Global Change: CLEANFOREST WG4

T5.12 Experimental underpinning for projections of forest futures

[4] Institute of Ecology and Earth Sciences, University of Tartu, Tartu, Estonia

Abstract: Forests experience multiple concurrent effects from global change, such as climate extremes and atmospheric pollutants (e.g. carbon dioxide, nitrogen, sulphur). Key questions in forecasting the future environment are the effects of multiple interactive drivers at the same time rather than responses to changes in one factor, and the prediction of effects on whole ecosystems as opposed to disparate response variables. The CLEANFOREST COST Action unites research knowledge and link researchers working on both atmospheric pollutants and effects climate extremes at all scales in urban and peri-urban forests.

Our working group in the COST Action will advance the state of the art of experimental and monitoring approaches to understand forest responses to global change. We link three other working groups in the action looking at deposition trends, ecophysiology, and biogeochemistry and ask: where do we go next? How can the next generation of experiments and observations be designed? We aim to bring together different approaches used to understand the effects of deposition, moisture, and their interactions on eco-physiological parameters, forest health, growth, diversity, and biogeochemical processes. We specifically bridge the gap between experimental treatments and observational monitoring and identify where methods limit, where important knowledge gaps can be tackled in future.

Currently we have subgroups 1) investigating the effect of climate extremes events which occurred in past forest nitrogen deposition experiments 2) bridging existing monitoring networks working on forest ecosystem response to climate extremes and atmospheric pollution 3) examining how experimental timescale on affects observed responses from global change experiments.

We welcome participation in these activities, our working group and the COST ACTION in general.

Nutrient limitation in soils regulate the effects of elevated CO2 on soil N cycling at BIFoR-FACE (UK) and Euc-FACE (Australia)

T5.12 Experimental underpinning for projections of forest futures

Manon Rumeau[1, 2]

[5] School of Chemistry, University of Bristol, Bristol, UK

Abstract: Increasing atmospheric CO_2 concentrations in the atmosphere due to human activities, is projected to enhance photosynthesis and carbon storage of forest ecosystem. However, it is unclear how nutrient limitation will constrain the projected CO_2 fertilization effect. Therefore, it is essential to evaluate how nutrient limitation will affect the response of forests to rising CO_2 concentration and how it will feedback on nutrient availabilities and more especially nitrogen (N) which can become limiting with time.

The purpose of this research is to evaluate the response of N cycling processes to elevated CO_2 fumigation in a N-limited northern deciduous temperate forest and a phosphorus (P)-limited Eucalyptus dominated forest. The research was conducted in two Free Air Carbon Dioxide Enrichment (FACE) facilities: BIFOR FACE located near Birmingham, UK and EucFACE in New South Wales, Australia. Furthermore, EucFACE (P-limited forest) received partial phosphorus fertilization to study its effect on N cycling.

We employed a ^{15}N pool dilution method to assess gross protein depolymerization and gross mineralization at both study sites, along with the measurement of nitrous oxide emissions and extracellular soil enzyme activities.

Preliminary data from the N-limited forest (BIFOR FACE) indicate that elevated CO_2 increased belowground carbon allocation, resulting in higher dissolved organic carbon, microbial biomass, and microbial respiration. However, the additional carbon belowground solely stimulated gross ammonification (by 32%) and ammonium immobilization (by 18%), whilst gross nitrification was downregulated (by 35%) and N_2O production was un-affected under elevated CO_2. This suggests that root exudates selectively influence microbial communities for nutrient acquisition, toward a tightening of the nitrogen cycle to meet the higher nitrogen demand. However, how long the N supply will be maintained in the face of declining nitrogen deposition in future climates remains uncertain. In the phosphorus-limited forest, nitrogen depolymerization and mineralization remained unaffected by elevated CO_2 due to phosphorus constraining the plant's response (Andresen et al., 2020). However, the response of these processes when phosphorus limitation is relieved is currently under investigation.

Results from this research aim at improving our understanding of forest response to future climate by unveiling the role of nutrient limitation in future C uptake.

Response of Oak Forest ecosystem to manipulated drought and nutrient limitation

T5.12 Experimental underpinning for projections of forest futures

Abstract: Drought is one of the global change drivers which plays a significant role in forest adaptation and mitigation potential by its impacts on forest ecosystem functioning and health. Experiments can provide vital insights that are needed for model development and future projections. We have been carrying out a manipulated drought and ring barking experiment to quantify the response of Oak Forest ecosystem to environmental stresses such as drought and limited nutrient supply.

Bac-Stop is a fully replicated field manipulation experiment with rain exclusion shelters around 32-year-old sessile oak trees on sandy soils to create drought effect and ringbarking as a proxy for water and nutrient deprivation. The trial comprises 3 environmental treatments (Drought, Ring barking and Control) in 6 blocks and 8 trees in each treatment per block, total of 144 trees, being intensively monitored since May 2020. Soil moisture and temperature are monitored using theta probes, and tree physiological responses are monitored by TreeTalkers, which are sensors mounted on the trees measuring hourly tree sap flux, tree growth, tree humidify index, canopy development and condition, air temperature, air relative humidity and tree oscillation. Soil physical and chemical properties and tree fine roots and foliar morphological and nutritional traits have been measured. First results suggest immediate drought impacts on soil moisture down to tree rooting depth compared to Control. Both tree growth and Stem Humility Index have significantly declined in the first Autumn in the Drought treatment (3 months after drought started) and continuously from July 2022 (12 months after drought started). Foliar, soil and roots analysis suggest reduced photosynthetic capacity and carbon uptake and nutrient imbalances related to Drought and Ring barking, which links to the decrease in tree growth. Multispectral band data (12 bands of near infra-red and visible spectra) is being analysed now to investigate the conditions of the canopies using vegetation indexes such as NDVI, etc. Summer drought 2022 simulated similar magnitude of drought in Control as in the Drought treatments, confirming the validity of the Bac-Stop experiment in monitoring real climate change conditions and tree responses in the future.

Root Dynamics Under Elevated CO2 in a Free Air Carbon Enrichment (FACE) Experiment

Abstract: Evidence supporting a carbon fertilisation effect, where increasing levels of carbon dioxide (CO_2) in the atmosphere lead to photosynthetic enhancement in trees, suggests that forests can sequester more carbon under elevated CO_2. However, it remains largely unclear where and for how long this carbon is stored within the forest ecosystem. To sustain photosynthetic enhancement under elevated CO_2 concentrations, trees are likely to require higher intake of water and nutrients from the soil, which should stimulate root growth. This ongoing study (2022-2026) investigates the hypothesis that fine root biomass and turnover rates will increase, and proliferation will be higher at greater depths, as a consequence of elevated CO_2.

This study is carried out at the Birmingham Institute of Forest Research (BIFoR) FACE experiment, the only FACE experiment in a mature, temperate forest simulating atmospheric CO_2 concentrations to those predicted to be the mid-century planetary norm. Changes in fine root biomass and depth distribution were measured across elevated and ambient CO_2 treatments. For each treatment, we had 12 replicates consisting of soil cores to a depth of 1 vertical metre, deeper than the standard 30cm, because elevating CO_2 has previously shown changes in fine root depth distribution. Dry weight of fine roots and morphological traits were assessed, notably through high resolution scanning. Changes in fine root growth rates are calculated from minirhizotron images taken at monthly intervals over a 2 year period, with 15 replicates per treatment.

Fine root biomass was not significantly higher under the elevated than ambient CO_2 treatment but, at the time of writing, interim findings focused on analysis of two-thirds of the 1-metre cores, show indication of change in root allocation in this system under elevated CO_2. Fine root biomass declined approximately exponentially with depth under both elevated and ambient CO_2 conditions, but this slope of decline was lower under elevated CO_2. This suggests that trees invest in increased root proliferation at greater depths under elevated CO_2. It is vital that the consequences of increased atmospheric CO_2 on plant carbon allocation are understood to improve the accuracy of models projecting the future of forests as global carbon sinks.

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

A proposal for the 2025 Italian Forest Inventory

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Gherardo Chirici[1]

[4] Arma dei Carabinieri, Comando per la Tutela della Biodiversità e dei Parchi, Italy

Abstract: The design of the last two Italian National Inventories was based on a three-phases sampling scheme. In the first phase, a 1 km × 1 km grid was superimposed to the national territory and a tessellation stratified sampling (TSS) was implemented by randomly and independently selecting a point in each quadrat while in the second and the third phase subsamples of the first phase points are selected by suitable stratified sampling schemes.

Since 2005, the Italian National Inventories has been performed every ten years with the aim of obtaining estimates of totals and densities, and their precision, of those variables which are important for assessing the state and the evolution of forest areas in Italy. However, nowadays, there is a growing need to rapidly monitor short-term evolution. Therefore, a modification of the Italian National Inventory design is required to carry out an annual inventory, which must be sustainable in terms of available resources.

To this end, it is proposed to consider a one-phase sampling scheme based a suitably customized version of TSS and to visit only a portion of sampled points on the ground each year, so as to complete the visit of the entire sample in five years. In particular, TSS is performed on a grid obtained by suitably grouping an adequate number of 1km x 1km quadrats and by randomly selecting a point among the first-phase points of the previous inventories in the new grid. Furthermore, as regards the criterion for selecting the points to be visited each year, it is suggested to subdivide the new grid into regular polygons and to systematically visit each year the sampled points contained in the quadrat having the same position in the polygons. The proposed makes it possible to produce annual estimates of totals and densities, with estimates of their precision, and estimates of their changes between years. Finally, maps representing the spatial pattern of the variables of interest can be obtained together with maps of the corresponding precision.

A regional forest inventory network and its effects on capacity buiding, local development and forest governance

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Alexander Christian Vibrans[1]
Laio Zimermann Oliveira[1], André Luis de Gasper[2]
[1] FlorestaSC, Universidade Regional de Blumenau, Depto. de Engenharia Florestal, Rua São Paulo, 3250, 89031 Blumenau-SC, Brazil
[2] FlorestaSC, Universidade Regional de Blumenau, Depto. de Ciências Naturais, Rua Antonio da Veiga, 89030 Blumenau-SC, Brazil

Abstract: Regional or national forest inventory programs generate critical data for forest management and conservation at strategic levels, as well as for forest governance, landuse and territorial planning purposes. However, their role as subsidiaries of the development of qualified and specialized field crews, data analysts and young (post-)graduate researchers does not appear to be fully appreciated. In this sense, forest inventory programs can strengthen institutions such as universities and (local) research agencies. Data acquisition, processing and analysis/interpretation is underpinned by the generation of a substantial amount of knowledge about multiple topics on forestry. Such knowledge enables society to develop scientific and technological independence, which could lead to actions aimed at enhancing social equity, well-being, and sustainable use of natural resources. Here, we present an example of this type of endogenous development promoted by a state-level forest inventory and monitoring program called "FlorestaSC", which is carried out by local senior and young Brazilian researchers, and is mostly funded by the state government. It aims the monitoring of forest cover (by use of remote sensing techniques) and of forest composition, diversity and structure (by means of 500 systematically located 0.4 hectare field plots, now measured for the third time since 2007). Estimations of biomass and carbon stock and changes, species distribution modelling under climate change effects, determination of threatened tree species and of priority areas for conservation and secondary forest management recommendations are the main topics, that are relevant for implementing a new forest policy framework and forest and land use governance. As a result of a friendly data-sharing policy formulated at its very beginning, the FlorestaSC program has active a network of scientific partnerships with multiple research groups and institutions from Brazil and abroad. These partnerships allow for an intense knowledge sharing experience that have led to integrated research proposals, advanced data analysis, contributions to global databases (e.g., GFBI, sPLOT, TRY), capacity building, and high-impact scientific publications. Such relevant outcomes facilitate continuous fundraising and enhance the credibility of the information generated by the program for the local government and society.

An empirical model for assessing the hindering factors of thinning in the planted forests in Japan using tree-level NFI database

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Shingo Obata

Abstract: Planted forests in Japan, comprising about 25% of the nation's total land area, have an important role in timber production and ecosystem services. Since most planted forests in Japan are unsuitable for timber production, it is important to induce them to provide ecosystem services through continuous cover forestry. However, the stand density of the large portion of the planted forests is not controlled through thinning, even though the normal tree planting method in Japan densely plants the seedlings (3000 per ha) with the assumption that they will be thinned after they reach a specific age. The stands without thinning are likely to provide poorer ecosystem services (e.g., reduced quality of harvested wood, soil runoff), and promoting thinning is an important issue in the forest policy. The factors that limit thinning in a large area of plantation forests are expected to be the combination of different types of variables, such as vegetation structure, location, history of silvicultural operation, and socioeconomic elements. However, a detailed analysis of the factors hindering thinning is still needed.

Therefore, this study aims to reveal the factors that influence the occurrence of thinning in planted forests under overcrowded conditions across Japan.

The third (2009-2013) and the fourth (2014-2018) Japanese National Forest Inventory databases are employed as field plot data. The database is made from the sample survey that assumes grid points at 4 km intervals throughout the country. First, from the single-tree data within the plots in the third term, we extracted plantation forest stands of which species is any of the six plantation species. Then, overcrowded forests are selected using the Relative Yield Index as the indicator of crowdedness (n=2,437). From the selected dataset, we clarify the relationship between changes in the basal area between the third and the fourth term and forest structure (e.g., age, species composition), environmental factors (e.g., climate, topography, landscape), and socioeconomic factors (e.g., conservation policy, size of the forest industry) using the hierarchical modeling framework. The result of this study is expected to be utilized to predict the spatial pattern of the transition of planted forests in Japan.

Analyzing the distribution of mixed forests using the national forest inventory data in Sweden and Finland

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Daesung Lee[1]

[6] Instituto de Ciencias Forestales ICIFOR, INIA-CSIC, Ctra. A Coruña km 7.5, 28040 Madrid, Spain

Abstract: The distribution of mixed forests has not been informed well while the definition can vary by country. The question on how to measure and quantify mixed-forests is still an important issue. In this study, we compared the definitions of mixed forests by varying the mixture proportion and analyzed the distributions of mixed forests with main factors. The used materials were the National Forest Inventory (NFI) data from Sweden and Finland. The definition of mixed forests was analyzed on the basis of stand basal area instead of stem number to take different tree sizes into account. The studied sites were limited to the forest areas that are available for wood production. As a result, the total area of mixed forests in each country was increased gradually as the threshold criteria for being monoculture (the minimum proportion of a dominant pure species in a stand) were tighten. As the criteria were changed from 65% to 85%, the proportion of mixed forest area was turned from 24% to 49% in Sweden and from 21% to 42% in Finland. The 75% threshold criteria were applied to present the rest of the results since it has been also used in other studies and NFI results. In the results, the mixtures with pine-spruce, spruce-birches, and pine-spruce-birches were the most frequent stand types in both countries. Out of the mixed forest area, the proportion of peatland (peat thickness ≥ 30 cm) was small with less than 10% compared to mineral soil in both countries. The proportion of mixed forest area increased as the vegetation zone moved from north boreal to hemiboreal and the stand development reached at a mature stage. It revealed that the proportion of mixed forest will decrease in the future if there is no appropriate action for forest management planning. Overall, the possibility and degree of harmonization to use the NFI data across the countries were able to be examined. The results are expected to be used as a reference to find an adequate definition of mixed forest and to provide basic information of the distribution by main factors.

Approaches for integrating a space-based biomass map with national forest inventories in the tropics

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Natalia Málaga[1]
Daniela Requena Suarez, Sytze de Bruin[1], Martin Herold[2]
[1] Laboratory of Geo-Information Science and Remote Sensing, Wageningen University and Research, Netherlands
[2] GFZ German Research Centre for Geosciences, Potsdam, Germany

Abstract: The field of space-based biomass has experienced significant advancements in recent years, resulting in the availability of various global or large-scale biomass products. Concurrently, countries in the tropics have made remarkable progress in establishing their National Forest Inventories (NFIs), with some currently facing challenges to complete their first round of measurements or conducting re-measurements. This presents a timely opportunity to explore how space-based biomass data can support ongoing NFIs. Here, we will share insights gained from integrating national forest inventories with space-based biomass data in diverse contexts, specifically focusing on the estimation of subnational aboveground biomass emission factors. Drawing upon examples from two NFIs implemented largely in tropical humid forests (in the Peruvian Amazon and Guyana), as well as two NFIs implemented largely in tropical dry forests and woodlands (in Tanzania and Mozambique) and a global biomass map, we will discuss the best practices for developing country-specific strategies for the integration of NFIs and space-based biomass data. These practices consist of tailoring approaches to meet country-specific needs, exploring different map-to-plot assessment strategies for each biome, and defining the model-assisted estimator, which heavily relies on a country's NFI sampling design and plot configuration. Through the aforementioned examples, we aim to provide lessons learned for effectively combining NFIs and space-based biomass data for national reporting purposes. Furthermore, we will also highlight the challenges encountered in these integration exercises. The presentation will reflect on the potential of utilizing space-based biomass data to enhance the accuracy and reliability of biomass estimation in NFIs, contributing to more comprehensive reporting of a country's forest carbon stocks.

Assessing the influence of the minimum sampling size and element piece in deadwood stocks

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Daniel Moreno-Fernández[1]
Patricia Adame[1], Laura Hernández[1], Isabel Cañellas[1], Iciar Alberdi[1]
[1] Instituto de Ciencias Forestales (ICIFOR-INIA), CSIC, Ctra. La Coruña, Km. 7.5, 28040 Madrid, Spain.

Abstract: Deadwood plays a relevant role in maintaining forest ecosystem functionality, serving as a refuge for many species and acting as a determinant of carbon pool and nutrient cycling. However, its presence has been associated with an increase in forest fire damage as well as other perturbations. Consequently, the interest in deadwood has arisen during the last decades leading several countries to incorporate deadwood sampling in their National Forest Inventories field tasks. However, the differences among countries in deadwood protocols, such as minimum sampling size or deadwood elements sampled (stumps, snags, logs, branches, etc), may hamper the comparison among countries. To address this issue, we aim to evaluate every deadwood component's contribution to the overall deadwood stock and explore the influence of the minimum sampling size on overall deadwood stock. These analyses are conducted for the main forest types defined in Spain using the deadwood data obtained from the Spanish National Forest Inventory. Our findings reveal that the lying and standing components of deadwood store the largest amount of biomass, whereas the stumps and accumulations played a minor role in terms of biomass storage The total deadwood stock exhibited a nonlinear decrease as the minimum sampling size increased. Our results provide relevant insight for the harmonization and comparison of deadwood data among countries as well as for the development of standardized methodologies for assessing deadwood stocks. Finally, this research allows more accurate evaluations of the ecological functions and dynamics of forest ecosystems.

Building regional capacities in Latin America and the Caribbean for harmonizing forest information

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Carla Ramirez-Zea[1]
Iciar Alberdi[2], Joberto ee Freitas[3], David Morales-Hidalgo[1]
[1] Food and Agriculture Organization of the United Nations
[2] Forests Science Centre (ICIFOR-INIA)
[3] Federal University of Amazonas

Abstract: Latin America and the Caribbean (LAC) recognizes the importance of networking for enhancing forest information. During the Thirty-first meeting of the LAC Forestry Commission (COFLAC) in 2019, delegates recommended to the Food and Agriculture Organization of the United Nations (FAO) provide support for building-up the National Forest Inventory (NFI) network in this region. In 2020 the initiative was presented to 11 countries, led by the Brazilian Forest Service with collaborative support from FAO and the Institute of Forestry Sciences of the Higher Council for Scientific Research of Spain. The first collaborative work is the publication about the state of the art of the National Forest Inventories in LAC[1]. The publication paved the way for the next harmonization efforts, focused on three prioritized variables: forest area, volume, and aboveground biomass.

This paper describes the harmonization process of forest definition for NFIs in LAC, highlighting the paramount importance in terms of unified reporting for international assessments, such as the Global Forest Resources Assessment (FRA), the Nationally Determined Contributions (NDCs), the progress reports on climate change, and for the mechanism of Reducing Emissions from Deforestation and Forest Degradation (REDD+). During the study consultations were conducted with 23 LAC countries regarding the thresholds for the main criteria used to define forests, including minimum area (0.5 ha), canopy cover (10%), and tree height (5 m). The analysis revealed that 40% (9) of the countries reported forest areas below the minimum area threshold, 35% (8) reported canopy coverage above the threshold, and less than 1% (2) reported tree heights below the minimum threshold. The reasons reported for not adhering to the FRA thresholds are special situations in forest ecosystems, technological limitations, and the opportunities and potential use of FRA criteria for the countries.

The study discusses the challenges for the LAC region to broaden the harmonization results with those responsible land use and land cover monitoring and securing adequate funding resources to operationalize the FRA definition. Addressing these challenges may need additional time for the interpretation using new thresholds, and for updating the time series of the greenhouse gas inventories.[1] https://doi.org/10.4060/cb7791en

Collaborative network of permanent forest plots in Portugal: knowing the present to be able to predict the future

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Mariana Amaro[1]

[7] Centro de Estudos Florestais (CEF), Instituto Superior de Agronomia (ISA), Universidade de Lisboa (UL)
[8] University of Trás-os-Montes and Alto Douro (UTAD)
[9] University of de Évora (UE)

Abstract: Forecasting forests growth and yield facing climate and global changes is increasingly challenging. Yet the ability to accurately predict forest development remains the basis of forest management. In Portugal, numerous research projects from universities, forestry companies and public entities, across different forest systems, tree species and stand structures, which included the installation of plots, have generated important datasets. However, given the long timeframe needed for planning and difficulties in securing funding for proper monitoring, so far, there has been no comprehensive overview based on a broader survey of Portuguese forests. For the first time, in Portugal, the Experimental Forest Plots Network Project, included in the TransForm Agenda[1], aims to establish a network of permanent plots, covering the main forestry species and the various associated silvicultural systems to represent the diversity of forest systems and stand's structure and yield across distinct forest regions. It will be possible to assess the responses to climate change in different forest species and silvicultural systems. It will also contribute to providing complementary data to the National Forest Inventory (NFI) so that Portugal can join the European ICP Forests plot network, and thus contribute to providing data and information to the national and European scientific community on the state of the Portuguese forest. A new governance model and information sharing processes will be defined specifically for this purpose. This innovative project will create a unique opportunity to enhance, in a collaborative way, sound knowledge about the forests in Portugal. It is also expected that the leverage of synergies will contribute to significantly increase the decision-making capacity.Key words: permanent forest plots network; climate change studies; international forest knowledge; ICP Forests European; National Forest Inventory.

[1] This study was developed under the Mobilizing Agenda "TransForm -Transformation of the forest sector towards a resilient and low-carbon economy", supported by the PRR-Recovery and Resilience Plan and the European Next Generation EU Funds.

Collaborative Networks for Trustworthy Forest Data: The Role of Forest Inventory Networks in the FAO-FRA Capacity Development Programme

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Anssi Pekkarinen[1]
David Morales-Hidalgo[1]
[1] Food and Agriculture Organization of the United Nations (FAO), Rome, Italy.

Abstract: The Food and Agriculture Organization of the United Nations (FAO) has monitored global forests through its Global Forest Resources Assessments (FRA) since 1948. These assessments serve as an invaluable source of information regarding forest resources, their management, and use, and serve policy formulation and decision-making processes at various levels.

Over time, the FRA has undergone a transformation from an FAO-led exercise to a country-driven process where the officially nominated FRA National Correspondents are directly involved in the data collection, analysis, processing, documenting, and reporting of their data and metadata to FAO. Complemented by enhanced technical methodologies, including digital reporting and review, remote sensing, and provision of tools for statistical time-series modeling, this approach has increased global capacity to measure and monitor forests and more accurate and transparent reporting.

In addition to countries' active participation in the FRA process, networking among the FRA National Correspondents and their collaborators is key for successful FRAs and continuous improvement of quality and consistency of the data reported to FAO. Regional forest inventory networks (FINs) are major contributors to these efforts, as already demonstrated by the excellent results achieved at the European level (ENFIN [1]), and in North and South America (NAFC[2] and red IFN-LAC[3]).

These networks facilitate enhanced collaboration and knowledge sharing among countries, supplementing the existing FRA capacity-building program by promoting the adoption of best practices in forest inventory and assessment. By serving as conduits for exchanging knowledge and experiences, they can boost technical capabilities and harmonize forest data across regions, fostering a comprehensive understanding of global forest resources.

The forest inventory networks can assume multiple roles within the FRA capacity-building program. They can offer platforms for countries to exchange experiences and advocate for proven methodologies and innovative approaches in forest assessment. Furthermore, FINs can support standardizing assessment methodologies and indicators, facilitating meaningful comparisons between countries.

This paper will elaborate on the potential synergies between the FRA capacity-building program and the NFI-Networks.

Collaborative Solutions for Reliable Forest Data: The potential role of a Global NFI Network of Networks

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

David Morales-Hidalgo[1]
Anssi Pekkarinen[1], Carla Ramírez-Zea[2], **Rocio Condor**[1], Iciar Alberdi[3], Joberto Veloso de Freitas[4]
[1] Food and Agriculture Organization of the United Nations (FAO), Rome, Italy
[2] Food and Agriculture Organization of the United Nations (FAO), San Jose, Costa Rica
[3] Forests Science Centre (ICIFOR-INIA), CSIC, Madrid, Spain
[4] Federal University of Amazonas (UFAM), Forest Science Department, Manaus, Brazil

Abstract: Networking has emerged as a powerful tool in national forest inventories, bringing together countries, experts, and organizations to share experiences and improve national forest inventory practices. This paper emphasizes the importance of establishing a network of networks for national forest inventories, leveraging collective knowledge and experiences to enhance:

1. *Capacity development* by establishing regional NFI networks, including workshops, training programs, and technical exchanges. These initiatives foster the development of a skilled workforce and facilitate the transfer of expertise across countries and regions, ultimately enhancing the overall quality of national forest inventories.
2. *Knowledge sharing* is pivotal in networking national forest inventories, enabling participating countries to exchange experiences, address common challenges, and celebrate successes. This exchange of information enhances the efficiency of national forest inventory processes by promoting harmonized methodologies, standardized definitions, and shared tools.
3. *Harmonization of data collection and reporting practices*. Acquiring common data protocols, quality assurance standards, and data-sharing mechanisms ensures forest data's consistency, comparability, and reliability. This harmonization process enhances national, regional, and global data transparency and facilitates informed decision-making by policymakers, researchers, and stakeholders.
4. *Transparency* is vital to accountable forest management, and networking in forest inventories might be crucial in promoting data transparency. Through promoting the open sharing of forest data, methodologies, and results, networking enables peer review processes and collaborative platforms for feedback and improvement. This iterative process enhances forest data's transparency, credibility, and usefulness.

Additionally, networking provides a platform for sharing technological advancements in national forest inventories.

On a global scale, establishing a network of networks for national forest inventories aims to strengthen the process of regional networking. Nowadays, three regional NFI networks are working to improve forest data: the European National Forest Inventory Network (ENFIN), the monitoring and inventory working group of the North American Forest Commission, and more recently, the Latin American and the Caribbean Forest Inventory Network (IFN-LAC). By leveraging the collective expertise and experiences of existing networks and potential future networks, this

initiative fosters collaboration, promotes harmonized methodologies, and contributes to global efforts to understand forest dynamics, assess climate change impacts, and implement sustainable forest management practices.

European National Forest Inventories and their potential for large scale monitoring and reporting – Experiences and Visions

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Klemens Schadauer[1]
[1] Austrian Research Centre for Forests (BFW)

Abstract: Forest and forest related policies in Europe demand huge efforts in monitoring and reporting. National Forest Inventories (NFIs) provide information for a large set of indicators for this purpose on the national scale. Due to different environmental and social conditions leading to different forest policies at the national scale, the NFIs are designed to primarily focus on the national needs. They employ statistical sampling which means that they can also be used on a super-national scale with specific estimation techniques. For this the national definitions of the indicators have to be analysed in comparison to a common definition and the transformation path from the national to the international scale has to be developed. This is the harmonisation process on which the European National Forest Inventory Network ENFIN has been working for the last 20 years.
Due to increasing quality of remote sensing (RS) data sources new options and challenges for this process have emerged. On one hand, European scale Earth Observation data can provide a standardized data source for developing maps at very large scales but they still have comparably low resolution and usually do not contain 3D information. On the other hand, RS data collected on the national scale have very high resolution, but harmonization is required before using them at the European scale. In any case, the ground truth data for training and validation – usually based on NFIs – have to be harmonized. The best results can be achieved with a suitable combination of all three data sources.
Finally the combination of remote sensing wall-to-wall data and statistically sampled field data with known designs are an interesting field for the compilation of maps and improved estimations at different spatial scales. The different approaches from the past and for possible future developments will be presented with selected examples.

Integration and Publication of Forest Inventories and Land Cover Maps with Semantic Web Technologies

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

José M. Giménez-García[1]
Guillermo Vega-Gorgojo[1, 2], Cristóbal Ordóñez[2], Felipe Bravo[2]
[1] Group of Intelligent and Cooperative Systems, Universidad de Valladolid, Spain
[2] Departamento de Producción Vegetal. Instituto de Investigación en Gestión Forestal Sostenible (iuFOR), ETS de Ingenierías Agrarias, Universidad de Valladolid, Avda. de Madrid 44, 34004 Palencia, Spain

Abstract: Modern forestry management increasingly relies on the use and publication of large datasets, such as forest inventories, land cover maps, and stand characterization. However, these datasets are generated and published by different agents, following different methodologies and different formats and schemas. Working with integrated data is currently a challenge in forestry research.

Semantic Web technologies have emerged in the last decades as a solution to publish heterogeneous data in an interoperable way. These technologies include the Resource Description Framework (RDF), the Web Ontology Language (OWL), and the Protocol and RDF Query Language (SPARQL), standardized by the World Wide Web Consortium (W3C). They enable the publication of self-describing data that can easily interlink with other sources. The concepts and relationships between them are described using ontologies, and the data can be published as Linked Data on the Web. This data can be downloaded or queried online using a SPARLQ endpoint. Linked Open Data (LOD) promotes globally and openly accessible Linked Data and has been gaining traction in the last decades. National and international agencies promote the publication of governmental data as LOD, and research fields like biosciences or cultural heritage make an extensive use of Semantic Web technologies.

The European Cross-Forest project [1] addressed the integration and publication of forest inventories and land cover maps data from Spain and Portugal with Semantic Web technologies. The result is a set of ontologies and LOD datasets that integrate all their data. This data is linked to other sources such as the National Center for Biotechnology (NCBI) taxon ontology [2], DBpedia [3], and Wikidata [4]. All the results (ontologies, tools, and LOD datasets) are publicly available with Open Access license in GitHub [5] and queryable through a SPARLQ endpoint [6]. The Forest Explorer [7] allows navigating the data using an interactive map. Current lines of research include adding the temporal dimension to the data, allowing to follow the evolution of forests through time, and integrating additional forestry and geographical data, such as regional or stand inventories, or spatial planning information.

Latin America National Forest Inventories: similarities and differences

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Joberto Veloso de Freitas[1]
Iciar Alberdi[2], David Morales-Hidalgo[3], Carla Ramirez-Zea[4]
[1] Federal University of Amazonas (UFAM), Forest Science Department, Manaus, Brazil
[2] Forests Science Centre (ICIFOR-INIA), CSIC, Madrid, Spain
[3] Food and Agriculture Organization of the United Nations (FAO), Forestry Division, Rome, Italy
[4] Food and Agriculture Organization of the United Nations (FAO), Forestry Division, San José, Costa Rica

Abstract: National Forest Inventories (NFI) play a crucial role in providing forest information for decision-making processes related to national policies, programs, and projects in numerous countries worldwide. While in the past the main purpose was to guarantee the availability of forest resources, today NFIs also needs to meet other aspects such as climate change, biodiversity and conservation, non-wood forest products and disturbances, meeting the increasing demand for both national and international level. To ensure the quality of information, it is important that countries seek to improve comparability through harmonization initiatives, especially across the borders where similar forest types are shared. The objective of this study is to evaluate the similarities and differences between national forest inventories in Latin America and the Caribbean (LAC) to support the harmonization of variables of common interest and improve collaboration in the region. The evaluation was developed in the framework of the Latin America Forest Inventories Network (IFN-LAC) analysing the NFI´s methodologies of 20 LAC countries, thematic questionnaires sent to the countries IFN-LAC focal points on specific aspects of the methods and virtual meetings held to discuss specific topics with a view to harmonizing variables. Most countries plan their NFI to be permanent and continuous (86%), with 5-year cycles (76%), and there are countries with cycles between 4-10 years, while some prefer its implementation for a single evaluation over time (14%). Some countries (33%) adopt the strategy of carrying out the cycle measurements in panels that define annual sub-samples for data collection. The systematic distribution of sample units predominates among the countries (43%), with some combining random distribution and stratification (29%). Permanent sample units have been preferred by the countries (76%), but temporary plots (14%) and a combination of both are also used (10%). Cluster plots predominate in the region (67%), with circular (50%) and rectangular (25%) sample units being preferred. Remote sensing methods are mainly employed to improve NFI planning (80%). Countries in the LAC region are actively developing their national forest inventories and, by establishing a collaborative tecnical networks, it is possible to significantly improve the availability and quality of information within the region.

Logarithmic transformation or weighted nonlinear fitting approach?

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Ioan Dutca[1, 2]
[1] Transilvania University of Brasov
[2] Buckinghamshire New University

Abstract: Logarithmic transformation of both response and predictor variables is a common approach used to fit allometric models. It has been recommended that logarithmic transformation should be used for populations with lognormal residuals (i.e., multiplicative errors), whereas weighted nonlinear models should be used for populations with normal residuals (i.e., additive errors). However, in practice, the distribution of model residuals is rarely tested to find which fitting method should be used. Here, using virtual populations of trees for three species (i.e., European beech, Norway spruce and Sessile oak) with normal and lognormal distributions of aboveground biomass (AGB) residuals logarithmic transformation and weighted nonlinear approaches were applied to investigate what are the consequences of interchanging the fitting methods on population estimates. Using weighted nonlinear approach for populations with lognormal distributions was as accurate predictor of population AGB as the logarithmic transformation. However, using log transformation approach for populations with normal residual distributions, showed that, for small sample sizes and with populations that exhibit large residual AGB variability, log transformation is a biased estimator. The bias was positive and relatively similar for all three tree species, suggesting that logarithmic transformation tends to overestimate the true population biomass by up to 2.5%. Nevertheless, using a correction factor based on the calculated mean of back transformed residuals rather than on commonly used estimated mean, resulted in a reduction of this bias up to insignificant levels. Therefore, weighted nonlinear approach can be safely used to populations with either normal or lognormal distributions, whereas, when using logarithmic transformation care should be taken if distribution of residuals is not lognormal, especially when sample size is small and residual variability is large.

Monitoring and reporting of transparent forest data and information under the Paris Agreement: The role of National Forest Inventory networks

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Jenny Wong Lai Ping[1]
[1] United Nations Climate Change Secretariat, Bonn, Germany

Abstract: The Framework Convention on Climate Change (UNFCCC) recognizes the critical role of forests as terrestrial carbon sinks for combatting climate change and calls for transparency of climate actions, including those in the forest sector. The Paris Agreement continues to uphold the principle of transparency. It established the Enhanced Transparency Framework (ETF) with the aim to build mutual trust and confidence among countries in their monitoring and reporting of climate actions and to track progress of such mitigation actions. Forests play a key role in all aspects of the implementation of the Paris Agreement. Numerous countries, both developed and developing, have identified forest and land use-related mitigation and adaptation measures and actions as part of their climate targets in their nationally determined contributions to fulfill the goal of the Paris Agreement.

The world is now in an era where transparency of data and information and actions are indispensable for ensuring coordination among relevant ministries and agencies and effective decision-making at all levels. Transparent, robust and comprehensive data and information on greenhouse gas emissions and climate actions are essential for informing national policies, plans and strategies and helping countries meet their international commitments on climate change. The same applies to forest data and information and its reporting to multilateral environmental agreements. Additionally, robust institutional arrangements, including for national forest inventories (NFI) as part of national forest monitoring systems and GHG management systems, form the basis for ensuring transparent data and information from these processes and systems and for meeting the requirements for reporting under the ETF.

The aim of this review analysis is to highlight the importance of transparency in monitoring and reporting and for building trust in climate actions. The analysis will provide an overview of the requirements and necessary elements for monitoring and reporting on the forest and land use sector in the ETF and the challenges faced. This background will serve as a basis for stimulating discussions and exploring potential collaborative solutions offered by strong institutional arrangements and collaborative networks (such as NFI networks) and to facilitate identification of effective capacity-building needs of developing countries.

Monitoring benefits of boreal forests in West and East: provisioning ecosystem services as proxy variables

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Vladimir Naumov
Altamash Bashir[1], Per Angelstam[2, 3]
[1] The Norwegian University of Science and Technology, Department of Psychology, Norway
[2] Inland Norway University of Applied Sciences, Campus Evenstad, Norway
[3] School of Forest Management, Swedish University of Agricultural Sciences SLU, Sweden

Abstract: Background: The ecosystem service concept was introduced to highlight the importance of composition, structure and function of representative ecosystems for human well-being. There are many approaches to monitor the benefits of forest landscapes. However, existing monitoring methods need to include not only mapping and quantification of provisioning ecosystem services, but also other ecosystem services.

Aims: This study (1) reviews monitoring methods developed to map and quantify provisioning ecosystem services in boreal forest landscapes, and (2) describes how such methods can be used to assess also other ecosystem services. Boreal forest landscapes can be found in North America, Nordic countries and Russia.

Methods: We reviewed literature using sources in both English and Russian. Forest mensuration to survey the amount of timber has a long history of development. Tree growth is only measured comprehensively in areas under intensive forest management. Hence, approaches to monitor forest biomass are more developed in the Western countries compared to Russia. The current trend in monitoring of provisioning ecosystem services is moving towards the use of remote sensing data combined with digital analysis in forest management. However, differences between managed and naturally dynamic forests provide a challenge to applying these techniques more generally. We argue that results from monitoring of provisioning ecosystem services can also be used as a proxy to estimate other ecosystem services. For example, timber volume, tree species composition and diameter at breast height determine the amount of biomass, and thus carbon stock. To model supporting (or habitat) services and thus biodiversity, tree species and age classes derived from National Forest Inventory data can be used. However, non-marketable ecosystem services such as regulating and cultural ecosystem services require further research to validate the precision of existing models.

Conclusions: To conclude, provisioning ecosystem services have various trade-offs and synergies with other ecosystem services. Thus, in order to minimize efforts and costs related to monitoring, other ecosystem services could be modelled using existing National Forest Inventory data, comprehensive forest management unit plans, and methods to mapping and quantification of provisioning ecosystem services.

New Zealand's Forest Inventories – can they provide valuable forest data from a remote corner of the globe?

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Thomas Paul[1]
Steve Wakelin[1], David Pont[1]
[1] Scion (NZ Forest Research Institute), Rotorua, New Zealand

Abstract: New Zealand has so far played a minor role as a participant to multi-national NFI networks. Reason for this is that NZ did not have a specific National Forest Inventory but rather more regional or estate focused surveys with often varying methods and objectives. However, driven by the need to nationally quantify the role of forests to mitigate climate change, the New Zealand Government committed itself since 2002 to monitor its indigenous forests and intensively managed plantation forests. The starkly different forest types led to the development of many specific methods and techniques, but also common sampling standards for those two types of forests. We will present a number of methodological developments, that have relevance for forest inventories that need to accompany a wide range of forest types – from temperate old growth rainforests to subalpine to plantation forests – and the capture of forest metrics such as above ground biomass and carbon to accurately and precisely characterise various forest types and the changes within. In the future technology such a Terrestrial Laser Scanning will become important for forest inventories to enable the homogenization of data and analysis. Important common foundations for forest inventories across such a wide range of forest types are discussed and we provide results from the current annual inventories in planted and indigenous forests of New Zealand in context with the wider global picture.

Toward comparable species richness estimates across plot-based inventories

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

[5] Division of Forestry and Forest Resources, Norwegian Institute of Bioeconomy Research, Ås, Norway

Abstract: To understand the state and trends in biodiversity beyond the scope of monitoring programs, biodiversity indicators must be comparable across inventories. Species richness (SR) is one of the most widely used biodiversity indicators. However, as SR increases with the size of the area sampled, inventories using different plot sizes are hardly comparable. This study aims at producing a methodological framework that enables SR comparisons across plot-based inventories with differing plot sizes. We used National Forest Inventory (NFI) data from Norway, Slovakia, Spain, and Switzerland to build sample-based rarefaction curves by randomly incrementally aggregating plots, representing the relationship between SR and sampled area. As aggregated plots can be far apart and subject to different environmental conditions, we estimated the amount of environmental heterogeneity (EH) introduced in the aggregation process. By correcting for this EH, we produced adjusted rarefaction curves mimicking the sampling of environmentally homogeneous forest stands, thus reducing the effect of plot size and enabling reliable SR comparisons between inventories. Models were built using the Conway–Maxwell–Poisson distribution to account for the underdispersed SR data. Our method successfully corrected for the EH introduced during the aggregation process in all countries, with better performances in Norway and Switzerland. We further found that SR comparisons across countries based on the country-specific NFI plot sizes are misleading, and that our approach offers an opportunity to harmonize pan-European SR monitoring. Our method provides reliable and comparable SR estimates for inventories that use different plot sizes. Our approach can be applied to any plot-based inventory and count data other than SR, thus allowing a more comprehensive assessment of biodiversity across various scales and ecosystems.

United States forest land area: why land cover and land use estimates differ

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Lara Murray[1]
Mark Nelson[2], Kurt Riitters[3], Sonja Oswalt[3], Sean Healey[4], Jennifer Bakken[4], Thomas Albright[2], Andy Gray[5]
[1] United States Department of Agriculture, Forest Service Research & Development
[2] USDA Forest Service, Northern Research Station
[3] USDA Forest Service, Southern Research Station
[4] USDA Forest Service, Rocky Mountain Research Station
[5] USDA Forest Service, Pacific Northwest Research Station

Abstract: Tracking distributions and changes in forest land area is essential for monitoring resource conditions, trends, sustainability, and zero net deforestation commitments. Land cover describes conditions at a given time and land use describes longer term social and economic intent for which land is used. Forest land area estimates may differ significantly between land use and land cover information sources, leading to disparate conclusions. Furthermore, gross gains and losses of land area may be masked when reporting only net change. While remote sensing-based estimates from national land cover maps have suggested net losses in United States forest cover area during recent decades, in situ sample-based estimates of forest land use from the USDA Forest Service (USFS) Forest Inventory and Analysis (FIA) Program show net gains during the same period. Much of this discrepancy is attributed to underestimation of gross gain in forest cover, resulting in overestimation of net cover loss; this is a common challenge in remote sensing-based land cover products. We present United States forest land use and land cover estimates and discuss differences.

Using NFI data on mound occurrence and forest variables to evaluate how forest management practices have impacted red wood ants (Formica rufa group)

T5.13 Forest without borders: National Forest Inventory Networks and their potential for large scale monitoring and reporting

Emil Andersson[1]
Emma Holmström[1], Therese Löfroth[1], Lisa Petersson[1]
[1] The Swedish University of Agricultural Sciences, SLU

Abstract: In boreal coniferous forest ecosystems, red wood ants (RWA) are ideal targets for conservation efforts. They are highly visible, through their construction of large mounds, and function as a keystone species that provides protection and resources for many associated species. Recently, there has been an international call to monitor and protect RWA populations. In Finland and Switzerland, National Forest Inventories (NFIs) have previously been used to register RWA mound occurrence, in order to evaluate distribution and habitat requirements for RWA.

In our study, we make use of the The Swedish National Forest Inventory (NFI) which celebrated its 100th anniversary in 2023. For the last 20 years, the NFI has also been registering RWA mound occurrences. During the 2021-2023 seasons, we have added sampling of RWA specimens to the Swedish NFI measurements. From the collected specimens, the RWA species are identified, and the species identity for the registered mounds can then be mapped. From this data, we can establish a correlation between the distribution of RWA mounds and long-term environmental data collected from the same sites. This correlation enables us to predict the forest variables that play a significant role in shaping the habitat for the different RWA species. By analyzing both present-day environmental data and historical records, we can identify forest management practices and stand development types that positively impact the *Formica rufa* group ants. These connections between management practices and RWA population dynamics also allow us to forecast future changes in RWA populations by modeling the future development of Swedish forests. Furthermore, we can compare our variables with those from studies conducted in other European countries, thereby highlighting similarities and differences in RWA habitat requirements across regions. Ultimately, these findings can be used to establish new guidelines for forestry and logging practices that promote the conservation of wood ants, and thereby many other species associated with RWA mounds.

T5.14 Gender Equality in Forestry: Past, Present and Future

A gender perspective on the organizational culture in Swedish forestry education

T5.14 Gender Equality in Forestry: Past, Present and Future

Dianne Staal Wästerlund[1]
[1] SLU, Department of Forest Resource Management, Sweden

Abstract: The Swedish forestry education has traditionally been dominated by men. Women were excluded with entry requirements until the 70-ties and it is only during the last decades that the percentage of female students has reached approximately 30%. This male dominance still has its effect on the content of the education program as well as its way of execution. During a period of 9 years, 277 students were asked to describe what the education program promoted as proper values for a Swedish forestry professional as part of their final exam on an organizational course. The absolute majority mentioned the dominance of the clearcut forest management model in the content of the program while other models were hardly covered. Female students were especially critical to the dominance of production forestry compared to conservation forestry or other eco-system services than timber production. To be a member of the corps of forestry students, demands are being made on attitudes towards political questions such as the number of wolfs allowed in Sweden or the consumption of meat. Although the university has introduced compulsory codes of conduct among the students as well as gender awareness courses among teachers during the years of study, no change in the descriptions of the students can be found. Discussions with teachers show that they find this subject difficult to incorporate in their teaching. The majority of students have a meritocratic view on how gender should be regarded in the recruiting process of young professionals and most seem to expect that gender issues will seek to matter as more women enter the sector

Data Justice and Forest Governance

T5.14 Gender Equality in Forestry: Past, Present and Future

Daniel Brockington[1]
Rose Pritchard[2], **Jocelyne Sze**[3]
[1] Institut de Ciència i Tecnologia Ambientals de la Universitat Autònoma de Barcelona (ICTA-UAB) and ICREA
[2] University of Manchester
[3] University of Sheffield

Abstract: Data sets about forests, their use and dynamics are becoming larger, with greater spatial precision in their detail as well as greater temporal frequency in their availability and updating. Digitised forest governance depends upon the effective use of large data sets. But large data sets, generated through machine learning, algorithms and intensive use of diverse remotely sensed data also bring challenges of data justice. These data are, of necessity, simplifications. But sometimes bias can be built into the omissions systematically. Further, different actors with interests in forest governance vary in their capacity to access, comprehend and act upon large datasets, potentially reinforcing social injustices. The challenge of data justice approaches is to identify how these biases and access inequalities can adversely affect diverse forest residents, users, managers and visitors. In this paper we present initial findings into the risks that data justice approaches highlight, with reference to concrete examples, what dangers they pose to whom, and how they might be mitigated.

Digital Economy Enabling Natural Forest Protection Project in China

T5.14 Gender Equality in Forestry: Past, Present and Future

Yafang Zhang[1]
Yukun Cao[1]
[1] School of Economics and Management, Northeast Forestry University, Harbin, China

Abstract: Digital technologies such as 5G, Internet and big data provides a new impetus for natural forest protection. Since the implementation of the Natural Forest Protection Project in 1998, it has played a vital role in the protection and restoration of natural forest resources, the improvement of forest quality and the construction of ecological civilization. The natural forest ecosystem is complex and there is a mutual feedback effect between natural change and project implementation. The implementation of natural forest resource protection project in China lacks an effective evaluation method to distinguish natural change and project implementation effect. Digital technology enables the implementation effect evaluation and management decision-making improvement of natural forest protection projects through natural forest resource change tracking, resource supervision perception and digital ecological restoration, and provides better naturalization implementation paths and schemes for natural forest resource protection and restoration and sustainable management.

First indigenous women volunteer wildland fire brigade in Brazil: From spectators to effective agents of integrated fire management

T5.14 Gender Equality in Forestry: Past, Present and Future

Ana Luiza Violato Espada[1]
Mariana Senra de Oliveira[2], Dinalice Souza Xerente[3], Pedro Paulo Gomes da Silva Xerente[4], Marcelo Siqueira de Oliveira[1], Maíz d'Assumpção[5]
[1] U.S. Forest Service International Programs Brazil
[2] National Center for Wildfire Prevention and Suppression – Prevfogo / Brazilian Institute for the Environment and Renewable Natural Resources - Ibama
[3] Xerente Indigenous Women Volunteer Forest Brigade
[4] Association of Xerente Indigenous Fire Fighters
[5] Brigada 1 Association - Prevention and Wildland Firefighting; Brazilian National Network of Volunteer Fire Brigades

Abstract: Greater efforts to include both indigenous communities and women in integrated fire management can bring insights to the use of fire in wildland fire management. However, women are commonly discriminated against in the analogous hypermasculine culture documented within wildfire management. We sought to present the case of the Xerente indigenous women working as volunteer firefighters in a savanna ecosystem transitioning to the Amazon rainforest. 2021, twenty-nine women created the first women-only indigenous volunteer wildland fire brigade prompting a landmark for all indigenous women in Brazil. Based on a singular case study design, we collected data from in-depth interviews, document analysis, and participant observation. We found that fire management training and new technical skills acquired led the Xerente women to go beyond fire suppression within the Xerente Indigenous Land in Brazil. The Xerente women became effective agents in climate action strategies, particularly those related to environmental education connecting efforts of Prevfogo/Ibama with the understanding of the villages about integrated fire management. Also, these women were crucial to implement restoration activities and strengthen food security as they collected seeds and produced local plant seedling species. Implications of this case include pioneer initiative in the Brazilian context in shifting gender roles in a male-dominant strategy to mitigate and suppress wildfire; working closely with male allies, the Xerente women also secured fire management tools and equipment to perform their tasks; and the Xerente women can serve as role models for other indigenous women claiming space for their voices and recognized actions on climate change mitigation and adaptation.

Gender and Bioenergy; Factors Influencing Adoption of production and Conservation Technologies in lower Eastern Kenya

T5.14 Gender Equality in Forestry: Past, Present and Future

Josephine Musyoki[1]
Emily Kitheka[1], Nellie Oduor[1], Timothy Namaswa[1], Joseph Githiomi[1], Jane Mutinda[2], Albert Luvanda[1]
[1] Kenya Forestry Research Institute
[2] Kenyatta University

Abstract: ABSTRACT:

This paper examines the influence of gender aspects in adoption and continued use of biomass energy production and utilization technologies in Eastern Kenya. The region suffers deforestation, environmental degradation and threatened species as result of overexploitation of tree resources for woodfuel production. The government of Kenya and development partners has developed and promoted energy conservation technologies in the region for increased access to sustainable energy resources in rural areas geared towards achievement of sustainable development goals (SDGs) relating to increased access to clean and affordable energy, the eradication of poverty, environmental sustainability, climate action as well as gender equality and the empowerment of women. Despite these efforts, adoption and continued use of improved bioenergy technologies has been low. The objective of the study was to determine gender aspects influencing adoption of sustainable bioenergy production energy saving technologies at household and community levels. The study was carried out in selected sub-counties of Kitui County using a survey design. Structured questionnaire and thematic guidelines for group discussions were used to collect data from 192 respondents and community groups. SPSS and Excel were used for data analysis. Results revealed that, at zero point zero five percent level of significance, adoption of improved technologies were positively correlated to income and awareness levels of the consumers. Inadequate awareness on benefits of improved and efficient bioenergy technologies among men, biased land and tree resources ownership, cultural roles and responsibilities, lack of inclusive decision making in most households and over dependance on men and subsistence farming for financial support by women were indicated as key factors influencing adoption of improved technologies. The study concludes that though women are culturally responsible for food and cooking energy security at household level, high poverty among women and lack of awareness on the socio-economic benefits among men affects adoption and continued use of improved abd efficient bioenergy technologies. The study recommends financial empowerment of women, inclusive decision making and mainstreaming gender at all levels of project implementation for increased awareness and adoption of bioenergy conservation technologies for environmental conservation and improved livelihoods.

KEY WORDS: Gender, bioenergy, improved technologies, adoption

Gender and Indigenous Equity in the Forest Stewardship Council (FSC)

T5.14 Gender Equality in Forestry: Past, Present and Future

Marion Karmann[1]
Anakarina Perez Oropeza[1], Sinta Dewi[1]
[1] FSC International, Adenauerallee 134, 53113 Bonn, Germany

Abstract: Diversity and gender equality are important focal points in FSC's work, both related to the certification scheme and within the FSC membership and the secretariat's staff structure. The FSC Global Strategy 2022-2026 shows a holistic approach in demanding support for increasing inclusiveness in all of its three strategies.

At the international level, FSC established the Permanent Indigenous Peoples Committee (PIPC) as an advisory committee to the FSC Board of Directors on Indigenous Peoples' involvement in FSC. In parallel, the FSC Secretariat works with the independent FSC Indigenous Foundation to create innovative solutions to support Indigenous communities.

FSC International also established a Diversity and Gender Task Force (DGTF) with a Board representative and has a Senior Manager, Gender and Diversity guiding FSC's diversity and inclusion efforts. The DGTF and the Senior Manager have sought to contribute to the equal distribution of power and influence between economic, social, and environmental interests, and also between women and men, regardless of their age, gender, race, religion, sexual orientation, or ethnic background.

We will give examples about the ongoing activities of the PIPC and DGTF, and we will present an analysis of publicly accessible forest management reports, showing how certified forest operations have taken action towards more inclusiveness in order to conform with FSC requirements and to maintain their certificates. In addition, we will explain how and when gender and diversity specialists and researchers can engage effectively in FSC processes to contribute certification requirements leading to more gender and Indigenous equity in forest management, while responsibly delivering forest products and services.

How to achieve gender equality and diversity in forest-related sectors? Bridging the education–practice gap with a Massive Open Online Course (MOOC)

Abstract: Gender equality and diversity are crucial elements of sustainability transitions as expressed within the United Nations Sustainable Development Goal 5: Gender equality. Despite their importance, gender equality and diversity concepts and training are often missing in forestry curricula. Gender insensitivity and a limited set of fully trained educators limit progress in fully implementing these concepts throughout forestry curricula. Consequently, forestry professionals often have limited capacities to assess, articulate, and address gender and other social inequalities embedded in forestry and forest-related domains (e.g. bio-economy, agriculture). This serious gap

compromises the relevance of forest science education and forestry practices across the globe, as voiced through the International Forestry Students Association's (IFSA) Open Letter in 2022. The IUFRO Task Force (TF) on Gender Equality in Forestry strives to reduce this educational gap by developing and offering the first Massive Open Online Course (MOOC) on Gender Equality and Diversity in forest-related sectors under the sponsorship of SLU Global and the University of Padova. Online education represents an opportunity to make the best competencies within the IUFRO TF available worldwide to forestry students, professionals and interested parties alike. Thanks to the module-based structure, course materials are easily integrated into universities' own curricula. The focus on cases of best practices and practical tools for advancing equality, diversity, and inclusion make the course useful also for professionals in vocational training. We present the results from the first offering of the MOOC in spring 2024 and address lessons learnt for future offerings of the course.

Learn How to Gain Traction on Gender Diversity and Inclusion in the Forest Sector

T5.14 Gender Equality in Forestry: Past, Present and Future

Kelly Cooper[1]
[1] Centre for Social Intelligence Inc.

Abstract: Starting in 2018, the Free to Grow in Forestry initiative focused on creating a sector-wide approach to addressing the gender diversity gap in Canada's forest sector. The goal was to create a national action plan aimed at increasing the number of women in senior executive roles and in technical positions.

This public-private funded partnership brought together representatives from the public, private, not-for-profit, academia and Indigenous communities to unite their efforts toward this goal and to create a new shared vision for the sector – one where Canada has a diverse and inclusive workforce that provides the foundation for a thriving forest sector and healthy communities. The national action plan focused on three pillars of work:

- Gathering data on gender diversity in Canada's forest sector for the first time
- Identifying best practices that can improve workplace culture
- Creating a narrative and communication shareables that can shift the image of the sector to be more welcoming of all people.

We achieved far more than what we set out to do with the National Action Plan and the momentum created turned this from an initiative to a global *movement*. (See Free to Grow in Forestry: www.freetogrowinforestry.ca.)

Within Canada, executives across the public, private, not-for-profit and academia circles are no longer questioning that gender diversity adds value to their bottom line. They recognize diverse thinking creates innovative solutions and have shifted gears into leading the change.

The focus now and in the future is learning about "the how":

- *How* do you create an inclusive workplace culture where diversity is recognized as a business imperative?
- *How* do you become an effective ally so that individuals who may have previously been excluded are now confident with bringing their "whole selves" to work?
- *How* do you reduce the polarized thinking on diversity and inclusion and other obstacles, so you can get on with innovating, creating better business outcomes, and a thriving workplace environment?

Come join me to get the answers to these questions and more.

Promoting gender equity and women empowerment considering workplace and maternity barriers: the Brazilian Forest Women Network working groups

T5.14 Gender Equality in Forestry: Past, Present and Future

Barbara Bomfim
Ana Paula Mendes Mendes Teixeira[1], Barbara Ibanez[1], Etienne Winagraski[1], Luciana Sá[1], Margarida Ribeiro da Silva[1], Mariana Zanetti[1], Patricia Nazário[1], **Rafaela Kern**[1]
[1] Rede Mulher Florestal (Brazilian Forest Women Network)

Abstract: Historically, the forest sector has been largely male-dominated. In Brazil, while women's participation in the sector has recently increased, gender equity is still not widely discussed. To address this issue, the Brazilian non-governmental organization, Rede Mulher Florestal (RMF; Forest Women Network), was founded. RMF promotes respect for diversity and equal opportunities for women in forestry through four thematic working groups (WGs), with the following strategic objectives: (i) promoting education, training, and extension actions led by the Education WG, (ii) creating an environment for discussion and implementing actions aimed at equality and women's empowerment led by the Equality and Empowerment WG, (iii) identifying actions aimed at supporting maternity and diagnosing the challenges and incentives to motherhood for women in the labor market led by the WG Maternity and Women in the Workplace, and (iv) identifying barriers to the presence of women in decision-making and pointing out strategies to increase the presence of women in these spaces, led by the WG Women in Decision Making. The WGs have been promoting gender equity in the Brazilian forest sector by holding thematic workshops with members and non-members, conducting semi-structured questionnaires for women in decision-making and mothers working in the forest sector throughout Brazil, and implementing a mentoring program for female members. Through these actions, RMF has been able to address issues related to gender equity within organizations in the forestry sector. The workshops led by the Education WG have focused on mapping the challenges, strategies, and verifiers for gender equity in the sector. Additionally, RMF has identified barriers to gender equity and developed good practices to promote diversity in the forestry sector. Overall, the Rede Mulher Florestal has made significant contributions to promoting a forestry sector that values diversity and gender equity. In its nearly five years of existence, the organization has helped to generate unprecedented data on gender and contributed to a wider discussion on the importance of gender equality in the forest sector.

Rooted Inequalities in Forest Education: Insights from a students' perspective

T5.14 Gender Equality in Forestry: Past, Present and Future

Theresa Klara Loch[1]
Barbara Öllerer[2]
[1] Faculty of Environment and Natural Resources, Chair of Forest and Environmental Policy, University of Freiburg
[2] University of Natural Resources and Life Sciences, Vienna (BOKU), Institute of Forest, Environmental and Natural Resource Policy and EFI Forest Policy Research Network

Abstract: Gender inequalities, harassment and sexism still persist in forest education, and often, specific masculine or feminine qualities are attributed to certain roles, tasks, positions or professions. Even though gender in forestry is increasingly addressed by research and organisations, the role of gender-aware forest education is not yet seen to its full extent. Outdated understandings of gender roles displayed by cis-heteropatriarchy prevail in education and research and result in a non-integration of other genders. More FINTA* within the forestry sector and an intersectional perspective on discrimination are essential for the future development of the sector and society at large.

The International Forestry Students' Association - IFSA - is the biggest international network of students of forestry and related fields. The organisation is managed by students and follows its mission to enrich its members' education. Within education, gender continues to play a decisive role in forestry and IFSA actively highlights the importance of the topic and demands key stakeholders to take proactive steps towards a more gender-aware learning environment.

In 2021, IFSA published an open letter emphasising the role of education for a more gender equal forestry sector. Its publication triggered conversations both outside of IFSA and amongst its members. Appreciating the importance of the topic and leading to sharing experience, these conversations opened up spaces which are partly not available in the universities themselves. This presentation will contribute outcomes, insights and impressions from focus group discussions among IFSA students to the session. They suggest that while the unique experiences vary, there is a common theme across different countries and regions that not all genders have the same opportunities in education and personal development. Overall, students identified a lack of gender equality and diversity in the forest curricula.

With this presentation, IFSA introduces a students' perspective into the academic discourse. Informal exchanges at meetings and guided discussions within the frame of the IFSA Gender Sub-Commission's work offer IFSA members an inclusive and trustworthy space for exchange about experiences they have made. Additionally, the Sub-Commission contributes to the development of a Massive Open Online Course (MOOC) on Gender Equality and Diversity in forest-related sectors.

The Evolution of Equity, Diversity, and Inclusion in Canada's Forest Sector

T5.14 Gender Equality in Forestry: Past, Present and Future

Maureen Reed[1]
John Boakye-Danquah[1], Stephen Wyatt[2]
[1] University of Saskatchewan, School of Environment and Sustainability, Canada
[2] Université de Moncton, Forestry and Environmental Management Department, Canada

Abstract: Most major forest sector organisations in Canada have made public commitments to promoting equity, diversity, and inclusion (EDI), specifying women, Indigenous peoples, new Canadians, youth, and other groups, yet Canada's forestry sector continues to lag behind other employment sectors in recruiting and retaining a diverse and inclusive workforce. In this paper, we present data from forest sector policy documents, the Canada Census, and interviews with present-day workers in the sector to illustrate how EDI has been framed over time, persistent challenges faced by equity-deserving groups, and constructive advice for making forestry equitable and inclusive.

We make three key observations. Firstly, women's employment outside the home and pay equity issues were initially framed as human rights issues. The early emphasis on women has transitioned to a broader framing on equity and inclusion or belonging, while contemporary arguments for change emphasize the contributions and benefits of EDI for the private sector. Secondly, early conceptions of inclusion focused on women – typically white and middle-class – with little interest for other equity-deserving groups. Academic research and government data reflected this focus, inadvertently overlooking employment trends and the needs of groups such Indigenous Peoples, People of Colour, and LGBTQ2+ people. The absence of disaggregated data hindered an understanding of these issues and hampered progress. Thirdly, employers, educators, and other organisations are now becoming increasingly active in promoting awareness and progress in EDI. In forestry, however, current employees from equity-deserving groups report many of the same barriers revealed by researchers in the 1990s, Forestry education also lags in its representations of forestry work and its advancement of equity issues. Canadian experience illustrates that advancing EDI in the forest sector remains an on-going challenge, posing questions about how best to accelerate the transition towards a diverse and inclusive workforce.

The Potential of Artificial Intelligence and Enabling Technologies for the Management of the Brazilian Amazon Rainforest: A Decade of Lessons Learned

T5.14 Gender Equality in Forestry: Past, Present and Future

Igor Barboza[1]
Stibniati Atmadja[2]
[1] Department of Forest Sciences, Technical University of Dresden.
[2] Center for International Forestry Research – World Agroforestry Center

Abstract: Our research investigates the relevance of Artificial Intelligence and its Enabling Technologies (AIET) in the conservation and management of the Brazilian Amazon Rainforest (BAR). Historically, technology has accelerated business and economic transformations, fundamentally reshaping society. The impacts of technology can vary across stakeholders and evolve, either empowering or disempowering different groups. AIET holds transformative potential for forest management and conservation.

Our goal is to characterize the transformative potential of AIET, identify associated risks, and determine who may be affected to minimize those risks. AIET can enhance agility, interoperability, and decision-making support within and across sectors such as carbon markets, supply chains, and the implementation of infrastructure and command and control actions. It can also contribute to more efficient biodiversity conservation practices. Understanding the distributive impacts of AIET in the BAR is crucial due to the significant disparities in access to information, technology, and political and economic power among actors and stakeholders.

This research aims to bridge the gap between technological advances and their adoption in the BAR. We examine AIET applications aligned with the Action Plan for Deforestation Prevention and Control in the Legal Amazon (PPCDAm) and REDD+ initiatives. Specifically, we focus on characterizing AIET, including technologies and techniques like Random Forest, satellite and bioacoustic sensors, cloud computing, internet of things, and big data, which have assisted REDD+ initiatives in halting deforestation and catalyzing sustainable forest transitions in the BAR. Additionally, we develop a comprehensive mapping of stakeholders involved, technological synergies, and main actors applying AIET in the BAR, using the International Database on REDD+ projects and programs (ID-RECCO) as a starting point.

By reviewing the literature on forest-related AIET applications in global south rainforests and conducting interviews with i) AIET Users and Implementers in Forest Management, ii) Forest Users and Stakeholders, iii) and Forest Administrators and Policy Experts, we explore the challenges, risks, outcomes, and opportunities of applying AIET to create, implement, and improve economic instruments in the BAR region, in alignment with the PPCDAm's 4th axis and its lines of action.

WoFo - Women in Forestry International

T5.14 Gender Equality in Forestry: Past, Present and Future

Dagmar Karisch-Gierer[1]
Iza Pigan[1], Ragnhildur Freysteinsdottir[1], Maren Ammer[1], Nike Krajnc[1], Lesya Loyko[1], **Kathrin Böhling**[1]
[1] WoFo International, St. Barbara im Mürztal, AT

Abstract: We are aware that forests are essential to sustain life on Earth, and it's time to say that women are crucial for the sustainability of forests.

To address the climate crisis and shift to real sustainable development, we must engage all human resources, knowledge and perspectives available, involving all people.

These ideas together with intensification of women's networking in forestry led to establishing Women in Forestry International (WOFO), an umbrella organization established to promote the interests of women in the forest and wood sector internationally.

WOFO is a result of a collaboration between women from several countries and was registered by founders from six countries: Austria, Germany, Iceland, Poland, Slovenia, Ukraine

The mission of WOFO is to be a leading international organization that brings together women in forestry and to make them stronger, more visible, and heard.

The main goal of Women in Forestry International is to connect existing networks for women in forestry, to support the creation of new networks and initiatives, and to make them more influential and integrated at the national and international levels.

Each existing women's organization or network in the forest area is welcome as well as individuals or other organizations which support gender equality and share WOFO's interest and values. Thus different types of membership are foreseen.

Joining WOFO International allows its member to:

- build relationships and exchange ideas with other women in the forestry sector
- share skills, information, and expertise
- empower and support women in the forest-based sector
- collaborate and open linkages between networks and initiatives of women in forestry
- make women in forestry visible and audible – to speak and be heard in forestry and the forest-based sector
- improve the performance of your organization or network and become a partner in international processes and discussion

Women and timber management: From assigned cook to strategic decision-maker of community land use

T5.14 Gender Equality in Forestry: Past, Present and Future

Ana Luiza Violato Espada[1, 2, 3]
Karen A. Kainer[2, 3]
[1] U.S. Forest Service International Programs Brazil
[2] University of Florida, School of Forest, Fisheries, and Geomatics Sciences
[3] University of Florida, Tropical Conservation and Development Program / Center for Latin American Studies

Abstract: Numerous studies on community forest and land use show clear benefits of including women in natural resource management. Women's empowerment in collaborative timber management, however, is understudied and rarely achieved on the ground. We focused on women's participation in seven community-based timber projects within three Brazilian Amazonian extractive reserves, asking: 1. What resources (actual allocations, future claims and expectations) have shaped women's roles in collaborative timber management? 2. How do community women perceive their role in collaborative timber management? 3. Have community members and partner organizations perceived gender equity in collaborative timber management? Over 15 months, we carried out in-depth interviews with 52 respondents, conducted participant observation, and led focus group discussions that included community concept drawing activities. We uncovered that while these collaborative timber management projects still centered on male workers, in two of the three extractive reserves, empowerment processes ultimately opened spaces for greater engagement by women overall in strategic administrative and logging coordinator positions. We added to the scholarly conceptualizations of women's empowerment, demonstrating that 'power through' _can lead to more permanent empowerment levels. Although normative values associated with gender (i.e. men stronger than women) were subtly embedded in the actual allocation of both human and social resources (capacity building and networks, respectively) for collaborative timber management, integration of a few women in male-centered training efforts provided venues for transformative agency towards women's placement in strategic timber management positions. Supporting such transformative processes to empower women in community land use and forestry requires awareness of gender-based discriminatory attitudes and practices on the part of men and women, as well as innovations by policymakers, community members, government, and non-governmental organizations.

Women in forest conservation and the bioeconomy market

T5.14 Gender Equality in Forestry: Past, Present and Future

Ana Carolina Casemiro Vieira[1]
Ana Luiza Violato Espada[2]
[1] Beraca Institute for Valuing Biodiversity - Brazil
[2] U.S. Forest Service International Programs Brazil

Abstract: The socio-bioeconomy model through Community-Based Forest Management has already been widely discussed and implemented in the Brazilian Amazon. The connection between sustainable forest resources uses and both the cosmetic and pharmaceutical market is an important economic and social development strategy for local populations that, through their traditional management practices begin to generate a diversified economy linked to the forest resources use seasonal calendar.

Forest-based women are engaged within this strategy by the multiple use of natural resources through seeds and fruits collection to feed their families and provide medicinal plants and vegetable oils that corroborate with traditional medicine in these territories. However, women’s role in the use and management of natural resources is often invisible in their territories, weakening their participation in the family economy and in the governance of their territories. With the development of biodiversity value chains and the opening of the global markets for forestry products, women begin to play a significant role in sustainable forest management, nature conservation, income generation and social reproduction of families.

The study addresses five community territories in the Amazon and four biodiversity value chains, namely copaiba, patua, passion fruit and forest restoration. In this summary, we will present the experiences accumulated by the institution in the process of strengthening value chains linked to the productive inclusion of women in different processes of community enterprise, from forest management to socio-productive management and commercialization of production.

Our study highlights the role of women in socio-biodiversity value chains linked to high value-added markets, revealing the relevant of women’s role in forest restoration chains and in the sustainable management of forests products, strengthening low carbon strategies and high social impact economies that contribute to gender equity in traditional Amazonian territories.

T5.15 Global forests in a hotter and drier world: Assessing forest damage and tree mortality from climate change-accelerated insect outbreaks and infectious diseases

Disentangling Norway Spruce Responses to Bark Beetle Infestation and Drought Stress by Continuous Eco-Physiological Monitoring and Field Spectroscopy

T5.15 Global forests in a hotter and drier world: Assessing forest damage and tree mortality from climate change-accelerated insect outbreaks and infectious diseases

Anna Candotti[1]
Irene Menegaldo[1], Luca Da Ros[1], Enrico Tomelleri[1]
[1] Faculty of Agricultural, Environmental and Food Sciences, Free University of Bolzano, Piazza Università 5, 39100 Bolzano, Italy

Abstract: In recent decades, there has been a significant rise in the occurrence and severity of insect-caused forest disturbances, such as those caused by spruce bark beetles. These disturbances, driven by climate change, have led to widespread tree mortality on a global scale. Understanding and effectively managing conifer defense mechanisms is crucial in order to prevent bark beetle outbreaks. However, accurately differentiating between canopy responses caused by bark beetle infestation and other stressors, like drought, is essential for precision pest management. This study focuses on a manipulation experiment conducted in the Latemar Forest, located in the Eastern Italian Alps. The objective of our experiment was to unravel the initial indicators of drought stress and bark beetle attacks at the individual tree level. To achieve this, we employed continuous monitoring techniques, combining physiological measurements and spectroscopy, to observe the response of Norway spruce trees to drought and infestation over a manipulation experiment. The manipulation involved two treatments: drought stress induction and bark beetle attraction. Our monitoring approach involved the use of an Internet of Things (IoT) device capable of recording various environmental parameters, including radial growth, sap flow, air temperature, and relative humidity. In addition, we regularly monitored soil moisture content, needle chemistry, and needle spectral signatures. By analyzing this comprehensive dataset, we were able to track changes in the trees' response mechanisms throughout the growing season and distinguish between the effects of bark beetle infestations and drought stress. In fact, the contrasting temporal behavior across the two treatment groups of sap flow and needle spectral properties provided valuable information for distinguishing among the two treatments. Our results shed light on the eco-physiological processes that impact Norway spruce trees under bark beetle and drought stress. Given the projected increase in the frequency of abiotic and biotic disturbances due to climate change, our findings contributed to a deeper understanding of the complex interactions between trees and their environment. Ultimately, this knowledge will support early damage recognition and inform future management strategies aimed at mitigating the impacts of climate change on forest ecosystems.

Does stand structural diversity increase disturbance resistance?

T5.15 Global forests in a hotter and drier world: Assessing forest damage and tree mortality from climate change-accelerated insect outbreaks and infectious diseases

Niko Kulha[1]

[2] Univ. Grenoble Alpes, INRAE, LESSEM, France

Abstract: Diverse forests are often considered to be more resistant (defined here as the ability of ecological systems to persist through a disturbance event) than structurally homogeneous stands. However, the relationship between diversity and forest resistance has often been examined only for biotic disturbances and in terms of tree species diversity, while other disturbance agents and the effect of diversity in structural attributes on resistance have received much less attention.

We used data from plots that were disturbed by storm, fire, snow or biotic disturbance from the French, Spanish, and Finnish National Forest Inventories to quantify the plot-level relationship between stand structural diversity and disturbance-induced tree mortality. We tested whether diversity in tree diameter, basal area and species composition, as well as trait-based disturbance sensitivity and climate, were related to disturbance resistance at the plot level.

In this communication, we present empirically derived examples of the relationship between structural diversity and disturbance resistance. We also discuss how this information can be interpreted to increase forest resistance in the face of global change and changing disturbance regimes.

Drought-impacts on Europe's forests: Was 2018-2022 unprecedented?

T5.15 Global forests in a hotter and drier world: Assessing forest damage and tree mortality from climate change-accelerated insect outbreaks and infectious diseases

Cornelius Senf[1]
Rupert Seidl[1]
[1] Technical University of Munich

Abstract: Forests globally are under increasing pressure from climate and land use change. Of particular concern are climate extremes, such as droughts. Recent drought events in Europe (2018-2022) were likely unprecedented and amplified by simultaneously extreme dry and hot conditions. Ample evidence suggests that these recent drought events have had substantial impacts on Europe's forests. A systematic assessment of the recent drought impacts on Europe's forests is, however, missing. We thus do not know whether the observed impacts of recent drought events on forests in Europe were, in fact, unprecedented or within the past range of variability. We here compile evidence from a pan-European forest monitoring system based on Earth Observation to (i) show that drought is an important driver of tree mortality dynamics, (ii) quantify the recent wave of tree mortality caused by the 2018-2022 drought/heatwave events in light of the recent range of variability, and (iii) assess how increasing drought-related mortality could impact the structure of Europe's forests in the near future.

Emerging biotic risks to European forests and the state of national disturbance monitoring systems

Abstract: The forest disturbance rate has dramatically increased across Europe, which has been corroborated by remote sensing and terrestrial forest inventories. Insects and pathogens have considerably contributed to this increase, accounting for ca 50% of total forest damage after 2010. Except for the prominent tree-killing insect in Europe *Ips typographus*, reports about "unexpected" mortality events caused by organisms previously considered insignificant have become increasingly frequent. Compiling and evaluating such observations is essential for identifying emerging biotic risks in Europe and adapting current monitoring and risk management systems. However, these data are scarce because no harmonized monitoring system exists in Europe, and available information is compiled from national reports with different detail, temporal and geographical coverage, and methodology.

This research aims to identify changes in forest disturbance patterns across temperate and boreal Europe at the level of insect and pathogen species, identify organisms and processes that may require attention in future monitoring and management, and evaluate the capacity of national forestry agencies to detect emerging changes in forest biotic risk. Species-specific two-decadal forest damage series from 24 European countries were evaluated. National forest monitoring systems were assessed from the view of their temporal and geographical coverage, data consistency, level of biological

detail (e.g., herbivore and host species), and other attributes.

Ips typographus was the prominent species that considerably increased its activity across Europe though deceleration due to host depletion was reported, for example, from Hungary. Increasing pine mortality from *I. acuminatus* and *Tomicus spp.* was another distinct feature recently identified across different environments. The importance of drought as a driver of biotic impacts consistently increased across Europe. Only several countries operate systems able to detect emerging risks and deviations from the historical trends at the species level. Actions improving Europe`s forestry preparedness to face increasing biotic risks need to be taken, such as harmonization of national disturbance monitoring systems, focusing on species-level data that allow understanding of emerging ecological changes, and open provision and sharing of data.

Evaluation of Sentinel-2 time-series ability to detect dieback intensity of silver fir, Norway spruce and scott pine stands on European mountains

T5.15 Global forests in a hotter and drier world: Assessing forest damage and tree mortality from climate change-accelerated insect outbreaks and infectious diseases

[2] TETIS, INRAE, AgroParisTech, CIRAD, CNRS, Université Montpellier, 34093 Montpellier, France
[3] Institut National Géographique (IGN), LIF, 54000 Nancy, France

Abstract: Conifers have undergone a sharp increase in mortality in European temperate forests over the past decades. The monitoring of changes in tree health is a major challenge to evaluate the dynamic of dieback and the vulnerability of the different stands to climate change. To achieve this, image times series acquired with Sentinel-2 satellites are particularly suitable thanks to their frequent revisit time and fine spatial resolution. However, their capacity to identify species and the dieback stage is limited. Consequently, we aim to combine Sentinel-2 times series with field assessment in order to quantify the extent of forest decline at national scale.

We have coupled about 250 Sentinel-2 images with more than 3.500 field assessments of trees dead branches, leaf and needle loss spread over four years of monitoring (2018-2022), to evaluate the health status of *Abies alba, Picea abies* and *Pinus sylvestris* located in French mountain forest systems. For each of the studied species, we linked the evolution of different vegetation indices obtained from remote sensing to the stand health assessed in the field. We compared their ability to identify different dieback stages for pure and mixed stands and for different ecological gradients. The most suitable vegetation indices for each species was then used to quantify the dieback surfaces evolution over the whole French mountains.

This study establishes the base for a cost-efficient monitoring method to evaluate the dynamic of stress symptoms for different coniferous species, suitable for broad forest areas.

Evolution of the bark beetle crisis in Norway spruce forests: A spatial and temporal remote sensing analysis in Belgium and North-eastern France.

T5.15 Global forests in a hotter and drier world: Assessing forest damage and tree mortality from climate change-accelerated insect outbreaks and infectious diseases

Arthur Gilles[1]
Jonathan Lisein[1], Juliette Cansell[2], Nicolas Latte[1], Christian Piedallu[3], Hugues Claessens[1]
[1] Liège University - Faculty of Gembloux Agro-Bio Tech - Forest is life
[2] Centre National de la propriété forestière
[3] Université de Lorraine, AgroParisTech, INRAE, Silva, 54000 Nancy, France

Abstract: In 2022, Europe emerged from eight of the hottest years on record, leading to significant spruce mortality across Europe. The particularly dry weather conditions of 2018 triggered an outbreak of bark beetles (*Ips typographus*), causing the loss of thousands of hectares of Norway spruce (*Picea abies*) stands, including in southern Belgium and north-eastern France.

A methodology for detecting the health status of spruce was developed based on dense time series of satellite imagery (Sentinel-2). The time series of satellite images allowed the modelling of the spectral response of healthy spruce forests over the seasons: a decrease in photosynthetic activity of the forest canopy causes deviations from this normal seasonal vegetation index trajectory. These anomalies are caused by a bark beetle attack and are detected automatically. The method leads in the production of annual spruce health map of southern Belgium and north-eastern France. The resulting map are used to assess the damage caused by bark beetle and to study the relation between the dieback and environmental conditions.

Lasted six years (2017-2022), bark beetle has destroyed 12.2 % (23,674 ha) of the spruce area in southern Belgium and north-eastern France. This study area is composed of three bioclimatic areas: Plains, Ardenne and Vosges, which have not been equally affected by bark beetle attacks. The plains were the most affected, with 50% of spruce forests destroyed, followed by the Ardenne, which lost 11.3% of its spruce stands. The Vosges was the least affected region, with 5.6% of spruce stands lost.

Forecasting invasion patterns to minimize the impacts of invasive forest insects and pathogens at large scales

T5.15 Global forests in a hotter and drier world: Assessing forest damage and tree mortality from climate change-accelerated insect outbreaks and infectious diseases

Emma J. Hudgins[1, 2]
[1] Department of Biology, Carleton University, Ottawa, Canada
[2] School of Agriculture, Food, and Ecosystem Sciences, University of Melbourne, Parkville, Australia

Abstract: Urban and forest trees are crucial to future global wellbeing, but are at high risk of mortality from invasive insects and pathogens. To plan effective mitigation, managers must know which tree species in which communities will be at the greatest risk, as well as the likely impact of possible management intervention options. This presentation will cover recent projects relating to forest health in the face of forest insect and pathogen invasions and climate change. Firstly, I will discuss a recent optimal control framework to determine the ideal management strategy for urban tree persistence in the face of emerald ash borer *(Agrilus planipennis).* We found that the best management strategy always included a combination of site-focused (biological control) and spread-focused (quarantine) management measures, and that failing to use a mixed strategy could result in losses of upwards of one million street trees in the next 30 years. Secondly, I will discuss a game-theoretic approach used to understand the optimal interprovincial transfer of funds to control cross-border spread of a climate-assisted expanding species, the mountain pine beetle *(Dendroctonus ponderosae),* in Western Canada. I will end with more recent work on forecasting native forest tree range shifts in response to climate change, for use to plan effective protection measures via combined forecasts of the impact of invasive pests and pathogens and climate change. We expect that the northward movement of many tree species will facilitate the acquisition of effective protected areas minimizing these dual risks in less costly regions in the future. We highlight the need for ground-truthing of tree distributions to minimize uncertainty in these predictions.

Immediate and lasting effects of the 2018 hot drought on beech forests: challenges and opportunities for detection, monitoring, and assessment

T5.15 Global forests in a hotter and drier world: Assessing forest damage and tree mortality from climate change-accelerated insect outbreaks and infectious diseases

Brigitte Rohner[1]
Arthur Gessler[1], Marco Ferretti[1]
[1] Swiss Federal Institute for Forest, Snow and Landscape Research, WSL

Abstract: Changes in regional and global hydrological cycles and temperature regimes have profound implications for forest health, functioning, and growth, ultimately influencing their role in carbon sequestration. In 2018, a severe hot drought affected large parts of central Europe, resulting in forest damages, particularly premature leaf senescence in deciduous tree species. This study conducted a specialized survey on selected plots of the Swiss National Forest Inventory from late summer 2018 to 2023 to investigate the immediate response of beech (*Fagus sylvatica* L.) forests to the hot drought, assess potential lasting effects in subsequent years, and evaluate the effectiveness of standard forest health monitoring protocols in detecting these effects. Our focus was on three vitality indicators: (i) severe crown transparency, (ii) severe leaf browning, and (iii) growth in terms of basal area increment.

During late summer 2018, the frequency of damaged beech trees exhibiting severe leaf browning and crown transparency was significantly higher compared to long-term baseline monitoring data. The occurrence of crown damages was primarily influenced by factors such as previous growth, species composition, tree size, and precipitation deficit. In 2018, tree growth was substantially lower compared to the long-term average, particularly for trees displaying severe crown transparency or leaf browning. However, more favorable weather conditions in 2019 resulted in a significant recovery of crown conditions and growth. The ongoing monitoring of these trees in subsequent years offers valuable insights into their medium-term health development and aids in identifying delayed reactions of tree vitality, including the potential occurrence of mortality.

Our findings indicate that severe crown transparency and leaf browning observed in late summer 2018 reflected a rapid drought-induced canopy deterioration in beech forests, leading to an immediate reduction in growth. Notably, these immediate effects were not captured adequately by the standard long-term forest health assessment. Therefore, we discuss opportunities to adapt the design of forest damage monitoring protocols without compromising data comparability over time.

Mapping of drought and bark beetle induced spruce mortality and forest structure changes based on aerial imagery. From local to regional scale.

T5.15 Global forests in a hotter and drier world: Assessing forest damage and tree mortality from climate change-accelerated insect outbreaks and infectious diseases

Abstract: In recent years an accelerated spruce dieback has been observed in mountainous forests of Europe. Hot summer and warm snow-free winters, consistent with expected climate-change scenarios, conditioned the spread of bark beetle infestations.

To learn more about the dynamics of bark beetle infestations and forest dieback an area wide mapping and quantification of dead trees in time series is necessary. Remote sensing is the tool of choice for area-wide, large-scale detection of deadwood and forest damage. Because of their high spatial resolution (10-50 cm; 20 cm for our study area), area coverage of hundreds to thousands of square kilometers and spectral resolution that includes an infrared (I) band in addition to red, green and blue (RGB), aerial imagery offers an adequate data basis for tree-level deadwood detection at local and regional scales.

Based on orthophotos and digital surface models (DSMs) from image matching of stereo aerial imagery, a method for single-tree deadwood mapping was developed for the spruce dominated stands in Baden-Württemberg, Germany. Process automation enabled upscaling of deadwood mapping from the local (single reserves, visual interpretation) to the regional scale (natural and administrative regions) and data analysis across all forest management types.

We present an example of deadwood mapping results at the regional scale in Black Forest from two time series (2018-2020 and 2021) along with remote sensing-based maps of associated forest structures such as forest cover, tree cover, forest height and forest height heterogeneity, forest height types and canopy gaps. These data can be used to conduct analyses of tree mortality, forest dynamics, and provide insights into the processes of insects‘ infestation and spruce dieback in the wake of climate-change induced droughts and heat waves at local and regional scales. It can also serve as a reference for satellite-based deadwood or forest dieback maps with coarser resolution at larger spatial scales.

Post-disturbance landscape structure and regeneration composition in Central Europe imply high future risks

T5.15 Global forests in a hotter and drier world: Assessing forest damage and tree mortality from climate change-accelerated insect outbreaks and infectious diseases

Tomáš Hlásny[1]
Roman Modlinger[1], **Prosper Washaya**[1], Martin Leiner[1], Daniel Tyšer[1], Martin Slavík[1], Lukáš Bílek[1], Peter Surový[1]
[1] Faculty of Forestry and Wood Sciences, Czech University of Life Sciences in Prague

Abstract: The ongoing bark beetle outbreak in Central Europe, the Czech Republic, is currently Europe's most severe natural disturbance. Nearly 100 mil of m^3 of Norway spruce trees were killed during the last five years, representing ca one-quarter of total biotic damage in Europe. The practiced management included heavy salvage logging that severely affected the environment, including amount and structure of disturbance legacies. Here we focused on the disturbance core area that is nearly 10 000 km^2 large, and lost more than 40 % of the forest. We conducted a multi-scale assessment of the post-disturbance landscape structure, focusing on the pattern of disturbance legacies and regeneration conditions, which can decisively determine the structure and composition of the emerging forest generation.

First, the entire core area was tessellated into a hexagonal grid with a hexagon diameter of 7 km; this value was determined through the incremental spatial autocorrelation analysis. The proportion of disturbed forest and several landscape metrics (mean patch size, patch size variability) were identified for each hexagon. The disturbance mapping was based on a classification of optical and Synthetic Aperture Radar data from the Sentinel mission. Second, a pair of 8 ha study sites was selected in a representative subset of hexagons. A post-disturbance landscape mosaic was mapped on each site based on an optical image taken from a drone. Main disturbance legacy categories were identified, such as the surviving advanced regeneration and mature trees, patches of standing and downed dead trees, etc. Third, a ground sampling was conducted in 2×2 m plots located in a center of the previous sites, evaluating a species composition of the regeneration layer and its vertical differentiation.

The results imply considerable homogenization of the forest landscape. Although forest regeneration locally shows an increased diversity, Norway spruce remains abundant. This likely accounts for regeneration browsing by game, which favors non-spruce species, spruce dominance in a seed bank, and spruce planting despite its poor prospects. We conclude that the risk of developing a low-resilience forest generation dominated by vulnerable spruce is high; avoiding this development requires fast and large-scale corrective actions.

Remote sensing in alien invasive pest monitoring in forests in Croatia

T5.15 Global forests in a hotter and drier world: Assessing forest damage and tree mortality from climate change-accelerated insect outbreaks and infectious diseases

Nikola Zorić[1]
Ivan Balenović[1], Dinka Matošević[1]
[1] Croatian Forest Research Institute, Jastrebarsko, Croatia

Abstract: Monitoring of pests, native or alien invasive, is a one of key activities in prevention of damages in forests. Conventional monitoring methods (pheromone traps, visual transects, glue rings etc.) are time consuming and require significant financial inputs. Development of remote sensing sensors, GPS technology and geographic information systems (GIS) support novel approach towards detecting pests which has the potential of accurately measuring pest damage and populations on a whole area basis. Accurate and efficient monitoring of insect populations is a key point to improve pest control and mitigate damage. Technical limitations of remote scouting, especially resolution of satellite and aerial images, have until recently precluded wide scale adoption. Recent technological advancements have increased resolution of visible and NIR sensors while also decreasing size and cost providing more affordable ways to assess forest health. Therefore, usage of small aerial vehicles or drones equipped with multispectral sensors could provide a better insight into forest health and damage caused by pests. Recent technology advancements have the possibility of live multispectral images in normalized difference vegetation index (NDVI), where differences in chlorophyll concentration are seen, which provides a valuable information for scientists directly in the field. With a relatively low-cost platform we have insight on the area with better resolution than with those from satellite. Surveys of invasive alien and quarantine pests in forests are being conducted in Croatia. European food safety authority (EFSA) is recommending usage of unmanned aerial vehicles (UAVs) as a versatile remote sensing-based toolkit for monitoring forest health and occurrence of forest pests. Using DJI Mavic 2 Pro UAV we have inspected forest area in Croatia for detection of disturbances caused either by abiotic or biotic agents. Disturbances are easily detected by smaller vegetation index value from those which are without any disturbance.

Using spectral pathways to study epidemiological spread of insect and disease disturbances in forests

T5.15 Global forests in a hotter and drier world: Assessing forest damage and tree mortality from climate change-accelerated insect outbreaks and infectious diseases

Abstract: Management of problematic insect and disease disturbances requires the early detection of outbreaks, rapid mapping of spread, attribution of outbreaks to an agent, and predictive modelling.

The increased density and availability of Earth Observation data facilitates the early detection of forest disturbances. However, remotely detecting biotic disturbances before they are visible to the naked eye typically requires observations with a level of spectral and spatial detail that is only obtainable using airborne platforms, but not from spaceborne sensors.

Distinguishing whether stress symptoms are caused by biotic or associated abiotic agents, such as drought, can be challenging. Using remotely sensed spectral pathways and radiative transfer models to infer changes in specific physiological canopy attributes has proven useful in this regard. Furthermore, combining remote-sensing based detections of physiological anomalies with epidemiological spread models has proven helpful to estimate whether plant stress is associated with a pest outbreak or not. Nonetheless, identifying the specific biotic agent that is causing stress, typically requires further contextual information and on-the-ground analysis. Deep and machine learning models that can analyse spectral, temporal and spatial pathways of forest disturbances simultaneously and alongside ancillary geospatial data, e.g., on meteorology, provide novel opportunities for significant progress in attributing detected disturbances to causal factors.

Some obstacles to progress in using remote sensing to understand epidemiological spread of insect and disease disturbances, particularly at continental scale, are relatively low-tech. They include the availability of detailed maps showing host and reservoir plant distributions and the collection of high-quality reference data on outbreaks and how they progress through time and space. Such reference data are particularly needed to make optimal use of deep learning models, as these tend to require large volumes of training data.

More complex challenges include the need to better understand plant-physiological and plant-defense responses to particular pathogens, that are at the basis of any spectral signal associated with infection. Finally, there are challenges in better representing the accuracy of remote-sensing-based predictions, because they may be highly scale-dependent, and because they should be propagated through epidemiological models that use these predictions.

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

A low-cost and portable near infrared spectrometer connected to a smartphone for identifying Dalbergia, Diospyros and substitute species in Madagascar

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

[4] UMR AGAP Institut, Univ Montpellier, CIRAD, INRAE, Institut Agro, F-34398 Montpellier, France

Abstract: Rosewood and palisander, known as Dalbergia wood, along with ebony from the Diospyros tree, are highly sought-after precious woods from Madagascar. These woods are globally traded and valued, but their overexploitation has led to their scarcity. Therefore, it is crucial for forestry services to possess the capability to identify these wood species as they leave the forest, during transportation, at the point of sale, and prior to export, ensuring only authorized species are exploited. Previous studies have demonstrated the potential of using near infrared (NIR) spectroscopy in laboratories to identify precious wood species through wood samples, yielding promising results. However, utilizing portable NIR devices directly in the field requires addressing perturbations caused by external factors that can affect their performance in wood species identification, such as wood moisture and sample shape. To address these concerns, wood cores were collected from seven Dalbergia species, nine Diospyros species, and six other potential substitute species from Menabe and Masoala forests. Initially, the wood samples were stabilized at different humidity levels to account for the fluctuations in humidity encountered in the field. Subsequently, corrections, including orthogonalization of external parameters (EPO), were applied to the training models. Furthermore, the study investigated the calibration transfer between different NIR instruments to correct for variabilities resulting from instrument changes. Additionally, calibration transfer between different sample types, specifically cores and wood blocks, was considered to ensure field applicability regardless of the wood's shape. Finally, an easy-to-use smartphone application was developed using Userland, Linux, and R software. This application enables easy data acquisition, transfer, and analysis by utilizing a miniature NIR spectrometer connected to the smartphone via Bluetooth. Depending on the species being identified, the discrimination accuracy varies from 70% to 100%. This innovation enables cost-effective and user-friendly application of NIR technology in the field for wood species identification, particularly beneficial in financially limited developing countries.

Advancing Ancient Egyptian woods identification

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Alan Crivellaro[1]
Flavio Ruffinatto[2], Giulia Antonia Resente[2], Tina Beck[3], Monika Zöller-Engelhardt[4]

[2] University of Turin, Dep. Agricultural, Forest and Food Sciences (DISAFA) (Italy)
[3] Freie Universität Berlin, Department of Egyptology (Germany)
[4] Institute for Ancient Studies, Johannes Gutenberg University Mainz, Department of Egyptology (Germany)

Abstract: Despite the abundance of preserved wooden objects and archaeobotanical remains from pharaonic times and their unequalled historical and cultural value, their wood identification has only rarely been undertaken today. Moreover, the restriction on removing samples from archaeological excavations in Egypt hinders the possibility of studying them locally due to facilities' long waiting lists and difficult access. Therefore, we designed a combined macroscopic and microscopic wood identification key for Egyptian objects, including only timbers used during the third millennium BCE, one of the peak epochs of wooden object production in Ancient Egypt. Our wood identification key suggests a step-by-step process that at first only applies easy-to-observe macroscopic characters that require no sampling. Then, the identification key aims at the most accurate level of identification reachable, including targeted microscopic features and underlying the limits of the process and suggesting possible solutions. The new identification key works as a base for an initial screening and wood species identification of Egyptian objects and will soon be tested on museum collections. This guided wood identification procedure allows the revealing of new insights into the use of ancient Egyptian timbers, which enables further innovative research in both wood anatomy and Egyptology.

An automated timber identification system for Guibourtia ehie and two Melicia species

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Emmanuel Ebanyenle[1, 2]
Ophilious Lambog[3], Xin Jie Tang[4], Yi Hong Wong[4], YongHaur Tay[4]
[1] CSIR - Forestry Research Institute of Ghana, Fumesua Campus, Kumasi - Ghana
[2] CSIR College of Science and Technology, Fumesua Campus, Kumasi - GHANA
[3] Forestry Commission, Timber Industry Development Division, Habour Area, Takoradi, Ghana
[4] Agritix, Kuala Lumpur, Malaysia

Abstract: To strengthen the Ghanaian capacity in timber identification, we developed a wood identification image-based artificial intelligence (AI) model for Black Hyedua (*Guibourtia ehie* (A. Chev.) J. Leonard), Iroko (*Melicia excelsa* (Welw.) C. C. Berg; *Milicia regia* (A. Chev.) C. C. Berg.) using the Xylorix platform. Fifteen to twenty authenticated heartwood samples of each species of Odum and Black Hyedua were collected across Ghana. For each sample, about ten transverse cuts were made using heavy duty utility knives. Ten macroscopic images were captured per cut at different orientations using the Xylorix Harvester mobile application and verified. Corresponding AI models were built and evaluated using a new batch of images collected from specimens which are not used for model training. Two types of datasets, i.e. positive and negative datasets were collected for each of the models Odum and Black Hyedua. Positive dataset represents images of wood species that should be identified correctly as the target wood species by the trained model, while negative dataset represents images of any other wood species. In total, 889 images of 431 positives and 458 negatives were tested with the Odum model, while 1,088 images of 431 positives and 657 negatives were tested with the Black Hyedua model. The test results for Odum indicated an average precision value of 0.96 and an AUC-ROC value of 0.96. The test results for Black Hyedua model also exhibited similar patterns with 0.99 and 0.98 AUC-ROC and average precision, respectively. The performance plots for both models also showed higher prediction values for positives and lower prediction values for negatives with minimal overlaps. Field testing with the Odum and Black Hyedua models have shown satisfactory results. These AI models, once integrated into Xylorix platform, will allow any enforcement officer to turn their smartphone into a wood anatomist, and hence have the ability to verify or identify relevant wood species in the field in a matter of a few seconds. In this way transparency in timber trade will be greatly enhanced and contribute to curbing timber trafficking in Ghana.

Anatomical characteristics of Balfourodendron riedelianum (Engl.) Engl.

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Belén González Garcete[1]
Felicia Zárate[1], Silvia Genes[1], Delia Ramirez[1]
[1] Forestry Technology and Industries Area, Forestry Engineering Career, Faculty of Agricultural Sciences, National University of Asuncion.

Abstract: Wood anatomy is the branch of biology that studies the xylem in order to know it and give it a correct use in industrial processes (Giménez et al. 2005). Therefore, the general objective of the research is to describe the macroscopic and microscopic anatomical characters of the wood of *Balfourodendron riedelianum* (Engl.) Engl. The research was carried out in the Wood Technology Laboratory located in the Forestry Engineering Department, Faculty of Agricultural Sciences, National University of Asuncion. Samples of wood and plates available in the xylotheque of the institution, collected from different sites in the Eastern Region of Paraguay, were used. The macroscopic and microscopic characters of the three cutting planes (transverse, tangential and radial planes) of the species *Balfourodendron riedelianum* (Engl.) Engl. were observed, the macroscopic characters were observed through a stereoscope with a magnification of 32x and the microscopic characters through a microscope with three different magnifications (4x, 10x and 40x). All the characteristics were noted in the corresponding spreadsheets. The species presents a wood with uniform diffuse porosity, vessels in radial pattern, with a grouping of pores, mostly radial, multiple (2 and 3 vessels) and in smaller quantity solitary pores and grouped in 4 vessels, also presents content. It does not present axial parenchyma in bands and the fibers are septate and non-septate. There is a visibility of the rays and these are uniseriate and multiseriate, composed of two or more types of cells (heterocellular) and does not present stratification. Comparing the two types of characters (macroscopic and microscopic), it is concluded that there is a significant difference in the observations, for example, the grouping of pores, in macroscopy can not be observed more than 2 vessels, contrary case in microscopy, where up to 4 vessels are observed. This is due, in addition to the different graduations, to the different parts of the tree that were used to make the specimen and the slide respectively.

App macroHOLZdata and CITESwoodID: Computer-aided identification and description of internationally traded and CITES-protected timbers

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Gerald Koch[1]
Immo Heinz[1]
[1] Thünen-Institute of Wood Research, Hamburg (Germany)

Abstract: The knowledge about recognition and utilization of the most important internationally traded timbers is of prime importance to forestry and wood industry as well as timber trade and even control authorities. As an important tool for this purpose, the databases **macroHOLZdata** and **CITESwoodID** developed at the Thünen Institute for Wood Research has been programmed as mobile Apps for smartphones and tablets. The databases enable the user to identify/localize trade timbers by means of macroscopic wood structural features. In addition, the digital learning tools allow access to a data pool with timber specific information on properties, utilization, and other relevant characteristics.

In detail the Apps **macroHOLZdata** and **CITESwoodID** offer:

- an interactive identification of 150 important trade timbers (macroHOLZdata) and 53 CITES-listed timbers (CITESwoodID) based on macroscopic features which can be observed with the unaided eye or with a hand lens,
- numerous high-quality illustrations of wood characters and timbers alike featuring transverse and longitudinal surfaces,
- a database with pertinent information on wood properties, processing, and utilization (macroHOLZdata)
- a textbook with definitions, explanations, procedures, etc. for most features used in the description.
- internationally available (iOS and Android) using tablet PC and smartphones

The Apps are primarily designed for all institutions, companies and individuals involved in international trade and control of wood and wood products to combat illegal logging. They are also well suited for education and advanced training of students and for timber industry in the fields of wood identification, wood properties and utilization. The application and features of the databases are presented on the basis of practical exercises.

Automated wood species identification in microscopic images of fibrous materials using machine learning / AI

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Stephanie Helmling[1]
Lars Nieradzik[2], Jördis Sieburg-Rockel[1], Thomas Weibel[2], Stephanie Wrage[1], Petra Gospodnetić[2], Janis Keuper[2, 3], Henrike Stephani[2], Markus Rauhut[2], **Andrea Olbrich**[1]

[2] Fraunhofer Institute for Industrial Mathematics ITWM
[3] Offenburg University - Institute for Machine Learning and Analysis (IMLA)

Abstract: Illegal deforestation is a global problem that affects us all. The laws designed to prevent this are only as good as they can be controlled over a wide field. Meanwhile, the global production of paper and fiberboard is constantly increasing. The wood species composition of a small amount of these materials is currently analyzed at great expense by highly qualified wood anatomists. In order to improve this time-consuming process, our latest research project was initiated. The goal of this project is to simplify the application of the controls worldwide by using machine learning. To achieve this, a methodology for the systematic generation of a large image dataset of macerated wood references was developed. For the dataset, stained specimens of vouchered wood samples were prepared. Overview scans of entire slides allow the display of as many individual cells as possible in five focal planes in one image file. The first dataset contains more than 2,000 of these huge microscopic images of hardwood and softwood genera. These images form the basis for a modern image recognition software that uses deep neural networks to detect and correctly identify the contained species. The final solution will be the first approach for the fully automatic identification of the most common wood species in fibrous materials. A modular and generalizable combination of artificial intelligence solution is used to achieve this goal.

The presentation will show how microscopic images of fiber samples can be analyzed with these algorithms by using a specifically designed graphical user interface. It will close with a comparison between wood anatomists and artificial intelligence.

The project is carried out by the Thünen Institute of Wood Research in cooperation with the Fraunhofer Institute for Industrial Mathematics (ITWM) and funded by the Fachagentur Nachwachsende Rohstoffe e.V.

Digitizing a xylarium beyond shared meta-data: the importance of quantitative wood anatomy, images and chemistry

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Hans Beeckman[1]
Yafang Yin[2]
[1] Service of Wood Biology, Royal Museum for Central Africa, Tervuren, BELGIUM
[2] Wood Anatomy and Utilization Department, Chinese Research Institute of Wood Industry, Chinese Academy of Forestry (CAF) Beijing 100091, CHINA

Abstract: Xylaria are big institutional collections of wood samples that serve as scientific reference material. They are a result of long-term collecting efforts of multiple expeditions in the past, often in regions that are nowadays difficult to explore for logistical, conservational, or political reasons. Xylarium specimens have been key for comparative wood anatomy and establishing databases supporting botanical identification of traded timber.

Strong tendencies in actual state-of-the-art research include the rising importance of quantitative approaches and the substantially improved means for producing, sharing, and analyzing images. At the same time there is a growing interest in combining microscopic observations of wood with chemical assessments. These trends urge for coordinated efforts of digitizing the invaluable information held in xylarium samples, apart from sharing metadata that are available for many xylaria.

Quantitative features typically show variability, contrary to most of the qualitative characteristics commonly used in wood identification. There is indeed variability within species, but also within a single tree, e.g. vessel element or tracheid dimensions vary from pith-to-bark, in the height direction and according to different organs (trunk, roots, branches). More emphasis on quantitative features implies a statistical approach that typically needs study material consisting of more specimens than a classical wood anatomical description. This is a good reason for strengthening the network efforts between xylaria.

There are also engaging perspectives for a bigger role of image-based assessments. Capturing a maximum of wood anatomical information in a collection of images involves taking pictures from the three principal angles, at different magnifications, different fields of view and using as well optical light, electron beams and X-rays. This digitizing process results in a multitude of images. Handling high resolution images in a standardized and efficient way is still challenging, but necessary to fully exploit the opportunities of deep learning.

Beyond wood anatomy, several chemical analyses are also relevant for identification and provenance determination, including measurements of metabolites, stable isotopes and elemental assessments.

Concerted actions will be key to share data that are maximally Findable, Interoperable and Reusable (FAIR principles).

In search of species level identifications for African CITES timber species: potential of combined methods and importance for provenancing

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Maaike De Ridder[1]
Victor Deklerck[2], Kévin Liévens[1], Ruben De Blaere[1], Nils Bourland[1], Mélissa Rousseau[3], Michael Monnoye[1], Steven Janssens[4], Brecht Verstraete[4], Peter Kitin[5], Hans Beeckman[1]
[1] Royal Museum for Central Africa, Wood Biology Service, Belgium
[2] Royal Botanic Gardens, Kew, UK
[3] Ghent University, Belgium
[4] Meise Botanic Garden, Belgium
[5] Forest Service, Forest Products Laboratory, USA

Abstract: The Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) aims at regulating the trade of selected species. Appendix II groups species that are not necessarily threatened with extinction but in which trade is controlled to avoid utilization incompatible with their survival. High-value African timber genera *Afzelia* spp., *Khaya* spp. and *Pterocarpus* spp. entered the appendix recently, joining previously listed e.g., African *Dalbergia* spp., *Pericopsis elata* and three *Guibourtia* species.

Apart from document checks, wood sampling is needed to verify both labelling and origin of African timber genera. Several identification methods are more developed than current provenancing methods. Complementary to the ongoing development of last-mentioned methods, exact botanical identification up to the species level is an often overlooked source of information for provenancing. Currently, different species within genera remain hard to distinguish using only one method. We provide an overview of combined methods that substantially help to identify African CITES genera up to species level (e.g., wood anatomy combined with DART for *Afzelia* sp.). If certain species are associated with well-defined distribution areas, knowledge at this species level provides valuable information on provenance. Our first objective is to develop sample protocols allowing for multiple analyses and combine results to determine the potential for species level identifications (DART TOF mass spectrometry, wood anatomy, stable isotopes, genetics…).

Knowledge on the CITES species also benefits from analyses of lookalikes. The decision on listing all species of a genus as CITES is often based on the risk of (un)intentionally mislabeling true critical species as lookalikes. Our second objective is to provide a data-based definition of the term 'lookalike', by creating indices of similarities based on InsideWood species descriptions. First, a set of macroscopic features is tested on reference wood samples. Then, a combination with more subtle microscopical features is made to determine sound criteria for lookalikes of African CITES species.

Our results confirm the power of joining forces for sound identifications. Hands-on tools are being developed to assist stakeholders without scientific background (e.g., apps using AI, sample protocols) and results are translated into recommendations for future CITES-listings.

New advances in DNA-based methods for modern and archaeological woods identification in China

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Yang Lu[1, 2, 3]
Lichao Jiao[1, 2, 3], Yafang Yin[1, 2, 3]
[1] Research Institute of Wood Industry, Chinese Academy of Forestry, Beijing100091, China
[2] Wood Collection of Chinese Academy of Forestry, Beijing 100091
[3] Wood Specimen Resource Center of National Forestry and Grassland Administration, Beijing 100091

Abstract: Scientific and accurate wood identification is an important basis of wood science and its relevant disciplines. The rapid development of DNA-based methods for wood identification is expected to break through the limitations of the traditional wood identification method based on wood anatomy and realize the identification of wood at the species level. Both modern and archaeological woods face difficulties including high levels of DNA degradation and complex composition of inclusions that hinder DNA acquisition from wood cells, and the establishment of stable and efficient DNA identification methods for wood is still a worldwide demand and challenge. In this paper, we focus on three typical wood materials, i.e., modern wood rich in extractive, ancient architectural wood, and waterlogged archaeological wood, for investigation on establishing a stable DNA identification method at the species level using obtained DNA sequence information. This work will offer scientific guidance and technical support for the conservation of forest resources and understanding of wooden heritage.

Origin Traceability of Santalum Wood Using Stable Isotope and Mineral Elements

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Chuanyang Lin[1, 2, 3]
Yang Lu[1, 2, 3], Lichao Jiao[1, 2, 3], Yafang Yin[1, 2, 3]
[1] Research Institute of Wood Industry, Chinese Academy of Forestry, Beijing 100091
[2] Wood Collection of Chinese Academy of Forestry, Beijing 100091
[3] Wood Specimen Resource Center of National Forestry and Grassland Administration, Beijing 100091

Abstract: The purpose of this study is to analyze the feasibility of tracing the origin of woods based on stable isotopes and mineral elements, and to clarify the influence of heartwood and sapwood on the accuracy of wood origin identification. In this study, *Santalum* wood samples from major growing areas of China, namely Dongfang of Hainan Province, Zhanjiang and Zhaoqing of Guangdong Province, and Australia, were selected as the research objects. Five stable isotope ratios ($\delta^{13}C$, $\delta^{2}H$, $\delta^{18}O$, $\delta^{15}N$ and $\delta^{34}S$) and 38 mineral elements contents of heartwood and sapwood samples were determined by stable isotope ratio mass spectrometer (EA-IRMS) and inductively coupled plasma mass spectrometer (ICP-MS), and the origin discrimination was carried out by stoichiometric method. The results showed that there were significant differences in stable isotope ratio and mineral element content between sapwood and heartwood of *Santalum*. Therefore, the sampling radial positions of wood samples should be fully considered in practical application to obtain the best discriminant accuracy of origin traceability. The average cross-validation accuracy of the method based on the orthogonal correction of stable isotope ratio partial least squares discriminant analysis (OPLS-DA) was 80% for the four geographic origins, and the average accuracy of the method based on the mineral element content was 96%. Isotope ratios of $\delta^{13}C$, $\delta^{18}O$ and $\delta^{2}H$ and mineral elements including Mo, Pd, Cr, Cd, Ti, Sr, Ca, Sn, Sb, La, Rh, Nd, Pr, Sm, V, Pb, Gd and Ce are the key indicators for origin tracing of *Santalum* wood samples. This method can trace the origin of *Santalum* woods in large-scale geographic space, and provides an effective method for combating illegal timber harvesting and conserving species diversity.

Phytochemical analysis of Pterocarpus species by chromatographic and spectrophotometric techniques for complementing existing way of identification

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Surendra Singh Bisht[1]
Kamal Mishra[2], Shashika S.[2]
[1] Chemistry and Bioprospecting Division, Forest research Institute, Dehradun 248006, India
[2] Institute of Wood Science and Technology, 18th Cross Malleshwaram, Bangalore - 560003, India

Abstract: *Pterocarpus santalinus* L. f., commonly known as Red sanders, yields economically important high-priced wood. Due to its high price and rich hue, illegal harvesting and trading of Pterocarpus heartwood appears to be widespread. The identification of authentic *P. santalinus* wood is difficult because it shares morphological and anatomical similarities with other Pterocarpus species. Moreover, the Convention on International Trade in Endangered Species (CITES) has limited resources to guide the identification of Pterocarpus wood. In this study, chromatographic and spectrophotometric analysis of heartwood of *P. santalinus* Linn collected from trees grown in eight different locations was carried out. Thin layer chromatography (TLC) fingerprints of methanolic extract of *P. santalinus* heartwood revealed distinct spots at retention factor (Rf) 0.94 (light brown), 0.91 (purple), 0.79 (blackish-brown), 0.75 (light purple), 0.60 (yellow), 0.51 (dark red) and 0.28 (brownish red) in normal phase. High performance liquid chromatography (HPLC) analysis indicated at least 11 common peaks at retention time (tR) of 3.1, 3.5, 8.9, 11.1, 12.8, 13.5, 14.9, 15.7, 17.9, 18.3, and 26.5 (minutes). Ultraviolet visible spectrophotometric analysis of methanolic extract of heartwood exhibited consistency in major absorbance peaks at ~280 nm, ~320 nm, ~472 nm and ~505 nm. Similarities in chromatographic pattern between the *P. santalinus* samples from different locations were evaluated using principal component analysis (PCA). The developed fingerprints of methanolic extract of *P. santalinus* heartwood were also compared with those of *Pterocarpus marsupium*, *Pterocarpus soyauxii*, and *Pterocarpus macrocarpus*. The results demonstrate that HPLC and TLC fingerprints can supplement wood anatomy and other techniques in accurate identification of above *Pterocarpus* species. Spectrophotometric analysis can be helpful to differentiate *P. santalinus* from *P. macrocarpus* and *P. marsupium*, but *P. santalinus* and *P. soyauxii* could not be distinguished. Usefulness of these techniques for discrimination of some of the commonly occurring species in *Pterocarpus* genus was assessed.

The role of multi-stakeholders' dialogue in addressing timber trafficking: implications for science-based wood identification methods in Ghana

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Emmanuel Ebanyenle[1, 2]
Marshall Adams[3], Ophilious Lambog[4], Destina Samani[3]
[1] CSIR - Forestry Research Institute of Ghana, Fumesua Campus, Kumasi - Ghana
[2] CSIR College of Science and Technology, Fumesua Campus, Kumasi - Ghana
[3] United States Forest Service International Programs, Accra - Ghana
[4] Forestry Commission, Timber Industry Development Division, Habour Area, Takoradi - Ghana

Abstract: The implication of stakeholder dialogue for science-based wood identification is currently under-researched. A multi-stakeholder's dialogue was organized to raise awareness and understanding of stakeholders about timber trafficking issues in Ghana, and it implication for science-based wood identification in Ghana. This study was inspired by Delphi methodology, a structured and iterative process used to gather and distill expert opinions on a particular issue. The stakeholder dialogue revealed three emerging issues. First, stakeholders identified the following issues to be hampering efforts to combatting timber trafficking in Ghana: weak law enforcement due to inadequate personnel, lack of capacity in science-based wood identification methods, weak coordination among law enforcement and CSOs and community, porous borders, political interference, and lack of clear guidelines to process trafficked illegal timber. Rural poverty and livelihoods issues appear to be a critical driver for illegal timber activities in Ghana. Demand for cheap timber and conversion of forest lands for other uses also promote illegal timber logging in Ghana. Variations in definition of legal timber and disparities in timber trade tariffs among the West African countries were being exploited by illegal timber traffickers. Furthermore, data on illegal timber trade or crimes, timber species, and number of successful prosecutions are not readily accessible, even if available. Second, the stakeholders suggested enhancing the capacity of law enforcement agencies by developing and deploying science-based wood and charcoal identification methods in Ghana will contribute to combatting illegal logging in the West Africa, particularly African Rosewood (*Pterocarpus erinaceus*). Although African Rosewood is banned in Ghana, the forest fringe communities continue to convert it into charcoal and trafficked. In the absence of applicable charcoal identification tools, Africa Rosewood is threatened due to overexploitation in the West Africa. In addition, improving intra and inter-agency cooperation, and developing a decision guide for handling trafficked timber and charcoal. Also, empowering forest fringe communities and CSOs and promoting livelihood programs could contribute to reducing illegal logging. Third, critical recommendation was the need to engage Ghana's neighboring countries by organizing a subregional dialogue to discuss and agree on common principles to combat transboundary timber and charcoal trafficking.

The twofold role of wood anatomy on a local Congolese timber market: a tool for species level identification and a direct link to the nearby forest.

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

[4] University of Ghent

Abstract: Tropical rainforests in the Democratic Republic of the Congo (DRC) are harvested continuously for international and local timber trades. Statistics on internationally traded species are reported, but knowledge on local timber trade is scarce. As a collaboration between Congolese and Belgian researchers, a study was performed on timber locally processed and sold on markets in and around the city of Kisangani in the Tshopo province (DRC).

A total of 116 timber samples were gathered in Kisangani markets and subsequently sanded, photographed, microsectioned and identified. Apart from this process, detailed inventory data including tree species taxonomy, geographical distribution, abundances and diameter was gathered in contiguous 0.5 ha sampling plots lined up on a 79 km long transect line in the Yangambi forest near Kisangani. The standing volume was estimated using volume tables. Furthermore, growth increment data of these tree species was gathered in adjacent permanent monitoring plots.

The objective of this research is thus twofold: exploring the potential of classical wood anatomy to identify African timber up to the species level and comparing the identified species to the composition of the surrounding forest to gain insights on the impact of local logging.

Several topics on wood anatomy are discussed: the difficulties during the identification process, the use of supporting data to improve identification (for example the locally used names and geographical restrictions), the number and causes of misidentifications on local markets and the benefits of species level identifications to assist in combatting illegal timber trade.

Concerning the impact of local timber markets in the neighboring forests, the data we gathered enables us to select species that may be threatened by local exploitation. At the same time, lesser-known species on the international timber market arise in local markets. These species require further research to assess their opportunities as they could lower the pressure on the internationally traded timbers. This shows how wood anatomy forms a promising go-between to study the link between local timber trade and forest use in the tropics and highlights the importance of the botanic identification of timber to evaluate the carrying capacity of tree populations for logging.

The use of near-infrared spectroscopy in the traceability of commercial cargo of Cedrela odorata from origin to the final consumer in Brazil

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Paulo Fontes[1]

Abstract: The traceability of commercial timber cargo is one of the preventive measures to combat illegal timber trade in Brazil. Even though there are simple or complex methods to determine the origin of wood, there is no standard procedure stablished yet. NIRS technology combined with multivariate data analysis have proved to be a fast and efficient methodology for species identification, as well as a promising tool for geographical origin determination. This study aimed to track a commercial cargo of 19,114 m³ of *Cedrela Odorata* from the legal extraction area in the Amazon region (Jamari National Forest) to the final consumer located in the city of Ubatuba (São Paulo), which totalizes 3,100 km covered by land. The cargo was packed and transported by truck to protect it from weather. The NIR spectra obtained at the origin were used to create a SIMCA model, which was applied to the spectra obtained at the destination of the cargo. It reaches a compatibility rate of 81%. That means that most of the samples were within the model acceptance area and were high compatible with the initial cargo. When applied to *C. Odorata* samples from other origins, the number of samples within the acceptance area did not go over 32%. When testing the model on other species (*Erisma uncinatum*, *Swietenia macrophylla*, and *Micropholis melinoniana*), this rate was no more than 34%. These latter values corroborate the practicality, precision, and reliability of the NIR instrument for in-field tracking of wood cargo.

Tropical timber integral research in southern Ecuador: Characterization, identification and scientific advances.

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Andrés Armijos Montaño[1]
Keyla Cartuche Peralta[1], Darwin Pucha Cofrep[1]
[1] National University of Loja, Laboratory of Tropical Wood Anatomy.

Abstract: Southern Ecuador is a region recognized for its biodiversity and richness in forest species; however, it faces different challenges of deforestation due to overexploitation and lack of information on native species to monitor and regulate the timber trade at the national level. In this context, this study focused on the characterization and similarity of timber in 100 forest species (96 broadleaf and 4 conifers) through the analysis of 141 variables related to their physical and organoleptic properties, and anatomical characteristics (qualitative and quantitative).

An unsupervised data analysis (dendrograms) was used to analyze the clustering of the species according to their properties. In addition, a principal component analysis (PCA) and correlation matrices were used to evaluate the significance of the analyzed characteristics and their interaction between species.

The results identified four distinct groups of woods. The first group consists of semi-heavy species (*Grias peruviana, Weinmannia fagaroides, Clethra revoluta, etc.*), the second group includes hardwoods such as *(Myrcianthes discolor, Lafoensia acuminata and Chionanthus pubescens, etc.*), the third group corresponds to soft woods (*Heliocarpus americanus, Ochroma pyramidale, Ochroma pyramidale, etc.*), and the fourth group, the largest, is made up of porous woods (*Inga densiflora, Salix humboldtiana, Cedrela montana, Piptocoma discolor, etc.*).

We also found a direct relationship between the basic density of the wood and characteristics such as color, cell wall thickness of the fibers, the presence of solitary vessels, number of vessels per mm2, the presence of rays of two different sizes and different patterns of axial parenchyma.

These findings are relevant for species identification based on wood density, highlighting the high variability of wood characteristics among forest species in southern Ecuador. This allowed the identification of unknown species with a potential for use similar to the species that are currently highly exploited, emphasizing the importance of generating more information on a greater number of species to facilitate decision making in sustainable forest management in Ecuador.

Use of DNA in tracing the geographic origin of planted tropical timber Neobalanocarpus heimii (chengal) in centurion planting trials

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Lee Hong Tnah[1]
Chai Ting Lee[1], Chin Hong Ng[1], Kevin Kit Siong Ng[1], Zakaria Nurul Farhanah[1], Soon Leong Lee[1]
[1] Genetics Laboratory, Forest Research Institute Malaysia, 52109 Kepong, Selangor, Malaysia

Abstract: In the context of forensic forestry, the unique features of DNA within a timber could be used to facilitate the identification and determination of origin. With the aim to manage and utilize forest genetic resources in a sustainable manner, extensive DNA databases for various important tropical tree species, including *Neobalanocarpus heimii*, have recently been developed at the species, population, and individual levels using chloroplast DNA (cpDNA) and short tandem repeat (STR) markers. To use these DNA databases for forensic applications, as recommended by the UNODC Best Practice Guide for Forensic Timber Identification, four laboratory standard operating protocols (SOPs) for *N. heimii* were developed as a guide to generate forensic evidence for judiciary purposes. In this case study, as the origin of the planted timber species at Forest Research Institute Malaysia (FRIM) was mostly unknown, our objective was to trace the origin of *N. heimii* stands on the FRIM campus using SOPs and DNA databases. FRIM was once a former mining area, but it has been successfully transformed into a man-made forest since the 1920s. Using four chloroplast DNA (cpDNA) and ten nuclear short tandem repeat (nSTR) markers, we generated DNA profiles for 111 *N. heimii* individuals from four planting trials. Our findings showed that the DNA approach can be used to trace the geographic origins of species. The origins of the *N. heimii* on the FRIM campus are diverse, including northern, western, southern, and eastern Peninsular Malaysia. Each of the four planting trials demonstrated a high level of genetic diversity equivalent to natural stands. Thus, these planted *N. heimii* should be regarded as a valuable germplasm bank for the conservation of the species' genetic resources as they constitute a substantial gene pool of diverse origins.

Using genetics to identify species in the highly diverse and closely related subfamily Dipterocarpoideae in Southeast Asia: how far can we go?

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Abstract: Illegal logging is a major global issue driving deforestation and biodiversity loss. As such it is imperative that scientific tools to identify timber species are developed. Tropical forests on the island of Borneo are amongst the most heavily logged in the world and are dominated by species in the subfamily Dipterocarpoideae, the largest subfamily of the Dipterocarpaceae. Species in this family are of major importance in the timber trade and are used for wood, essential oils, balsam and resins. The use of DNA identification methods as a tool for demonstrating compliance in the timber supply chain has grown in the last decade, improving the traceability of tropical hardwoods and supporting legal and responsible forest utilisation. But for groups where species resolution has been challenging, such as the subfamily Dipterocarpoideae, what level of discrimination can be achieved using these methods? For the eight most species rich genera of Dipterocarpoideae, including the complex genus *Shorea*, we have explored the potential of chloroplast and nuclear DNA markers to identify economically important traded timbers from Indonesia and Brunei. First, we compared phylogenies based on the analysis of chloroplast and nuclear data to resolve the complex evolutionary relationships for the species in the subfamily. We then describe the taxonomic resolution achievable using these markers and present DNA identification tests aimed at different end users. We present the most efficient chloroplast genome regions for species identification that can be used to rapidly verify timber identity using Sanger sequencing or similar methods. We also present an array of the most discriminatory single nucleotide polymorphisms (SNPs) for when further discrimination is required and high-throughput sequencing is available. The development of tests using more than one type of marker provides options for a wide range of end users and will ideally increase the uptake of DNA identification tests to rapidly verify timber identity and support a strong and vital international tropical timber trade.

Utilizing NIR light for the non-destructive identification of wood species

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Abstract: Near infrared spectroscopy (NIRS) is an effective and non-invasive method for investigating the properties of materials and it can be used for the identification of wood species. We have utilized NIRS for the identification of wood species used in ancient and culturally significant wooden Buddhist statues, and we were able to achieve a successful separation of wood species using multivariate analyses. We could separate the samples into softwood and hardwood using the full range of NIR wavelengths (830-2500 nm). Furthermore, we obtained higher accuracy using relatively shorter NIR wavelengths (830-1150 nm) than longer ones (1150-2500 nm), for the separation of two look-alike conifer species (*Torreya nucifera* and *Chamaecyparis obtusa, Chamaecyparis obtusa* and *Chamaecyparis pisifera*, *Cryptomeria japonica* and *Thuja standishii*). To determine the factors which can be used to separate the species of wood, light transmittance and reflectance were measured in 21 conifer species using a spectrophotometer equipped with an integrating sphere and light within a wavelength range of 500-1200 nm. Transmittance values varied not only among different species, but also between the sapwood and heartwood in certain species. The intensities increased from about 600 - 700 nm and showed peaks or shoulders in the ranges of 870 - 900 nm and 930 - 950 nm, and at around 1100 nm in all samples. Differences between the spectra of sapwood and heartwood were observed within several species and the patterns of difference were the same between species within the same genus. Peaks at around 1100 nm were observed in both the sapwood and heartwood of all samples. Maximum conductivities of light at these peaks were relatively lower in wood species with helical thickenings (genus *Pseudotsuga*, *Torreya*, *Taxus*). Based on these results, it can be seen that the anatomical characteristics of wood influence the transmittance of light, and make the positive separation of wood species possible with the use of NIRS.

Valorizing xylaria using computer vision-based wood identification: a case study on the INERA-Yangambi xylarium

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Abstract: Xylaria provide crucial reference materials for botanical studies, wood anatomical research, and forensic investigations. However, the accuracy of specimen identification within these collections is not always guaranteed, as specimens with dubious origins can enter collections, risking research integrity. Ascertaining the taxonomy is therefore crucial.

Although a full wood anatomical assessment could theoretically identify all specimens, this process would be impractically time-consuming, requiring years of intensive microtomy work. Artificial intelligence offers a faster, more economical solution. Computer vision-based wood identification uses wood images as diagnostic information to develop models that can distinguish timbers. This method enhances the reliability of xylaria, thereby increasing the trustworthiness of the research performed on them.

The objective of this study was to classify 58 Congolese wood genera through precise multiclass classification. The Xception architecture was leveraged on macroscopic cross-sectional RGB images, utilizing the SmartWoodID database derived from the Tervuren xylarium as training data. A total of 1700 specimens were divided into training (80%) and test (20%) datasets while maintaining species balance. Images were cropped into square patches with a side length of 5.42mm. Five-fold crossvalidation was used for evaluation, and the most performant model was applied to the xylarium of the INERA-Yangambi research center.

Performance was assessed by calculating recall scores for all genera across folds for all patches, and for aggregated results per specimen. The predicted genus for each specimen was determined by majority vote on patch predictions and compared to the specimen's recorded genus. In total, 193 specimens of the INERA-Yangambi xylarium were classified. Among these, 57 specimens were misclassified at the genus level.

This research demonstrates that AI can significantly enhance the accuracy and reliability of xylaria, facilitating more dependable botanical and wood anatomical studies.

World Forest ID - The world's largest geolocated reference database; designed to tackle deforestation with science

T5.16 IAWA-IUFRO Symposium: Advancing Methods and Applications of Wood Identification

Abstract: The illegal timber trade is the most profitable natural resource crime, valued at USD 50-152 billion per year, with up to 90% of tropical timber in global supply chains potentially illegally sourced. In addition, conversion to agriculture is the main driver of tropical deforestation, causing loss of biodiversity, livelihoods and ecosystem function. World Forest ID is a U.S. non-profit organization developing the world's largest georeferenced database of timber and agricultural samples, with the ambition to create a new global standard for credible, science-based verification of species and origin. World Forest ID emerged from a consortium of partners which included the US Forest Service, World Resources Institute (WRI), Royal Botanical Gardens, Kew, and the Forest Stewardship Council (FSC). Our reference database houses (1) geolocated physical wood and forest risk commodity samples collected globally, and (2) analytical data against which species identity and harvest origin claims can be verified. As of April 2023, we have collected over 23,000 wood samples (>9,000 trees, >60 countries and >350 species) and over 1,000 soy, cocoa and coffee beans (> 6 countries). The scientific methods used by World Forest ID affiliated labs include Stable Isotope Ratio analysis, DART-TOF Mass Spectrometry, Trace Element analysis, DNA analysis and wood anatomy (manual and machine vision). These different data types are then combined in machine learning models, together with species distribution and satellite data, to increase the accuracy of both species identity and harvest origin determination. As collections for World Forest ID continue to be carried out across the globe, the reference database and data analysis models become an increasingly valuable tool for both enforcement and industry stakeholders.

T5.17 Inclusion of environmental variables and ecological services as part of the decision process in intensive silviculture: lessons from around the world

A Bio-physically Driven Dominant Height Model for Loblolly Pine Plantations

T5.17 Inclusion of environmental variables and ecological services as part of the decision process in intensive silviculture: lessons from around the world

Abstract: Dominant height (DH) models are commonly used as a productivity drivers for growth and yield systems due to the relative independence of dominant trees average height pattern with respect to stand density. However, scientists have well identified that growth trajectory of DH over time doesn't follow a stationary progress over successive years, being subject to, sometimes, severe stochastic fluctuations. These fluctuations are naturally expected by plant physiologists, as they represent the interaction between the soil physical and chemical properties, and yearly weather variations. One of the main sources for such variations correspond to changes in light interception capacity between sites and within a rotation cycle. To improve projection stability for intensively managed plantations, a model was built to describe even-aged stand leaf area. According to literature, such model, together with incident light, would result in a better productivity indicator. Our leaf area index model incorporates a delay component meant to reflect the influence of past years in carbon accumulation, through a delay differential equation formulation. The height model was calibrated simultaneously with a dominant height model that included leaf area and estimated annual intercepted light as independent variables. Calibrations were done using satellite derived leaf area indices and long-term permanent sampling plots for loblolly pine. Our model showed that sites with higher foliage production capacities correctly influenced higher dominants heights than sites with lower. This empirical model resulted in an easy tool that can be incorporated into traditional growth and yield systems.

A climate driven growth and yield system for clonal Eucalyptus plantations in Brazil

T5.17 Inclusion of environmental variables and ecological services as part of the decision process in intensive silviculture: lessons from around the world

Cristian Montes[1]
Otávio Campoe[2]
[1] University of Georgia, United States of America
[2] University of Lavras, Brazil

Abstract: There has been a renewed interest in implementing systems to forecast *Eucalyptus* plantation productivity using environmental variables, mainly due to the expansion of planted areas to drier sites and predicted climate change. Brazilian *Eucalyptus* plantations are distributed over a very wide climatic range covering many soil classes; therefore, there is a need to include site-specific predictors to allow for a more comprehensive interaction between climate variability and tree growth. That is why a group of 10 companies in Brazil with universities and research institutes started the IPEF-ModProd Cooperative Research Program aiming at producing growth and yield systems that include different clonal *Eucalyptus* genotypes as well as climatic predictors that will allow future spatialized estimates for stand productivity under changing climate. This work presents a growth and yield model that relies on three ecological indicators for the water balance: water deficit, excess water, and available water based on a 60-year (1960-2020) dataset. The model was calibrated to 30 sites for 300+ plots covering more than 3,500 km from north to south of Brazil. Ten different genotypes were included, allowing for specific values for each. Indicators were summarized for each site, accounting for spatial and temporal variations. Variations were an integral part of the system, allowing for better calibration in the parameters. Our new framework increased the site's accuracy and allowed us to include climate (either static or dynamic), with explicit uncertainty associated with productivity prediction.

Changing silviculture tactics if water instead of nitrogen became the limiting factor in the boreal forest

T5.17 Inclusion of environmental variables and ecological services as part of the decision process in intensive silviculture: lessons from around the world

[3] Department of Forest Resource Management, Swedish University of Agricultural Sciences, SE-901 83 Umeå, Sweden

Abstract: The forests in the conifer dominated boreal northern Europe are primarily managed for fibre and high quality timber. Forests available for wood supply in Sweden are predominantly planted stands with Norway spruce (Picea Abies) or Scots pine (Pinus Sylvestris), with long rotations of 50-80 years. Most of the management guidelines used by contractors, companies and the forest agency, originates from experiments and empirical data from the years 1950-2000. The models and guidelines are usually nationwide, using latitude as the covariate explaining for site variation in climate and soil productivity. During recent years we have demonstrated an increased precision in growth and yield modelling and silvicultural guidelines, when replacing fixed attributes of region or latitude, with spatial and temporal dynamic variables. Examples of such variables are water availability, soil moisture indices and available photosynthetic active radiation.

Decades of forest research in Sweden have proved an increased growth with treatments with applied nitrogen fertilization, but similar response have not been demonstrated with irrigation alone. Therefore, limited nitrogen availability has influenced the management guidelines, in terms of tree species selection, spacing, thinnings and rotation length.

However, the recent years with repeated droughts and subsequent secondary stressors on the two major tree species, indicate the need of a shift in management guidelines for conifer plantations in northern Europe, to be able to adapt to water and nitrogen as the limiting factors for sustainable growth and tree health. We have studies on both seedlings and mature trees where water availability and/or precipitation to a certain degree explain results of survival, growth and tree health. Therefore, we suggest new strategies for forest management in Sweden, where the risk of water stress have a significant impact on silviculture tactics.

Modeling radiata pine plantations above and belowground carbon sequestration under contrasting soils at harvesting age.

T5.17 Inclusion of environmental variables and ecological services as part of the decision process in intensive silviculture: lessons from around the world

Rafael Rubilar[1, 2]

[1] Cooperativa de Productividad Forestal, Universidad de Concepción, Departamento de Silvicultura, Facultad de Ciencias Forestales, Concepción, Chile
[2] Centro Nacional de Excelencia para la Industria de la Madera (CENAMAD), Pontificia Universidad Católica de Chile, Santiago, Chile.

Abstract: The increasing demand to mitigate climate change effects have fostered the adoption of forest plantations as strategies to ensure a sustainable timber supply and serve as carbon sinks. This study focuses on the critical need to understand and quantify the whole rotation long-term effects of Pinus radiata plantations as above and belowground carbon sinks and drivers of soil carbon stocks under contrasting soil-site conditions. We model the relationship between forest productivity at harvesting age and whole site (plantation & soil) carbon sequestration.

We selected 10 sites on volcanic ash soils (Paleudalf) and sandy soils (Xeric Psamments) and quantified the accumulated carbon in aboveground biomass and belowground biomass using local allometric equations and in situ measurements of forest floor (litter and surface residues) and mineral soil (up to 1 meter deep). Our findings indicate that plantations on volcanic ash soils showed a significant correlation between stand volume and total site carbon stock ($r2=0.73$, $p< 0.001$), with an average of 444.1 Mg C ha^{-1}. Carbon was primarily accumulated in the mineral soil (57%), followed by total biomass carbon (40%). At sandy soils a significant correlation between stand volume and aboveground biomass carbon was observed ($r2=0.71$, $p< 0.001$), with an average total carbon of 315.8 Mg ha^{-1} distributed 51% in aboveground biomass (51%) and 43% in the mineral. Carbon in the forest floor at both sites was less than 6%.

Our study underscores the importance of incorporating soil and climate attributes into forest productivity models. Our findings provide a deeper understanding of the potential of Pinus radiata as a carbon sink for climate change mitigation and lay the groundwork for the development of models estimating intensively managed forest plantations whole site carbon accumulation and base lines for intensively managed plantations sustainability.

Modelling of radiata pine productivity using 3-PG to estimate the effect of subsoiling, fertilization, and weed control on a gradient of soils

T5.17 Inclusion of environmental variables and ecological services as part of the decision process in intensive silviculture: lessons from around the world

Abstract: Understanding the site-specific effects and intensive silviculture on forest plantations is essential to maintain and improve productivity and carbon sequestration, especially in the context of climate change. Therefore, evaluating the long-term effects of early silvicultural treatments serves to justify these practices and model forest productivity. *Pinus radiata* D. Don is one of the most planted conifers in the world, however, few studies have evaluated the effect of early silvicultural treatments on forest productivity up to harvest age. Our objective was to evaluate rotation length growth responses of radiata pine to soil preparation, fertilization, and weed control at three contrasting sites and evaluate the 3-PG (Physiological Processes Predicting Growth) model on prediction of long-term silvicultural responses. We evaluated sites in the central valley of Chile, corresponding to an excessively drained dry sand (DS), a well-drained and compacted red clay (RC) and a well-drained highly fertile recent volcanic ash (RV) soil. These soils-sites represent a broad range of site conditions where radiata pine is planted in Chile. Stands were established in 2000 with 4 blocks in a split plot factorial design that included soil preparation (subsoiling vs shovel) as main plots, and fertilization at planting (only B vs NPKB) and weed control (none vs 2 year banded) as factorial randomized treatment plots within the main plots. Annually diameter at breast height and height were measured, and survival and cumulative volume were estimated for each treatment. Rotation age results for cumulative volume showed that early gains from weed control were increased over time at the DS site (20% gain), maintained over time for RC site (8% gain) and lost over time for RV (7% loss). Fertilization had the greatest response at the RC site (8% gain), small responses at the DS site (2% gain) and negative responses at the RV site (4% loss). Interestingly, subsoiling showed null or negative responses at the three sites and negative effects increased over time (decreasing to a 20% loss at RV site). Given site-specific responses and silvicultural treatment, we will model productivity using 3-PG and the effect of these silvicultural practices and implications under climate change scenarios.

Productivity of Norway spruce and Scots pine in Sweden

T5.17 Inclusion of environmental variables and ecological services as part of the decision process in intensive silviculture: lessons from around the world

[3] Skogforsk (The Forestry Research Institute of Sweden), Ekebo 2250, 268 90 Svalöv, Sweden

Abstract: Scots pine (*Pinus sylvestris* L.) and Norway spruce (*Picea abies* L. Karst.) are the two most important commercial tree species in Sweden. Despite the rich tradition of silvicultural research and experience in cultivating both species, there is still a lack of comprehensive studies comparing their growth at the same sites. This study aimed to examine differences in productivity between the two species in Sweden based on a set of long-term plots established to investigate stand production of both species. The single-species plots were planted in close proximity, thus ensuring very similar site conditions. Long-term stand development was simulated from the inventories performed in 102 locations with species comparisons, representing a wide range in fertility (100-year site index range 15-38 m) and geography. Productivity was assessed in terms of full-rotation mean annual increment (MAI). On average, Scots pine yielded 35.4% higher MAI compare to Norway spruce at low and medium fertility sites, whereas at high fertility, Norway spruce had a 13.4% higher MAI. Results from this study indicate that from a production point of view, Norway spruce should only be planted on the most fertile sites exceeding a site index of ~31 m. This outcome is contrary to majority of the previous findings and general recommendations for forestry management in Sweden.

Relationship between topography and growth of Colombian Pine in the Colombian Andean zone

T5.17 Inclusion of environmental variables and ecological services as part of the decision process in intensive silviculture: lessons from around the world

Edilber Sebastian Guerrero Martinez[1]
Diana Camila Zuñiga Buitron[1], Adriana Maria Marin Velez[2], Dylan James Craven[3], Jorge Andres Ramirez Correa[1]
[1] Universidad del Cauca
[2] Smurfit Kappa Colombia
[3] Universidad Mayor

Abstract: Colombia, known for its diversity of native woody tree species, predominantly relies on exotic pines and eucalyptus for commercial reforestation due to their established technological packages ensuring long-term productivity. However, the use of exotic species remains a controversial topic, requiring the study of native timber species for future commercial reforestation projects. *Retrophyllum rospigliosii* (commonly known as Colombian Pine), a native conifer with promising morphological characteristics, emerges as a viable candidate for commercial reforestation. To evaluate its suitability, Smurfit Kappa-Carton de Colombia established an experimental 12-hectare plantation in the department of Cauca (southwest Colombia) in 1998. This study aims to assess the relationship between topography and the growth of *R. rospigliosii* in the Colombian Andean zone, employing topographic variables to estimate its site index. Height growth data from 30 plots which has been subject to ongoing monitoring for the last 20 years, were utilized to derive site index information, and eight topographic variables were generated using a photogrammetric digital elevation model. The site index equation was modeled using the Bertalanffy model, yielding an R^2 value exceeding 98%. This model was used to generate three site index classes ranging from 9.2 to 16.6 meters. Principal component analysis identified aspect, profile curvature, and plant curvature as the most important topographic variables, explaining 86% of the site index variability. Remarkably, areas with a western aspect and convex curvatures exhibited higher growth, suggesting that *R. rospigliosii* thrives in microsites with reduced light and nutrient availability due to lower water flow. Given the difficulty of controlling topography through forest management practices, the species' selectivity for specific microsites and its relatively low growth rate, the practical feasibility of using *R. rospigliosii* in commercial reforestation appears questionable. Consequently, further research is needed to explore alternative native timber species that better meet the requirements of large-scale reforestation projects in Colombia.

Vegetation Management Effects on Early-Seral Native and Non-Native Vegetation Abundance, Species Richness, and Diversity in the Pacific Northwest

T5.17 Inclusion of environmental variables and ecological services as part of the decision process in intensive silviculture: lessons from around the world

Emily Von Blon[1]
Carlos Gonzalez-Benecke[1]
[1] Oregon State University, Dept. of Forest Engineering, Resources, and Management, United States

Abstract: The long-term productivity and success of forests are strongly dependent upon seedling performance during the first few years following planting. Given that the Pacific Northwest of the United States (PNW) experience severe summer droughts that result in intense competition for soil water resources, competing vegetation management (VM) is critical for successful seedling establishment. However, to ensure sustainable forestry, it is necessary to understand the effects of silvicultural treatments, particularly VM, on ecosystem services such as native and non-native species richness, diversity, and abundance. The Competition and Site Interactions Experiment (CoSInE) began in 2016 to understand the effects of VM regimes on seedling physiology, growth and survival, as well as early-seral vegetation community characteristics across the diverse landscapes of the PNW. CoSInE includes 11 sites installed in Oregon and Washington States, that each involves 8 treatment plots with a combination of a pre-planting herbicide application and a post-planting herbicide application during the first and second growing seasons. An inventory of height, diameter, and health status for all 64 Douglas-fir seedlings within each treatment plot was conducted annually during the dormant season. During the peak of each growing season, an assessment of vegetation abundance and height by species is conducted in the five 3 m^2 permanent vegetation plots installed within each treatment plot. The effects of the VM regimes across all sites on native and non-native species richness, vegetation abundance, and diversity of different growth forms (forbs, ferns, graminoids, shrubs and brambles) throughout the first 5 growing seasons were evaluated. While results were site-specific, they suggest that, across all sites, by growing season 5 for all native and introduced species, there was no VM effect on abundance and species richness but continued effect on diversity. For native species, there was no VM effect on species richness and diversity but continued effect on vegetation abundance. Results on each growth form will be presented. Our results indicate a short-term effect of VM on reducing early-seral vegetation abundance and diversity, generally ranging 1 or 2 years after herbicide application.

T5.18 Initiatives and Equity for Forest Education in a New Era

BioEquality – gender equality in the Nordic bioeconomy

T5.18 Initiatives and Equity for Forest Education in a New Era
Sofie Andersson[1]
Mimmi Blomquist[1], Anna Meisner Jensen[1], Tatiana Proisy[2], Elsa Ramberg[1], **Jonas Rönnberg**[1], Annie Roos[3], Maria Tunberg[1, 2]
[1] Swedish University of Agricultural Sciences (SLU, Sveriges lantbruksuniversitet)
[2] Analysys Mason
[3] Linnaeus University (Linnéuniversitetet)

Abstract: The BioEquality project addresses gender inequality in the Nordic bioeconomy, it focuses particularly on forestry and agriculture which are two of the region's most gender-segregated sectors. Digitalisation and increased automation of heavy work could benefit gender equality in the sectors. However, this has not yet happened. The project therefore aims at exploring how the digital transformation impacts gender equality among young individuals in the Nordic bioeconomy and how digital development can be leveraged to advance gender equality.

It is believed that to create opportunities for influence and participation in the digital development of the bioeconomy, it is necessary for tomorrow's employees -whom are today's students- to gain a deeper understanding of this problem and be involved in identifying and implementing solutions. To support this objective, various methods were implemented. A systematic literature review, interviews and focus groups with experts led to the redaction of an academic article as well as a handbook. It is specifically designed for teachers and students in forest and agricultural education. The method handbook consists of easily accessible texts, videos, podcasts and other material aiming to create a common understanding of the subject and its challenges and facilitate conversations to create participation and ownership over the issue.

A second phase of this project, currently in its pilot phase, aims to invest further in the future of forestry and agriculture by focusing on a younger audience, namely students between 12 and 15 years old. Study visits are offered to learn more about how AI is used in agriculture and forestry. The visits are organised at technology testbeds for the digital bioeconomy, i.e. environments where businesses, academia and other organisations can interact in the development, testing and introduction of new products, services, processes, or organisational solutions. By visiting the testbed and experiencing digital innovations pupils will get a deeper understanding of what it means to work with AI and digitalisation in the bioeconomy. Expected results are an increase in young girls' interest in studies in digitalisation and hopefully in the future, a decreased gender gap in the sectors.

Current Status of Forest Science Education in Undergraduate Universities in Japan

T5.18 Initiatives and Equity for Forest Education in a New Era

Mariko INOUE[1]
Katsuaki SUGIURA[2], Sumire KAWAMOTO[3]
[1] Tama Forest Science Garden, Forestry and Forest Products Research Institute
[2] Nihon University
[3] Forestry and Forest Products Research Institute, retired

Abstract: In the new era, where global trends are shifting towards sustainable forest management, this study highlights the current state of Japanese forest education to introduce regional differences worldwide.

The Japanese school education system has been controlled by the Ministry of Education, Sports, Science and Technology. In 1991, universities underwent educational reforms that were implemented by the Ministry. This study conducted a nationwide survey in 2021 to investigate the status of forest science education in universities and colleges.

The survey included faculty members from 27 schools, with 25 having existing forestry curricula and two being newcomers. These schools were categorized into three types based on their education system for university faculties and departments: eight schools had specialized forest science divisions within departments, ten schools had dedicated forest science courses in departments of agriculture, and seven schools had forest-related specialized subjects in comprehensive divisions in departments of agriculture.

Approximately 6,000 (0.2% of the total number of university students) students were enrolled in forest science-related programs, with a male-to-female ratio of 6 to 4. Around 400 teachers, including those specializing in wood science, were involved in forest science education. Roughly half of the graduates entered the workforce, while about 40% continued their studies in graduate school. Around half of the graduates from forest science courses pursued careers in forest management, including positions in government agencies, forestry associations, and private companies, such as forestry extension supervisors and professional engineers.

The curricula of 30 educational courses across 24 schools offered a variety of subjects, with 400 required subjects and 714 elective subjects. Educational programs were classified into three types based on their inclusion of forest science content: 12 schools offered diverse forest science content as required subjects, 10 schools provided various forest science content as electives, and 4 schools offered only a limited number of forest science subjects. Determining the key elements of forest science education was challenging due to the differing approaches.

In conclusion, it is necessary to reexamine forest science education in undergraduate universities and include essential content that aligns with social demands, particularly in the context of professional human resource development.

Developing an inclusive and interdisciplinary training program on "forest-based climate solutions"

T5.18 Initiatives and Equity for Forest Education in a New Era

Jacob Bukoski[1]
Loren Albert[1], Quintana Clark[2, 3], Erica Fleishman[4], Reem Hajjar[1], Suhyun Jung[1], David Lewis[2], Rajat Panwar[1, 5], Chris Still[1], Martin Storksdieck[6]
[1] College of Forestry, Oregon State University, USA
[2] College of Agricultural Sciences, Oregon State University, USA
[3] College of Education, Oregon State University, USA
[4] College of Earth, Ocean, and Atmospheric Sciences, Oregon State University, USA
[5] College of Business, Oregon State University, USA
[6] STEM Research Center, Oregon State University, USA

Abstract: Forest-based climate solutions are being promoted globally to provide benefits such as sequestration of atmospheric carbon, habitat for species, and improvement of rural livelihoods. Yet scientific uncertainties, governance challenges, and a limited workforce constrain the development and implementation of effective policies and initiatives for forest-based climate solutions. To address these challenges, we are developing an inclusive, interdisciplinary training program on forest-based climate solutions at Oregon State University. In this talk, we will describe the design of this program, including our incorporation of current pedagogy on inclusive and effective education in science, technology, engineering, and mathematics (STEM), as well as the expected learning outcomes for participants. Key features of the program include i) cohort- and team-based learning focused on research projects relating to forests, society, and climate change, ii) the engagement of faculty and participants from five different colleges across the university (the Colleges of Forestry; Earth, Ocean, and Atmospheric Sciences; Agricultural Sciences; Business; and Education), iii) field-based workshops and intensive bootcamps to develop key skills, and iv) internships at policy and research institutions. We will also discuss our plans to make the program inclusive and accessible, including recruitment, retention, and support of students from under-represented groups, and engaging Oregon State University's online education platform, the Ecampus. Our talk will exemplify our efforts to create a modern, inclusive, and interdisciplinary program that is responsive to a growing theme (forest-based climate solutions) within global forest education.

EUROSILVICS: Open-access repository for education support in silviculture and forest ecology

T5.18 Initiatives and Equity for Forest Education in a New Era

Frits Mohren[1]

[1] Department of Environmental Sciences, Wageningen University and Research, Wageningen, The Netherlands

Abstract: Increasingly, academic teaching in silviculture and forest management is part general BSc and MSc programmes in environmental sciences, land use, and resource conservation and management. As a result, dedicated teaching and disciplinary knowledge in silviculture and forest management may receive less attention. While this allows emphasis on problem solving skills and academic competences, it also calls for alternative means to provide access to classical forestry topics such as silviculture and forest management. The EUROSILVICS project, funded by the Erasmus+ Collaborative Partnership programme, is carried out to make traditional, disciplinary knowledge in silviculture and forest management available for use in a wide array of teaching, ranging from academic programmes in forestry and forest management, to professional teaching and vocational training in forest ecology, silviculture and forest management.

EUROSILVICS creates a common digital resource for higher education in forestry, based on a repository with educational material of the participating institutions made available as an Open Access Library for Learning. Education material in national languages will be reviewed, and translated into English to allow for international use. The project involves 6 European universities: Leuven University (prof. Bart Muys, BE), Ghent University (prof. Kris Verheyen, BE), the Austrian University of Life Sciences BOKU (prof. Hubert Hasenauer, AT), Eberswalde University for Sustainable Development (prof. Peter Spathelf, DE), and the Swedish University of Agricultural Sciences SLU (prof. Gustaf Egnell, SE), and is coordinated by Wageningen University and Research WUR (prof. Frits Mohren, NL).

The project is centred around the establishment of a dedicated open access platform for forestry education material, both basic and applied, including supplementary material as exercises, excursions, and links to relevant websites. The project includes a robust review and editing procedure for quality assurance, links to other open sources and to repositories of professional associations, and outreach to individual users as well as other institutions involved in forestry-related education.
The project runs from 2022 and 2025, and aims to contribute to education in forestry in Europe and elsewhere, and to wise and sustainable management and use of forests as nature-based solutions for resource supply in the bioeconomy and for climate mitigation.

Forestry Capacity Building in Climate Change

T5.18 Initiatives and Equity for Forest Education in a New Era

Soozin Ryang[1, 2]
Yeongjoo Lee[1, 2]
[1] Asian Forest Cooperation Organization (AFoCO)
[2] AFoCO Regional Education and Training Center

Abstract: With the Paris Agreement on Climate Change becoming effective in 2016 with the membership of 195 nations, the global society firmly entered the epoch of climate change. Nations initiated the setting of voluntary greenhouse gas reduction targets, subsequently necessitating the development of reduction strategies tailored to each sector. Globally, major greenhouse gas emitters encompass electricity and heat production, agriculture, forestry, land use, construction, transportation, industry, and various other energy sectors. Currently, the forestry sector contributes to 14% of the total carbon emissions, a relatively modest percentage compared to other sectors. However, it is also among those sectors with the most significant potential for reduction, anticipated to decrease present emissions by 75% by 2030. Indeed, the forestry sector stands as the solitary mitigation agreement achieved during the Paris Agreement, and it remains the only greenhouse gas sink acknowledged by the United Nations. In a carbon-neutral scenario projected for 2050, the forestry sector is expected to generate approximately two million new jobs. Although modest when compared to other sectors, this figure underscores the importance of human resource development, particularly given the anticipated impact of the forestry sector on climate change. Therefore, as each country develops climate change and carbon-neutral scenarios, addressing the issue of human resource development for the forestry sector becomes crucial. Grounded on this premise, this paper intends to articulate how future talent development in the forestry sector can be approached, employing AFoCO's roadmap as a guiding framework.

Forestry Education in the AI Era: Challenges, Opportunities, and the Transformative Impact of AI on Teaching and Learning

T5.18 Initiatives and Equity for Forest Education in a New Era

Guangyu Wang[1]
Suzy Zeng[1], Joris Jun[1], **Anil Shrestha**[1], Kebiao Huang[2], Cao Long[2]
[1] APFECM, Faculty of Forestry, University of British Columbia, Vancouver, BC, V6T 2E9, Canada
[2] Asia-Pacific Network for Sustainable Forest Management and Rehabilitation, Beijing, China

Abstract: In the rapidly evolving era of Artificial Intelligence (AI), forestry education faces both challenges and opportunities. This talk will explore the implications of AI and online teaching methods on forestry education, highlighting the potential for transformative learning experiences and the need to address associated challenges. The presentation will discuss the role of AI in forestry education and its impact on traditional teaching approaches- how AI technologies, such as machine learning algorithms and data analytics, can enhance forest-related research, management, and decision-making processes; how AI can assist in bridging gaps in access to education, facilitating remote learning, and fostering collaboration among students and professionals; and how AI-based tools can enhance forest monitoring, conservation planning, and sustainable management practices. Additionally, the talk emphasizes the importance of adapting forestry education to leverage the benefits of AI while mitigating potential risks. It calls for a balanced approach that combines technical skills, critical thinking, and ethical considerations in preparing future forestry professionals for the challenges and opportunities in the AI era.

High-Quality Education Equity in China Forestry Higher Education: A Practical Research from the Perspective of Sino-Foreign Cooperation in a New Era

T5.18 Initiatives and Equity for Forest Education in a New Era

JIN WANG[1]
RUOYI CHEN[1], **YIZHONG FU**[1]
[1] International relations office,Beijing Forestry University

Abstract: Teaching quality is the key to talent cultivation in universities. The past decade has witnessed the trend of the China higher education from popularization to universalization, thereby the focus of forestry higher education in China has been transitioning from education equality to education quality. Based on collaborative cultivation of international innovative talents and international collaborative innovation in scientific research, Chinese forestry-related universities are striving to promote the adjustment of the connotation, form, and global layout of Sino-foreign cooperative education. And by establishing a Sino-foreign cooperative education platform, efforts have been made to introduce international advanced discipline construction experience and achievements, strengthen the construction of basic disciplines, emerging disciplines and interdisciplinary disciplines, ensuring the continuous improvement of the quality of world-class forestry higher education in line with China's national conditions and benchmarks. Via the integration, coordination, and exploration of not only local consciousness and cultural feelings, but also global perspective and modern concepts, a set of high-quality teaching quality assurance system, which is generally recognized by students and their parents, has been established for the entire process of student development, in response to new challenges of imbalanced and insufficient forestry higher education, helping to promote the comprehensive green transformation of economic and social development in a new era.

Innovative Sustainable Forest Management Education in the Asia-Pacific Region

T5.18 Initiatives and Equity for Forest Education in a New Era

Suzy Zeng[1]
Guangyu Wang[1], Anil Shrestha[1], Hailan Chen[2], Chris Crowley[2], John Innes[1], Shiyi Zhang[3]
[1] Asia Pacific Forestry Education Coordination Mechanism (AP-FECM), Faculty of Forestry, University of British Columbia (UBC), Canada
[2] Centre for Teaching, Learning and Technology, University of British Columbia (UBC), Canada
[3] Asia-Pacific Network for Sustainable Forest Management and Rehabilitation(APFNet), Beijing, China

Abstract: The concept of Sustainable Forest Management (SFM) has emerged globally as an essential element for the sustainability and conservation of the world's forests. Regional gaps exist in how to continually and equitably update forestry professionals and practitioners around the world with new knowledge of SFM and new technologies to manage natural resources and implement effective policies. Providing global access to open and credential high-quality education resources and opportunities becomes extremely important to narrow the regional gaps and improve SFM practices.

To address the challenges, a joint educational online program entitled Innovative Sustainable Forest Management Education in the Asia-Pacific Region was initiated in 2014. Content experts from regional forestry universities in the Asia Pacific Forestry Education Coordination Mechanism (AP-FECM) network were invited to develop coursework and formed an international collaborative development team with broad knowledge of SFM. A total of 14 online graduate certificate courses were developed with their fundamental content as Open Educational Resources (OER).

As the only SFM online program of its kind, since 2016, the joint educational program provides world-class forestry education resources created and supported by leading professors and experts from internationally recognized universities around the world. Its OER courses reached out to over 15,000 learners from over 90 international economies and its instructor-led repurposed OER Courses by AP-FECM had over 3800 learners from over 135 universities, based on our records before and during Covid-19 Pandemic until 2020.

As a key unit to operate and manage the project, the Executive Office (EO) of the AP-FECM is responsible for continuously encouraging global utilization of the curriculum and increasing international recognition of the project. Phase III of the project will be on agenda in 2023 to have another handful of courses developed. More relevant content experts are sincerely invited here to join the great effort toward promoting Sustainable Forest Management and increasing equity in forest education around the world.

INTERNATIONAL COLLABORATIONS TO COPE CHALLENGES OF FORESTRY EDUCATION IN NEW ERA: A SUCCESS STORY

T5.18 Initiatives and Equity for Forest Education in a New Era

Mohammed Al Amin[1]
[1] UNIVERSITY OF CHITTAGONG, INSTITUTE OF FORESTRY AND ENVIRONMENTAL SCIENCES

Abstract: This study examines international collaborations on forestry education of Bangladesh and focused the contributions on gender equity and strengthening the capacity of students to cope the challenges of forestry sector from local to global scale. Forestry education of Bangladesh had a serious setback on gender equity before 1985. As no female student was admitted in Institute of Forestry and Environmental Sciences, University of Chittagong (IFESCU), the pioneer national institution on forestry education. A paradigm shift of forestry education took place in 1985 when FAO and UNDP lead initiatives came enforce as a collaboration project at IFESCU. The collaboration opens the door for female students successfully and introduced a new curriculum to meet the demand of pro-people forestry as earlier forestry education of Bangladesh built on British colonial regimented, white-collar mechanism. On the other hand, another serious impediment faced by the forestry education at IFESCU during COVID19 pandemic, when all the (in person) class room activities were stopped for 565 days and lead the academicians to think alternate ways like using online platforms particularly accustomed to flipped classroom (good example(s) google classroom, zoom platform). Again, IFESCU embraces collaboration initiative with Asia Pacific Forestry Education Coordination Mechanism (APFECM) and participated APFCEM designed and University of British Columbia delivered online courses particularly on sustainable forest management, geospatial sciences and helped to redesign new curriculum introducing new arena of knowledge on global change, biodiversity conservation, forest-people conflict management, landscape level restoration, geo-spatial technological interventions, invasive species management, carbon management and trading, panel wood and wood processing to meet the global to local demand. More than 2000 graduates with 367 females were passed from IFESCU, employed and successfully served at home and abroad. This study discussed all prospects and constraints of collaborations. And concludes that international coordinated collaboration mechanisms may pave the way of success for developing nations to get global standard of graduate to meet the future demand in new era, The collaborations act as knowledge bridge between developed and developing world with generic nature, may be implemented another part of the world.

Proposing innovative competence-based training experiences to enhance forest management through a blended approach.

T5.18 Initiatives and Equity for Forest Education in a New Era

Elena Andriollo[1]
Thomas Campagnaro[1, 2], Lisa Wolf[3], Jana Baumgartner[3], Mauro Masiero[1], Neil McIntosh[4], Tommaso Sitzia[1, 2]
[1] Department of Land, Environment, Agriculture and Forestry, Università degli Studi di Padova (Italy)
[2] National Biodiversity Future Center (Italy)
[3] E.C.O. Institut für Ökologie (Austria)
[4] EUROPARC Federation (Germany)

Abstract: Biodiversity loss is one of the most pressing environmental challenges that humanity is facing. Within the European context, the Bird and Habitats Directives are pivotal to preserve and restore biodiversity by creating a network of protected areas across the EU territory, called Natura 2000. These Directives have been recently strengthened through the EU Biodiversity Strategy to 2030 which commits to restore forest ecosystems and protect old-growth forests. Nevertheless, their implementation state is considered insufficient due to the lack of skills to plan, manage, and restore Natura 2000 sites. Increasing the capacities of protected area managers through training is seen as a crucial aspect to achieve effective biodiversity governance. LIFE ENABLE (LIFE20 PRE/DE/00009) project aims to build practical skills among Natura 2000 and Protected Areas managers to address current and future challenges in nature management by creating a European competence-based training system called "European Nature Academy". Through the analysis of previous learning activities, the identification of knowledge and skill gaps, and the acknowledgement of the most successful training approaches, LIFE ENABLE aims to create new training opportunities to empower managers to address their needs. One of the courses developed within LIFE ENABLE is the "Forest Course" which aims to increase the capacities of managers working in forest habitats. The course is focused on forest ecosystems, including forest species and habitats and their ecology, and considering the planning and management of Natura 2000 sites. The initiative aims to develop, deliver, and test innovative training approaches, which combine blended learning with field experiences. Learners can improve their knowledge on jurisdictional, managerial, and ecological aspects characterizing forest-protected areas and apply newly acquired knowledge practically in the field. Additionally, the course allows learners to meet other managers working across the EU territory, exchange ideas or experiences, establishing a new expert and peer-to-peer network from which future collaborations opportunities might emerge across Europe.

The course is designed to meet the needs underlined by managers, such as ensuring learner-provider interactions, proposing replicable and scalable solutions, fostering a proactive role by local actors, sustaining collaborations across Europe, and ultimately supporting an effective implementation of biodiversity-oriented policies.

Social spontaneity as a mediator of associations between naturalistic settings visit frequency with caregivers and children's problem-solving ability

T5.18 Initiatives and Equity for Forest Education in a New Era

Hye-Jung Cho[1]
Suji Jung[2], Jo Jang-Hwan[3]
[1] Department of Child Development and Family Studies, Seoul National University,
[2] Department of Psychology, University of California San Diego, La Jolla, CA, USA
[3] Department of Forest Sciences and Landscape Architecture, Wonkwang University

Abstract: Children's exposure to naturalistic settings is declining, despite the positive link between play in naturalistic settings, learning, and development. Alternative educational initiatives such as visiting forests or implementing nature-based learning opportunities are increasing in popularity in Korea and internationally, yet little is understood about their impact on children's development. In this study, we examine the mediating role of social spontaneity (a positive social relationship with peers, and the ability to easily get involved in peer groups) on the relationship between naturalistic setting visit frequency with caregivers and children's problem-solving ability. A total of 862 Korean mothers with preschool-age children (3 to 5) were recruited for survey administration. The result of mediation model with PROCESS macro supported the partial mediating role of social spontaneity, indicating that naturalistic settings visit frequency with caregivers leads to better problem-solving ability both directly and indirectly through enhancing social spontaneity.

key words: forest, naturalistic settings, problem-solving, social spontaneity, forest visit with caregiver

T5.19 Innovating advisory systems to cope with complex forest governance

Agroforestry advisory services at the intersection of agriculture and forestry in Finland

T5.19 Innovating advisory systems to cope with complex forest governance

Tanja Kähkönen[1]
John Casey[2], Michael den Herder[1]
[1] European Forest Institute
[2] Teagasc

Abstract: Agroforestry is a land use system at the intersection of agricultural and forestry land uses. In Finland agricultural and forestry advisory services are in their own silos with agricultural advisory services being targeted to farmers and forestry advisory services targeted to forest owners. Whereas navigating purely agricultural and forestry advisory services is rather straightforward, the case is not the same for those who need advisory services in agroforestry. However, as agroforestry is a new, yet previously common land use practice in Finland, there is a need to have more targeted advisory services on it as opposed to having advisory services on conventional agriculture and forestry only. The Agroforestry Business Model Innovation Network (AF4EU) aims at promoting agroforestry in Europe through innovation driven interactive regional agroforestry innovation networks involving stakeholders from across the value chain in a multi-actor manner with Finland being one target country for it. In this study we explore perceptions of different stakeholders, namely farmers and advisors, on agroforestry advisory services in Finland focusing especially on advisory services on agroforestry related business models. Opportunities, barriers, and challenges that farmers associate with agroforestry and agroforestry related business models are explored. The data is collected through interviews and surveys targeted to stakeholders participating in the regional agroforestry innovation network in Finland. Besides farmers' and advisors' perceptions, we explore the regulatory framework for agroforestry in Finland in relation to developing agroforestry advisory services suited for local conditions. The results of this study bring new insights to policy makers, researchers, and advisors to develop advisory services on agroforestry in Finland and beyond, particularly in those regions where agroforestry is not among the mainstream land use practices.

Alternatives and openings for forest pluralism: Participatory research for democratic advisory and decision-making in Swedish forestry

T5.19 Innovating advisory systems to cope with complex forest governance

Elias Andersson[1]
Luis Andrés Guillén[2]
[1] Department of forest resource management, Swedish University of Agricultural Sciences
[2] Southern Swedish Forest Research Centre, Swedish University of Agricultural Sciences

Abstract: The demand for diversified forestry in Sweden has been widely acknowledged for a long period, but its realization is lagging, highlighting the need for substantive changes in implementation. Previous studies have underlined the dominant and hegemonic position of present regime of the "Swedish forestry model"; focused on e.g. even-aged and clear-cut forestry, timber production, a high degree of Norwegian spruce or Scots pine monocultures and an advisory system that is dominated by timber purchasing organizations, that hampers innovations of forest management. By scrutinizing and challenging present procedures and knowledge production for forest advisory services and planning, this study aims at exploring behavioral, organizational, technological, socio-ecological challenges and openings for transformative, as well as incremental, changes towards a more diversified forest management, as well as the condition of agonism and pluralism in forest-related knowledge production, participatory processes, management, service provision and planning. To facilitate the demand for more diversified management that better matches forest family owners' needs and societal goals, we undertake a number of participatory processes that combines an organizational understanding of advisory, through private and public advisory organizations, with a poststructuralist approach to knowledge production on advisory and forest management within women forest owner's networks. The focus is on challenging hegemonic positions, knowledge, practices and understandings by investigating equivalence and differentiating logics as basis for alternatives, collective identities, subjectivities, resistance and discursive spaces to improve the understanding of advisory, relations, agency and democratic decision-making processes in private forest ownership beyond normative rationales.

Forest advisors' values and attitudes impacting on the outcome of the advisory process

T5.19 Innovating advisory systems to cope with complex forest governance

Anne Matilainen[1]
Merja Lähdesmäki[1], Outi Hakala[1], Sami Kurki[1]
[1] University of Helsinki Ruralia Institute

Abstract: Forest advisory processes are typically facilitating forest policy goals to the practical level. Thus, no wonder that several studies have analyzed the factors affecting the outcomes of forest advisory processes. Some of them have considered the role of the forest owners as a target group, while others have concentrated on the importance of tailoring the advising processes and methods for different kinds of forest owner types. However, significantly less focus has been put on the forest advisors' role, even though their impact on the advising process is equally important.

The forest advisors' personality, values, attitudes towards forest management, and behavior influence how and what information is brought to the discussion with forest owners, which in turn impacts on the success of the advising process and further achievement of forest policy goals. Through understanding the effect of these issues, service providers can consciously change their advising methods to improve their performance.

This study aims to understand how the forest advisors' personal opinions, attitudes and values influence the advising processes. For this, an e-questionnaire was sent out to the Finnish Forest Centre advisors (n=50). In addition, the characteristics of the advised forest owners, outcome of the advising process in a form of implemented forest management activities, the used contact method as well as the general customer feedback were collected from the Forest Centre's database. The data was analysed by using statistical methods. The results revealed that the more positive opinion the advisers had on the forest owners' own skills and knowledge regarding forest related issues, the better was their success rate in the advising process. In addition, for example the advisor's age and sex compared to the ones of advised forest owner had an impact on the success rate.

Forest certification and extension service as tools for efficient transfer of knowledge for forest smallholders

T5.19 Innovating advisory systems to cope with complex forest governance

Antonio Brunori[1]
William Hubbard[2], Becky Barlow[3], Jeff Stringer[4]
[1] PEFC Italy
[2] University of Maryland
[3] Auburn University
[4] University of Kentucky

Abstract: Sustainable Forest Management certification is a recognised tool to support sustainable development in forest management, and it is developed in all Continents since the early 90s. The role of extension, advice, and knowledge systems for the growth of this important tool has been crucial in several Countries, but in specific cultural contexts it was more successful than in other. In this contribution, we wish to describe and explore the different approaches in bringing forest certification (and the related chain of custody certification) in several Country contexts with different advisory systems, describing positive or negative results in implementation.

Forest-related Advisory Service Providers in Japan: From Extension System to Networking

T5.19 Innovating advisory systems to cope with complex forest governance

Ryoko Ishizaki[1]
[1] Forestry and Forest Products Research Institute

Abstract: The Japanese forestry extension system was introduced to Japan after World War II under the direction of the United States. The extension system operated in the 1950s and 1960s as a primary policy instrument for small-scale forest owners but was later relatively neglected, as the government focused on public investment. However, interest in advisory services in Japanese forest policy has increased recently, enhancing and encouraging knowledge interchanges through diverse means.

This study aimed to understand (1) the development of the forestry extension system in Japan with a focus on knowledge generation and power balance, (2) recent changes in forest-related advisory services and their contexts, and (3) the characteristics of advisory service providers in Japan.

Instead of a top–down approach, voluntary self-learning was emphasized for forest owners in the early stage of the forestry extension system during the 1950s. However, the extension system was gradually transformed into a means of directing responses to occasional government priorities. In the latter part of the first decade of the 21st century, the government again began to focus on personnel training to deliver forestry advisory services. However, this did not necessarily mean that it unfolded within the forestry extension system. Conversely, discrete actors exhibited a growing move to form networks through which they could share forest-related information and learn from each other. Such networking endeavors were characterized by the diversity of forms and participating members. Essentially, these networking initiatives comprise voluntary activities undertaken by forest owners and other actors. However, forest administrations often provide networking opportunities and contribute to the gathering of a wide-ranging group of actors. Forest-related service providers now seem to exist in a variety of forms and are engaged in seemingly chaotic relationships instead of functioning within an organized system.

How does a systems approach guide our understanding of forest advisory services?

T5.19 Innovating advisory systems to cope with complex forest governance

Anna Lawrence[1]

[1] Centre for Mountain Studies, Perth College UHI, University of the Highlands and Islands, UK

Abstract: Forest advisory services can be understood as a system, which consists of the stakeholders (e.g. the various service providers and forest owners) and linkages between them (modes of communication, tools and methods) in service to objectives (management and policy goals). Our conceptualisation of this as the FOrest Knowledge and Information System (FOKIS) in 2020 was modelled on parallel analysis of the AKIS in agriculture. Most users of this paper focus on its description of patterns and trends in ownership, advisory service provision and methods. The systems element of the approach has received less attention. This paper revisits the value of such an approach (a) as an guiding concept to who is participating, in what, why, and how, in different contexts; (b) to understand the multiple values and goals of different actors; (c) to understand innovation, as a complex non-linear phenomenon; (d) to focus on credibility, trust and usefulness of information. It reviews progress in the light of current policy, forest management and research developments to help identify areas for useful comparative analysis. It considers the implications of the European focus, and looks more widely to consider the effects of context, connection and consequences. Themes include the following. 1. If functioning as a system, does the FOKIS serve an overarching purpose (such as sustainability or adaptability)? 2. The fit of a country's FOKIS to historical, social and ecological conditions may appear to lock in a particular approach; what is the scope for learning and flexibility (e.g. through networking)? 3. What are the impacts and outcomes of different FOKIS and their components? Some of the greatest impacts of forest management result from the activities of institutional (e.g. commercial and investment) forest owners; this component of FOKIS is under-researched. 4. Comparisons with studies of AKIS highlight the value of research into communication between components of the system (e.g. between different services, or between different types of owners) and in focusing on innovation as well as knowledge. 5. How do 'soft' aspects of the system including personal values and cultural or professional norms affect the evolution of the FOKIS, and its impact?

Nudging forest professionals to give forest management alternatives for climate change mitigation

T5.19 Innovating advisory systems to cope with complex forest governance

Marjo Maidell[1]
Fredrik Carlsson[2], Paula Horne[1], Olli-Pekka Ruuskanen[1]
[1] Pellervo Economic Research PTT, Finland
[2] University of Gothenburg, Department of Economics, Sweden

Abstract: The demand for different forest ecosystem services is increasing. In certain countries, forest management decisions often rest with non-industrial private forest owners, who have diverse objectives for their forests. This diversity provides a promising context for the production of different forest ecosystem services through incentives and persuasion rather than strict regulatory control. Additionally, drivers such as urbanization and aging population will increase the need for advisory and forest management services. However, there is limited knowledge about attitudes and actions of forest professionals who provide these services, despite their significant role in forest owners' decision-making.

Our study focuses on the behavior of forest professionals and the alternatives they provide to forest owners with a particular focus on climate change mitigation. Our research questions are: i) what owner- and professional-specific factors affect the management alternatives forest professionals offer to forest owners, ii) how well do professionals consider the preferences of the owners when giving advice, and iii) can professionals be nudged to provide alternatives that support both the owner’s individual objectives and climate change mitigation?

We take reference of the literature on financial advisors and implement a choice experiment (CE) survey targeted at forest professionals. The CE is designed for a forest management activity that is relevant for climate change mitigation: continuous cover forestry. We execute key informant interviews to deepen the understanding of the interaction during the advisory service and to identify and validate the attributes of the CE. Continuous cover forestry is currently not a mainstream practice and involves uncertainties compared to traditional even-aged forest management. However, some owners may be willing to accept these uncertainties if they believe that this will bring other potential benefits. Based on these findings, we will explore if and how a nudge can influence the alternatives offered by professionals to forest owners.

The results of this study will give stakeholders insight into the complexity of different factors influencing forest professionals’ decisions when guiding forest owners. This knowledge can be used to develop and diversify advisory services towards tailored solutions to forest owners with different forest management objectives, including those related to climate change mitigation.

Services for forest owners at the Swedish Forest Agency: scrutinizing the shift from advice to information

T5.19 Innovating advisory systems to cope with complex forest governance

Keeli Curtis[1]
Vilis Brukas[1]
[1] Swedish University of Agricultural Sciences, Southern Swedish Forest Research Centre

Abstract: Local forestry advisors at the Swedish Forest Agency (SFA) have traditionally played a very important role in influencing forest management across the country. However, in recent years SFA's ability to provide individualized advice has been in decline, while private advisors have taken over much of the contact with forest owners. This study explores the range of services provided by SFA today, revealing that SFA does indeed still provide services to owners, though in new constellations and nontraditional forms. Different kinds of services are provided by the local forestry consultants versus the specialized personnel at the headquarters. These two groups of service providers have contrasting competence areas, tools, target groups, and rationales. Informed by analyses of written SFA documents and interviews with service provides at SFA, we scrutinize the effectiveness of SFA's tools for meeting forest owner goals and broader policy objectives.

FOKIS is the key point of departure for this study, providing an overall analytical frame. Drawing from the theories of knowledge management and service-dominant logic, this study develops a framework for examining advisory services on the spectrum from information to advice. Information services are typically unidirectional and more general in scope. Advice, in contrast, requires a specific context (e.g. a particular forest stand) as well as interaction between the advisor and receiver. The extremes of the spectrum are associated with the ability to transfer different forms of knowledge, and their effectiveness varies widely depending on the policy goal and target group. These services can be synergistic, however, when opportunities arise to combine them over time. We problematize the tension between information and advice in relation to the ongoing trends of digitalization and the diminishing personal interaction between advisor and forest owner. In similar vein, we examine the effectiveness of advisory services in the context of the sharpening organizational struggle between providing advice versus the legal enforcement. We hypothesize that these core tensions create fundamental challenges for effective innovations of advisory services at SFA.

Strong sustainability forest services – Decision support for a more sustainable forest use in private forests

T5.19 Innovating advisory systems to cope with complex forest governance

Anu Laakkonen[1]
Katri Rusanen[1], Tuomo Takala[1], Hannes Pasanen[1], Veera Tahvanainen[1], Jani Holopainen[2], Jari Vauhkonen[1], Jukka Tikkanen[1]
[1] University of Eastern Finland, School of Forest Sciences, Finland
[2] University of Eastern Finland, UEF Business School, Finland

Abstract: Our society is currently transitioning towards the concept of strong sustainability in which the planetary boundaries set the main criteria for evaluating human activities. Due to the various expectations for the utilisation of forests, this transition has proven to be challenging for the forest sector. Such transition to strong sustainability is also called for in the decision-support services for private forest owners. So far private forest owners have not been supported in considering forest use from the foundations of strong sustainability. Prior research has already configured the central reasons why such services have not been developed: the difficulty of detecting demand for these services under the current regime and the difficulty to move away from prevailing value creation logics. Hence, this research project focuses on solving the lack of strong sustainability-oriented decision-support services for private forest owners.

The research aims at creating an innovative strong sustainability business model for forest services and developing education for forestry experts to respond to the needs of the sustainability transition. By reviewing literature and interviewing forestry experts and forest service companies we will investigate the development of a strong sustainability forest service business model. Then we will analyse the practicality of the developed business model by introducing it to forest service companies. In addition, we will investigate what kind of expertise forestry experts and service companies need to provide such forest service. Thus, the issue is studied on three levels: the forest ecosystem level, the forest management planning level and the operational level.

We hypothesise that through the strong sustainability business model, sustainability challenges could be solved while providing new business opportunities for forest service companies. The value creation logic of these forest services should promote the well-being of nature and people beyond economic gains from wood production but also fulfil the forest owners' other objectives. These new business models could for instance relate to restoring ecosystems or producing non-timber forest products and services. In addition, we hypothesise that the future expertise of forestry experts is two-fold, forest planning and operations should be seen through both ecological and traditional forestry lenses.

Updating policies and strategies to achieve sustainable growth and job creation through wide target groups participation

T5.19 Innovating advisory systems to cope with complex forest governance

Natasa Lovric[1]
[1] European Forest Institute

Abstract: This study focuses on the need for an updated policies and strategies in Finland and the EU that aim to achieve sustainable growth and job creation through wide stakeholder, advisor, policy maker and private forest owners (PFO) cooperation and comprehensive analysis of forestry and the bioeconomy trough showcasing all Finnish regions. The Sustainable Growth and Jobs 2021–2027, Finland's ERDF Structural Funds Programme, is one of fourteen regional forest programmes in Finland based on regional divisions. This program integrates economic, ecological, and social objectives, serving as a development plan and work programme for the entire forest sector in all regions. The polices and strategies has the potential to create significant opportunities for the advancement of forest-based livelihoods for the above mentioned target groups. A key objective of the strategy would be to fully harness the sustainable wood potential and promote local wood processing and the multifaceted use of forests through prioritized actions. It emphasizes the need for developing diverse forest utilization, including ecosystem services, bioenergy, and tourism. This study aims to identify these prioritized actions through participatory policy maker, stakeholder involvement, by including private forest owners and advisors. The goal is to optimize the vast potential of private forests, thereby enhancing forest policy instruments and facilitating their implementation by fostering exchange of experiences and policy learning among FOREXT (European Forest Advisory Organisations Network).

Utilising gamification in forest advisory systems to support forest owners' learning self-efficacy.

T5.19 Innovating advisory systems to cope with complex forest governance

Philip Chambers[1, 2]
Sari Pynnönen[3]
[1] University of Eastern Finland, Finland
[2] Gamification Group, University of Tampere, Finland
[3] Natural Resource Institute Finland, Finland

Abstract: Forest owners are increasingly being asked to adopt online and mobile-enabled forest advisory systems which have been created by forestry service providers to aid forest owners in their decision-making. Oftentimes, artificial intelligence (AI) is employed to assess the need for various operations and forest owners then have to decide whether to agree with these AI-generated recommendations or not. While these technological innovations aim to aid problem-solving and help decision-making, they do not necessarily consider the varied levels of knowledge about forestry concepts and individual motivations that forest owners have. Therefore, forest owners may have little confidence in using these tools and their uptake and acceptance may be affected negatively. New or inexperienced forest owners may not fully understand what they are being asked to make decisions about and current forest advisory systems do not acknowledge this or address the motivation of forest owners to learn about their forests. Therefore, applying gamification design to forest owners' information systems could be one innovative option to address this.

Gamification refers to the use of game-like or playful elements in non-game settings. These may be applied to information systems to motivate users to better understand the data they see, increase engagement with that data, and encourage user enjoyment of using the system. Gamified, or motivational information systems, are often encountered in daily life e.g., fitness tracking and language learning applications. These applications utilise gamification affordances, the most common being badges, levels, and leaderboards.

In this study, gamified and non-gamified versions of an online learning platform module are used to test the effects of learning self-efficacy in forest owners in Finland. The gamification elements in the module design are assessed to see how they affect participants' motivations and confidence in decision-making as they relate to self-efficacy and educational attainment.

In this presentation, the preliminary results of this study are presented and the effects of utilising gamification and motivational information systems in forest owner education applications and forestry advisory services are examined.

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

A classification and interpretation of approaches to natural capital valuation to pursue more sustainable and multifunctional forest management

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Simone Martino[1]
Stanislav Martinat[1], Katy Joyce[1], Samuel Poskitt[1], Maria Nijnik[1], Mike Rivington[1]
[1] The James Hutton Institute, Craigiebuckler, AB15 8QH, Aberdeen, Scotland, UK

Abstract: This paper reviews existing Natural Capital valuation (NCV) approaches in the context of woodland, forest, and riparian ecosystems. To classify these approaches, it adopts a methodology proposed by the UK ENCA, an initiative that helps researchers and practitioners to better understand the values of nature and takes these values into account in the decision-making processes. In addition, the perspectives of policy and decision makers operating in the Scottish forest context on valuing nature have been integrated into this research.

The findings indicate that 'traditional' economic analyses (e.g., monetary valuation) of forest management options (through welfare valuation methods) currently receive reduced attention in the scientific literature. Landscape scale initiatives addressing the relationships between people and places tend to more frequently inform the values associated with woodlands. Methods that are being increasingly employed to capture stakeholder non-utilitarian values include participatory GIS mapping, scenario planning, and multi-criteria analysis. These methods could help identify, explore, and quantify even less tangible (e.g., cultural) ecosystem services (ES). Mixed methods are developing to elicit changes in stakeholders' decisions concerning forestry and on forest ES (e.g., timber production, carbon sequestration, tourism) under changing climate scenarios, (e.g., valuing losses from the increased drought and wildfires) and for different climate policy options. In addition, many studies address place-based NCV working towards the integration of contextual and relational values into forest/woodland relevant decisions and considerations derived from the workshop suggest implementing NCV by integrating a range of transcendental and shared values (arising from an eco-centric perspective of valuation) into the classical, instrumental value lens. This would help informing broader aspects of woodland development and sustainable forest management that may foster more effective nature conservation and the use of forest for multiple purposes (including timber) and support the management of conflicts.

Abstract: Forests are one of the most relevant terrestrial ecosystems in terms of their geographical extent, biodiversity and nature's contributions to people (NCP). Decision-making about forest adaptation to climate change is particularly important, as forest dynamics are determined by long-lasting management decisions. Therefore, assessments of forest ecosystem services and NCP have been increasingly used for policy-making from local to global scales. However, there are still important challenges to improve decision-making by better understanding the spatial, temporal and social dimensions of NCP - and their interactions. Here we aim to assess the main current challenges regarding these three dimensions, also indicating potential ways forward in order to better inform policy and decision-making. The main identified challenges are: (1) for the spatial dimension, identifying the relevant spatial scales and drivers of NCP supply and demand and their spatial mismatch; (2) for the temporal dimension, improving the predictive understanding of the temporal dynamics in NCP, accounting for the fact that service supply and demand are both dynamic and

frequently uncoupled; and (3) for the social dimension, considering the diversity in NCP social perceptions and the social mismatches and legacy effects arising from NCP management decisions. We describe these challenges and their interactions and suggest potential solutions and recommendations for policy-makers and forest managers. The main solutions we identify include methodologies to integrate the spatial scales at which a given NCP is supplied and demanded, measuring and anticipating spatial and temporal mismatches, and incorporating temporal and spatial variability of social perceptions of NCP. Finding solutions to these challenges is essential to increase the accuracy to estimate how NCPs contribute to human well-being, considering the complexity and heterogeneity at the spatial, temporal and social levels.

Appraising participatory natural capital valuation in research and governance for supporting improved forest resilience & pathways to societal impact.

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Sam Poskitt[1]
Katy Joyce[1], Simone Martino[1], Kerry Waylen[1], Maria Nijnik[1]
[1] The James Hutton Institute

Abstract: Recognising the values associated with Natural Capital (NC) is increasingly considered important in research and governance that aims to strengthen forest resilience. Recently, researchers have adopted more holistic, transdisciplinary and participatory methodologies for NC valuation, in attempts to account for people's diverse relationships with and values for the natural environment. This is often done with an expectation that incorporating input from stakeholders can improve the efficacy of research findings for policy and practice, and identify pathways to societal impact. However, it is not clear to what extent such approaches and information regarding valuation of NC are being operationalised. In this paper we combine findings from: i) a thematic synthesis of academic publications on research pertaining to use participatory approaches for NC valuation; and ii) a review of policy documents regarding the incorporation of participatory NC approaches into forest policy in the UK and Scotland, with the aim of identifying current synergies, as well as exploring how forest governance can benefit from NC valuation. We find that, although the adoption of participatory methods has served research interests well, in the sense of increasing the richness and granularity of understanding around NC, this has rarely seemed to directly influence practice. Adjacent to this, whilst secondary Scottish policy increasingly includes participatory consultations in attempts to operationalise concepts related to NC and its valuation, such approaches appear to falter after the testing phase. This raises questions about how to embed the results of both research and policy consultations in practice within various spheres of decision-making that shape Scottish forest governance. We argue that many of the outputs of participatory NC approaches may have limited useability or influence in national-level decisions, as currently framed. However, more locally-situated and site-specific decision-making would benefit from moving towards full co-production of research and local agency in governance. We conclude by suggesting ways in which NC can learn from other fields with a strong focus on integrated and end-user-oriented methodologies, to help appraise the credibility, salience and legitimacy of knowledge outputs and production processes, which may help ensure future valuation initiatives improve the management of forest ecosystems.

Are fancy decision support tools sufficient to convince a pessimistic forest decision-maker?

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Gintautas Mozgeris[1]
Nerijus Pivoriūnas[1], Ekaterina Makrickienė[1]
[1] Vytautas Magnus University, Agriculture Academy, Faculty of Forest Sciences and Ecology, Department of Forest Sciences, Lithuania

Abstract: The use of decision support tools to assess, facilitate, promote, and enhance forest management practices is a common approach in modern forestry. These tools often incorporate features to account for climate change and its impact on forest growth, global timber demands and prices. They also simulate future trends in forest ecosystem services, as well as the behaviour of forest owners or managers. However, computer-based decision support systems have never gained popularity among forestry decision-makers in Lithuania. One possible explanation for this is that the forest sector in Lithuania still struggles to adapt a command-and-control approach in forest governance, which is a remnant of the totalitarian socialism era. This approach involves strict adherence to guidelines set by central authorities and heavy reliance on the opinions of established experts. This study aims to demonstrate how different forest management scenarios are interpreted and accepted by various forestry stakeholders with different professional and ideological backgrounds. The simulation of forest development and the delivery of diverse ecosystem services within a relatively large state forest estate were carried out under three alternative scenarios: production-oriented management, multifunctional management, and set-asides, each emphasizing the maximization of specific groups of ecosystem services. However, the delivery of ecosystem services belonging to the three most important groups—timber supply, biodiversity protection, and carbon sequestration—were predicted to remain at least non-decreasing over time. Subsequently, we conducted interviews with two groups of professionals actively engaged in the forest sector but with different educational backgrounds and professional experiences: traditional foresters and modern environmentalists. The aim was to evaluate the impact of alternative forest management approaches on the delivery of ecosystem services. The interpretations based on the modelled data showed less variation between the groups compared to a quick assessment of scenarios based solely on their identification, highlighting the significance of forest decision-makers' preconceived notions and biases.

Assessing and comparing the multi-service potential of different forest types: methodological challenges and perspectives for forest management

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Andrzej Affek[1]
Ewa Kołaczkowska[1], Anna Kowalska[1], Edyta Regulska[1], Jacek Wolski[1], Jerzy Solon[1]
[1] Institute of Geography and Spatial Organization Polish Academy of Sciences

Abstract: People expect forests to provide many ecosystem services (ES) simultaneously and in a sustainable way. Potential of forest ecosystems to provide multiple ES should be the basis for sustainable forest governance and use. However, estimating multi-service forest potential is a complex process. Even minor modifications at any stage of the assessment (formulating assumptions, selecting and defining services, constructing indicators, selecting source data) may affect the results. The aim of this study was to propose pathways to assess and compare multi-service potential of various forest types and discuss methodological challenges and opportunities for implementation in forest management.

Our case study was State Forests in Poland, covering 7.16 million hectares. We selected 17 key forest ES for the assessment, including timber, forest fruits, mushrooms, global and local climate regulation, air purification, pollination, habitat maintenance, and providing environmental settings for recreation, health regeneration and education. Due to the lack of standard ES assessment procedures, knowledge gaps, as well as the need to match indicators to existing data, a significant part of indicators are original proposals. We used data from the Polish Forest Data Bank, as well as satellite data, literature and expert assessment to calculate the proposed indicators. To capture the diversity of forest ecosystems, the national classification comprising 36 forest habitats was applied. The ES potential of these habitats was estimated based on the characteristics of sites with stands over 80 years old.

We showed that forests in Poland have the capacity to provide many important ES for people, and that their potential varies substantially depending on the type of forest and region. Only certain forest types can be considered multi-service hotspots, e.g. mountain forests on fertile soil with moderate moisture content. The main challenge for us was the weighting of services. Although being aware that ES are not equally important, due to lack of sufficient premises and appropriate source data, we treated each service the same (weight=1). Still, the developed analytical pathways can be used as a reference point and framework for a standard procedure for monitoring the forest ES potential.

This research was funded by WWF Poland.

Can forest carbon offsets contribute to the net zero commitment? Pathways and barriers to develop sustainable and credible carbon offset in Spain.

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Paola Ovando[1]
Verónica Hernández-Jiménez[2], Richard Hewitt[3, 4], Natalia Cagide[1]
[1] Institute for Public Goods and Policy (IPP), The Spanish National Research Council (CSIC)
[2] The Observatory for a Culture of the Territory (OCT)
[3] Department of Geography, Complutense University of Madrid (UCM)
[4] Institute of Economics, Geography and Demography, The Spanish National Research Council (CSIC)

Abstract: Using nature to capture and store carbon in soils and vegetation as a way of offsetting greenhouse gas (GHG) emissions is gaining a renewed interest for many organizations to support their net zero commitments. In Spain, the National Office for Climate Change launched in 2014 a Carbon Footprint Registry where organizations can document on their carbon footprints, their efforts to reduce GHG emissions or offset them through domestic afforestation/reforestation actions, including interventions to restore forested areas impacted by wildfires. The number of organizations participating in the Registry is limited, although it is growing quickly along with the number of forestry-carbon-sink projects promoted, posing challenges concerning the quality and sustainability of the resulting offsets. In this study, we investigate the potential and feasibility for generating forest carbon offsets that are truly additional, long-lasting, and are aligned with sustainability principles. To address our research question, we used in-depth-interviews and a participatory workshop to investigate the perceptions and priorities of stakeholders taking part directly or indirectly in the Registry around the performance and future perspectives of forest carbon offsets in Spain. This analysis was complemented by public data analysis on registered forestry-carbon-sink projects and offsets. Participants identified key barriers, risks, and opportunities around four main topics affecting forest carbon offsetting in Spain. Those include carbon and co-benefits accounting and valuation, long-term maintenance of forestry-carbon-sink projects, transparency in carbon markets, and management of risk. Key barriers included lack of consideration of ecosystem services or of the role of soils in carbon offsetting in the online tools used by the Registry, lack of diversity of types of carbon removal projects, or lack of resources in the National Office for Climate Change. Participants proposed and prioritized pathways towards a future transition such as increasing resources to grow the technical rigor and coverage of the types of projects that can be registered, including projects of forest management and habitat enhancement in the actions considered for carbon offsetting, incentivizing communications between key actors in forestry sector and organizations offsetting their carbon footprints, or the creation of a carbon price observatory to offer reference values to the registered members.

Co-creation of governance innovations for sustainable forest ecosystem services: behavioural approach

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Abstract: The high complexity of forest ecosystem services (FES) calls for novel governance arrangements for their sustainable provision. To understand the potential for FES governance innovations, it is essential to determine key influences of their emergence and development. This requires constant reflection and reconfiguration of governance arrangements to varying contextual conditions and actors. The paper is concerned with co-creation of FES governance innovations, contexts and actors that influence their development using behavioural approach. We use a newly designed role board game (RBG) – an interactive agent-based model for co-creation of novel governance demonstrated on six governance innovation cases in Europe. We aim to determine: *(i) How can governance innovation be co-created for long-term sustainability transformation in diverse forestry contexts? (ii) What motivates actors' behaviour towards sustainable provision of forest ecosystem services? (iii) What are the lessons learned to foster FES governance innovation co-creation?* The results indicate institutional robustness, biophysical conditions and actors' dynamics as key contextual conditions for sustainable FES provision. The RBG as an innovative method for simulation of real-world processes, assessing natural and social values interconnection and co-creating novel social practice while learning about ecosystem dynamics and potentially changing human behaviour.

COMMUNITY FOREST MANAGEMENT IN HIMALAYAS: STRENGTHENING RESILIENCE OF ECOSYSTEM SERVICES AND SOCIETAL UPLIFTMENT OF COMMUNITY- MANAGED FORESTS

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

HONEY BHATT[1, 2]
[1] Honey Bhatt, Govind Ballabh Pant National Institute of Himalayan Environment, (GBPNIHE), Kosi- Katarmal, Almora, Uttarakhand, India
[2] Harshit Pant Jugran, Govind Ballabh Pant National Institute of Himalayan Environment, (GBPNIHE), Kosi- Katarmal, Almora, Uttarakhand, India

Abstract: The community forest management (CFM) is an integral component of sustainable forest management scenario across the globe. The rural poor community relies on the local forest ecosystems for their sustenance and livelihood generation. This direct link between community and forest has significant implications for societal upliftment and have various umbrella impacts on the forest dependent communities.

In the global context, forest management is currently challenged by the need to address an increasing demand for a wide range of ecosystem services. The study aims to enhance understanding by acknowledging ecosystem services that can strengthen local communities and align stakeholders to define priorities and objectives for the sustainable forest resource management, employing a scalable local-to-landscape approach.

To address this, we have conducted a study to identify the Forest Ecosystem Services (FES) under Community managed forest (CFs) as one of the notable examples of management of forest resources by active participatory approach of local communities in Himalayan region. We have investigated the stakeholder's perceptions and awareness towards these FES and their influence on local community's livelihood and resources.

The study was conducted in six CFs (referred as Van Panchayats – VPs) and data on the perception of community was collected from households through focus group discussions and semi structured interviews using participatory rural appraisal techniques like ranking and listing.

Our findings have revealed that local communities perceived reducing trends in the accessibility of various FES (mostly provisioning) particularly fuelwood and freshwater. However, study identified that local communities helps in managing forest fire, used to worship local deities inside CFs, protects the aesthetical value and perform eco-restoration activities at degraded sites by planting indigenous species.

In light of these findings, there is an immediate need to prioritise the socio- cultural conservation based incentives of local communities in policy formulation. This approach could assist in addressing difficulties within the forest ecosystem, contribute to the societal implications of ecosystem services at the local level, gradually improve forest management, and provide a foundation for future studies.

Conceptualizing Organizational Models for Sustainable Forest Management: Embracing Innovation and Complexity

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Davide Pettenella[1]
Nicola Andrighetto[2], Giorgia Bottaro[1], Francesco Loreggian[1], Mauro Masiero[1], Laura Secco[1]
[1] TESAF Dept. - Univ. of Padova
[2] ETIFOR - Benefit Co.

Abstract: In recent decades, epochal changes and challenges (i.e., climate change, fragmentation and abandonment of forest properties, changes in the ownership structure), together with disturbing environmental, social, and economic events (i.e., wildfires, wars, economic crises) are pushing the forestry sector to increase efforts in finding innovative solutions to foster sustainable forest management enabling the transition towards climate neutral, resilient, and green society. Traditionally, the research in the forestry domain has focused on product and process innovation, and more recently on innovations in business systems, non-wood forest products, and social and institutional innovations. Although organizational innovation was recognized and documented in scientific literature, the focus is mostly on northern countries. Additionally, consistent conceptualization works have been conducted separately for traditional business models and social innovation, somehow failing to capture all innovative forms of organizations working in forestry (e.g., networks, associations, partnerships, social entrepreneurship, etc.). Thus, the organizational domain in forestry seems less clear, as no recent frameworks cover the intersection of organizational and social innovation in forestry. In literature, concepts relevant to innovation in organizational models in forestry are either overlapping or discriminating against innovative networked models being characterized by multiple actors. The paper proposes a conceptualization of the organizational model as a concept embracing different approaches that capture the existing variety of organizations in European forestry. We present an analytical framework used to describe and characterize organizations in the forestry sector according to multiple criteria. The framework was drafted referring to existing theories in forest governance, organizational studies, and social innovation; then it was tested (and further refined) through a semi-systematic literature review on organizations operating in forest management in Europe. Various forms of organizational models were identified, and organizations were categorized and characterized according to selected criteria. This exercise confirms that forest management organizations are complex entities that can be described with several diverse arrangements. The framework can be used by policy and decision-makers for planning business and innovation strategies, as well as for cross-sectoral policy integration necessary for the improvement of sustainable forest management.

ECOFOREST and RIVERTOOL: Empowering Stakeholders for Sustainable Forest Expansion through Spatial Analysis and Decision Support

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Alessandro Gimona[1]
Bethany Wilkins[1, 2], Marie Castellazzi[1], Andrea Baggio Compagnucci[3], Etienne Charpin[1, 4], Faye Jackson[5], Iain Malcolm[5], Scott Newey[6], Brian McCreadie[7], Zisis Gagkas[1], Rob Brooker[1], Robin Pakeman[1]

[5] Marine Scotland, Freshwater Laboratory,Scotland, UK
[6] Game and Wildlife Conservation Trust,Scotland, UK
[7] Scottish Environment Protection Agency,Scotland, UK

Abstract: Forests and woodlands offer a multitude of benefits to humanity. They serve as a valuable source of timber and food, while also playing a crucial role in carbon storage to mitigate the impacts of climate change. Additionally, they contribute to the reduction of flooding and soil erosion, as well as providing recreational opportunities for people and serving as habitats for various species that we strive to conserve. Nevertheless, forests can also encroach upon important habitats and, if planted on carbon-rich soils, may result in a net loss of carbon from the landscape.

In Scotland, forests cover approximately 19% of the country. The Scottish Government has set an ambitious goal to expand forest coverage by several thousand hectares per year in the coming decades, with the aim of supporting rural economies, safeguarding the environment, and benefiting local communities. To achieve this expansion in a manner that effectively protects and promotes ecosystem services and biodiversity, it is imperative to identify and prioritise suitable areas for planting while avoiding counterproductive locations.

To address this challenge, decision-makers must consider multiple, spatially explicit factors and their interactions within the landscape. Given the complex nature of this problem, which necessitates interdisciplinary knowledge and modelling, there is a critical need for tools that facilitate the exploration of different options.

In response to this need, we present two web-based interactive tools: ECOFOREST (Ecosystem services-based Criteria for Optimal Forest Expansion and Restoration) and RIVERTOOL (Riparian Vegetation Ecosystem Services-based Ranking Tool). These tools synthesise over thirty geographic data sets and several modelling results for the benefit of the user. They employ spatial multi-criteria analysis, a highly flexible approach that enables the generation of priority zonations for new planting. Users can customise the importance assigned to a selected set of spatial criteria and constraints, allowing for tailored decision-making processes.

ECOFOREST and RIVERTOOL significantly enhance the ability to explore various options for forest expansion. By utilising spatial multi-criteria analysis, these tools empower decision-makers to

make informed choices that prioritise ecosystem services and biodiversity conservation, while supporting sustainable landscape management.

Economic valuation of forest ecosystem services in Kisangani and its implications for sustainable forest management

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Pitchou Tshimpanga[1]
[1] Université de Kisangani (UNIKIS), Faculté de Gestion des Ressources Naturelles Renouvelables (FGRNR), Kisangani, Tshopo, RDCongo

Abstract: A study was conducted to evaluate the economic value of ecosystem services provided by the Kisangani forest in the Democratic Republic of Congo. The study found that the Kisangani forest provides crucial ecosystem services such as climate regulation, biodiversity, timber production, and water filtration, with an estimated annual economic value of USD 97.5 million. However, the study revealed that illegal logging and conversion of the forest into agricultural land has led to a loss of ecosystem services and a decrease in their economic value, impacting the quality of life of local communities and the country's economy.

The discussion highlights the importance of economic valuation of ecosystem services as a tool to make informed decisions regarding sustainable forest management, but it must be used alongside other approaches such as community participation and logging regulations. It is also crucial to recognize the cultural and social significance of the Kisangani forest for local communities and ensure their needs and values are considered in forest management.

This study underlines the necessity of protecting the Kisangani forest for the benefit of local communities and the wider economy, emphasizing the importance of a holistic approach to forest management that takes into account both economic and cultural factors.

Estimating proximity effects to wildfire fuels treatments on house prices in Cibola National Forest, New Mexico, USA

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Ryan Fitch[1]
Julie Mueller[1], James Meldrum[2], Christopher Huber[3]
[1] Northern Arizona University
[2] U.S. Geological Survey, Fort Collins Science Center
[3] U.S. Geological Survey, Science and Decisions Center

Abstract: Forested landscapes in the Western US are subject to growing size and severity of wildfires, in part due to historical management strategies focusing on wildfire suppression. Forest restoration treatments and fuels reductions, including thinning and prescribed burning, can reduce the frequency and intensity of wildfires. Extensive restoration and fuels treatment efforts are underway across many areas in the Southwestern US, including New Mexico. The tradeoff between amenity values provided by forested landscapes and the wildfire risk associated with forested landscapes is becoming increasingly important to understand as development in the wildland-urban interface increases. Understanding how house proximity, relative to forest restoration or fuels treatments, is capitalized into home sale prices can provide useful information into how individuals value forested landscapes that have been altered to reduce wildfire risk or severity. We use a Hedonic Property Model to estimate the average treatment effect of proximity to forest restoration or fuel treatments in New Mexico, US. We use matching methods to estimate the average treatment effect of proximity to forest restoration. We find that proximity to the forest has a positive amenity value; however, proximity to recent forest restoration or fuel treatments results in a decrease in house sale prices. We combine the results of our two models and calculate that homes not within one kilometer of a treated forest and within one kilometer of Cibola National Forest sell for an average $73,626 premium. The average premium drops to $22,996 for homes within one kilometer of a forest that has been recently treated and within one kilometer of Cibola National Forest.

Exploring Forest Stakeholders' Perspectives on Payment for Ecosystem Services in the European Union

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Diana Carolina Huertas Bernal[1]
Miroslav Hájek[1]
[1] Czech University of Life Sciences, Faculty Forestry and Wood Sciences, 165 00 Prague, Czechia

Abstract: Forests and biodiversity play a vital role in sustaining human life. The intricate relationship between forests and the everyday products and services we rely on has prompted the need for sustainable development processes that ensure the responsible use of natural resources while preserving them for future generations. Despite such efforts, forest ecosystems face alarming declines due to deforestation, resource overexploitation, and the impacts of climate change. This research aims to investigate the perspectives of forestry actors within the European Union regarding available financing mechanisms, mainly focusing on payment for ecosystem services. In-depth interviews were conducted with experienced forestry professionals from twelve member countries, employing a semi-structured approach to explore their knowledge, experiences, and utilization of payment for ecosystem services. Preliminary findings indicate significant variations in the implementation and utilization of compensation payment schemes, despite regulatory frameworks. Most interviewees (over 70%) demonstrate awareness of compensation payments; however, they perceive limited practical implementation primarily due to alternative incentives that align more closely with their interests. Conversely, some interviewees highlight the underdevelopment or mere proposal status of payment mechanisms in their respective countries.

Moreover, personal interest and private capital investment were identified as the primary drivers of conservation efforts for forests or ecosystems of interest. Furthermore, existing payment programs were found to be highly specific, limiting alternative forest management approaches. At the same time, access requirements and lengthy application processes posed barriers to their socio-economic and environmental benefits. Insights from forest stakeholders provide valuable suggestions to policymakers for improving the dissemination and accessibility of ecosystem service payment mechanisms, aiming to promote diversified and sustainable forest management within the European Union.

Forest Digital Twin to Support Sustainable Woodland Management and Planning

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Chen Wang[1]
David Miller[1], Alessandro Gimona[1], Maria Nijnik[1], Yang Jiang[2]
[1] The James Hutton Institute, Aberdeen, UK. AB15 8QH
[2] Faculty of Arts, Cultures and Education, University of Hull, UK. HU6 7RX

Abstract: Forests and woodlands offer many benefits, including timber, food, carbon storage, mitigation of flood and soil erosion, biodiversity habitats, water quality and flow regulation, shelter for livestock and recreation. Forest Digital twin potentially offers a much richer capability to monitor, analyze and simulate current and future forest state and support woodland management and planning.

In this work, using a case study from Scotland (Glensaugh Climate Positive Farm), we explored scenarios of woodland change and consider the multiple environmental and socio-economic benefits in terms of natural capital asset index, carbon storage, ecosystem services and biodiversity.

This approach combines Spatial Multi-criteria Analysis (sMCA) with interactive 3D GIS-VR platform and immersive forest and climate data visualisation, to showcase scenario models of different tree species and planting densities in Glensaugh which provides an innovative framework to integrate spatial data modelling, analytical capabilities and visualisation. It also allows the planner to incorporate high level of information and interaction into the development process, to get immersive experiences of the proposed scenarios and to capture user/stakeholder comments efficiently.

The Digital twin prototype for Glensaugh Climate-Positive Farming was used at the GISRUK 2022, 2022 Royal Highland Show and EGU 2023. Audience feedback suggested that the virtual environment was very effective in providing a more realistic impression of the different land-use and woodland expansion scenarios and environmental characteristics. This suggests considerable added value from using digital twin technology to better deal with complexity of data analysis, scenarios simulation and enable rapid interpretation of solutions.

Findings show this method has a potential impact on future woodland planning and enables rapid interpretation of forest and climate data which increases the effectiveness of their use and contribution to wider sustainable environment.

Forest ecosystem services Web map as innovative tool for society

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Zuzana Sarvašová
Maroš Sedliak[1]
[1] Natonal Forest Centre, Slovakia

Abstract: The paper describes the use of an integrated approach to assess the provision of ecosystem services in the forests of Slovakia with an orientation towards the end-user. Methodologically and analytically, it is based on the current state of the forest, using the dependence between the characteristics of the forest ecosystem, the applied management, the condition of technical equipment and the provision of ecosystem services.
New element is an application of an original system based on various spatial and attribute data. The proposed assessment model is based on publicly available forestry data from related sectors, verified by field surveys in the areas characterised by the different main forest functions (e.g. wood production, carbon sequestration, water regulation, hunting and recreation) in the sense of a citizen science approach. The assessment of forest ecosystem services enables the interactive mobile application, in which it is possible to identify valuable locations in terrain and store them in the geospatial layer.
The goal is to create a new interactive web-map application displaying the forest ecosystem services assessment results using spatial and attribute data on forest ecosystem services for forest owners/managers and the public. Its use consists in raising public awareness on the importance of forest ecosystem services, designing possible support instruments to forest managers (payments for ecosystem services), and in building consensus among different stakeholders on priorities in the use of ecosystem services.

Governance Innovations for forest ecosystem service provision – Insights from an EU-wide survey

Abstract: In this talk, we analyse the occurrence of governance innovations for forest ecosystem service (FES) provision in the forestry sector in Europe and the factors that influence innovation development. Based on a European-wide online survey, public and private forest owners and managers representing different property sizes indicate what type of governance innovation activities they engage in, and why. To investigate forestry innovations as systems, the analysis focuses on biophysical, social and technical factors influencing innovation development. Our results show that most innovation activities are largely oriented towards biomass production. Accordingly, most forest owners implement efficiency-driven optimisation strategies for forest management and technological improvement for provisioning of services supply, to generate income and create pathways to societal impacts. In contrast to income generation, the provisioning of regulating and cultural services is not yet a prominent part of forestry innovation activities. Reasons are rooted in a market-oriented economic rationale focusing on timber production, which is related to a lack of financial resources to compensate for other FES provision or institutions to provide backup and security to forest owners and managers for engaging in innovation development outside wood production. If other FES beyond timber provision shall be provided, new forms of communication and cooperation, and innovation in FES valuation and financing are needed. Given that the provision of a wide range of FES is a politically well-established objective for forest management in Europe, a strategy is needed that helps to align actors and sectors for supporting related forest management approaches and business models. The current revision of the forest related policy framework on EU level under the EU Green Deal poses a window of opportunity for better fostering of novel governance approaches for a more sustainable provision of FES.

Healing interiors: in search of yet non-quantitative dimensions of social sustainability in building with wood concepts

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Abstract: Buildings and built environment affect human wellbeing in many ways, creating an opportunity to develop sustainable, restorative buildings and materials. This ongoing research project studies human behavior and chosen psychophysiological parameters to create a holistic view on humans' wellbeing related to different living environments. The aim is to use a multidisciplinary approach to create better understanding on how novel material choices in built environments and interiors affect human's stress levels in longer term, and how psychophysiological load can be relieved by introducing different novel engineered wood and nature-based materials into housing. The study utilizes the Living Lab of Wood Construction at the University of Helsinki – a unique test bed for holistic wellbeing research. The research applies ambulatory health metrics technologies to obtain anonymous data from the voluntary study subjects randomized into cross-over trial. The study subjects live in both wooden and non-wooden housing for six weeks, and their heart rate, heart rate variability, skin electrodermal activity, and sleep metrics are monitored together with the self-assessments and targeted focus group interviews of perceived wellbeing. The study provides new knowledge on longer-term impacts of interior materials in built environments for human wellbeing. The results help design building materials that may provide stress-relieving, healthy and restorative environments for users in home or work environments. Moreover, the study aims to connect principles of sustainability assessment as part of the assessment of human psychophysiological wellbeing. Suitability of selected wellbeing assessment methods and biomarker measurement technologies are evaluated as part of a more comprehensive assessment of sustainability in the building with wood concepts. The results achieved will be discussed in the presentation.

How much does it cost to preserve Madagascar‘s humid forests through a conservation basic income

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Herizo Andriambololona

Abstract: The northeastern region of Madagascar houses some of the world's most diverse forests, which are currently facing significant threats due to shifting cultivation practices employed by smallholder farmers. Although protected areas have made progress in curbing deforestation over the past decade, they have inadvertently caused severe injustices for the local population. These include the loss of land for future agricultural expansion and restricted access to timber and other forest resources, resulting in a decline in people's well-being. To ensure long-term support for protected areas, it is crucial to explore alternative conservation approaches that balance conservation success with the welfare of local communities.

One such approach gaining momentum in global conservation discourse is the concept of a conservation basic income. Our study aims to gather empirical evidence on the viability of implementing a conservation basic income to mitigate deforestation in northeastern Madagascar. We have conducted interviews with households residing in various villages within the buffer zone of Masoala National Park. Through these interviews, we have assessed the opportunity cost for the lost access to ecosystem services by communities. We have then investigated community's preferences regarding different forms of conditions and levels of compensation associated with a conservation basic income. In this presentation, we will share our preliminary findings and discuss their implications for designing an effective conservation basic income.

It is evident that the current situation calls for urgent action to safeguard the ecological integrity of these forests while addressing the socio-economic needs of the local population. By embracing innovative approaches like the conservation basic income, we can strike a balance that not only protects the rich biodiversity of northeastern Madagascar but also ensures the well-being of its inhabitants. Our research aims to contribute valuable insights towards achieving this delicate equilibrium, and we look forward to sharing our progress and engaging in discussions on the practical implementation of a conservation basic income.

How Natural Capital Accounts can support forest governance in an innovative way. Applications from INCA and LISBETH on woodland and forests in Europe

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Alessandra La Notte[1]
[1] Senior research fellow at the University of Siena

Abstract: The System of integrated Environmental and Economic Accounting- Ecosystem Accounts (SEEA EA) was adopted as a standard by the United Nations Statistical Commission in 2021. Based on UN SEEA EA, regulation proposals on ecosystem accounts are being advanced in the Europe and in the United States, and a vast implementation program is being applied by the UN together with the Word Bank all around the world. The accounting of Ecosystem services is reported through Supply and Use tables that allocate the transaction of flows of services from ecosystem types to economic units, in physical and monetary terms. The "Woodland and forests" ecosystem type provides a vast range of services that support human activities in many ways: from the provision of ecological inputs, to the removal of pollutants, to the protection against physical and biological threats, to the contribution to global challenges (such as climate change and biodiversity loss). Ecosystem service satellite accounts can show that "Woodland and forests" provide much more than the timber provision service to the forestry sector; the majority of flows are indirect use values and also non-use values of which economy and the whole society greatly benefit. Such quantitative measurements can be used in a variety of ways: from the time series analysis, to the computation of composite indicators and sustainability scoreboards; they can also be used as input variables in conventional economic tools to assess the economic impacts of changes that affect forest ecosystems. This presentation illustrates each of these cases with concrete applications processed through the Integrated system for Natural Capital Accounting (INCA) project, founded by the European Commission, and further developed through the LInking ecosystem Services and Benefits to Economy THrough bridging (LISBETH) initiative.

Incorporating participatory assessment methods into natural capital valuation

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Maria Nijnik[1]
David Miller[1], Simone Martino[1], Sam Poskitt[1], Katy Joyce[1], Stanislav Martinat[1], Chen Wang[1], Margaret McKeen[1]
[1] James Hutton Institute

Abstract: Keywords: ecosystem services, forest, stakeholders

The objective of this trans-disciplinary research is to analyse and advance existing methods of valuing nature. The specific objectives are:

- What are the gaps in natral capital (NC) valuation?
- Which of the dimensions of value would it be helpful to consider?
- How could these values be captured, measured, and valued to support more robust and end-user friendly knowledge transfer and decision-making systems?

We analysed a range of methods to value NC and ecosystem services (ES), and based on the review of literature (3,415 papers) and empirical examples examined main opportunities and challenges of valuation, to answer the question: can the augmented use of participatory and digital techniques offer new perspectives to enhance the basis for decision-making? We question when/where certain valuation methods are most pertinent, and how to integrate participatory, analytical, and digital tools for outputs to be most useful for end-users.

The team has adopted a mix-methods' approach and a participatory environment, in which stakeholder engagement and advanced science are being brought together. Preliminary findings suggest that monetary valuation alone can be insufficient and/or inappropriate because NC and ES are complex; there are inter-dependencies and uncertainties; components of NC may be unique or 'critical'; and as robust primary valuations are lacking. A proper combination of methods could enable more meaningful values to be placed on nature, while active involvement of stakeholders can offer a means for learning, and the co-development of capabilities to enhance the use of valuation knowledge in forest-related decision-making.

We anticipate that this research (the first of its kind in the UK) can underpin design of the framework and content of a toolkit of importance for stakeholders and a more participatory NC valuation could better inform policy decisions as to resource allocation, management, and use. Further research is required on best approaches for incorporating stakeholder perspectives into new strategies targeting the green recovery, and for translating the social capital created through participation into more effective actions on the ground.

Acknowledgments:

This project is supported by the Scottish Government through its Strategic Research Programme (2022-2027), project JHI-D5-1 in the Natural resources Theme.

Integrating ecosystem service supply-demand into social innovation: spatial distribution and area identification

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Jianying XU[1]
Tiantian ZHANG[1], Xinru LI[1]
[1] College of Resource, Environment and Tourism, Capital Normal University, Beijing 100048, China

Abstract: Mismatch of ecosystem service supply-demand has been considered as the main driving forces of ecological degradation. Places with high human pressure could be distinguished by analyzing spatial distribution of ecosystem service supply-demand. Here, taking Wolong Natural Reserve in southwestern China as case study, we evaluated ecosystem service supply-demand ratio from the perspective of local community. The results found spatial heterogeneity of ecosystem service supply-demand in the study area. The area and proportion of areas with high supply and demand for ecosystem services are relatively low and concentrated, mainly concentrated in the central residential areas and areas with concentrated cultivated land resources. Regions with surplus, equilibrium and deficit of ecosystem service supply-demand were identified by comparing ecosystem service supply-demand ratio. Totally, 96.25% of the total study area exhibited a surplus of ecosystem service and 3.52% exhibited equilibrium of ecosystem service. Only 0.23% of the total study area exhibited deficit of ecosystem service. But relating to specific ecosystem service, deficit area of freshwater supply and soil conservation reached 7.08% and 8.97% respectively. Also difference of supply-demand existed among local stakeholders. Conservative stakeholder confronted with the most deficit area of traditional crops, soil conservation and maintaining soil fertility. Aggressive stakeholder confronted with the most deficit area of freshwater. Combing local ecological and socio-economic status, we found that spatial distribution of deficit area resulted from local physical conditions, local livelihood dependence and ecosystem services accessibility. Finally, ecological risk zone and ecological conservation zone were put forward and divided in the study area by synthesizing local ecosystem services supply and demand.

Mapping Citizens' perceptions of cultural ecosystem services provided by urban green spaces and comparative analyses between Germany and South Korea

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Jaewon Son[1]
Somidh Saha[1, 2]
[1] Institute for Technology Assessment and Systems Analysis (ITAS), Karlsruhe Institute of Technology (KIT), Germany
[2] Institute of Geography and Geoecology (IFGG), Karlsruhe Institute of Technology (KIT), Germany

Abstract: Cultural ecosystem services are non-material benefits people obtain from nature, including recreation, aesthetic enjoyment, physical and mental health benefits, and spiritual experiences. While those benefits directly influence human well-being and are distinguishable from other ecosystem services, they are challenging to measure due to their subjectivity and complexity. Thus, there needs to be more research on cultural ecosystem services and approaches in comparing perspectives on cultural ecosystem services across the countries. With the case study on German and Korean cities, this research examines public perceptions of cultural ecosystem services from green spaces, especially urban forests. A map-based online questionnaire was conducted via the Maptionnaire software to allow accurate and detailed assessments of cultural ecosystem services with spatial data, and involve residents in assessment and management. The questionnaire results showed that the perceptions of cultural ecosystem services vary not only between countries but also based on their social, behavioral, and economic background. Based on the participatory mapping, the spatial distribution of cultural ecosystem services in each city was visualized, which can contribute to a better appreciation and easier understanding of the social and cultural values from urban forests for end users. The result of this study will provide insights into maximizing co-benefits in nature-based solutions, improve forest policy and governance, and support decision-making by incorporating public perception and values of cultural ecosystem services in two countries.

Monetary estimates to justify investments in forest restoration. Applications in Europe

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Alessandra La Notte[1]

[1] Senior research fellow at the University of Siena

Abstract: Ecosystems provide services to economy and society. Ecological processes become services when an ecosystem potential supply interacts with a socio-economic demand. On the one hand, the match between these two sides generates a service flow; on the other hand, a mis-match may occur when a potential flow is not used, or when there are no ecosystems able to provide the needed services. Thanks to the INCA approach, it is possible to locate spatially and measure mis-matches in terms of ecosystem services in physical terms. Such mis-matches can be eventually translated in monetary terms. This valuation estimates the flows of the services that are yearly lost because ecosystems are not able to provide them to human activities. When computing a cost-benefit analysis, this kind of assessment can support and justify the need for restoration actions. Woodland and forests are the ecosystems that provide most of services for a variety of uses (ecological inputs, pollution removal, protection and global target compliance) to many users (economic sectors, households, government). The Nature Restoration Law in Europe and the Kunming-Montreal Global Biodiversity Framework advocate for restoration actions in both terrestrial and marine ecosystems. This presentation illustrates a concrete application on matches and mis-matches of forest ecosystem services. They are assessed in physical and monetary terms. The monetary valuation of lost flows is eventually discussed in terms of advantages of carrying out and implementing restoration actions where ecosystem services mis-matches occur.

Natural capital in the Dutch building sector: local and global impacts

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Nico Polman[1]
Monica van Alphen[1], Heleen Bartelings[1], Luke Brander[2], Elisa Ciravegna[1], Victoria Guisado[2], Vince van 't Hoff[2], Tom Kisters[1], Luiz Magalhães-Filho[3], Carlotta Quagliolo[3], Peter Roebeling[3], Mieke Siebers[2], Willem-Jan van Zeist[1]
[1] Wageningen Economic Research
[2] Foundation for Sustainable Development
[3] Universidade de Aveiro

Abstract: There is a great need for housing in the Netherlands. The nationwide goal is to construct 900,000 new homes until 2030. This will put pressure on local natural capital (e.g. land, drinking water and recreational activities) and on global natural capital (e.g. construction materials). Taking care of natural capital can be pursued through a nature-inclusive approach to the urbanization task facing the Netherlands. Mass timber products are, potentially, a sustainable alternative to traditional building materials but the environmental benefits and circular economy aspects need to be evaluated (Ahn et al., 2022). However, where demand for timber increases, the maximum supply is limited by sustainability constraints and the willingness and ability of suppliers to increase supply (Lerink et al., 2023).

The need to include natural capital in integrated policy-making is gaining traction nationally and internationally, as recognition of the central role of nature in a future-proof and sustainable society grows. In ecosystem accounting literature, a new phase started revolving around the testing, engagement and adoption of ecosystem accounting (Comte et al., 2022). A key step is the link between ecosystem accounts and users, in view of the need for more integrated forms of policy-making.

In this paper we focus on the natural capital required in the form of building materials. We focus on the impact of timber construction through changes in the value of the world's forests directly and indirectly affected by Dutch construction. To provide this global context, we use meta-analytic value functions to include the value of forests in all regions relevant to the Dutch Building Challenge. The use of timber is analyzed using the MAGNET macroeconomic model, which includes the value of ecosystem services at the country level. The aim of this paper report is to map the policy playing field and understand what knowledge on natural capital accounting and forestry is needed to further develop the guidance and implementation structure for integrated policy making.

Pareto in the landscape: analyzing the potential supply of ecosystem services on a landscape level through efficiency analysis

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Vasja Leban[1]
Lidija Zadnik Stirn[1], Špela Pezdevšek Malovrh[1]
[1] University of Ljubljana, Biotechnical Faculty, Department of Forestry and Renewable Forest Resources, Slovenia

Abstract: In this study, we utilized the concept of Pareto efficiency to develop a framework for analyzing multiple ecosystem services (ESs) on a broader scale than individual ecosystems. Within this framework, ESs are considered as outcomes of functioning landscapes that require inputs to operate. These inputs represent the costs associated with managing various land uses or the average cost of producing products and supplying ESs linked to specific ecosystems. Given limited resources and the provision of ESs, the problem can be formulated as a mathematical linear program, enabling the use of operational research methods. We employed Data Envelopment Analysis (DEA) to examine the efficiency of different Units of Assessment (UAs) in producing ESs with given inputs and regression analysis to assess the factors influencing UAs efficiencies. To validate the framework, we selected a region in Southwest Slovenia and divided it into 627 UAs, each measuring 1 x 1 km. We modeled 17 ESs that had been previously identified as important and utilized freely available spatial data sources. The software tools used for organizing, producing, and visualizing the results were ArcGIS PRO 3.0, InVEST 3.10.1, and MS Excel. We employed Win4DEAP 2.1 software to conduct the DEA analysis and Gretl 2022c to run a Tobit regression analysis to identify the key factors influencing efficiency. The most efficient UAs are characterized by a larger share of forests and a smaller share of urban or other agricultural land uses. These UAs supply the most ESs for lower inputs, thus serving as benchmarks for inefficient UAs. Importantly, considering the costs of management as inputs in the presented framework adds an economic component, which is often overlooked in ESs analyses on a landscape level. The framework provides the foundation upon which more sophisticated models, such as dynamic models, can be built.

Spatial patterns of supply and demand for forest ecosystem services in Europe

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Abstract: Forest ecosystems provide multitude services to the society. Indicator-based assessments focus on their supply and valuation studies look at their demand. Basic economics states that equilibrium is where supply meets the demand. Does it exist for Europe's forests? In this study we aim to answer this question. Data for eleven forest ecosystem services is drawn from two Europe-wide surveys, where supply is provided by forestry practitioners and demand is provided by general population. Supply and demand data is then further extrapolated on a 1-kilometer spatial resolution for almost all of Europe's forests through application of machine learning, which combines survey-data with Europe-wide geospatial data. Results show patterns of supply and demand across Europe, describe how forests could be clustered based on these patterns and also link supply and demand data to forest descriptors (e.g. growing stock, tree species composition, protection status, distance to the city, etc.). Aside these direct results, the study also advocates for the notion that some methodologically sound and comparable data on both supply of and demand for forest ecosystem services is needed to sustainably govern forest ecosystem services provision.

The role of the innovation system in local payments for forest-water-related ecosystem services provision

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Zuzana Dobšinská[1]
Klára Balikova[1], Michaela Korená Hillayová[1], Marek Trenčiansky[1], **Martina Štěrbová**[2], Jaroslav Šálka[1]

[2] Department of Forest Management, National Forest Centre – Forest Research Institute Zvolen, Zvolen, Slovakia

Abstract: Almost all drinking water from surface sources in Slovakia is tied to forest ecosystems. Most water reservoirs (nine in Slovakia) for drinking water "production" and abstraction points are in forested areas. Providing such services relates to the forest management practices that forest owners and managers apply. To secure the provision of water-related services, innovative local payment schemes can be implemented. A functioning innovation system is needed to fulfil this task. The paper identifies the innovation system prerequisites to support local payment schemes for ecosystem services (PES) adoption in Slovakia. We analysed the three basic functions provided by the innovation system: information, coordination, and incentives. Data were collected using a standardised questionnaire sent out to stakeholders from forestry, nature protection, water management and civil society. The service valuation was carried out using the alternative cost method, where the positive impact of forest stands was alternated with water treatment costs. Results show that the state should communicate information on payment implementation possibilities and provide a regulatory framework. Respondents identified priority areas, mainly around water reservoirs, favouring local schemes. State authorities play a key role in designing and implementing PES schemes and should introduce innovative governance models to finance ecosystem services. The forest owners near the water reservoirs represent the supply side. Water companies, municipalities, and residents represent users. The innovation system should provide monetary and non-monetary incentives to motivate interested actors to provide water quality and quantity services. Monetary incentives should be either regulatory or public-private. Based on these findings, we proposed a PES scheme that would cover the costs of forest management changes to increase the water protection service. The experimental assessment confirmed that dependence on water treatment costs increases with the decrease in the forest cover of the water reservoir basin. The value of the water protection ecosystem service of the forest was quantified in the range of 1.67 - 8.90 € per hectare per year. The stakeholders consider such local payments an innovative mechanism for financing forest ecosystem services in Slovakia.

Valuation and governance of ecosystem services of nature protection areas in Slovenia

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Anže Japelj[1]

[4] University of Ljubljana, Biotechnical faculty

Abstract: Protected areas are key elements of landscapes that are to facilitate conservation of either ecosystems and ecological hotspots or artefacts of past human interaction with nature. Different types of parks (national, regional and landscape) are an important part of nature protection system in Slovenia and are complementary to stricter nature conservation aspirations, such as nature reserves, natural monuments, Natura 2000 sites, etc. Their management usually focuses on above mentioned aspects of nature protection, however parks can contribute to wellbeing in other, perhaps previously ignored, ways as well.

The aim of the study is to identify and assess ecosystem services in five parks throughout Slovenia (Logarska dolina, Škocjanske jame, Kozjanski park, Goričko, Triglavski park) but in a highly participatory format and to investigate whether or not these protected areas provide more diverse and more abundant ecosystem services that surrounding non-protected areas. This is important in a wider context of empowering protected areas as in theirs, to some extent neglected, role in the society. We designed and implemented a series of workshops where we identified relevant ecosystem services in each park, then we made a link between ecosystem services and types of ecosystems that provide them, and in the last stage are evaluating their potential provision. We also addressed possible conflicts of interest in use of ecosystem services. Among all identified ecosystem services, we picked three, which are being spatially represented (mapped); grassland productivity in relation to grazing and grass fodder, recreational landscape attractiveness, and pollination potential.

The entire approach outlined above is also being implemented in a format of guidelines that are to be used by parks (and perhaps other protected areas in Slovenia) in future management. It lays down a participatory and innovative process of valuation and governance of ecosystem services in protected areas in Slovenia, that had not been implemented up to this moment, but it also serves as a platform for connecting managers of protected areas with local communities and decision-makers. Something which is not always in place, but is imperative to successful management.

Valuing Ecosystem Services of Trees and Woodlands in the United Kingdom in improving Mental Health: an Avoided Costs approach

T5.20 Innovation in valuation and governing of forest ecosystem services to strengthen forest resilience and create pathways to societal impacts

Vadim Saraev[1]
Gregory Valatin[1], Tim Taylor[2], Matthew Bursnell[1]
[1] Forest Research, UK
[2] European Centre for Environment and Human Health, Department of Public Health and Sports Sciences, University of Exeter Medical School, UK

Abstract: Trees and woodlands can impact mental health through a variety of pathways. However, few monetary estimates currently exist of the value of the associated forest ecosystem services.

We estimate the direct cost savings – including those to the National Health Service, considering four pathways through which trees and forests can impact mental health, based upon relationships identified in the wider literature. The pathways considered are (i) the impact of visits to UK woodlands on improving mental health; (ii) the impact of physical activity in woodlands in improving mental health; (iii) the impact of street trees in reducing anti-depressant prescriptions; and (iv) the impact of a greater proportion of greenspace in a neighbourhood on improving mental health. Dose-response relationships are used to estimate improved health outcomes. Indicative economic values are based on avoided treatment costs and reduced work absences.

To minimise potential risks of double counting, estimates are given separately for each pathway. Cost savings associated with street trees reducing antidepressant use are estimated at £16 million per year, those due to physical exercise in forests at £18 million per year, those associated with visits to UK woodlands are estimated at £185 million per year, and trees' contribution via neighbourhood greenspace at £394m per year at 2020 prices.

Drawing upon population projections for the UK, the natural capital value over 100 years (from 2020) is estimated to be just over £11 billion for the mental health benefits of visits to woodlands. The aggregate value for woodland visits and street trees of mental health benefits is estimated at just over £12 billion.

This paper provides a first estimate of the value of the natural capital benefits of trees and woodlands for mental health in the United Kingdom and can be compared to other natural capital values to help support further development of UK natural capital accounts and policy.

Potential areas for future research include additional work to quantify the impact of woodland visits on reducing the prevalence of mental health conditions such as anxiety, the long-term benefits of exercise in woodlands, and the extent to which associated benefits vary between woodland types.

T5.21 Modelling forest scenarios as if people, climate and biodiversity mattered.

T5.22 Modelling forest trajectories under climate stress and changing management

A Pan-European Perspective on Past Disturbance Effects on Vertical Forest Structure

T5.22 Modelling forest trajectories under climate stress and changing management

Simon Besnard[1]
Alexandra Runger[1], Martin Herold[1, 2]
[1] Helmholtz GFZ German Research Centre of Geosciences, Section 1.4 Remote Sensing and Geoinformatics, Telegrafenberg, Potsdam, Germany
[2] Wageningen University and Research, Wageningen, the Netherlands.

Abstract: This study investigates the relationship between vertical forest complexity and past disturbance regimes across Europe. Forests are essential components of the global carbon cycle, serving as vital carbon sinks and regulators of climate. Understanding forest structure is crucial for accurate carbon storage quantification and predicting future ecosystem dynamics. Disturbances, both natural and human-induced, can have significant impacts on forest structure and alter the carbon balance of ecosystems. These alterations affect vegetation composition, forest density, and vertical structure, ultimately influencing ecosystem processes such as carbon sequestration, biodiversity, and habitat suitability. Therefore, comprehending the linkages between past disturbance regimes and vertical forest complexity is fundamental for assessing forest responses to disturbances.

We use Level 1B product waveform data from the Global Ecosystem Dynamics Investigation (GEDI) to characterize vertical forest complexity. The GEDI waveform data provide detailed information on the vertical distribution of vegetation, enabling us to assess the degree of forest structure complexity at a pan-European scale. We derive a vertical complexity index by extracting features from each waveform, such as waveform height, width, skewness, kurtosis, and the number of peaks, and combining them in a single index using dimensional reduction techniques (e.g., Principal Component Analysis). We also introduce and utilize the EUForest4ModelCube, a comprehensive pan-European Earth Observation forest data cube. We leverage the EUForest4ModelCube to extract Landsat-based temporal dynamics of disturbances to identify and classify events from 2000 to 2020. Additionally, we use the EUForest4ModelCube to estimate the biomass gap due to disturbance regimes, defined as the difference between potential maximum and actual biomass, as a complementary disturbance metric, using the ESA-CCI biomass product at 100m for 2010, 2017-2020. The integration of the EUForest4ModelCube, GEDI waveform data and the derived disturbance metrics allows for a thorough exploration of the influence of past disturbances on vertical forest complexity across European forests.

Through this analysis, we aim to investigate the widespread pan-European coupling between past disturbance regimes and vertical forest complexity. The findings of this study will contribute to a better understanding of the relationship between disturbance and vertical forest structure, providing valuable insights for forest management and conservation strategies in Europe.

Applying deep neural networks to develop high-resolution future forest and disturbance scenarios

T5.22 Modelling forest trajectories under climate stress and changing management

Marc Grünig[1]
Werner Rammer[1], Cornelius Senf[1], Rupert Seidl[1]
[1] Technical University of Munich, TUM School of Life Sciences, Ecosystem Dynamics and Forest Management

Abstract: Climate change challenges forest ecosystems and amplifies forest disturbances and their wide-ranging impacts on ecosystem services, biodiversity, and carbon storage. The ability to predict detailed vegetation dynamics and disturbance scenarios on large geographical scales is therefore gaining in relevance. To inform decision-makers, it is essential to incorporate both the direct effect of climate change as well as the interaction between forest development and disturbances into such scenarios. Here, we used the scaling vegetation dynamics (SVD) framework to upscale forest dynamics from stand and landscape scale to the continental scale to simulate high-resolution (100 x 100m) forest development trajectories. We couple those trajectories with process-informed statistical disturbance modules calibrated on remote sensing-based map products to further produce future disturbance scenarios under climate change.

SVD is a framework to simulate vegetation transition in response to environmental conditions. The predictions for these vegetation transitions are driven by a deep neural network (DNN), which is trained on forest simulations from process-based models. We established a database of local climate change simulations covering 10 million simulation-years across 13’500 locations in Europe. Coupling those simulations with auxiliary information of climate and environmental conditions, we created a training dataset for the DNN. The trained DNN predicts vegetation state transitions in response to environmental conditions, allowing to upscale forest dynamics efficiently. To initiate SVD on the continental scale, we compiled remote sensing products to establish a pan-European dataset on the current state of Europe’s forests (i.e., species composition, leaf area index and canopy height). Furthermore, we developed disturbance modules for wind, fire and bark beetles. These modules were built as process-informed statistical models based on historical disturbance and capture the relationship between environmental conditions and the occurrence of disturbances. These statistical models are integrated into the dynamic forest simulations in SVD, creating a feedback loop where the effect and extent of disturbances are contingent upon forest development states and, conversely, where disturbances can abruptly alter forest states. Our study is the first continental scale application of SVD and provides valuable insights into the potential impacts of climate change on European forests.

Assessing climate change impacts on Japanese cedar plantations: Mitigation and adaptation measures in shrinking scenarios

T5.22 Modelling forest trajectories under climate stress and changing management

Abstract: Achieving a balance between mitigation and adaptation to climate change in forestry has gained increasing significance in forested countries worldwide. Numerous studies have assessed the impacts of climate change on planted forests, analyzing the effectiveness of both mitigation and adaptation strategies by comparing present and projected future conditions within the same geographical area. However, the extent of planted forest can vary over time. In the case of Japan, the ratio of planted forest to the total forested area showed a rapid increase after World War II; however, it is currently anticipated to decline due to the challenges posed by an aging society with a diminishing number of children. In this study, our objective is to investigate the interaction between the shrinking area of planted forest and the effectiveness of mitigation and adaptation measures in addressing climate change on a nationwide scale. The process-based carbon cycle model for Japanese cedar (*Cryptomeria japonica*, Toriyama et al., 2021, PLOS ONE) plantations, based on Biome-BGC model, is updated in two ways: 1) by extending the tree age to encompass higher age classes, and 2) by incorporating the growth patterns of the two major genetic types of Japanese cedar. We utilize climate scenarios (GCMs of MRI-ESM2.0 and MIROC6) and spatial scenarios of Japanese cedar plantations at a 1-km resolution. These scenarios cover a historical trend spanning from 1960 to 2010, as well as future projections extending to 2090. Future trends are generated by considering different rates of harvesting (high/low) and re-planting of Japanese cedar (high/low). This approach results in four different future scenarios: baseline, active regeneration, passive regeneration, and transition to broad-leaved forests. These scenarios exhibited 87%, 76%, 72%, and 41% respectively of the remaining area of Japanese cedar plantations in 2090, relative to the area observed in 2000. The projected increase in net primary production in future scenarios generally exhibited lower values in the southwestern region of Japan compared to the northeastern area. We further investigate the impacts of regional zoning, based on the four scenario types, on the outcomes of climate change mitigation and adaptation.

Assessing European forest trajectories under climate change with a high resolution forest resource model, EFISCEN-space

[4] ETH Zurich

Abstract: European forest are rapidly changing: pressures from climate change and disturbances are increasing, as well as demands for goods and services. Analysing these future trends and where they clash has always been a huge challenge because of limited access to national forest inventory data (NFI). Over the past 10 years, we have been gathering detailed NFI plot data and its individual tree measurements. Now the database comprises > 300,000 NFI plots and > 4 million remeasured trees, thanks to 17 NFIs. For the demand side, we compiled the European Forest Industry Database (EUFID), which encompasses the location and capacity of 6,000 forest industry facilities, categorized into three value-chains: sawmills, pulp and paper, and bioenergy.

We developed the EFISCEN-space model, which now has spatially explicit distribution of timber resources at national forest inventory plot level, including details about the species and diameter composition. We fitted climate dependent tree growth functions, mortality functions and ingrowth functions, as well as litterfall rates and soil carbon models. High resolution (1x1 km) projections of the future carbon balance European forests, soils and harvested wood products will be presented, under trajectories of forest management changes (restoration needs) and changing societal demands with an industry accommodating and following these changes.

Assessing healthy forest regions and their ecosystem functions in Europe

T5.22 Modelling forest trajectories under climate stress and changing management

Charlotte Gohr[1, 2, 3]

[2] Centre for Econics and Ecosystem Management, Eberswalde University for Sustainable Development
[3] Leuphana University Lüneburg

Abstract: Unsustainable forest management practices and escalating impacts of climate change on forests significantly affect the forest health and the provision of forest ecosystem services crucial for human well-being. The project "Healthy Forest Regions" aims to address this challenge by engaging policy- and decision-makers and empowering key actors to safeguard forest ecosystem functionality, enhance biodiversity conservation, and ensure the provision of forest-based ecosystem services for sustainable regional development. It is a European project, implemented in 6 countries (Germany, Slovenia, Slovakia, Croatia, Austria, Czech Republic). We employ remote sensing and leverage the capabilities of the Google Earth Engine to define healthy forests by assessing forest ecosystem functions and their regulating services such as the temperature regulating effect and the buffering capacity. The cooling function of healthy forests is based on the land surface temperature at Landsat resolution. Trends over time and the relation to adjacent forest regions gives insights into the current functionality of these regions. The product is an accessible website that informs about the developments over time in each Healthy Forest Region. Additionally, users can select their own region and can assess information about their forests. Another key output of the project includes strategies for effectively communicating the value of healthy, functional forests and their ecosystem functions in promoting human health and well-being. This is implemented by workshops for actors in the regions. Ideally, our findings will assist actors in adopting sustainable forest management practices and formulating effective climate-change mitigation strategies.

Climate-Driven Shifts in Tree Recruitment: Implications for the Adaptation Potential of European Forests

Abstract: Climate change has emerged as a significant threat to forest ecosystems worldwide, impacting their dynamics and compromising the provision of essential ecosystem services. This study focuses on European forests, aiming to understand the effects of climate change on tree recruitment. While stand and landscape-scale projections have shed light on the importance of tree regeneration in forest dynamics, large-scale models often lack realistic representation of climate change impacts on forest regeneration. This research addresses the knowledge gap regarding the current state of forest regeneration and actual changes occurring at a European scale, thereby

enhancing our understanding of the adaptive capacity of European forests under climate change. By incorporating a dynamic tree recruitment model into the empirical forest growth model EFISCEN-SPACE, we utilise a comprehensive dataset of national forest inventories from 17 European countries to accurately represent the current forest state and investigate recruitment dynamics under the climate change scenario RCP 6.0. The study examines the density and compositional changes of tree recruitment, as well as their spatial patterns across Europe. Tree recruitment densities decrease with rising temperatures and water limitations, following a north-to-south gradient. Compositional shifts occur across all forest types due to a combination of climate change impacts and changing forest management paradigms. By applying a uniform concept to investigate shifts in tree recruitment at a pan-European level, this research identifies potential limitations to the adaptive capacity of European forests and contributes to our understanding of how these forests will respond to climate change. The findings of this study have implications for forest management strategies aimed at maintaining the health and sustainable provision of ecosystem services in European forests.

Climatic turning points in productivity of four main tree species in Central Europe

T5.22 Modelling forest trajectories under climate stress and changing management

Abstract: Local environmental conditions determine tree species productivity that can be further modulated by forest management. However, the ongoing climate change modifies forest productivity patterns, which may affect ecosystem sustainability. Here we aim to identify climatic turning points in species productivity in Central Europe identified by the shifts in local species ranking due to the changes in climatic conditions, manifested by the replacement of the productive superiority of one species by another one. We focus on four main tree species in Central Europe: European beech (*Fagus sylvatica* L.), Norway spruce (*Picea abies* (L.) H. Karst), Scots pine (*Pinus sylvestris* L.), and oak (*Quercus* spp.) and their response to climate change defined by 14 climate models driven by two RCP scenarios.

We examined the productivity response of the four tree species to changed climatic conditions by predicting forest development at 86 research sites distributed along a large environmental gradient with a process-based model Biome-BGCMuSo that simulates cycling of carbon, nitrogen, and water in terrestrial plant ecosystems with a daily time step. The data come from long-term experiments and cover five European countries including Croatia, Hungary, Slovakia, the Czech Republic, and Poland, at latitudes from N 43.889° to 54.559°, longitudes from E 12.62 to 23.72°, and elevations from 20 to 1,325 m a.s.l. Their mean annual precipitation total varied from 450 to 1,720 mm, the mean annual temperature range from 2.56 to 14.9°C, and soil depth fluctuates between 0.4 and 2 m.

The experimental design allowed us to compare the simulated performance of individual tree species and to identify the turning points in their productivity under local environmental conditions. The results revealed the pattern of winner and loser tree species across Central Europe, and indicated the site-specific potentials to compensate the decline in the productivity of one species by the increased productivity of another species. These findings provide valuable information about possible changes in tree species composition that can mitigate adverse effects of climate change and sustain future forest productivity.

Closing the DAta gap to develop Land Surface MOdels for COngo Basin forests (DAMOCO)

Abstract: Ground-based data suggest tropical forest carbon sinks might soon become less effective at slowing the accumulation of CO_2 in the atmosphere. However, Earth System Models fail to reproduce the observed trends of forest carbon sink saturation/decline, partly due to important gaps in the existing data underlying these models. The DAMOCO project intends to fill one of those most important data gaps concerning a tropical region of paramount importance: the Congo Basin.

In this project, we are first collecting and/or valorizing data covering all the successional gradients (pioneer, regenerating and mature forest) of the most dominant forest types of the Congo Basin. By combining different but complementary scientific approaches, we produce multi-temporal records of forest dynamics: (i) sub-daily estimates of carbon and water fluxes collected with eddy covariance equipment on the first flux tower in central Africa, (ii, iii) decadal-scale changes in carbon balance and biodiversity through repeated tree and tree trait measurements from a network of permanent forest inventory plots, and finally, (iv) millennial-scale changes in biodiversity through the analysis of ancient charcoal from soil profiles located next to the plots.

Secondly, we will combine this data to parametrize a state-of-the-art process-based Land Surface Model (ED2) for the central Congo Basin. Once the model is optimized, we will use it to upscale carbon and biodiversity dynamics for the entire central Congo Basin, apply it to test forest resilience to climate and land-use change in the region and simulate future carbon and biodiversity dynamics under climate and land-use change scenarios.

Here, we present the early progress and results of the project. In particular, we focus on our first ancient charcoal data which suggest a gradual change in species composition throughout the Holocene, related to past long- and short-term droughts and fluctuations in population density. Furthermore, we provide an outline of how this paleodata will be integrated and combined with the other data sources in the ED2 Land Surface Model.

Development of geospatial afforestation options and estimation of carbon storage under climate change in North Korea

T5.22 Modelling forest trajectories under climate stress and changing management

Eunbeen Park[1]
Hyun-Woo Jo[2], Mina Hong[1], Woo-Kyun Lee[1, 2]
[1] OJEong Resilience Institute (OJERI), Korea University
[2] Department of Environmental Science and Ecological Engineering, Korea University

Abstract: North Korea, located in the Mid-Latitude Ecotone, faces significant forest degradation caused by climate change and deforestation. However, the country lacks an efficient long-term and spatial restoration plan. To address this gap, this research aims to develop an optimal forest restoration plan for North Korea, aligned with the national restoration target, through the use of biophysical modeling. We focus on modeling afforestation targets and evaluating future management options. In order to identify suitable areas for afforestation, we identified degraded and deforested regions and determined appropriate forest species. Given the limited availability of forest resource information in North Korea, we utilized time-series satellite data, land cover maps, and South Korea's yield tables to evaluate the potential impact of afforestation under climate change. Based on the identified afforestation options, we simulated simple management scenarios that align with North Korea's national restoration target. The findings of our study offer valuable insights to policymakers and technical officials tasked with formulating regulations and action plans for forest management in North Korea. The geospatial analysis and afforestation modeling conducted in this study contributes to the development of effective strategies and guidelines for the restoration and sustainable management of forests in the country.

Disentangling land management and global change drivers of historical shifts in California forests

T5.22 Modelling forest trajectories under climate stress and changing management

Polly Buotte[1]
John Battles[1], Charles Koven[2], Anthony Walker[3], **Lara Kueppers**[1, 2]
[1] University of California Berkeley
[2] Lawrence Berkeley National Laboratory
[3] Oak Ridge National Laboratory

Abstract: Our ability to confidently predict future forest structure and dynamics at landscape to regional scales requires capturing interactions among increasing atmospheric CO2 (iCO2), climate changes, and land management. In the Sierra Nevada Mountains of California, forest biomass and tree density have increased alongside shifts in species composition since European settlement. Observations and experiments suggest that iCO2 has promoted a positive global carbon sink through increased water use efficiency. There is also evidence that over the 20th century, tree harvest, fire suppression and climate changes have influenced these forests. However, no study has yet quantified the relative importance of these multiple drivers of forest change and how they may vary across the region. We used the vegetation demographic model, CLM-FATES, to simulate transient forest change over the 20th c. in the mixed conifer forest – the most widespread forest type in the Sierra Nevada. By implementing factorial scenarios with single and combined drivers, we determined that fire suppression increased biomass by 27 ± 12% and iCO2 increased biomass by 12 ± 2% over the 20th c. Fire suppression decreased light demanding pine density and relative abundance, while iCO2 increased shade tolerant functional types. Fire suppression effects on biomass were more pronounced in relatively cooler, wetter portions of the domain, while iCO2 most increased biomass in warmer, drier areas. Harvest slightly increased pine density, but reduced pine size because it was only applied to large diameter trees. The results, which reproduce observed changes in water use efficiency and are consistent with empirical studies of fire suppression and harvest effects, suggest that capturing these interacting drivers is both possible and necessary to predicting ongoing forest change.

Do models of forest dynamics correctly capture tree regeneration?

Abstract: Under the pressure of climate change, increasing disturbance impacts, and changing societal demands on forest ecosystem services, it is becoming ever more important to understand future forest trajectories. Models of forest dynamics are pivotal for assessing long-term forest dynamics considering the impacts of climate, and tree regeneration is a key process in forest dynamics, particularly in the context of forest resilience and climate change. However, an assessment of the ability of models to accurately represent tree regeneration is lacking. We used 15 models that were built to capture long-term forest dynamics at the stand, landscape, and global

levels. They comprise both empirical as well as process-based approaches. With these models, we simulated tree regeneration at 200 unmanaged sites in European forest reserves, representing large environmental gradients across Central Europe. The results were evaluated against comprehensive observed data from these forests. Most of the models overestimated regeneration levels, which is compensated in some models by high simulated mortality rates. Simulated species diversity of regeneration matched observed ranges. Models simulating higher species diversity at the stand level did not feature higher regeneration diversity. The effect of light availability on regeneration levels was captured better than the effect of temperature and soil moisture, but patterns were not consistent across models. Increasing complexity in the tree regeneration modules of the models was not related to higher accuracy of simulated tree regeneration. Overall, individual model design was more important than scale (stand, landscape, global) and approach (empirical, process-based) for accurately capturing tree regeneration. Despite considerable mismatches between simulation results and data, it is remarkable that most models captured the essential features of the highly complex process of tree regeneration reasonably well while not having been parameterized with such data. We conclude that much can be gained by evaluating and refining models of tree regeneration, and we provide a set of research recommendations. The representation of forest dynamics in these models would become much more robust, particularly in the face of climate change and post-disturbance dynamics, thus strongly reducing the uncertainty in long-term projections of future forest dynamics.

Drought response of rear edge bottomland forests in the largest green corridor of the the Po Plain

T5.22 Modelling forest trajectories under climate stress and changing management

Giorgio Vacchiano[1]
Sebastian Brocco[1], Osvaldo Pericolo[2], Paola Nola[2]
[1] University of Milan, DISAA, via Celoria 2, 20133 Milan, Italy
[2] University of Pavia, Department of Earth and Environmental Sciences, Via S. Epifanio 14, 27100 Pavia, Italy

Abstract: Climate change poses significant challenges to forest ecosystems worldwide, particularly in vulnerable regions such as rear edge forests and bottomland hardwoods. Understanding the resilience of these forests to climate-related stressors, specifically drought, is crucial for effective conservation and management strategies. This study aimed to assess the temporal and spatial variability of resistance and resilience to drought in the forests of Ticino Park, witha specific focus on natural formations of Scots pine in plain and hilly environments.

To evaluate the temporal variability of drought response, dendrochronological analyses were conducted on three populations of Scots pine. These analyses examined the growth response of the trees to climatic conditions over both long-term and short-term periods, providing insights into their resistance, resilience, and recovery following drought events. By examining the growth patterns and incorporating climate data, a comprehensive understanding of the forests' adaptive capacity was obtained.

Furthermore, the spatial variability of resistance and resilience to drought assessed using multi-temporal analysis of remote sensing imagery, specifically the Enhanced Vegetation Index, derived from Landsat data. This analysis allowed for the detection of changes in vegetation dynamics in response to extreme climate events. Descriptive statistical models were developed, incorporating topographic, climatic, seasonal, and structural variables, to elucidate the factors influencing the forests' resistance and resilience to climatic extremes.

Finally, we simulated carbon sink in different forest formations of Ticino Park under various climate change scenarios. Utilizing the Carbon Budget Model simulator, the growth of the forests and their carbon sequestration potential were predicted based on available data from the park's forest management plan. These simulations provided valuable insights into the future carbon dynamics of the forests under different climatic and management scenarios.

Overall, this research contributes to our understanding of the resilience of rear edge forests and bottomland hardwoods to drought in the context of climate change. The findings can inform adaptive management strategies, aiding in the conservation and sustainable management of these important forest ecosystems.

Early management decisions after natural disturbances and their long-lasting legacies

T5.22 Modelling forest trajectories under climate stress and changing management

Moritz Baumeister[1]
Markus A. Meyer[1]
[1] Department of Agriculture, Ecotrophology and Landscape Development, University of Applied Sciences Anhalt, 06366 Köthen, Germany

Abstract: Forest ecosystems are projected to experience disturbances in greater intensity and severity due to further rapid change of climatic conditions. The early management of disturbed forest sites often includes salvage logging and the planting of tree species. To understand the influence of this early management decisions on the forest trajectories, it is essential to aggregate the current empirical findings regarding their effects on ecosystem services and biodiversity. In a first step the study systematically reviews existing empirical studies and meta-analyses addressing the effects of early management after disturbances on forest trajectories. In a second step the individual-based process model iLand is parameterized and applied to the Harz mountains in central Germany. The outcome is used to evaluate if the projected trajectories based on empirical findings can be reproduced by the model. The modelled scenarios include the management of salvage logging, tree planting and a non-intervention natural regeneration scenario. A scenario analysis will be conducted with the iLand model to compare different early-stage forest managements and investigate their long-term legacies for future forest ecosystems beyond the scope of available empirical data.

The negative effects of management decisions like salvage logging have been demonstrated for several species taxa and ecosystem services. Removing biological legacies on large-scales has the potential to reduce ecosystem resilience on the long-term even if measures of preventing further insect outbreaks and mitigating subsequent disturbances may seem appropriate on the short term. The decision of which tree species is planted often targets a specific outcome (e.g., timber volume). The paradox situation of persisting clear singular management targets in parts of the forestry sector in a rapidly changing world is addressed by discussing the anticipated uncertainty encountered on projected forest development on a landscape scale by the iLand model. We address uncertainty by multiple simulation runs for the same scenario and evaluate the difference in variance of outcomes between management scenarios. To understand the consequences of post-disturbance management for forest trajectories it is important to minimise negative consequences of current management decisions for future forests under further enhanced environmental change.

Eco2Adapt - Maintaining ecosystem services in a changing climate: a case study from the Swiss Alps

T5.22 Modelling forest trajectories under climate stress and changing management

Maximiliano Costa[1]
Harald Bugmann[1]
[1] Forest Ecology, Institute of Terrestrial Ecosystems, ETH Zurich, Switzerland

Abstract: The European project Eco2Adapt aims to support stakeholders, forest owners and practitioners to manage forests and optimise social and environmental resilience using the concept of nature-based solutions. The project combines interdisciplinary knowledge from scientists and stakeholders in Europe to understand perceptions and provide incentives for adaptive management and policy. The project is based on Living Labs (LLs). These consist of a network of case studies located at regional scale in climate hotspots across Europe. Data from the LLs will be used to refine models to determine temporal socio-economic pathways, to calculate alternative adaptation strategies for multiple risk analysis, and to consider interactions between large bundles of ecosystem services in a spatial setting. One of the models that will be used in the LLs is LandClim, a spatially explicit forest landscape model developed to assess climate and management impacts on forest dynamics. In addition, LandClim has several modules to simulate the effects of natural disturbances, such as storms or bark beetle outbreaks. One of the Living Labs is located in the Swiss Alps, in the canton of Grisons in the Surselva valley. The case study represents the alpine environment with a wide range of species and altitudes. Special attention is given to the forest's protective function against natural hazards (e.g. rockfall and avalanches), as this is the most distinctive feature of this Living Lab. Sustainable wood production is a key ecosystem service that would also need to be investigated, especially under different climate change scenarios. The ultimate goal for the Swiss Living Lab is to assess how different management practices affect the sustainable provision of wood and the protective function of forests in the future.

Ecological range and spread of selected Kenyan forest species in changing climate

T5.22 Modelling forest trajectories under climate stress and changing management

Jesse Owino[1]
Alice Adongo[1], Peter Angaine[1], Chemuku Wekesa[1], Samson Ojunga[1], Angela Muthama[1], Gabriel Muturi[1]
[1] Kenya Forestry Research Institute

Abstract: The impacts of climate change on forest ecosystems are of growing concern, particularly in regions characterized by high biodiversity such as Kenya. Understanding the ecological range and spread of tree species under changing climatic conditions is essential for effective conservation and management. This study investigates the ecological range and spread of five selected Kenyan forest species, namely Liquidambar stracyflua, Alnus junguiana, Cynometra webberi, Brachistagia spiciformis, and Cestrum aurantiacum, in the context of a changing climate. Using species distribution modeling techniques, historical occurrence data, environmental variables, and climate projections were integrated to assess the potential shifts in the distribution of these tree species. MaxEnt, a widely used modeling tool, was employed to generate current and future distribution maps of the selected species.

Preliminary findings indicate distinct responses among the studied species to projected climate scenarios. Liquidambar stracyflua and Alnus junguiana demonstrate a potential expansion of their ecological ranges towards higher elevations, reflecting their preference for cooler and more humid conditions. Cynometra webberi and Brachistagia spiciformis exhibit a contraction in their suitable habitats, indicating their vulnerability to increasing temperature and altered precipitation patterns. Cestrum aurantiacum, on the other hand, demonstrates a relatively stable distribution range, with minimal projected shifts under the changing climate.

Furthermore, the study explores the ecological factors influencing the range dynamics of these tree species. Elevation, and biotic interactions were considered as important determinants of species distribution. The findings from this research provide valuable insights into the potential impacts of climate change on the distribution and spread of selected Kenyan forest species. The projected shifts in species ranges can inform conservation efforts, such as identifying suitable areas for assisted migration or reforestation programs. Moreover, understanding the ecological factors driving range dynamics contributes to a better understanding of species' responses to a changing climate. Considering other factors such as land-use changes and human activities is crucial for comprehensive conservation planning and adaptive management in the face of climate change.

Keywords: climate change, ecological range, species distribution modeling, Kenyan forest species, conservation, management strategies.

Ecosystem model projections on the impact of climate change and forest management on the provisioning of forest ecosystem services in Sweden

T5.22 Modelling forest trajectories under climate stress and changing management

John Bergkvist[1]
Fredrik Lagergren[1], Paul Miller[1], Maj-Lena Finnander Linderson[1], David Wårlind[1], Mats Lindeskog[1], Anna Maria Jönsson[1]
[1] Lund University, Department of Physical Geography and Ecosystem Science

Abstract: Ecosystem models provide useful tools for assessing the influence of changing climate conditions and of forest management on ecosystem structure and functioning. This work provides insight into potential outcomes for forest ecosystems in Sweden at the end of the 21st century, as projected by the dynamic vegetation model LPJ-GUESS for two climate change trajectories, RCP 2.6 and RCP 8.5.

Outcomes for multiple forest ecosystem services are assessed, comparing three future alternatives for forest management: (i) Business-as-usual (BAU) when the current Swedish management paradigm continues, (ii) Adaptation & Resilience (AR) where species mixtures and deciduous stands increase and monocultures decrease, and (iii) EU-policy (EUPOL) where the area managed as continuous cover and set-aside forest land increases.

End-of-century model projections reveal higher rates of carbon sequestration in forests managed as BAU when compared to AR or EUPOL, but also increased risks of storm damage and nitrogen leakage. In the EUPOL scenario, forests provide higher levels of deadwood and improved carbon storage, whereas the AR scenario offers a middle ground with moderate provisioning of multiple ecosystem services.

Our findings indicate that a climate trajectory representative of RCP 2.6 will have a relatively limited influence on the functioning of forests at the end of the century. For all three management scenarios, the model indicates a consistent increase in the carbon stored in woody biomass within the ecosystems, whereas the carbon stored in soil show small but steady decreases.

The implications of RCP 8.5 are larger changes in the rates of ecosystem carbon uptake and emissions, regardless of the given scenario of forest management, with an increase in net primary productivity in the range of 19-26% at the end of the century. Although overall woody growth is stimulated in RCP 8.5, the expected increased frequency and intensity of natural disturbances contribute to uncertainty regarding the extent of potential ecosystem carbon gains and losses.

Futures of European forests and forestry

T5.22 Modelling forest trajectories under climate stress and changing management

Minna Räty[1]
Leena Kärkkäinen[1], Mikko Kurttila[1], Mikko Weckroth[1]
[1] Natural Resources Institute Finland (Luke)

Abstract: The future of forests and forestry in Europe is determined by multiple factors, different actors, and variating expectations. The forest policies at different spatial scales ranging from global to regional level, set targets and limits for the sustainable forest management and use, to the whole forest-based sector. At the same time, climate change impacts e.g., growing condition and damage risks in the forests. Further, a need for biomass is increasing for various purposes. At the end, the forest management decisions are made by forest owners which as a group is heterogenic (e.g., state, investment companies and private owners) each having different and sometimes contradicting priorities for their forests. Consequently, modeling the future of forest resources is not a simple task.

In the Horizon Europe project EUFORE we aim at identifying the anticipated future trends on the supply side of forest resources in Europe. We consider future changes in 1) forest resources, 2) forest management (e.g., close-to-nature forestry, introduction of new tree species), 3) wood mobilization, 4) societal developments (e.g., evolving forest ownership structure, demographics, urbanization and emerging counter-urbanization), 5) climate-change impacts (e.g., changes in productivity, changes in species ranges, natural disturbances and extreme events), and 6) demands for ecosystem services and sustainability (e.g., biodiversity, non-wood forest products, recreation, protective functions of forests).

First, we make a literature review covering existing forest modelling studies and forest statistics. Starting from the current state and observed trends in the past derived from forest statistics and utilizing the results of previous studies we formulate future trends for chosen forest and forest related indicators and forest scenarios. The literature-based scenarios are modified, future developed and validated with a participatory method in workshops targeted at experts and stakeholders of different interests, sectors, and regions of Europe. The result will provide a Europe-wide outlook on the wood supply and forest state in 2040, which we are willing to present in the seminar.

Implications of climate change, CO2 fertilization and disturbance impacts on GHG emission projections in the large-scale forest model G4M

T5.22 Modelling forest trajectories under climate stress and changing management

Mykola Gusti[1]
Andrey Lessa Derci Augustynczik[1], Andre Deppermann[1], Fulvio di Fulvio[1], Nicklas Forsell[1], Pekka Lauri[1], Petr Havlik[1]
[1] International Institute for Applied Systems Analysis

Abstract: Climate change alters forest dynamics and is expected to increase forest damage due to windfalls, insect outbreaks, forest fires, and other disturbances. Climate change impacts involve complex interactions and forest processes, making changes in forest productivity context-dependent, with regional variations. Depending on the RCP scenario, the climate, atmospheric CO2 concentration, and the damage caused by amplified disturbances may change considerably by 2100, compared to the current levels, making accounting for the respective impacts on GHG essential. Typically, large-scale models do not account for climate change effects on the forest sink. Here, we address this issue and employ the large-scale Global Forest Model G4M to assess GHG emissions under different wood demand and CO2 mitigation policies in Europe. To account for the climate change and CO2 fertilization impacts, we apply a process-based 3PGmix model for deriving geographically explicit change in growing stock that is used in G4M for modifying forest increment. To consider the forest damage due to windfalls, insect outbreaks, and forest fires we use projections by Seidl et al. (2014) and downscale them to a 0.5x0.5° grid, taking into account the vulnerability index in each cell based on Forzieri et al. (2021) and the disturbance activity in each country given by Patacca et al. (2023). The damage data is implemented in G4M to force salvage logging of a specified amount of wood in the case of windfalls or reduced amounts in the cases of insect outbreaks or a forest fire, based on relevant forest attributes (e.g. age or tree height). The resulting forest productivity, in the case of acclimation to elevated CO2, remains stable under the RCP2.6 scenario. In the Mediterranean region, forest productivity is reduced due to the hotter and drier conditions. In montane forests of the temperate bioclimatic zone and boreal zone, forest productivity responds positively to increased temperatures. However, under RCP8.5 the forest growth decreases also in the boreal zone. The persistent CO2 fertilization counterbalances the negative effect of the decrease in precipitations in intensive climate change scenarios, while forest damage increases over 3 times by 2100, with higher values under more intense climate change scenarios.

Lowland forest structure and composition approach a turning point under increasing climatic stress

T5.22 Modelling forest trajectories under climate stress and changing management

Abstract: Climate change-induced decreases in forest vitality combined with an increase in natural disturbances may fundamentally shift future forest composition and structure. Recent studies have revealed irreversible shifts in mountain forest ecosystems under continued climate change. It remains an open question whether and when such shifts occur in lowland forests which might be more tolerant to climate change, but lack topographic buffering mechanisms. In this study, we investigate the future of temperate lowland forest ecosystem using the Meerdaalforest complex in central Belgium (Western Europe) as case study. Potential shifts in composition and structure were simulated using the mechanistic individual-based forest landscape model "iLand", incorporating a variety of climate projections and disturbance regimes. Finally, we analysed whether ecosystems might return to their initial state if temperature and precipitation revert to historic conditions.

Our findings show that natural disturbances currently have a limited effect on lowland forest composition and structure, although projections indicate that their impact (disturbed volume) could increase by up to 193% under the hottest and driest climate projections. Furthermore, lowland forests are susceptible to tipping points in forest composition and turning points in forest structure if temperature increases exceed 2°C. These shifts are particularly pronounced on fine-textured, well-drained soils, as soils with a high sand content are typically already dominated by more drought-tolerant species. As a result, the sandier sites can often revert more closely to their initial state, experiencing turning points rather than tipping points in their composition. We found that soil diversity may serve as a refuge for drought-sensitive species in lowland forests, similar to the role of topographic microrefugia in mountain forests.

Our study highlights the vulnerability of lowland forest composition and structure to climate change, if society fails to keep warming well below 2°C. However, our results also suggest that soil diversity may act as refugia in lowland forests, indicating that lowland forest resilience could benefit greatly from improved forest connectivity.

MEDFATE 3.0.0: A trait-enabled model to simulate Mediterranean forest function and dynamics at regional scales

Abstract: Several dynamic vegetation models exist that combine a detailed mechanistic approach to energy, water and carbon balances with the ability to represent vegetation structure and simulate demographic processes. However, examples of such models specifically designed for Mediterranean forest ecosystems are less common. Here we report the design, parametrization and evaluation of MEDFATE (v. 3.0.0), a cohort-based and trait-enabled model of forest dynamics, for its application over a region in the Western Mediterranean Basin. The model allows performing forest energy, water and carbon balances coupled to demographic processes, and can be used to simulate both fire and drought impacts on forest function and dynamics. 217 taxonomic entities are represented in the model, defined according to woody species codes of the Spanish National Forest Inventory. While forest inventory records were used to obtain some empirical parameter estimates, a large proportion of physiological, morphological, and anatomical parameters were matched to measured plant traits, with estimates extracted from multiple databases and averaged at the required taxonomic level. Estimates for non-observable key parameters were obtained using meta-modeling and calibration exercises. Missing values were addressed using imputation procedures based on trait covariation, taxonomic averages or both. The model properly simulated observed historical changes in basal area, with a performance similar to an empirical model trained for the same region. While strong efforts are still required to parameterize trait-enabled models for multiple taxa, and to incorporate intra-specific trait variability, we advocate for the adoption of trait-enabled and population-structured models for regional-level projections of forest function and dynamics.

Modeling Douglas-fir and Western Hemlock Seedling Mortality Using Competing Vegetation Abundance, Climate, and Soil and Plant Water Relations

T5.22 Modelling forest trajectories under climate stress and changing management

CARLOS GONZALEZ-BENECKE[1]
Claudio Guevara[1], Emily Von Blon[1]
[1] Oregon State University

Abstract: The Pacific Northwest of the United States (PNW) is expected to experience substantial climate change impacts, including increased temperatures and drought. Understanding the physiological responses of planted seedlings to water deficit is essential for their adaptation and survival. Analyzing the xylem's vulnerability to cavitation is a promising way to understand the limitations to water transport experienced by seedlings in the context of reforestation. This method has been used on a variety of tree species, including Douglas-fir (*Pseudotsuga menziesii*) and western hemlock (*Tsuga heterophylla*), but specific thresholds triggering mortality are not well understood. The Competition and Site Interactions Experiment (CoSInE), developed by Oregon State University's Vegetation Management Research Cooperative, began in 2016 with the aim to understand the effects of forest vegetation management (VM) regimes on seedling physiology, growth and survival, as well as early-seral vegetation community characteristics across the diverse landscapes of the PNW. CoSInE includes 11 sites installed in Oregon and Washington States. We developed models to estimate early-seral vegetation abundance and water use dynamics as a function of climate and soil characteristics. Models to estimate seedling pre-dawn and midday water potential were also determined for both, Douglas-fir and western hemlock. Laboratory determination of vulnerability to cavitation curves were validated with *in situ* measurements of seedling midday water potential and native hydraulic conductivity. The effect of water stress on seedling's xylem loss of hydraulic conductivity and its relationship with mortality were also determined for each species using laboratory and field assessments. The models developed are a useful tool for addressing the impact of VM treatments and genotype selection on seedling survival under changing climate and site conditions.

Modelling and Predicting Global-scale Suitable Areas for Sclerocarya birrea, (A. Rich.) Horchst, subspecies Under the Current and Future Climates

T5.22 Modelling forest trajectories under climate stress and changing management

Abubakari Munna[1]
Proches Hieronimo[2], Nyambilila Amuri[1], Dino Woiso[3]
[1] Department of Soil and Geological Sciences, Sokoine University of Agriculture, Tanzania
[2] Department of Agricultural Engineering, Sokoine University of Agriculture, Tanzania
[3] Department of Biosciences

Abstract: Marula, *Sclerocarya birrea* (*S. birrea*) (A. Rich.) Horchst, is a drought-tolerant and multipurpose tree native to Africa whose population is currently declining. The *S. birrea* subspecies have been used to restore drylands and introduced outside Africa as a pilot towards commercial cultivation. However, there is a global paucity of information regarding where its subspecies can successfully establish themselves beyond Africa with changing climates. We aimed to model and document environmental variables which define the global-scale suitable areas for *S. birrea* and its subspecies, and predict and quantify global-scale suitable areas for *S. birrea* and its subspecies beyond their native ranges under the current and future warming climates. We modeled and predicted areas by using MaxEnt algorithm using occurrence data from Africa and, climatic and topographical environmental variables, and the Max Planck Institute for Meteorology and Hadley Climate Center's global Earth Systems Models climate data under shared socio-economic pathways (SSPs) greenhouse gas concentrations, SSP3-7.0, for the year 2050 and 2080. The results show that the models' predictive power was robust, with Receiver Operating Characteristics (ROC)'s Areas under the Curves (AUCs) ranging from 0.90 to 0.98. Suitable areas for *S. birrea* are mainly defined by potential evapotranspiration of the coldest quarter and potential evapotranspiration seasonality; subsp. *birrea* by continentality and potential evapotranspiration of the coldest quarter; subsp. *caffra* by isothermality and potential evapotranspiration of the wettest quarter and subsp. *multifoliata* by temperature seasonality and precipitation of the driest quarter. Currently, suitable areas for *S. birrea* and its subspecies exist in all continents except Europe and Antarctica and, occupy 3,751,057 km^2 to 24,632,452 km^2 of earth's terrestrial area scattered in 54 to 107 countries predominantly in global biomes with climatic conditions ranging from desert tropical to temperate humid. Under future climates, the areas will retract by 64 to 100%, shifting to high latitudes and being limited to tropical desert-to-desert temperate, Mediterranean warm global biomes, and some regions of Eastern Europe will become suitable. Suitable areas for *S. birrea* and its subspecies exist beyond Africa, and they will retract and migrate to high latitudes under future warming climates.

Modelling forest ecosystem services resilience to drought and assessing its drivers in Mediterranean forests

T5.22 Modelling forest trajectories under climate stress and changing management

Abstract: Forests cover ca. 30% of the land surface, host a significant amount of Earth's biodiversity, and provide a multitude of material and non-material benefits to humans. While global environmental change is rapidly altering ecosystems, we still have a limited understanding of how forests and their ecosystem services may endure and recover from anthropogenic and natural disturbances. The resilience framework represents a powerful approach for assessing forest ability to withstand pressure and its drivers and, ultimately, understand how to preserve biodiversity and human well-being. Here we used a process-based forest model (MEDFATE) together with several sources of empirical data to estimate five forest ecosystem services (timber provision, water supply, carbon sequestration, erosion control, potential recreation value) and their resilience to the severe drought that hit Catalonia in 1994. The model was initialized and evaluated using data from ca. 3,400 plots of the Spanish National Forest Inventory. Our modelling exercise spans the period 1990-2016 and uses (i) actual weather (disturbed scenario), (ii) simulated, non-drought weather (undisturbed scenario), and (iii) simulated, extreme drought weather (extreme scenario). We estimated forest ecosystem services for each of these scenarios and calculated the resilience using the log response ratio between the disturbed/extreme scenario and the undisturbed scenario (counterfactual approach). Initial results based on leaf area index (LAI) dynamics for trees (DBH > 7.5 cm) showed the lowest resilience in the extreme scenario. Further, plots with low resilience values were observed at sites characterized by warmer and dryer climates (southern Catalonia). We expect similar results for the five forest ecosystem services. This work is part of the EU-funded project RESONATE (https://resonateforest.org/).

Modelling resilience to wind disturbances in production forests: a case study and its implications for management

T5.22 Modelling forest trajectories under climate stress and changing management

Jonathan Holder[1]
Mikko Peltoniemi[2], Annikki Mäkelä[1], Susanne Suvanto[2]
[1] Department of Forest Sciences, University of Helsinki, Finland
[2] Natural Resources Institute Finland (Luke), Finland

Abstract: In Europe, the frequency and intensity of disturbances has been increasing in recent decades. In the light of expanding demand for a variety of ecosystem services provided by forests, the resilience of these ecosystems is of growing interest.

The first part of this study focuses on the resilience of forest ecosystem services in a region dominated by even-aged production forests, examining the effects of a single disturbance event. In a 60.000 km^2 region in south-western Finland, we model the impacts of a severe wind disturbance that occurred in 2001.The process-based forest model PREBAS is initialised with national forest inventory (NFI) data acquired prior to the storm, and plot-level disturbance impacts are based on a special post-disturbance inventory. We analyse the effect of the storm event and the ensuing management on a range of forest variables and ecosystem services: growth, age structure, C storage in biomass and soils, available and harvested timber assortments, deadwood, biodiversity, and the supply of non-wood products. Resilience is quantified by the measures of perturbation and recovery rates. We apply a range of scenarios, considering multiple levels of disturbance intensity, the extent of salvage logging, and different post-disturbance management approaches. The results of the study support the formulation of post-disturbance management measures which increase forest resilience and maintain the long-term provision of ecosystem services.

In the second part of the study, an empirical wind disturbance model based on NFI data and a comprehensive dataset of salvage loggings is implemented in PREBAS. The modelling framework is applied in the same study area and initialised with 16x16m resolution multi-source NFI data. The occurrence and severity of wind disturbances are dynamically and spatially explicitly modelled based on stand structure, wind speed, topography, and management. Simulations cover a range of management and climate scenarios, and the long-term impact of wind disturbances on the ecosystem services mentioned above are analysed, as well as the efficiency of adapted management approaches to support these.

In addition, the two studies allow for a comparison of wind throws as pulse vs pressure disturbances on large scales, with implications for future wind disturbance modelling.

Modelling Swedish Forest Transpiration under future enhanced summer extremes

T5.22 Modelling forest trajectories under climate stress and changing management

Minchao Wu[1]
Fredrik Lagergren[1], Maj-Lena Finnander Linderson[1]
[1] Department of Physical Geography and Ecosystem Science, Lund University

Abstract: The escalating occurrence of droughts and heatwaves on a global scale poses a significant threat to ecosystems worldwide, including those in Sweden. The severe drought experienced in Sweden during the summer of 2018 had a profound impact on the country's forests, causing disruptions in their functioning and productivity. This situation presents a crucial challenge to the resilience of Sweden's forests in the face of future climate change. Uncertainty persists regarding the ability of these forests to adapt to rapidly changing climatic conditions while maintaining crucial ecological functioning, such as transpiration and carbon uptake capacity, as well as ecosystem services like biomass production. The maintenance of these functions and services is of great value to both Swedish society and the regional climate system. To assess the resilience of Sweden's forests to changing climate extremes, we conducted a study utilising recently available in-situ forest measurements, including comprehensive sap-flow measurements from research stations in the ICOS Sweden and SITES networks. We establish the ecosystem response based on observations from recent extreme droughts, which we thereafter use in LPJ-GUESS together with climate change scenarios to assess future changes in Swedish forest resilience. Our analyses revealed a significant decrease in whole-tree transpiration during the drought of 2018. Furthermore, we observed a distinct relationship between surface conductance and Bowen ratio at the ecosystem level, indicating strong vegetation feedback during drought compared to non-drought years. These findings suggest that the changes in forest functioning observed during the drought were substantial enough to affect the efficiency of land-atmosphere interactions, particularly in terms of water and carbon exchanges through the soil-plant-atmosphere continuum. Consequently, these changes are likely to have long-lasting effects on ecosystem productivity in subsequent years and increase the overall vulnerability of the forest to climate variations over an extended period.

Modelling the potential distribution of major plant species under climate change scenarios along an aridity gradient in Namibia

T5.22 Modelling forest trajectories under climate stress and changing management

Leena Naftal[1]
Vera De Cauwer[1], Ben Strohbach[1]
[1] Namibia University of Science and Technology (NUST)

Abstract: Climate change is expected to have major impacts on plant species distribution worldwide. These changes will affect plant species in one of three ways: the timing of seasonal activities, physiology and distribution. This study aims to predict the effect of shifting climatic conditions on the major vegetation units and their dominant species along an aridity gradient through Namibia. Namibia's vegetation is characterized by open woodland in the northeast to low open shrubland in the southern part of the country. These differences are a result of increasing aridity from north to south with a rainfall gradient from 600 mm to 100mm. A classification of vegetation was done for 1986 relevés using cluster analysis, a multi-response permutation procedure and indicator species analysis. Future projections for the most important climate variables were used to model potential future distribution of the presently dominant vegetation units. This modelling approach used two scenarios of Representative Concentration Pathways (4.5 and 8.5) from two Global Climate Models - the IPSL-CM5A-LR and HAdGEM2-ES for 2080. The predicted distribution shows a high expansion potential of *Eragrostis rigidior—Peltophorum africanum* mesic thornbush savannas, *Combretum africanum—Terminalia sericea* broad-leafed savannas and *Combretum apiculatum* savannas under both scenarios. For other vegetation types Climate scenarios of the IPSL-CM5A-LR, and the RCP4.5 of the HAdGEM2-ES predicts a north-to-south shift, whilst a south-to-north shift of the vegetation units is likely under the RCP8.5 of the HAdGEM2-ES. *Combretum apiculatum* savannas are predicted to become dominant over other vegetation units for both scenarios, with a percentage gain between 10% for the intermediate scenario, and 31% for the RCP8.5. Knowing the future distribution of these vegetation units is important to establish adaptive management strategies.

Modelling tree mortality from forest inventory data: which approach for which purpose?

T5.22 Modelling forest trajectories under climate stress and changing management

Jeanne Portier[1]
Nataliia Rehush[1], Jürgen Zell[1], Golo Stadelmann[1], Esther Thürig[1], Brigitte Rohner[1]
[1] Swiss Federal Institute for Forest, Snow and Landscape Research, WSL, Zürcherstrasse 111, CH-8903 Birmensdorf, Switzerland

Abstract: In recent years, increasing background tree mortality has been observed across many European forests. Numerous studies investigate how forests are responding to global changes to foresee how these forests will develop in the future, and to generate management recommendations accordingly. Forest inventory data are often used in such studies as they can provide representative data at regional to national scales. Modelling approaches based on such empirical data can help identifying and understanding the drivers of tree mortality, as well as predicting current and future forest development trajectories. However, forest inventory data are complex and their statistical handling presents some methodological challenges. In addition, tree mortality data are highly unbalanced (higher proportion of living trees compared to dead trees), which further complicates the modelling process and performance assessment. For these reasons, while the drivers of tree mortality are increasingly well understood, we are still lacking concrete and practical guidelines on how to develop well-performing empirical tree mortality models that account for the complexity of forest inventory data.

We used Swiss National Forest Inventory data (~4300 plots, up to 5 times remeasured over the last 40 years) to identify the characteristics of forest inventory data that should be accounted for when modelling tree mortality. We determined if and how these characteristics could be implemented in various modelling approaches such as generalised mixed models, a survey approach, random forest and convolutional neural networks. We compared the performance of these approaches when inferring the effect of environmental factors on tree mortality as well as when predicting tree mortality. We conclude that the best-suited modelling approach depends on the goal of the model, i.e., inferring or predicting. We stress that metrics used to evaluate the performance of a modelling approach must be adapted to unbalanced data, and provide recommendations on best practices for modelling tree mortality from forest inventory data. Our results can help future tree mortality studies to choose, based on their goal, which modelling approach would be most suitable as well as the appropriate metrics to evaluate the model's performance.

Predisposing and inciting stress factors leading to drought-induced mortality

T5.22 Modelling forest trajectories under climate stress and changing management

Gina Marano[1]
Ulrike Hiltner[1], Harald Bugmann[1]
[1] Department of Environmental Systems Science, Forest Ecology, Institute of Terrestrial Ecosystems, ETH Zurich, Zurich, Switzerland

Abstract: The increase in both frequency and magnitude of drought-induced mortality events in low-elevation forests in Europe represents a puzzling phenomenon to investigate. Indeed, both empirical and dynamic models fail to capture and reproduce mortality caused by the combined effects of climatic extremes and biotic stressors.

We examined the drivers and processes leading to mortality during the drought years of 2018-2019 in even-aged beech stands in Switzerland in two steps: by means of empirical models (e.g., drought indices) linked to tree-ring indices and through the dynamic forest gap model ForClim.

In the first step, we assessed the suitability of drought indices of different complexities to capture stand-level growth responses to extreme drought events based on the assumption of direct feedback linking growth decline to mortality. We found that even the best-performing index cannot capture mortality patterns as it is associated with carbon starvation alone.

We developed a novel modeling framework that accounts for a combination of predisposing and inciting factors, according to the Decline-Disease theory, in the ForClim model. In this context, we included a drought memory term as a predisposing factor and a drought duration term that accounts for soil water deficit in spring and autumn as an inciting factor.

In addition, we enhanced the response of both growth and mortality dynamics to environmental extremes (e.g., temperature) and soil water dynamics. Finally, we applied a pattern-oriented modeling approach to this new model version to account for the uncertainty arising from alternative process formulations.

The proposed phenomenological stress approach for drought-induced mortality modeling can reproduce mortality events induced by drought extremes in managed stands in Switzerland. We tested the scheme on sites along a climatic gradient from cold–wet to warm–dry conditions in Central Europe, where we simulated potential natural vegetation. Towards the dry range of the selected sites, our results indicate the progressive dominance of drought-tolerant species as an increase in the frequency of mortality events. We argue that under changing climate conditions, site conditions (e.g., soil water availability) will play a crucial role in stand level dynamics, particularly in terms of species response to drought events.

Simulating Central-European forests in the 21st century – Effects of climate change and management.

T5.22 Modelling forest trajectories under climate stress and changing management

Manfred J. Lexer[1]
Christian Hochauer[1], Christoph Pucher[1], Mathias Neumann[1], Herbert Formayer[1]
[1] University of Natural Resources and Life Sciences, Vienna (BOKU)

Abstract: Large-scale scenario analysis to project development of European forest resources and explore the effect of climate change and forest use scenarios is a key requirement for policy making and has attracted much attention recently.

In a recent study we harness the individual-tree based ecosystem model PICUS v1.5 to simulate 20 mill ha forests in five Central European (CE) countries (Germany, Czechia, Slovakia, Austria, Slovenia). In a quasi-spatial frame work we assigned 46 mixture types which had been defined based on the national forest inventory (NFI) data to 8x8 km grid-cells and distribute these mixture types over 1x1km sub-cells considering CORINE landcover types and regional age-class distributions. A gap-filling algorithm had been used to complete the information base for all 5 countries. PICUS includes disturbance modules for spruce bark beetles and wind storms. Current climate and three transient climate change scenarios were prepared for each 1x1km cell. Currently applied management regimes (BAU) had been operationally defined for the mixture types based on reports and interviews with experts from the five countries. BAU includes also a share of not actively managed forests. Five management response options from owner´s perspective were defined, including a no management option. BAU and the response options were then combined in six adaptive management scenarios for the entire CE forest area.

Under conditions of moderate climate change volume stocks can be retained under BAU management. If precipitation decreases, a drastic reduction of growth at lower elevations results, in parallel with a sharp increase of salvage harvests. Stocks decrease due to reduced increment and high tree mortality. Adaptive management is replacing productive coniferous and broad-leaved species by more drought and heat tolerant broadleaves which overall are less productive. The more extreme future climate develops the sooner adaptive management approaches reduce potential losses and stabilize production and stocks and perform better than the currently practiced management would. Non-native species such as Douglas fir improve the net effect of adaptation strategies further.

Beyond selected results we scrutinize currently available means and conclude on useful improvements.

Spatial vulnerability assessment of silver fir and Norway spruce dieback driven by climate warming

T5.22 Modelling forest trajectories under climate stress and changing management

[2] ONF

Abstract: A significant forest decline has been noticed these last years in Europe, mainly for coniferous species. Managers need tools to better anticipate these massive events. We evaluated the efficiency of easily available data about environmental conditions and stand characteristics to determine different levels of vulnerability. We combined remote sensing images, photo-interpretation, and digital models describing environmental conditions within a modelling approach to achieve spatial vulnerability assessment of the stands. We focused on silver fir and Norway spruce stands in the Vosges mountains (8,900 km², north-eastern France), where severe symptoms of decline are visible.

Silver fir were predicted highly vulnerable on 7% of their area *versus* 33% for Norway spruce. Using an independent dataset, we observed ten-times (silver fir) and two-times (Norway spruce) higher mortality rates in the units with a high level of vulnerability than in the others. About half of the model deviance was directly or indirectly explained by variables related to water stress (soils displaying low water availability, having suffered severe drying events these last years). Furthermore, the stands acclimatised to drought conditions were more resilient. Stand characteristics also influenced dieback spread, suggesting that an evolution of silvicultural practices toward mixed stands with broadleaved species and uneven-aged trees can contribute to better adapt to future climate conditions. We conclude that vulnerability maps based on easily available geographic information describing climate, soil, and topography can efficiently discriminate canopy mortality patterns over broad areas. They can be useful tools for managers to mitigate the effects of climate change on forests.

The value of a terrestrial ecosystem model for evaluating forest policies

T5.22 Modelling forest trajectories under climate stress and changing management

Abstract: Reflecting the importance of forests in some of the Nordic countries, national policies and private governance initiatives have affected forest management for a long time in these countries. In recent decades, there has been a shift from a highly regulated and rationalized forest management regime towards softer forms of governance and strengthened principles of freedom and responsibility but also wider considerations of the forests' multifunctionality. Forests are expected to play a crucial role for mitigating climate change by, in addition to timber, supplying resources for wood products, bioenergy or biofuels in accordance with international and national climate targets. At the same time, forests provide important ecosystem services, e.g., carbon sequestration or biodiversity conservation. The muti-faceted use of forests will lead to trade-offs and synergies of the national policies governing the use of forests.

In this study, we use the LPJ-GUESS terrestrial ecosystem model to assess the effects of important changes in forest policies on forest ecosystems that have been identified in recent decades in the case of Sweden. To this end, the changes in forest management and/or in land use that are associated with the selected policy changes are prescribed to the model. The focus of the analysis is on the effects on the carbon stocks and fluxes of the forest ecosystems (relevant for climate mitigation) and the structure of the forests that affect biodiversity. As part of the study, we evaluate the model's ability to simulate the state of Swedish forests against data from the Swedish National Forest Inventory. This allows for evaluating the robustness of the simulated effects of the recent policy changes on Swedish forest ecosystems and, thus, gives an understanding of the value of a comprehensive ecosystem model such as LPJ-GUESS for evaluating forest policies.

Transformation paths towards biodiversity-enhancing landscape structures for temperate multiple-use forests

T5.22 Modelling forest trajectories under climate stress and changing management

Jakob Albrecht[1]
Dominik Sperlich[1], Rasoul Yousefpour[1, 2], Marc Hanewinkel[1]

[2] DANIELS Forestry, University of Toronto, Canada

Abstract: To enhance biodiversity, the retention of old forest structures and deadwood (Retention Forestry), has been integrated in the management of multiple-use forests of Europe's temperate zone since over a decade. Balancing the provisioning of multiple ecosystem services (ES), however, poses a challenge for the development of biodiversity-oriented management strategies. This is additionally complicated through the impacts of climate change and increasing disturbances on forest ecosystems. We investigate optimal management portfolios and landscape structures for the enhancement of biodiversity while guaranteeing the flow of ES in the southern Black Forest area, by coupling ecological-economic models in a simulation-optimization framework.

We will present preliminary results of our study following three objectives:

- Forest landscape simulations will be carried out using the individual-based forest landscape and disturbance model (iLand model) with scenarios varying in climate, disturbance intensity and management.
- Based on the simulation results, we will analyse the responses of multiple taxonomic groups using empirical models parametrized for the study area.
- Finally, we will identify optimal landscape structures for promoting biodiversity and providing ES. Using optimisation techniques, we will derive a transformation path from the current state of the study landscape to the optimal landscape.

With our study we expect to provide a robust decision support for biodiversity-oriented management of temperate multiple-use forest under climate change and increased disturbance risk.

Tree level growth responses to climate evaluated at the stand level: Expected growth reductions for Scots Pine and Oak on dry sites in Europe .

T5.22 Modelling forest trajectories under climate stress and changing management

Carl Vigren[1]
Sonja Vospernik[2]
[1] Swedish University of Agricultural Sciences, Umeå.
[2] BOKU University of Natural Resources, Vienna

Abstract: Oak and Scots Pine, two of the most commonly managed xeric-/acidophilic species in Europe are being pushed out of their climatic niches. Using high spatiotemporal resolution climatic data from four non-correlated global circulation models (ACCESS1-3, CESM1-BGC, MIROC5, CMCC-CM) depicting the RCP 4.5 and RCP 8.5 emissions scenarios and retrieved historical data from the CHELSA high-resolution climate dataset repository, we could model the development of 72 in detail measured and previously described unmanaged stands at 15 sites from southern Sweden through northern Spain.

Tree-level growth simulations (no management) from 2017 to 2100 were run using a modified version of the PrognAus individual tree-based model which was outfitted with a newly published climate-sensitive diameter growth model (Vospernik et al. 2021). Results were post-processed to yield yearly stand-level summaries which could be used for extrapolation of the results.

Using only easily accessible variables we successfully manage to generalise our results to a prediction-oriented model (Linear Mixed-Model) of standing live volume year 2100, and contrast growth for unmanaged stands of 3 different species mixtures (Oak, Oak-Pine, Pine) at 3 separate latitudes (58°N, 50°N and 42°N) under the historical climate with 2 future possible scenarios (RCP 4.5, RCP 8.5). Our results indicate that stand-level growth will be hampered under both RCP 4.5 and 8.5. Growth losses relative historical scenario increase in severity from the Nordic countries to the Mediterranean (For Pine, 58°N:-8%, 42°N:-12%; For Oak, 58°N:-2%, 42°N:-7%;). In both percentual and absolute terms, growth decreases are larger moving from the historical scenario to the RCP 4.5 scenario than moving from the RCP 4.5 scenario to the RCP 8.5 scenario for all species mixtures. Oak shows the greatest resilience to change between RCP 4.5 to 8.5 – decreasing only for the lowest latitude, whereas Scots Pine is sensitive to the changes associated with the future climatic scenarios – the magnitude of percentual change between RCP 4.5 and 8.5 being c. 80% of that between the historical scenario and RCP 4.5.

Our study, with no climate-sensitive mortality, is likely optimistic in terms of the decreases that can be expected, with strong implications for dry-land forestry in Europe.

Uncertainty of water balance simulations related to soil parameterization in Alpine forests under climate change conditions

T5.22 Modelling forest trajectories under climate stress and changing management

[3] Department of Forest and Soil Sciences, University of Natural Resources and Life Sciences, Vienna, Austria
[4] Institute for Ecology and Landscape, Weihenstephan-Triesdorf University of Applied Sciences, Freising, Germany

Abstract: Climate-change-induced stress in forest ecosystems will have consequences for society worldwide. A decent understanding of future ecological conditions is required to identify suitable actions for dampening these stresses. A major impact of climate change is the gradual shift in water balance which can lead to drought stress in forest stands in many parts of the world. Soil-vegetation-atmosphere transport (SVAT) models are useful tools for investigating the water balance under current and future climate conditions. However, using such models in Alpine environments with spatially heterogeneous edaphic conditions strongly depends on the parameterization of soil properties. The present study investigates the sensitivity of water balance simulations and their uncertainty towards soil characteristics under current and future climate conditions. A lumped, physically-based SVAT model (LWF-Brook90R) was used to reproduce the water balance at 1823 mapped forest sites in Tyrol (Austria). For the soil parameterization, detailed laboratory analyses based on samples taken at multiple depths were available for 102 locations. At all other locations soil texture classes and bulk density in each soil horizon had been assessed with field methods. Based on interpolated meteorological observations and bias-corrected climate projections, the water balance was derived under current (1991-2020) and future conditions (2036-2065, 2071-2100). Using generic parameterizations of forest stands of native tree species (European beech, Norway spruce, European black pine), the uncertainty of the modelling results and derived drought stress indicators towards soil input parameters was evaluated. To do so, the soil parameters (texture, bulk density, organic content) were systematically sampled at each site to represent the respective texture class mapped in the field and the variability indicated by the laboratory results. The results suggest that soil parameterization has a strong influence on the resulting water balance components (e.g., evaporation, transpiration). Depending on the considered representative concentration pathway scenario, the soil-related uncertainty can be in the same order as projected changes due to climate change. This highlights the importance of reliable soil parameterizations for assessing climate change impacts on the water balance in Alpine forests. This work was carried out within the WINALP21 project, funded by the INTERREG VI-A program (grant number BA0100020).

Understanding forest resilience through simulation modelling

T5.22 Modelling forest trajectories under climate stress and changing management

[2] Ecosystem Dynamics and Forest Management in Mountain Landscapes, Technical University Munich, Freising, Germany

Abstract: Forests are facing an increasingly uncertain future due to climate change, shifting disturbance regimes, and changing societal demands. Hence, we need a better understanding of how forests will develop, recover after disturbances, and adapt to new conditions. In addition, it is not well known if such an adaptation is even fully possible and how forest management can actively support it. The concept of forest resilience, in its various definitions, has become a popular framework to approach these questions. Resilience can help us to understand the limits of forest recovery and adaptation and find potential tipping points. Methodologically, simulation models provide the capacity to explore a wide array of environmental and human drivers as well as forest responses over the large areas and long durations, which are necessary to approach forest resilience.

We explored the role of simulation modelling in understanding forest resilience, showing the breadth of existing applications as well as focus areas for further model development based on a literature review. Through several examples from Europe using landscape simulation modelling, we went deeper into the opportunities and limitations of using simulation modelling to understand the future development of forests through the resilience lens. These simulation studies explored potential tipping points of forest structure, composition and functioning under climate change and increasing disturbances as well as investigating how resilience can be fostered proactively through forest management.

Simulations from different European landscapes showed that, from an ecological viewpoint, forests are remarkably resilient, able to recover from substantial changes in climate and sustain ecosystem functioning even under increasing disturbances. However, once tipping points are reached, the simulated forests underwent drastic changes in composition, structure, and ecosystem functioning. Management had the potential to support forests in adapting to rapidly changing environmental conditions but could not fully avoid the impact of climate change and increasing disturbances.

These results show the potential of simulation modelling as a powerful tool in exploring the responses of forests to extreme environmental changes. However, there are several areas where further model development is urgently needed to understand forest resilience to these changes.

Using LANDIS-II to model potential outcomes of an experimental management system in coastal forests under climate change, windstorms, and wildfire.

T5.22 Modelling forest trajectories under climate stress and changing management

Colin Mast[1]
Melissa Lucash[1], Neil Williams[2]
[1] University of Oregon, Department of Geography, USA
[2] USDA Forest Service, Rocky Mountain Research Station, USA

Abstract: Our project supports management planning for the newly designated Elliott State Research Forest (ESRF), now the largest research forest in North America, which extends over 33,000 hectares of the Southern Oregon Coast Range. Oregon State University plans to implement an experimental Triad system of management that incorporates silvicultural treatments of varying intensities. Their goal is to take a sharing-sparing approach to determine how to produce timber at least cost to biodiversity. To answer this question, managers plan to divide the forest into subwatershed-level research units. Each unit will be allocated to one of four treatments comprising different proportional combinations of the following three stand-scale silvicultural strategies: 1) reserves, where the focus is on conservation of habitat and species with minimal active management; 2) intensive management, where maximizing timber production is the primary objective; or 3) extensive management (or ecological forestry), which attempts to balance timber production with broader ecological objectives, such as development of structural complexity. However, it is unknown how this management regime, interacting with wind and fire disturbances, will affect key ecosystem services. To answer this question and help refine the preliminary forest management strategy, we estimated changes in long-term forest and carbon dynamics under the proposed harvest design, windstorms, wildfire, and climate change using LANDIS-II, a spatially explicit, process-based forest simulation model. Our study landscape, modeled at a high spatial resolution (30m x 30m), includes the entire ESRF and a surrounding buffer to allow fires to spread into the forest. Our initial results indicate the importance of wind as a driver of mortality in mid- to late-successional Coast Range forests, a shift towards higher species complexity, the need for forest managers to consider how management practices interact with natural disturbances, and the potential inability of a shorter 70-year harvest rotation to produce more timber than the original 100-year rotation over in the long term. This project presents a novel opportunity to explore the ecological and economic impacts of different management scenarios on a newly developed research forest under windstorms, wildfire, and climate change.

Using provenance trials across a climate gradient in Europe to understand acclimation of Norway spruce photosynthesis under future climate scenarios

T5.22 Modelling forest trajectories under climate stress and changing management

Joanna Simms[1]

[2] University of Gothenburg
[3] Skogforsk
[4] Swedish University of Agricultural Sciences

Abstract: Four young Norway Spruce sites between France and mid-Sweden were compared, to see possible adaptions to a temperature difference akin to increases predicted under climate change. The use of clones between sites – cancelling out confounded acclimation -, temperature gradient, and the difference between wet and dry sites, has isolated some of the main limitations for future photosynthesis. These young sites' climate and shoot data over 6 years, were contrasted to mature Norway Spruce ecosystem data from the Integrated Carbon Observation System over as similar conditions as data allowed. Then, the northernmost site was modelled with climate predictions. These simulations were compared against current and future modelled data for the other sites. Acclimation was tested by running the model with climate, site and photosynthesis parameters interchanged to isolate individual effects. The Shared Socioeconomic Pathways (2 4.5, 5 8.5) generated by Coupled Model Intercomparison Project 6 were used for climate predictions. Ecosystem models: Stand Photosynthesis Program (SPP) and PREdict Light-use efficiency, Evapotranspiration and Soil water (PRELES) were respectively used to, upscale local measurements to a stand level, and then to apply the future climate projections.

After Bayesian calibration the models fit together well, allowing us to use tree level measurements to extrapolate to a landscape level. According to current results from PRELES, the future CO2 effect overshadows any other environmental parameters. However, when the CO2 effect is discounted; temperature, specifically its effect on the growing season rather than daily increases, has the second largest consistently important effect. In years with a significant drought effect, PRELES shows that the low soil water content restricted the potential photosynthesis. In the original data drought is seen in the mortality rate, rather than a change in photosynthesis potential; as we cannot measure the photosynthesis parameters when the tree cannot photosynthesise. Although CO2 and temperature have a more consistent effect, possible photosynthesis increases will not be fulfilled unless other environmental conditions allow, the soil water content being the limiting factor in this case. Acclimation to environmental conditions also limited potential increases, as seen by the reduction in predicted photosynthesis when applying the southernmost parameters to northernmost sites.

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

A cross-site model-data integration approach for tracking carbon and water fluxes dynamics under drought conditions in montane forests

Abstract: Under climate change, the frequency and intensity of summer drought and hot spells are predicted to be more extreme in the future. Contrasting impacts of climate change are particularly expected in montane forests, which are generally energy limited ecosystems and adapted to short growing seasons. Thus, it is crucial to understand how extreme events might impact forest ecophysiology and in turn shape the carbon and water cycle in such a particular bioclimatic area. Since the carbon and water cycles are tightly coupled through the process of plant photosynthesis, and because forests can respond on both short and long temporal scales to meteorological variability, with instantaneous and lagged effects, linking observations of carbon and water fluxes is of first importance to assess the forest contribution to climate-change mitigation.

In this study, we focus on two mountain ICOS monitoring sites:Torgnon (IT-Trf, Fluxnet) and Renon (IT-Ren, ICOS). The first is a European larch, and the second a Norway spruce dominated stand, two common forest species in the Alps While the European larch has been often considered to have an anisohydric behavior (i.e. weak stomatal regulation under drought conditions), the Norway spruce can be assumed isohydric. The undisturbed forests stands were monitored with the eddy covariance technique for long periods (Torgnon 2012-2023, Renon 1997-2023) and the areas were characterized by drought spells of different types, intensity and duration in the years 2017 and 2022. However, to understand how extremes might modulate the interaction between carbon assimilation, evapotranspiration and growth, a cross-site model-data integration approach is crucial. Here, we used modeling simulations by means of the process-based forest model 3D-CMCC-FEM in combination with fluxes estimates and complemented with ancillary records, i.e. satellite-based observations, dendrometric and sapflow measurements. We found that the parametrized model is suitable for tracking carbon and water fluxes dynamics and the resulting response to drought is quantitatively contrasting across the two experimental sites. Finally, we highlight the challenges in monitoring complex ecosystems and provide a framework of analyses of drought induced direct and legacy effects on montane forests and their potential consequences on carbon and water fluxes exchange in the alpine region.

Applied monitoring of forest dynamics for climate action planning in the United States

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Erin Glen[1]
Richard Birdsey[2], Nancy Harris[1]
[1] World Resources Institute
[2] Woodwell Climate Research Center

Abstract: Maintaining and expanding forests and urban tree cover are critical components of a multi-pronged climate strategy. In the United States, many local governments and land managers are developing Climate Action Plans (CAPs) which outline goals for reducing GHG emissions and bolstering resilience. However, due to a lack of clear guidance and accessible data, many land managers do not account for their forests and trees or for the potential enhanced role they could play within CAPs. To fill this gap, the Land Emissions and Removals Navigator (LEARN) tool provides open-source, automated analysis and calculation of GHG impacts associated with forests and trees within any area in the Continental U.S. The web tool analyzes national datasets from the U.S. Forest Service and U.S. Geological Survey to derive spatially explicit estimates of carbon emissions and removals from land cover change, forest disturbances, and changes to tree canopy on non-forest lands within an area of interest over a specified period. Ongoing research and development are underway to improve the accuracy, breadth, and disaggregation of geospatial data on forest dynamics. Wall-to-wall, 30-meter datasets of forest characteristics (e.g., stand age, stand height, stand origin) produced using plot data from the USFS Forest Inventory Analysis (FIA) database in a machine learning environment are priorities for integration into carbon calculations. Another key improvement may involve working with the USFS to integrate directly with the FIA database to improve accuracy of carbon calculations. This innovation would not only improve historical monitoring capabilities but will allow for dynamic carbon estimations based on ground measurements under a changing climate. The LEARN tool builds on this growing body of research by bringing together state of the art data and methods to provide tangible insights to land managers in a user-friendly, accessible environment. In doing so, LEARN is easing the burden on land managers and accelerating the transition from monitoring and planning to implementation of forest-based climate mitigation.

Are leaf and stem trait interactions good predictors of individual tree growth in a Tropical Dry Forests?

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Slendy Rodriguez-Alarcon[1]
Roy González-M[2], Enrico Tordoni[1], Carlos P. Carmona[1]
[1] University of Tartu
[2] Instituto de Investigación de Recursos Biológicos Alexander von Humboldt

Abstract: Trait-based ecology is built on the notion that traits impact individual performance. However, trait-growth relationships are rarely tested, particularly in tropical dry forests. This scarcity of investigation can partially be attributed to the challenges of accurately measuring growth rates and anatomical stem traits related to hydraulic properties across many individuals and species. Compounding these issues, many studies overlook intraspecific variation or use simple models that do not account for trait interactions or non-linear trait-growth relationships.

Here, we examined trait-growth relationships in woody species of Colombian dry forests, including traits and growth information measured in the same individuals. We analyzed stem and leaf traits related to growth and hydraulic safety efficiency in 967 individuals (263 species) in seven permanent plots (1ha). We assessed trait-growth relationships using random forest models for each plot with different trait resolutions (individual, plot, area) and complexity of trait interactions (low, medium, high).

Trait-growth relationships were generally weak without significant differences among trait resolutions or levels of interactions between traits. However, when accounting for leaf phenology, we detected a higher growth variation explained in deciduous species than in evergreen species. Finally, we also found that the effect of traits on growth was consistent across plots and phenological strategies, with both stem (vessel area and pit diameter aperture) and leaf (leaf area and specific leaf area) traits being ranked as the most important predictors.

Our results suggest that other factors not included in the analysis such as microenvironmental variability might influence trait-growth relationships in tropical dry forests. Indeed, this is an ecosystem with markedly seasonal climatic conditions that might have filtered species coordinated and adapted to this environment, which could be the reason behind the lack of importance of trait complexity interactions to explain growth variation. Furthermore, the importance of the traits depends on the group of leaf phenology considered, which indicates that growth is probably limited by different factors depending on the species' physiology. Therefore, a trait coordination approach at the whole-plant level is needed to understand better plants´ fitness and demographic rates in this particular ecosystem.

Assessing dead wood by integrating Full Area Sampling and Line Intersect Sampling: combing the best of both worlds

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Arno Thomaes[1]
Luc De Keersmaeker[1], Marc Esprit[1], Stefaan Goessens[1], Anja Leyman[1], Peter Van de Kerckhove[1], Kristine Vander Mijnsbrugge[1], Kris Vandekerkhove[1]

Abstract: Effective and comprehensive monitoring of quantity and quality of the dead wood component has become an important aspect of forest inventories. It's an indicator for structural and demographic dynamics of trees, but it is also an important variable for biodiversity assessments and carbon stocks. Assessing dead wood is however challenging due to its structural complexity and associated characteristics such as size, tree species and decay stage. Commonly applied survey methods for lying woody debris (LWD) are Full Area Sampling (FAS) and Line Intersect Sampling (LIS). In FAS , all LWD fragments above a specific size threshold are measured and positioned. This method provides a good estimate of the local volume of LWD, and also allows identification of each specific logs for remeasurement. This can, however, be extremely time consuming, especially in forests with accumulating amounts of LWD. LIS is based on incidence of LWD intersecting of a line. It has proven to be reliable and robust and takes much less time, but requires sufficient sampling to level out randomness, especially of rare but large elements. In general, LIS is inadequate for assessment of deadwood on a local (plot) scale, reliable figures need to be based multiple-plot scale. As a new approach, we propose a combined protocol by using FAS to position and measure all larger diameter trees and branches and LIS for smaller dimensions. This combines fast and easy sampling with good local estimates of dead wood at plot level and still allows larger logs to be linked to previous and future measurements to study its dynamics. We will present how to correct for double counts, asses the reliability of this method and time saved compared to FAS. Based on our results we propose a cut off level of 20cm diameter for the FAS.

Assessing forest ecosystem functions in Biosphere Reserves worldwide

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Charlotte Gohr[1, 2]

[5] Institute of Zoology, Zoological Society of London

Abstract: The establishment of protected areas is a prevalent measure to mitigate the loss of biodiversity and effects of climate change. Within the global network of protected areas, the World Network of Biosphere Reserves (WNBR) is aimed at "conserving biodiversity, restoring and enhancing ecosystem services, […] and empowering people to mitigate and adapt to climate change and other aspects of global environmental change." Although substantial resources have gone into establishing, promoting, and monitoring the WNBR and many studies have examined these issues, the ecological effectiveness or ecosystem functioning of forests within Biosphere Reserves is less well understood. By assessing forest ecosystem functions in Biosphere Reserves worldwide, we investigate the potential of these forests to contribute to sustainable development and assess the effectiveness of the biosphere reserves framework in supporting the development of resilient forests globally. This study develops a remote-sensing based method on a global scale with the Google Earth Engine using various ecosystem functioning indicators, such as the relative cooling and buffering capacity of forests. The main aim is to investigate possible differences of ecosystem functions in relation to their surroundings and thereby derive a quantification of the ecological effectiveness of forests in Biosphere Reserves globally. The main expected result is a ratio of ecosystem functioning inside and outside globally, which is a proposed proxy value for the ecological conditions. This will be derived by model estimations of 1) the behavior of different indicators globally, 2) each indicator related to different biomes. By using this approach, we hope to address certain challenges when conducting global ecological analyses, such as the integration of diverse regional parameters, biome-specific variables, or anthropogenic factors. Methodology and results should be applicable to other global forest monitoring approaches and could contribute to the evaluation of measures considered as ecosystem-based adaptations to climate change. If proven effective, the biosphere reserves framework could serve as a valuable model for managing forests in various regions.

Assessing role of forest by estimating potential soil erosion in a Himalayan watershed using empirical modelling

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Shachi Pandey[1]
Rahul Yadav Yadav[1], Vijender Pal Panwar[2], Raman Nautiyal[3], Parmanand Kumar[2]
[1] Forest Ecology and Climate Change Division, Forest Research Institute, Dehradun, India
[2] Forest Ecology and Climate Change Division, Forest Research Institute, Dehradun, India
[3] Indian Council of Forestry Research and Education, Dehradun, India

Abstract: In Mountain regions, soil erosion causes severe hazards, such as heavy rainfall, surface water flow on bare lands that contribute to land degradation. In Himalayan region, erosion leads to loss of forests, productivity and changes the hydrological behaviour of the lotic system. The relationship between ecological processes such as soil erosion and landscape spatial patterns is elucidated well by assessing spatial heterogeneity. Forest land use plays a significant role in controlling the loss caused due to soil erosion. However, it is important to understand the relationship between soil erosion and various land use to the importance of forests and also identify the erosion vulnerable zones to understand the role of a landscape. The study was carried out in the Himalayan subwatershed located between 30º 40' 30" N to 77º 43' 30" E and 30º 28' 30" N to 77º 51' 0" E. The elevation range varied from 431 to 1803 m above mean sea level (amsl) covering an area of 91.91 km^2. To estimate potential soil loss the Revised Universal Soil Loss Equation (RUSLE) was used on ArcGIS 10.3. Rainfall erosivity, soil erodibility were obtained by kriging data interpolation using remote sensing tools, and further analysis was performed to calculate potential soil loss under each land use. Soil sampling was conducted to assess soil quality and to compute the soil erodibility in the watershed. The results indicated that the estimated potential soil loss was maximum in settlement land use (19.42 tons/yr/ha) and minimum in forest land use (1.73 tons/yr/ha). The results showed that the estimated soil loss under each land use was significantly different. Dunn's post hoc comparison based on adjusted Bonferroni p-values suggested significant differences between the groups i.e., land use. Potential soil erosion in forest land use was significantly different from agriculture, barren, settlement and scrub land uses. The study indicated the importance of forests in the conservation of soil as well as water resources. It also suggested that the inclusion of land use criteria is crucial in the decision process for formulation of management strategies for conservation in a watershed.

Assessing the impact of climate change on natural forest regeneration dynamics across Italy.

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Abstract: Natural regeneration is critical for forests climate change adaptation, ecosystem restoration, and the preservation of biodiversity. Many forest models can robustly simulate the growth, development and mortality of adult tree species compared to the regeneration process. Indeed, how environmental conditions and management practices affect the success of seeds production, germination requirements, seedling establishment and saplings ingrowth remains the most uncertain processes to model. In order to tackle this challenging task, we implemented into the process-based forest model 3D-CMCC-FEM a new module to simulate the natural regeneration. This module includes key drivers such as temperature, light, and water availability, aiming to understand each factor's contribution to regeneration success. Since young saplings are more sensitive to changes in climatic conditions than adult trees, it is pivotal to investigate their plasticity and adaptation capacity at the stand scale. Because of these reasons, we selected three beech-dominated experimental forest sites and permanent monitoring plots along a latitudinal gradient on the Italian peninsula, as European beech thrives in diverse conditions. We systematically analyze model behavior by conducting a comprehensive assessment of parameter sensitivity. Our aim is to identify the key parameters and processes that contribute to the greatest variability in model output, particularly in relation to saplings recruitment. We performed short-term simulations, using observed climatic data, stands and soil data collected as input starting from the first year of available data to initialize the model. Model performances are shown, including the ability of the model to simulate carbon fluxes, specifically gross primary productivity (GPP) and structural variable such as basal area increment and height of trees. Furthermore, seeds production, density of newly saplings recruited simulated by the model will be compared with observed data in the permanent-sample plots applying a 'space x time' substitution. Subsequent long-term simulations will be conducted (at least 100 years) forcing the model in the same plots with climate scenarios data considering the factors such as, CO^2 fertilization effect, increasing mean temperature and water resource to investigate how these factors could affect growth and mortality of seedling and sapling under future climate change scenario.

Carbon Accumulation in European Forests: insights from old-growth beech forests in different environments within the UNESCO World Heritage Site 1133

Abstract: Natural forests can remove significant amounts of carbon (C) from the atmosphere annually and stock it for the long-term in living aboveground and belowground tree biomass and soil organic matter.
We used a network of representative old-growth beech forests from the UNESCO World Heritage Site "Ancient and Primeval Beech Forests of the Carpathians and Other Regions of Europe" to quantify Cstocks in living and dead biomass and soil. Old-growth forests covering biogeographic regions in Europe (Mediterranean, Alps, Carpathian Mountains, Atlantic Region) were compared to nearby mature managed forests in similar environmental conditions.
In each forest, we measured living and dead tree biomass in dendrometric sample plots, and calculated species-specific volumes converted to C stocks using available allometries and wood densities. Trees from different size classes were cored with increment borers to determine wood density variability according to size and naturalness (old-growth vs. managed) along environmental gradients. In each forest, soil organic C content was determined at different depths (maximum until 1 m) using a sample of cores or pits.
C density data from old-growth beech forests served to build a reference framework in different environments, necessary to assess the potential of forest restoration for climate-change mitigation.

Comparing drought effects on vegetation of natural forest reserves and adjacent managed forests in Southern Germany

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Abstract: Increased frequency of drought years with alarming forest decline is challenging forestry and society in Central Europe. The longevity of forest ecosystems as well as the extent and ecological diversity of forest areas hinder the attribution of causes and effects of the decline. Foresters, forest owners, conservation organisations and public are struggling for adequate responses to the crisis. While strict forest reserves (SFR) have often been perceived in terms of biodiversity conservation, climate change calls for reconsidering their role as a reference for forest management. In Central Europe, SFRs are the only forests, where mortality of trees and stands and their effect on vegetation can be observed without interference of timber harvesting. Further, they are indispensable for deciding whether managed or natural forests exhibit higher resistance and resilience towards climate change and to what degree silvicultural adaptation measures can be replaced by self-organised forest dynamics. An integrated analysis of the development of 16 SFRs in conjunction with adjacent managed forests along a climatic gradient in Southern Germany, ranging from subalpine spruce forest to colline mixed oak woodlands promises answers to these questions.
Our contribution reports on preliminary results of the work packages on the reaction of radial growth and water use efficiency of trees and on the dynamics of ground vegetation and tree regeneration.

Coupling functional and structural data to improve estimates of forest carbon fluxes and ecosystem responses to climate change

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Abstract: Forest ecosystems contribute to mitigating climate change through the process of photosynthesis. However, the increasing occurrence of climate extreme events has the potential to alter forest ability to sequester CO_2 from the atmosphere and to store it as plant biomass, with an increased risk of ecosystem transition from carbon sinks to carbon sources. The detailed effect of climate change on the timing and the functioning of different forest processes and its impacts at the tree vs. ecosystem level show high spatial and temporal variability. In this context, forest structure and the spatial heterogeneity of vegetation may represent a form of biological insurance against environmental changes. Further efforts are therefore needed to assess the resistance and resilience of forest ecosystems to climate change as mediated by forest structure.

The main objective of this study is to establish a quantitative link between the functional and structural properties of a European larch forest (*Larix decidua* Mill., IT-Trf, LTER site: LTER_EU_IT_078) in the Alps, located in the Aosta Valley (Italy) at about 2100 m asl. The eddy covariance method was used to measure carbon fluxes between the ecosystem and the atmosphere at two levels: the whole forest ecosystem, and the understory vegetation. Biometric measurements of tree growth were carried out in 2020 to quantify the carbon allocated to the wood biomass pool. Finally, satellite and UAV-based LiDAR observations were used to derive the composition and the structure of the various vegetation layers.

Results showed that only a small fraction of the total CO_2 absorbed by the ecosystem is allocated to stem growth and that due to the openness of the larch forest stand, the understory vegetation has around a 30% share of the total ecosystem gross primary productivity. The results are discussed by exploring the link between forest structure and the functioning of the whole ecosystem and the specific vegetation components.

Dynamics and relationships of belowground processes and aboveground growth and their impact on carbon burial in a mangrove forest

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Lilian Mwihaki Mugi[1]
Mark Huxham[1], James Kairo[2]
[1] Edinburgh Napier University
[2] Kenya Marine and Fisheries Research Institute

Abstract: Mangrove forests are extraordinary ecosystems, providing a wide range of benefits to humans, including exceptional carbon sequestration and protection against climate change impacts. They are globally threatened; finding new and more effective approaches to mangrove conservation is a conservation and climate mitigation priority. Different management approaches have been adopted, including the Payment for Ecosystem Services (PES) approach in mangroves of south coast of Kenya. The Vanga Blue Forest (VBF) project, designed to protect and restore 455 ha of degraded mangrove forest over 20 years, uses an incentive-based management approach where communities are compensated for their mangrove conservation efforts through a carbon credits scheme. Estimation of baseline levels of carbon, along with projections of forest growth, that are key components of this and similar projects (Bento, Kanbur and Leard, 2016), often need to use approximations and extrapolations from other sites, due to a scarcity of site-specific data and methods. Existing models that could be applied to predict mangrove forest productivity, and carbon capture and storage, are highly complex and data intensive, making it impossible to apply them at small-scales and with limited resources and capacity (Saatchi *et al.*, 2011; Baccini *et al.*, 2012; Willcock *et al.*, 2012; Langner, Achard and Grassi, 2014). It is in this context that experimental and theoretical techniques adopted from Lang'at et al., (2014) and Lynch et al., (2015) were applied to explore belowground processes and soil organic carbon build up dynamics in the study area. Modified sediment elevation tables and marker horizons (SET-MH) and root ingrowth were deployed across the study area within the permanent monitoring plots established under the Vanga Blue Forest (VBF) project and measured over time to assess sediment elevation/subsidence and surface accretion/erosion under different conditions. The findings will improve knowledge on forest productivity and carbon stocks and flows for local and global applications. They will also contribute towards tools, such as biomass and C storage models and sustainable extraction models, essential for the current management conservation efforts at VBF project.

Exploring the Carbon Dynamics of natural forests: Insights for Climate Change Mitigation and Sustainable Forest Management

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Thomas Nord-Larsen[1]
Johannes H.C. de Koning[1], Lars Vesterdal[1]
[1] Department of Geosciences and Natural Resource Management, University of Copenhagen

Abstract: Forests play a crucial role in the global carbon cycle by effectively sequestering and storing carbon, while its wood also serves as a substitute for carbon-emitting products and energy sources. However, deforestation, such as for agricultural purposes, contributes to the exacerbation of climate change.

The multifaceted role of forests, encompassing carbon storage in biomass and soils and the provision of sustainable resources for the green transition, has prompted an intensive scientific discourse on optimal forest management strategies to combat climate change. The natural forest serves as the reference in these investigations, representing the maximum potential carbon storage achievable over extended periods. These references are crucial for guiding discussions on forest management that plays an important role in global carbon management.

While natural forests are pivotal to understanding forest ecosystems and form a cornerstone of European forest and climate policies, they are not widely prevalent and are often under-researched. The beech dominated Suserup Skov in Denmark stands as a noteworthy exception, having been subject to repeated inventories and systematic studies during the past 30 years.

In this study we provide analyses of the long-term carbon dynamics of natural forests, focusing on Suserup Skov and other unmanaged forest areas, to understand their potential and limitations in mitigating climate change through carbon storage in biomass and soil. The study provides valuable insights for future forest management strategies, supporting the development of sustainable practices that maximize carbon sequestration and storage potential and contribute to global climate change mitigation efforts.

Forest structure, deadwood and tree-related microhabitats in high beech forest stands under different management regimes in southern Europe

Abstract: Beech (*Fagus sylvatica* L.) is one of the most important forest species in Europe from an ecological and socio-economical perspective, and the present structure of beech forests in Europe is the result of their long management history and other interacting factors. The aim of this study was to compare the complexity of forest structure, including deadwood and tree-related microhabitats as relevant biodiversity components, in high beech forest stands under different management regimes in southern Europe, ranging from actively managed stands to unmanaged old-growth forest stands. Fieldworks were carried out in 14 plots of 2500 m^2 (50 x 50 m) distributed in Italy, Croatia and Slovenia, seven plots with even-aged structure dominated by beech and 7 plots with uneven-aged structure, the latter mostly dominated by beech and silver fir (*Abies alba* Mill.). In each plot, all living trees with diameter at breast height (DBH) $\geq$ 3 cm were measured and the following data were collected: x,y coordinates, DBH, total tree height, height-to-base of the live crown, and crown's projections. Coarse woody debries, stumps, standing (including snags) and downed dead trees with diameter $\geq$ 10 cm were also measured (x,y coordinates, diameter, height or lenght, and decay level). Tree-related microhabitats were inventoried both for living and standing dead trees according to the classification system by Kraus et al. In each plot, the forest complexity was characterized by species composition, forest structural variables (e.g., stand denstity, basal area, and volume), spatial indices for vertical and horizontal (point pattern analysis) structure, amount and types of deadwood components and microhabitats. The results were discussed to compare the forest complexity and biodiversity features among the examined sites in relation to forest management activities carried out in the past in order to outline possible strategies for sustainable management practices oriented towards more structurally and compositional diverse beech forest stands. The study was carried out within the LIFE SySTEMiC project - LIFE18ENV/IT/000124.

Gas exchange of sun and shade-developed leaves is differently affected by drought: implications to scaling up models and silvicultural recommendations

Abstract: Droughts are becoming a recurrent event worldwide, which reduce carbon uptake and increase tree mortality risk threatening several ecosystem functions and services. Furthermore, global change is increasing the intensity, duration, and frequency of droughts due to a combined effect of scatter precipitations, atmosphere warming and soil erosion. However, droughts do not affect equally to all the species of a forest due to species-specific differences in shade tolerance, growth rate and functional traits related with drought resilience. In fact, within a forest there are many microclimates and tree species adapt their leaf physiology and anatomy mainly to changes in light intensity and quality. However not many studies consider adult trees and drought responses within the tree canopy. Here we provide novel measurements and concepts on how gas exchange responds to drought within tree canopies of four contrasted species in shade and drought tolerance. The study was carried on at the Natural World Heritage Site of “Hayedo de Montejo”, a relict and old European forest in Central Spain growing under Mediterranean conditions in a very dry and wet years. We performed photosynthesis-CO2 curves, photosynthesis-light response curves and changes in leaf hydraulic conductance in shade and sun developed leaves of the studied species growing in transects of less to more soil depth, and at the early summer in both years to avoid the seasonal and ontogenetic effects associated with leaf age. We show that shaded leaves are more susceptible to water stress than sun-developed leaves and that decreased photosynthesis is due to the combined effect of reduced stomatal and mesophyll conductances and higher biochemical constrains, while top canopy leaves are mainly limited by the stomatal closure. This results in lower carbon balance of the more shaded leaves within the canopy and earlier leaf shedding. We also found close coordination between decreased water supply and stomatal closure. More shade tolerant species were more affected by drought along the canopy, while more drought tolerant ones were able to maintain modest gas exchange rates but only in sun-exposed leaves. Climate change may promote open forests which may benefit the more drought albeit less shade tolerant species.

Integrated approach for monitoring the vulnerability of Mediterranean oak forests affected by drought-induced dieback: evidences and research avenues

Abstract: Rising aridity, mostly driven by higher temperatures and reduced water availability, will undermine the health status of many forest ecosystems. If climate warming proceeds at its current rate, the resilience of many seasonally dry Mediterranean forests will be threatened by altering their structure and impairing their functions. However, our understanding of vegetation-climate couplings is still partial, as we need data on responses at multiple temporal and spatial scales. In this context, we aimed to forecast oak forest responses to climate stressors, particularly during post-drought dieback episodes when tree vulnerability is exacerbated, through a combined, multiproxy approach. We focused on several oak species differing in drought tolerance but showing dieback events since the early 2000s. For all species, coexisting healthy and unhealthy trees were sampled, and analysed using dendrochronology, wood anatomy, stable isotope technique, non-structural carbohydrates, and pathology. We also explored how remote-sensing indices of vegetation activity and radial growth responded to drought. Our results pointed to changes in wood anatomy and growth related to major mortality mechanisms such as hydraulic failure and carbon starvation. In addition, we also modeled the probability of tree death as a function of tree size. We also pointed out that the resistance of oaks to droughts is strongly determined by the ability of their root system to extract water from the soil. We demonstrated that the effects of climate extremes such as droughts on vegetation can be detected either in terms of canopy greenness or radial growth reductions, thus hinting at the opportunity to combine remotely sensed data as a stand-level indicator of vegetation stress and to scaling up information from tree to stand levels using tree-ring data. Finally, our findings provided new insights on how trees showing ongoing dieback may keep their vital activities by changing their phenological performance, leading to potential implications on the global carbon and water balances of forest ecosystems.

Leaf phenological monitoring through IoT technology: the example of two beech forests in the Apennines

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

[3] Department for Innovations in Biological, Agri-Food and Forest Systems (DIBAF), University of Tuscia, Via San Camillo de Lellis 4, 01100 Viterbo, Italy

Abstract: Tree phenology refers to studying and observing the timing and sequence of recurring biological events in trees throughout their life cycle. Its study involves monitoring and documenting various seasonal changes and stages in the growth and development of trees, such as leaf emergence, flowering, fruiting, leaf senescence, and bud dormancy. To deeply comprehend the dynamics of tree phenology linked to the environment and its changes, tree physiological response parameters should be observed at high frequency in the long term. Recent technical development has made available IoT monitoring systems, comprising environmental and physiological parameters, to accomplish measurements of tree functionality with detail and large datasets. The TreeTalker is one of these instruments.

The TreeTalker technology was adopted to monitor trees in mountain beech forests at two altitudes in the Apennines (Matese, Molise). In particular, the light transmitted through the forest canopies, and its spectral components, measured by a spectrometer, were used to observe the tree's phenological activity in two growing seasons. Classical phenological observations were conducted on the same experimental sites. This study aims to assess variations in tree phenology in time (two years) and altitude (two elevations), comparing TreeTalker measurements and visual observations. We also tested the effects of environmental variables, such as temperature and precipitation, on phenological phases. According to our results, TreeTalker may help reduce the need for visual *in-situ* observations and continuously monitor leaf phenology, therefore providing new opportunities for supporting the mechanistic understanding of the processes underpinning tree growth responses to environmental changes.

Long-term monitoring of silviculture for temperate old-growth forest characteristics in eastern North America

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

William Keeton[1, 2]
[1] Rubenstein School of Environment and Natural Resources, University of Vermont, USA
[2] Gund Institute for Environment, University of Vermont, USA

Abstract: Many have wondered if silviculture could be used to restore characteristics of temperate old-growth forest in eastern North America, both in reserves and managed forests. After several decades of research, old-growth silviculture is employed operationally in a variety of settings, and long-term monitoring has proven pivotal for understanding lagged effects and outcomes across a range of responses. This talk will review several examples, focusing specifically on a system called *Structural Complexity Enhancement* (SCE). The hypothesis has been that SCE can accelerate rates of late-successional stand structural development faster than conventional selection systems. Response variables include financial viability, late-successional biodiversity, tree regeneration, and aboveground carbon pools. The experimental design and monitoring compares SCE against two modified selection treatments. Manipulations and controls were applied to 2 ha units and replicated four times at two research areas in the Green Mountains of Vermont, USA. The selection treatments and controls were replicated two additional times in the Adirondack Mountains of New York. Field data were collected over two years pre-treatment and 18 years post-treatment. Ten years after harvest, measured aboveground carbon in SCE units was 15.9% less than simulated no-harvest baselines, compared to 44.9% less in conventional treatments. All treatments were successful in maintaining overall richness and/or abundance of understory plants, terrestrial salamanders, and fungi. Statistical model results show that understory plant responses were strongly affected by treatment and less influenced by soil chemistry and drought stress. However, diversity for sensitive, late-successional herbaceous plants increased significantly in SCE units and decreased significantly in the semi-open canopied conditions within group selection units. Fungi and salamander responses were strongly associated with microsite characteristics, particularly coarse woody debris, and increased significantly under SCE, but showed no statistically significant decrease in silvicultural gaps. SCE is economically profitable or breaks even under the right site and market conditions. Potential applications include old-growth restoration, riparian restoration, carbon management, and low intensity commercial management. Adaptive silviculture promoting old-growth forest characteristics will contribute to biodiversity conservation and climate mitigation while providing both timber and non-timber economic opportunities.

Masting impact on leaf area index, light condition and growth of below-canopy trees in Fagus crenata forests, Japan

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Atsuhiro Iio[1]
Masaaki Naramoto[1], Qingmin Han[2]
[1] Shizuoka University
[2] Forestry and Forest Products Research Institute

Abstract: Masting is synchronous intermittent production of large seed crops in perennial plant populations, which occurs for 5 to 10 years interval in *Fagus crenata* forest. Since heavy seeding requires many resources, leaf area of fruit bearing trees decreases in mast years. Therefore, masting is expected to improve light conditions on forest floor and thus growth of below-canopy trees. However, study focusing on role of masting as transient gap is generally limited. Since climate factors directly and indirectly control masting, understanding the linkage between masting, canopy structure and growth of below-canopy trees is important to predict climate change impacts on forest dynamics. We thus monitor leaf area index, fruit production and growth of below-canopy trees in *Fagus crenata* forest for more than 9 years. The objective of this study is to test the hypothesis that masting play important role for sustaining below-canopy trees as transient gap.

Study site is 200-250 years old, almost pure beech forests at 550 m and 1500 m a.s.l. on Naeba mountain in Japan. Stand LAI and fruit production were measured for 16 years (from 2003 to 2007 and from 2014 to 2022) with litter trap method. Stem diameter increment was measured for all individuals in the stands for 9 years from 2014 to 2022. Light conditions on forest floor were estimated with hemispherical photography and radiative transfer model. Synchronous masting across the sites occurred at four times during the study period; 2005, 2015, 2018 and 2022.

Stand LAI significantly decreased in masting years, but returned to pre-masting level in the year following the masting events. Stem growth of below-canopy trees was markedly improved in the masting years, but peak of the improvement occurred in the years following of masting. A masting event at the 550 m site in 2018 did not reduce LAI exceptionally, but stem growth of below-canopy trees increased as well as other occasions. Therefore, masting events and subsequent reduction in LAI improve growth of below-canopy trees, but factors other than light condition, such as nutrient supply, may also contribute to the improvement of growth.

Monitoring above-ground biomass for multiple species-rich natural forests in Japan using UAV-LiDAR

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Kyaw Kyaw Htoo[1]
Md. Farhadur Rahman[1], Masanori Onishi[1], Yusuke Onoda[1]
[1] Graduate School of Agriculture, Kyoto University, Japan

Abstract: Conventional forest biomass estimate involves time-consuming and costly ground census (e.g., measuring DBH and height). UAV-LiDAR can collect crown geometrical information (e.g., height and area) for wider areas in a short time, making it an important tool for estimating forest biomass. However, the extent to which this technique can accurately predict biomass and growth of species-rich natural forests across a wide range of environments is still unknown. To investigate this, we acquired LiDAR data in multiple (currently 11) natural forests across Japan. A combination of LiDAR data, image segmentation, and ground validation was employed for accurate estimation of height (H) and crown area (CA). Above-ground biomass (AGB) and growth rates (GR) were calculated from the most recent five-year census data. We then compared a set of linear regression -and mixed models to determine the important parameters in determining growth rates.

The drone survey detected a total of 1938 individuals from 85 species (out of 10,644 stems belonging to 153 species with DBH > 5cm). The contribution of drone-detected individuals to the total biomass varied across different sites, ranging from 64 % in deciduous forests to 84 % in evergreen conifers. Consistently, canopy trees make up *c.a.* two-thirds of the total biomass in 1 ha underscoring their reliability in monitoring biomass dynamics. A strong correlation was observed between CA and AGB, and between GR and CA, both exhibiting significant variation among different sites ($p < 0.001$). CA was a better predictor of GR ($R^2 = 0.35$) than H ($R^2 = 0.14$). Together they can explain up to 37 % of GR variation ($R^2 = 0.37$). We found that adding species information much improved the estimation of GR ($R^2 = 0.49$).

In conclusion, the study demonstrates the effective application of UAV-LiDAR for detecting crown areas of tall canopy trees. It offers an innovative and reliable method for monitoring above-ground biomass in species-rich natural forests, providing valuable insights for their management.

Monitoring natural forests in the Andes-Amazon in three dimensions with multi-satellite sensors

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Yasumasa Hirata[1]
Wei Yang[2], Lenin Cruyff Ventura Santos[3], Noemi Serrudo Torobeo[3], Ethel Rubin De Celis Llanos[4]

[4] National Agrarian University La Molina

Abstract: The region from the Andes to the Amazon holds diverse ecosystems due to the different environments created by the great differences in elevation. These mountain ecosystems have multifaceted functions such as biodiversity conservation and global environment conservation that mitigate global warming and stabilize the global climate system, and provide various ecosystem services for human life. On the other hand, natural forests in this region are exposed to natural disturbances caused by forest fires and anthropogenic disturbances caused by human activities, and proper conservation and management of natural forests are necessary to maintain the functions that forests possess. The data obtained from the GEDI, which is LiDAR sensor and is onboard the International Space Station (ISS) by NASA, can provide three-dimensional information at observation points. However, the data is discrete and does not cover the entire area of interest. Therefore, the objective of this study is to develop a method for monitoring the extent and condition of natural forests from the Andes to the Amazon region by combining GEDI data with data from optical satellite sensors. First, we performed region segmentation on optical satellite Sentinel-2 images into regions of high similarity. The resulting objects were then classified on the object-based classification using data on land cover type and forest carbon stocks obtained from ground-truth surveys in the field. For objects classified as natural forests, GEDI data were used to assess the state of natural forest disturbance. The results showed that the more degraded the forest, the lower the height from the ground at the peak of the intensity of reflected energy from the forest canopy. Using this feature, it was possible to evaluate the condition of natural forests. However, the observed data at sites with very steep slopes showed significant slope effects and future development of methods to reduce the effects of slopes is required. In addition, the use of satellite LiDAR is not suitable for monitoring dwarf natural forests in high-elevation zones, and other monitoring methods using other sensors, such as high-resolution satellites, are needed.

Monitoring patterns of natural dynamics and biodiversity in several mature and old-growth forests through an ecological gradient.

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

[6] Gobierno de Aragón, Spain

Abstract: Natural dynamics over a long-term perspective is a very little studied aspect in southern european forests. Monitoring the relation between structure, biodiversity, demographic processes and natural disturbances is essential for better understanding the role of forests in key issues such as climate change and nature conservation. In the last years we have established a network of reference mature and old-growth forest stands through a broad ecological gradient for the long-term monitoring of key ecological aspects. From the sea level close to the Mediterranean Sea to the timberline in the Pyrenees mountains we explored forests dominated by different tree species: *Pinus halepensis, Quercus ilex, Juniperus thurifera, Pinus pinaster, Pinus nigra salzmanii, Quercus pyrenaica, Pinus sylvestris, Fagus sylvatica – Abies alba,* and *Pinus uncinata.* We installed two permanent plots (square and size 0.25 ha) per stand. Dendrometric values vary greatly among forest types. Montane forests belonging to the Alpine Bioregion showed the highest values of volume (658 m^3/ha), basal area (58 m^2/ha), Assman dominant height (28 m), and volume of dead wood (100 m^3/ha) probably as a consequence of higher Net Primary Production. Nevertheless, forests in the Mediterranean Biogeographical *Region* had the thickest (DBH 79 cm) and oldest (364 years) trees. The abundance of tree-related microhabitats was higher in hardwood forests, however the maximum values was obtained in a coniferous forest in the high Mediterranean mountains (*Pinus uncinata* in the Iberic Range). The analysis of the phases of the silvogenetic cycle helps to understand the functioning of forests and with a dendrochronological approach we reconstructed the stand historical dynamics tending to establish the current state of the forest. New technologies as terrestrial Lidar scanning and drones help us to have a more accurate representation of the forest structure. Studying insects and epiphytic lichens and bryophytes will allow us to verify the potential effects on the most sensitive species to habitat alteration. Long-term monitoring of these stands will enable to understand the resilience and mitigation effects of different mature forests to ongoing global change.

On the utility of forecasting seed production in forest trees

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Mario Pesendorfer[1]
Iris Oberklammer[1], Georg Gratzer[1]
[1] Institute of Forest Ecology, University of Natural Resources and Life Sciences, Vienna

Abstract: Masting, the intermittent production of synchronized bumper crops by population of plants, is a pervasive phenomenon in temperate and boreal trees. The resulting interannual variability in reproduction provides considerable challenges for foresters, land managers, and conservationists, as the resulting resources pulses affect not only natural tree recruitment, but also whole forest communities through trophic cascades built on seeds. Because our mechanistic understanding of and data foundation for seed production in forest trees has grown extensively over the last decade, anticipatory and long-term forecasts of annual seed production patterns may soon be available for many common species. Here, we discuss how such forecasts may be useful to plan the timing of forestry operations, land management decisions, and conservation actions. We present examples from ongoing forecasting efforts and their impact on the work of practitioners in forests. Furthermore, we highlight how anticipatory forecasts may also be useful to forest- and tree-related public health aspects, for example by predicting pollen density, tick abundance, or the rate of zoonotic disease transmission to people living in and near forests.

Pattern of natural dynamic of a sessile oak- European beech old-growth forest

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Any Mary Petritan[1]

[1] National Institute for Research-Development in Forestry ''Marin Drăcea'', Department of Forest Ecology, Romania
[2] Transilvania University of Braşov, Braşov, Department of Forest Engineering, Forest Management Planning and Terrestrial Measurements, Romania

Abstract: Old-growth forests are important sources of information. The Runcu-Grosi Reserve is one of the few remaining, good preserved sessile oak-beech old-growth forest in Europe. The 10-years dynamic of this rare old-growth forest was investigated based on the re-measurements of approximately 1880 trees with a threshold diameter of 5 cm, grown in 26 circular plots of 1000 m^2 randomly distributed. Three important processes of forest dynamics: ingrowth, mortality and increment of trees were investigated, and the effect of the main tree species on these processes. The ingrowth (the number of trees per hectare that passed the diameter threshold at the second inventory) ranged from 0 to 200 per hectare, with an average value of 63. Beech accounted for 71% of the new trees, followed by hornbeam (24%), while sessile oak accounted an insignificant percentage (0.02 %). The lowest average number of new trees was found in pure beech plots (25), three times lower than in plots dominated by beech or oak (75), but with no significant differences, due to the high variability. The average number of the tree per hectare that died, during the 10 years, was 113, which corresponding to an average volume of 107 m^3 ha^{-1} (17 % of the initial volume of living trees, ranged from 0.5 to 50%). Although, the percentage of trees that died was almost similar between plots of different composition, the oak dominated plots had the greatest volume loss trough mortality (19 % comparing to only 14% in pure beech), indicating that a greater number of larger trees died in these plots. Most of the trees that have died, are lying dead trees (more than 65% in both number and volume). While beech accounted for 67% of the number of trees that died, the Quercus species accounted for over 50% of the volume. The mean radial increment per 10 years was 2.72 cm, being similar in plots with different composition. Our results provide a valuable basis for understanding of sessile oak – European beech old-growth forest dynamic in a changing climate and will be completed with more information collected in inventory plots of 1 ha.

Shifts in wood anatomical traits after a major hurricane

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

[6] Department of Environmental Science, University of Puerto Rico, USA

Abstract: Trait variation across individuals and species influences the resistance and resilience of forest ecosystems to disturbance, as well as the ability of individuals to capitalize on post-disturbance conditions. In trees, the anatomical structure of xylem directly affects plant function and, consequently, it is a valuable lens through which to understand resistance and resilience to disturbance. In many tropical regions, disturbance regimes are historically dominated by cyclonic storms, which are predicted to occur with higher frequency and intensity under climate change. To determine how hurricanes affect wood anatomy of tropical trees, we characterized a suite of anatomical traits (vessel sizes, vessels grouping, tissue fractions) in wood produced before and after a major hurricane in Puerto Rico for 65 individuals of ten species. We quantified anatomical variation at different scales (within individuals, within species, among species), and evaluated trait shifts between the pre- and post-hurricane periods. We also assessed correlations between traits and growth rates. While most trait variation occurred among species, we also observed substantial variation within species and individuals. Within individuals, we found significant shifts for some traits that generally reflected increased hydraulic conductivity after the hurricane. We found weak evidence for an association between xylem anatomical traits and growth rates. The within-individual variation of xylem anatomical traits observed in our study may be related to post-hurricane recovery and growth. Other factors are, however, likely to decouple the direct relationship between xylem anatomy and diameter growth. While adjustments of wood anatomy may enable individual trees to capitalize on favorable post-disturbance conditions, these may also influence their future responses or vulnerability to subsequent disturbances.

Start with the forest: monitoring terrestrial carbon fluxes with geospatial data

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

David Gibbs[1]
Nancy Harris[1]
[1] World Resources Institute, Washington, DC, USA

Abstract: The Paris Agreement goal of limiting global warming to well below 2 degrees cannot be achieved without significant reductions in human-caused emissions from land. In order to reduce terrestrial carbon emissions, as well as maintain or increase carbon removals, we need to understand historical carbon fluxes. Ideally, terrestrial carbon flux monitoring would be sufficiently spatially resolved for actionability by a range of parties, as well as transparent, complete, consistent, and accurate. Numerous approaches have been used to monitor terrestrial carbon fluxes—both emissions and removals—but usually not within a targeted geospatial framework, and often with highly divergent, potentially conflicting results.

Here we build on a global geospatial, Earth Observation-based framework for monitoring forest carbon emissions, removals, and their net flux from 2001 onwards. This framework was developed to monitor carbon emissions from forest loss and carbon removals by standing and regrowing forests according to Intergovernmental Panel on Climate Change greenhouse gas inventory methods. Agricultural commodity companies, multilateral organizations, researchers, and civil society have applied this forest carbon monitoring data to their specific needs and regions of interest. Although forests contribute the majority of terrestrial carbon fluxes, there is increasing interest in more comprehensive terrestrial carbon monitoring, as demonstrated by the shift from deforestation-free commitments to conversion-free commitments among companies. Thus, we are expanding the forest carbon monitoring framework to cover fluxes from all land uses and land-use change, as well as agricultural emissions, through a stepwise, incremental approach.

This presentation will explain how an Earth Observation-based forest carbon monitoring framework can serve as the basis for monitoring carbon changes for all land, the progress made on broadening the framework beyond forests, challenges encountered, anticipated uses, and the potential for not just forests but all land to contribute to climate change mitigation.

Structural characteristics of natural European temperate forests – how do they relate to time since management?

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Lucia Seebach[1]
Veronika Braunisch[1, 2]
[1] Forest Research Institute of Baden-Württemberg, Wonnhaldestr. 4, 79100 Freiburg, Germany
[2] Conservation Biology, Institute of Ecology and Evolution, University of Bern, Baltzerstrasse 6, 3012 Bern, Switzerland

Abstract: In Central Europe, strict forest reserves are an important component of forest conservation strategies, aiming at restoring natural structural properties in previously managed forests. However, by time of designation most reserves had been more or less intensively managed and vary in stand and site conditions. Although important with regard to both, carbon storage and biodiversity, it remains unclear, how different structural characteristics of these forests are related to time since management cessation, and how this relationship is modulated by site conditions, forest type and climate.

We related forest structure characteristics to time since reserve designation ("reserve– age"), using *in situ* data from 85 unmanaged forest reserves in Baden-Württemberg, Germany, ranging from one to 99 years in age. While we expected a continual increase in *old-growth attributes, tree-related microhabitats (TreMs)* and *species and structural diversity* with "reserve age", we hypothesized a temporal decrease of *open structures*.

In line with our expectations, reserve age was strongly positively related to *old growth* attributes like dead wood volume, the number of giant trees (>80 cm diameter at breast height) and the proportion of forest in decay phase. Strong relationships were also found for *TreMs,* in particular for fungi and broken tree parts, and for indicators of *structural diversity*, such as the diversity of decay stages and the variance in stem diameter of dead trees. No significant trend was found for indicators of *open structures*, except for the volume of living trees, which showed a maximum for 30-year-old reserves.

While no differences were found between broadleaved and conifer-dominated forests, climate conditions significantly modulated the responses of most structural attributes to reserve age, except for the share of late successional phases, the diversity of decay stages and for *TreM* abundance of fungi and cavities. In addition, site productivity affected the response-level of living tree volume and the variance in the stem diameter of dead trees.

Our results provide evidence, that climate change will accelerate the development of structural complexity in natural forests and thus increase their potential to support forest biodiversity.

STUDY OF THE DYNAMICS AND CARBON STORAGE IN SWAMP FORESTS IN THE UCAYALI, MARAÑÓN AND TIGRE RIVERS IN THE PERUVIAN AMAZON»

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Cecilia Ballón[1]
Euridice Honorio[2], Julio Alegre[3]
[1] BALLON FALCON, CECILIA
[2] HONORIO CORONADO, EURIDICE
[3] ALEGRE ORIHUELA, JULIO

Abstract: In Peru, Amazonian peatlands are estimated to store 3.14 (0.44–8.15) PgC, representing 40% of the country's carbon, and in 3% of the forested territory (Draper et al., 2014). In this study we expand the knowledge of these formations, in swampy forests such as hydromorphic Aguajales and Varillales in the Loreto region. Ten permanent plots of 0.5 ha were evaluated with the RAINFOR standardized methodology. In five of these plots, the carbon content of the organic soil (peat) was evaluated. Biomass was estimated using the pan-tropical equation of Chave et al. (2014). Organic soils were characterized and carbon reserves were estimated by measuring apparent density and the percentage of total carbon. In addition, diversity descriptors, floristic composition and estimators of forest dynamics were evaluated. A similar basal area was obtained in the two formations, 27.4 to 28.2 m2/ha. Only in the hydromorphic Varillales was a high tree density of 892–1074 ind/ha higher than the Aguajales and other formations of the Amazon plain. Low values of richness and diversity were obtained due to the presence of monospecific species where Mauritia flexuosa is the most ecologically important species (130–185% of the IVI) for Aguajales and Pachita nitida (58–126% of the IVI) for hydromorphic Varillal. We found that swamp forests contain between 641.74–2189.75 MgCha-1, above and below ground. Furthermore, the hydromorphic Varillal has been found to be the most carbon dense ecosystem with 2187.80–2189.75 MgCha-1, of which approximately 90% is Soil organic carbon; these present an average peat depth of 4.50m, in contrast to the Aguajales of 0.96m. Regarding forest dynamics, for seven plots with an intercensal period of 2.26-5.8 years, the mortality, recruitment and turnover rate of individuals present high values, between 1.76-5.41%; 2.31–5.65% and 2.03–5% per year respectively.

Towards a functional monitoring network in Catalan forests (FUNBOSC)

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

[5] ICREA, Barcelona, Spain

Abstract: Forests are key for Earth functioning and provide human societies with numerous ecosystem services, including nature-based solutions that aid in climate change mitigation. However, environmental stress and disturbances, frequently magnified by anthropogenic global change, threaten forests and the services they supply. Our toolbox for large-scale monitoring of forest state and functioning includes forest national inventories, periodic surveys of forest health, remote sensing tools and forest ecosystem models. While these approaches have been refined over the years and now provide highly valuable information about forests worldwide, they also show important limitations when it comes to identifying how tree water use and carbon dynamics respond to stress/disturbance across different tree species and at large geographical scales. At the same time, decades of research on tree ecophysiology have equipped us with the expertise to measure tree water and carbon use at diel to seasonal scales. Here we present the initial design of a forest functional monitoring network (FUNBOSC) aimed at providing data on tree water use, tree water status and tree radial growth across forest stations in Catalonia (NE Spain, total forest area *ca.* 12,000 km2). This network will integrate sap flow probes, automatic dendrometers and tree water content sensors in wireless sensor networks to provide near real-time data. FUNBOSC will start with 10 initial stations to be deployed in the short term and which will be located in forests with existing ecohydrological monitoring and/or sites affected by drought-related forest die-off. We will present the prototype of a tree monitoring station and the infrastructure for data transfer, storage, processing and visualisation developed during a 6-month test period in a diverse Mediterranean forest (Can Balasc Biological Station, Barcelona). The data resulting from FUNBOSC will be publicly available and will contribute to improve our understanding of the response of water and carbon fluxes to climatic variability, derive early-warning signals of forest decline, improve forest ecosystem models and refine remote sensing indicators of forest functioning. FUNBOSC is designed to be integrated into broader, regional forest monitoring networks and its principles can be applied in other regional contexts.

Towards closing the seed dispersal loop: the role of temporal variation in seed rain for tree population structure in old-growth forests

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Georg Gratzer[1]

[3] Cary Inst. of Ecosystem Studies, Millbrook, NY, USA.

Abstract: Altered disturbance regimes in forests create unique challenges in terms of tree regeneration and carbon storage in future forests. Understanding spatiotemporal dynamics of tree seed production and dispersal is thus key to sustaining ecosystem function of old-growth forests. As the number of long-term studies and the availability of global data sets on tree seed production grow, the understanding of proximate factors driving tree seed production has strongly increased. However, to understand the effect of seed production and dispersal on long-term community dynamics and, ultimately, to evaluate the fitness consequences of different seed production strategies, it is important to link seed production and dispersal with tree population dynamics. This is particularly important because processes that act at different stages of dispersal, germination and seedling growth can be uncoupled and even have opposing effects. Here, we use a combination of empirical research on seed rain, tree regeneration, and seed predation in old-growth forests combined with the parameterization of a spatially explicit, individual based tree population model (SORTIE-ND). Specifically, we studied the consequences of temporal variation in seed production on long-term tree population dynamics including seed fate and the population dynamics of small mammals. We tested the following hypothesis: (1) through pronounced masting in species with palatable seeds, seed predators are driven into hunger cycles and reductions in populations leading to windows of opportunity for tree establishment through intermast seeding and (2) Intermast seeding creates spatial structure in trees and influences species composition and dynamics. We found that high spatial variability of seed rain for Fagus sylvatica was caused by distinct and stationary seed hotspots, seed input positively predicted the spatial structure of seedlings and saplings for this species. The signature of annual variation in seed rain fades with seedling mortality over time in all three focal species. We found that spatial variation in seed rain interacts with subsequent processes to shape the distribution of seedlings and saplings, but in ways that suggest decoupling of the processes between life history stages.

Tree growth during 50 years and stem respiration along elevation gradients in Japanese beech forests

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Masaaki Narmoto[1]
Akira Komatsu[1], Atsuhiro Iio[1], Hiromi Mizunaga[1], Yoshitaka Kakubari[1]
[1] Shizuoka University

Abstract: *Fagus crenata* (Japanese beech), a late-successional and climax species, is ecologically the most important forest species in the cool temperature zone in Japan. Japanese beech forests are distributed widely in Japan and at 550 to 1500 m in elevations around the Naeba mountains. The elevation gradients of the beech forest distribution in this area are about 1000 m and it means that there is the maximum difference in temperature of about 5 °C. The temperature environments might be one of important environmental factors for tree growth and respiration. And temperature trends to increase in recent days under global warming. We tried to evaluate the effects of temperature environment changes on tree growth and stem respiration for the Japanese beech forests grown at different elevations in the Naeba mountains.

Eight study sites were set at different elevations of 550, 700, 900, 1100, 1300 and 1500 m in 1970. All living tree with more than 4.5 cm in DBH were numbered and their spatial locations were recorded. DBH of trees in each study site were measured after growing season intermittently during 1970 to 2021. The tree growth and NPP were calculated and compared among sites and ages.

Stem CO_2 efflux were measured in situ seasonally from May to November in 2022. The measurements were conducted in 11 to 12 trees grown at four different elevations of 550, 700, 900 and 1500 m. Diameter increments were also measured by dendrometer bands. Stem respiration were divided into growth respiration and maintenance respiration, and analyzed.

Trends in climate oscillations drive spatio-temporal changes in tree reproduction phenology

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Giulia Resente[1, 2]
Renzo Motta[1], Davide Ascoli[1]
[1] university of Turin
[2] university of Greifswald

Abstract: Anthropogenic climate change is influencing the biosphere via a generalized warming trend and variation in global circulation patterns, with tremendous cascading effects on the phenology and timing of ecosystems processes and their interactions. Disentangling the mechanisms that link large-scale modes of climate variability to spatio-temporal patterns in tree reproduction can improve our understanding and prediction of forest ecosystems dynamics under the current climate crisis. In Europe, changes of the NAO have been affecting the inter-annual variability and large-scale synchrony in tree reproduction of key families such as Fagaceae, Betulaceae, Pinaceae and Cupressaceae. Our research investigates how NAO properties, seasonal patterns, cycles and trends in the last 70 years prompted large-scale reproductive pulses in beech forests, and how this mechanism and related processes (e.g., trophic cascade, human diseases) can be affected by predicted changes in climate. We expect that as the altered circulation patterns might lead to a shift in the intensity, duration, and frequency of NAO phases, it might as well impact the periodicity of the summer NAO, with tremendous implication for beech reproduction in the next decades.

Tropical forest response to climate change: advancing understanding with high-resolution and long-term data

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Robert Muscarella[1]
Julia Tavares[1], María Uriarte[2]
[1] Plant Ecology and Evolution, Institute for Ecology and Genetics, Uppsala University, Sweden
[2] Ecology, Evolution, and Environmental Biology, Columbia University, USA

Abstract: Tropical forests contain the majority of Earth's biodiversity and provide immense benefits to humans at both local and global scales. To date, however, we have a surprisingly poor understanding of how specific climate stressors (e.g., drought) affect these forests and, ultimately, scale up to ecosystem-level responses. Accurately forecasting the global consequences of climate change requires stronger mechanistic links between climate variability and the dynamics of tropical forests. We established a set of long-term monitoring plots in forests across a precipitation gradient (mean annual rainfall ranging from 900 – 3500 mm year) in the Caribbean island of Puerto Rico. We collected spatially-explicit, annual data on individual tree diameter growth and survival over 6 years to better understand demographic responses of species to climate variability. We collected complementary data on numerous functional traits (e.g., wood density, SLA, hydraulic vulnerability to embolism) to understand how traits mediate demographic responses to climate variability. Finally, we used information on species broader geographic distributions to contextualize growth responses to climate variation in terms of species climatic niches. Preliminary results show highly variable growth rates among species and across species ranges, as well as trait-mediated responses to climate variability. Ongoing work is will further assess climate-growth relationships in the context of species climate niches, local topographic position, and local biotic neighborhood to determine the processes the mediate growth depend on the climatic context. Overall, our study illustrates the value of long-term monitoring across regional environmental gradients to understand the variety of processes that govern forest dynamics.

UAV-LiDAR carbon modeling for REDD+ projects in Brazilian savanna (Cerrado)

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Silvio Henrique Menezes Gomes[1]
Danilo Roberti Alves de Almeida[1], Leo Eiti Haneda[1], Arthur Kaufmann Sanchez[1], Bruna Pereira de Azevedo[1], Diego Ribeiro de Aguiar[1], Renan Akio Kamimura[1]
[1] brCarbon Serviços Ambientais, São Paulo, Brazil

Abstract: The Cerrado formations (Brazilian Savanna) represent a diverse and unique tropical savanna biome. Despite its ecological significance and rich biodiversity, the Cerrado remains one of the most threatened biomes globally, primarily due to agricultural expansion and land-use changes. Understanding the biomass dynamics within these formations is crucial for effective conservation. Precisely estimating carbon stocks is a crucial undertaking for both climate change mitigation and conservation initiatives, particularly in the context of REDD+ projects. Traditional approaches, relying on costly field-based carbon measurement methods, encounter constraints related to their spatial coverage, impeding comprehensive and accurate assessments across expansive forested areas. To address this challenge, remote sensing with UAV-LiDAR emerges as a valuable solution that has the potential to overcome these limitations. By harnessing remote sensing technologies, carbon stock estimates can be scaled up, fostering transparency in carbon reporting. However, achieving dependable outcomes mandates the development of precise regional models and the adoption of high-accuracy techniques to ensure reliable and robust results. In this sense, we assess the capability of high-density UAV-lidar to estimate and map the aboveground carbon density (AGCt) of live trees in the Brazilian Savanna (Cerrado) using 45 field-based sample plots (30 m × 30 m). Three generalized least square regression models were tested, and we considered the presence/absence of palm trees as variable to improve precision in biomass estimates. We hypothesize that the presence of palm trees is an indirect indicator of higher soil moisture, occurrence of trees with higher canopy cover and biomass. We found that considering the presence of palm trees as a biological index of areas with higher carbon content improves the model accuracy by 27%. Comparing the LiDAR estimates and field-based control plots, we found a global uncertainty of 2.1% and sub estimates of 1.6% when applied to 1000 iterations of the resampling procedure. The findings of this study serve as a benchmark for future research endeavors aimed at generating accurate carbon maps and providing baseline data for the efficient management of fire and predicted climate change impacts on tropical savanna ecosystems.

Understanding forest stream flow regulation and restoration in the seasonal tropics: A view from Agua Salud

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

[8] Yale-NUS

Abstract: On an area basis, forests use more water than grassland. Tropical forests also more directly regulate stream flow due to deeper rooting and longer time periods of water use. Few long-term studies of stream flow exist for tropical watersheds at the precision and accuracy necessary to understand forest stream flow regulation. Even fewer studies examine the restoration of stream flow regulation over time. The Agua Salud Project in central Panama studies the ecosystem services provided by tropical forests in a seasonal climate and how they change with land use and climate change. Catchments in Agua Salud have been monitored continuously (5 minute averages) for 15 years, where monitoring not only includes forest, pasture, and invasive grass end members but also several active and passive forest restoration treatments (natural secondary forest recovery, exotic tree species (teak) plantation, native tree species plantation, invasive grass, silvopasture treatments). In 2013 researchers showed that the mature forest catchment had enhanced dry season stream flow relative to the pasture and showed that the forests greatly reduced storm runoff peaks and volume. Multi-year studies of different compartments of the water cycle (rainfall, throughfall, infiltration, stream flow) combined with natural tracer experiments help provide a mechanistic understanding of how forest stream flow regulation works.

Concurrent with stream flow monitoring, vegetation, soil, and micrometeorology have also been recorded in experimental catchments. Here trees, lianas and seedlings have been monitored annually for growth, mortality, and recruitment. Sap flux measurements help understand the water use of trees and forests.

The 15-year monitoring in Agua Salud includes the flood of record in the Panama Canal Watershed and other extreme storms. The period also captures one of the worst droughts during the last 100 years, the period for which rainfall data are available.

In this talk we will discuss the results of over a dozen studies undertaken to monitor and understand the mechanisms of stream flow regulation by forests. We will discuss this in relation to plantation and natural forest dynamics with special attention given to vegetation response to extreme weather events, one of the best windows into the effects of global change.

What is and what is not an old-growth forest? A case study from hemiboreal Latvia.

T5.23 Monitoring patterns and processes in natural forests to assess their contribution to climate-change mitigation

Daiga Zute[1]
David Ellison[2], Laura Kenina[1], Valters Samariks[1], Ieva Jaunslaviete[1], Aris Jansons[1]
[1] Latvian State Forest Research Institute "Silava"
[2] ETH Zürich

Abstract: The EU Biodiversity Strategy (2030) prioritizes the preservation of Europe's old-growth forests (OGFs). Protected areas should make up at least 30% of the EU land area, with 10% under strict protection, including all primary and old-growth forests. The mapping of OGFs, however, at EU and Member state level presents a challenge. Though knowledge on OGFs has improved, at the EU level, large uncertainty remains regarding the definition of old-growth due to both the lack of data and broad variation in OGF forest characteristics, including age.

A conceptual approach should be developed which, for each ecosystem, defines what is and what is not an OGF. This will permit an adequate mapping of OGF relevant protection areas at the EU and Member state levels. Current definitions, for example, suggest that once an old forest stand is lost, e.g., through natural disturbances, that the stand should no longer be considered an OGF.

The aim of this study is to assess the definition and presence of OGF stands across the territory of Latvia. Based on the OGF Guidance by European Commission (COM, 2023), we apply OGF criteria, select reference stands, and develop indicators and threshold values for hemiboreal forests with the goal of distinguishing, e.g., between patches of old trees which meet some OGF criteria, on the one hand, and forest stands that can be qualified as true OGF, on the other.

OGFs in hemiboreal Latvia have now been systematically studied for 8 years (since 2016) and have been assessed in the National Forest Inventory since 2004. Based on empirical data from established OG research sites, we assess the principal forest stand characteristics (H, DBH, N, M) for coniferous and broadleaved tree species growing on mineral and organic soils. Above- and below-ground carbon pools, including the deadwood pool, have likewise been assessed, making it possible to evaluate the climate change mitigation potential of hemiboreal OGFs.

We suspect that OGF cannot be defined by tree age alone and find broad variation across stands and stand structures.

T5.24 Moving towards digital forests for a sustainable future

Assessment of forest structural dynamics over a phenological cycle using mobile laser scanning

T5.24 Moving towards digital forests for a sustainable future

Daniel Kükenbrink[1]
Charis Gretler[1], Mauro Marty[1], Christian Ginzler[1]
[1] Swiss Federal Institute WSL, Landchange Science, Zürcherstrasse 111, Birmensdorf, CH-8903, Switzerland

Abstract: The phenological cycle is more and more affected by climatological changes. Spring activities such as the shooting and flowering of vegetation have occurred progressively earlier since the 1960s, changing structural dynamics of forest ecosystems. Changes in forest structure resulting from altered phenological patterns can impact ecosystem processes such as carbon and nutrient cycling, water availability, and biodiversity. Understanding phenological changes in forest structure is crucial for effective forest management and conservation.

Monitoring 3D structural dynamics in forest ecosystems on plot or stand scale can be labor intensive. With mobile laser scanning (MLS) becoming more prominent in forestry applications, repeated measurements of the 3D forest structure on plot scale are getting more feasible, allowing for an assessment of 3D structural dynamics over a phenological cycle.

In this contribution, we performed repeated MLS acquisitions on four sample plots in a mixed temperate forest close to Zurich, Switzerland. The sample plots have a size of 50 x 50 m2, corresponding to the sample plot size of the Swiss National Forest Inventory (NFI). MLS acquisitions were acquired on a weekly repetition cycle from March until June during the most dynamic vegetation period. Before and after that period, sporadic acquisitions have been performed to capture the entire spring phenological vegetation cycle.

From the acquired time series, the forest structural dynamics were analysed in terms of changes in vegetation density (i.e. plant area density) for various canopy strata (under-, middle-, and upper-storey), vegetation density profiles, extracted canopy height from the acquired point cloud, and the change in visibility within the canopy using an occlusion mapping approach.

Preliminary results show that repeated MLS acquisitions are well suited to assess small scale variations in 3D canopy structure, possibly giving important insights into phenological dynamics. Linking these structural dynamics with meteorological data and measurements of forest gas exchange, water- and nutrient cycles could deliver important information on the impact of climate change on forest structural dynamics and ecosystem functioning.

Augmented reality in forestry - Potentials and challenges

T5.24 Moving towards digital forests for a sustainable future

Thomas Purfürst[1]
Felipe de Miguel Diez[1]
[1] University Freiburg, Chair of Forest Operations, Germany

Abstract: In the process of digitising forestry (Forest 4.0), extensive data are generated and digitally stored as a digital twin of the forest and the processes taking place in it. While the data recording has been intensely investigated so far, the efficient provision of the processed digital data to the respective user on-site in the forest continues to be challenging. In particular, the visualisation of these digital data in a suitable, application-oriented form in the forest, e.g., for forest rangers or forest workers, has not yet been sufficiently solved. Currently, this is done, for example, via printed maps or digital representations on devices such as smartphones or tabs, which can only be used to a limited extent in daily work in the forest.

The field of augmented reality (AR) offers a promising approach to visualising stored digital data in reality. In AR, a computer-assisted extension of reality perception is carried out by inserting digital data in real-time onto digital images (smartphone/tablet) or projecting them into the viewer's field of vision with the help of a projection surface (e.g., AR glasses). Ideally, digital data and reality are spatially congruent, with data enrichment of reality taking place. In this way, the quantity, quality, and safety of work in the forest can be increased, especially for forest workers, district managers, and decision-makers, by displaying digital data and/or hazard information in real-time without having to restrict/interrupt the work in question.

The presentation shows the results of a feasibility study and the potential for the operational use of AR in the forest with an iPad as well as with the currently most frequently used AR glasses HoloLense2 from Microsoft. Furthermore, the scientific questions, the current solutions and the challenges that still need to be solved, such as data preparation and transmission, available technology, insufficient positioning accuracy and orientation under shielded conditions, and a potential gain in productivity and safety, will be addressed.

Construction of 3D Data on Urban Trees Using Integrated Investigation Method

T5.24 Moving towards digital forests for a sustainable future
Uk-Je Sung[1]
Yungu Lee[2], Jeong-Hee Eum[1]
[1] Dept. of Landscape Architecture, Kyungpook National University
[2] Human Resources Development Center for Big Data-based Global Forest Science 4.0 Professionals, Kyungpook National University

Abstract: Recently, cities and countries have implemented a 3D virtual space by applying the concept of a digital twin. The level of digital twin technology is classified according to how detailed it is to implement a building. Accordingly, while modeling technologies are focused on the realization of buildings, the level of implementation of trees, which are the main components of a city, is lower than that of buildings.

This study aimed to establish 3D data on trees that can be used to implement a 3D virtual space through various methods of tree investigations. Tree information was collected using three investigating methods: literature review, field survey, and remote sensing analysis with UAVs and terrestrial LiDAR. The investigating data was implemented with GIS-based data consisting of tree information such as location, height, treewidth, and bole height. The investigation site was the Jung-gu district in Daegu Metropolitan City, South Korea. The investigation focused on streets, schools, and residential areas where trees were planted the most in the city. First of all, a literature review was conducted for areas with literature data, and a field survey was applied for areas without literature data. A remote sensing analysis was conducted by collecting point cloud data and recognizing points as an object. In this study, aerial viewpoints were collected through UAVs, and ground viewpoints were collected through terrestrial LiDAR, and the two were integrated. The method was conducted only for a neighborhood park called National Debt Redemption Movement Memorial Park. The remote sensing results were compared with the field survey to improve the establishment method of 3D data on trees by the remote sensing method.

The results of this study can be used as basic data for building 3D spatial information and realizing digital twins in Daegu Metropolitan City. In addition, it is judged that they can be used for improving environmental effect analysis by 3D spatial information of urban forests.

Enhancing Forest Tree Species Mapping in High-Resolution UAV RGB-Imagery with Pseudo-Labeling-based Semi-Supervised Learning

T5.24 Moving towards digital forests for a sustainable future

Yanling Zou[1]
Xiang Liu[1], Holger Weinacker[1], Barbara Koch[1]
[1] Chair of Remote Sensing and Landscape Information Systems, University of Freiburg

Abstract: UAVs play a crucial role in forest inventory and forest management due to the accessibility of high-resolution RGB imagery. With the advancements in deep neural networks (DNNs), the utilization of UAV imagery for semantic segmentation has significantly enhanced the accurate mapping of tree species in diverse temperate forests. However, generating training data for semantic segmentation typically relies on a large amount of labor-intensive reference data. In this study, we propose PoLa-Net, a deep learning-based approach for classifying tree species from UAV imagery. PoLa-Net leverages pseudo-labeling techniques to train a semi-supervised semantic segmentation model by utilizing both unlabeled data and a limited amount of annotated data. We evaluate the performance of PoLa-Net on a dataset comprising very high-resolution (<2 cm) RGB imagery acquired by multi-copter UAVs over heterogeneous temperate forests in the southern Black Forest region of Germany. Our model achieves accurate classification of ten tree species, deadwood, and forest floor, with a best mean Intersection over Unit (mIoU) score of 73.9%. The experimental results demonstrate that PoLa-Net is a robust and efficient method for tree species mapping. Furthermore, the training strategy employed by PoLa-Net can be applied to analyze and process various types of air- and spaceborne remote sensing imagery data.

Estimating pan-Mediterranean reburn frequency using Earth Observation

T5.24 Moving towards digital forests for a sustainable future

Alba Viana-Soto[1]
Cornelius Senf[1]
[1] Technical University of Munich, Ecosystem Dynamics and Forest Management Group, Germany

Abstract: Fires are one of the most widespread natural disturbances and an important driver of forests ecosystem dynamics worldwide. Fire disturbance regimes have changed profoundly in recent decades as a result of climate and land use change, leading to an increase in the frequency, size and severity of forest fires. In the European context, the Mediterranean basin concentrates around 85% of the total burned area and recently suffered extreme fire seasons attributable to unprecedented dry and warm conditions (e.g. 2012, 2017, 2022). Previous research suggested that fire frequency has doubled after the 1970s due to land abandonment, with certain areas that burned in the late 20th century now burning again. This would result in fire-return intervals of 20-30 years and thus jeopardizing the time needed to reach maturity age in many species. Estimating fire frequency is, however, still challenging and it thus remains unclear if and where fire frequencies are changing in the Mediterranean.

Consistent information on fire disturbances is essential to understanding changes in forest fire regimes. We present a new approach to quantify fire disturbance regimes in Europe, building upon a newly developed pan-European forest disturbance map (Viana-Soto et al. in prep.). Disturbances are annually mapped from Landsat data for the period 1984-2022 using a machine learning approach and attributed to fire based on shape and spectral reflectance properties. Our approach further enables to detect multiple fire events per pixel and thus to estimate reburns and recovery trajectories.

Based on this new product our aim is to improve the quantitative understanding of fire disturbances in Mediterranean Europe's forests by: (1) identifying reburned areas (i.e., areas that burned multiple times over the last four decades), (2) quantifying the total forest area affected by reburn events, and (3) analysing whether reburn frequencies have changed over time and how this has impacted post-fire recovery dynamics. Results will provide insights on the fire frequency, how it changed over time and how reburns might hamper post-fire recovery, particularly in forest dominated by species that regenerate from seeds and thus need a certain fire-free interval to achieve both structurally and functionally maturity.

Exploring changes in forest structural diversity, biomass and tree species richness along a multi-species chronosequence in Denmark

T5.24 Moving towards digital forests for a sustainable future

Yamina Micaela Rosas[1]
Sebastian Kepfer Rojas[1], Davide Barsotti[1], Torben Riis-Nielsen[1], David Bille Byriel[1], Mathias Just Justesen[1], Inger Kappel Schmidt[1]
[1] Department of Geosciences and Natural Resource Management, University of Copenhagen, Denmark

Abstract: Forest structural diversity (FSD) is a key determinant of forest conditions, ecological processes, and dynamics, and is related to several ecosystem services such as biomass stock and tree species richness. Recent advancements in LiDAR remote sensing have enabled the assessment of FSD metrics at a high spatial resolution. These metrics had been described to analyses structural heterogeneity (internal and external), height, canopy and openness within an ecosystem. This study aimed to investigate changes in FSD metrics in oak, beech, and N. spruce forest chronosequences and their relationship to biomass stocks and tree species richness, using LiDAR and ground truth data. LiDAR data was extracted from 66 forest plots, spanning from 22 years to over 100 years since planting, using a density of 5.4 pulse/m^2 during leaf-off season in 2019. LiDAR metrics were calculated at point cloud and grid level ($1m^2$). Ground truth data, collected in 2022 following Danish National Forest Inventory protocols, included trees counts, species, height and diameter at breast height. We evaluated changes of FSD metrics through the years and the association with biomass, and tree species richness by employing regression and PCA analyses. Our results revealed significant age-related variations in FSD metrics. Older forests exhibited higher values in terms of height and internal heterogeneity, witch beech forests displaying grater internal heterogeneity than N. spruces forests. Canopy and external heterogeneity metrics showed significant differences among forest types, with N. spruce forests having higher canopy cover values, while oak forests displayed higher values of external heterogeneity across all ages. The relationship between FSD metrics and biomass and tree species richness varied. Biomass showed a strong relationship with age for all analyzed species, with biomass values increasing with height and internal heterogeneity. Conversely, tree species richness increased with age for oak and beech forests, and only in oak forests richness values increase with height and heterogeneity. This study contributes to our understanding of forest structure dynamics and its implications for biomass stocks and tree diversity, advancing our knowledge of forest ecosystems. Integration of LiDAR remote sensing with ground truth data enables comprehensive assessment and facilitates effective management strategies.

Exploring the dynamics in spring phenology of dominant deciduous tree species in Poland using Sentinel-2 time series

T5.24 Moving towards digital forests for a sustainable future

Ewa Grabska-Szwagrzyk[1]
Agnieszka Sulikowska[1], Agnieszka Wypych[1]
[1] Institute of Geography and Spatial Management, Jagiellonian University

Abstract: The variations in vegetation phenology observed in recent decades have large ecological impacts, particularly taking into account climate change. In this study, we leverage the capabilities of satellite imagery, specifically Sentinel-2, to develop spring phenology models for dominant deciduous tree species in Poland, such as common beech, pedunculate and sessile oak, European larch, silver birch, and black alder.
We utilized two spectral indices (MTCI and EVI) derived from the Sentinel-2 time series spanning from 2018 to 2023, combined with modeling and detection of the Start of the Season (SOS). In the next steps, we investigated multiple factors potentially influencing SOS such as topography, longitude, latitude, and meteorological conditions. In particular, we focused on evaluating the impact of air temperature conditions on the onset of spring activity among examined species. Approx. 50 thousand reference samples were used based on the Polish Forest Data Bank and a national-level map of tree species distribution.
Preliminary results indicate that Sentinel-2-derived indices can effectively track phenological patterns for the dominant deciduous tree species on a country scale. The analyzed species show interesting and distinct spatial patterns in phenology, which differ in the examined years. For example, later SOS characterizes stands in the northern part of the country located closer to the Baltic Sea. On the other hand, elevation impact on delayed spring response is important in the mountain areas – this effect in the case of common beech is observed above approx. 400 m a.s.l. The results also suggest that these patterns are different depending on the year, which results from high variability in meteorological conditions in Poland. Particularly high differences are observed between 2018 (advanced spring phenology), and 2021 (delayed spring phenology). The impact of different meteorological variables will be further studied in this research.
The results will offer valuable insights into the timing of seasonal changes in different deciduous species, contributing to a better understanding of forest ecosystems and their responses to changing environmental conditions. It can further aid in understanding the spatial and temporal dynamics of forests and supporting sustainable forest management practices.

From single trees to country-wide maps: Modeling tree mortality across Germany

T5.24 Moving towards digital forests for a sustainable future

Nikolai Knapp[1]
Nicole Wellbrock[1]
[1] Thünen Institute of Forest Ecosystems

Abstract: Several extremely dry years have caused dramatic increases in tree mortality since 2018 in many regions of Central Europe. In particular Norway spruce has been strongly affected, but also other species have shown signs of decreased vitality and increased mortality risk. Long term monitoring programs such as the ICP Forests Level I monitoring provide valuable information about tree loss rates at annual resolution and on a systematic sampling grid. The German Level I monitoring (crown condition survey) consists of 410 plots on a 16 km × 16 km grid with a total of ca. 10,000 trees. The loss reasons for sample trees have been recorded since 1998. In this project, the goals were 1) to model tree mortality at the survey plots as a function of environmental drivers and 2) to produce country-wide maps of predicted mortality for a number of common tree species in Germany.

All trees in the dataset that died due to a cause other than planned management or windthrow were included as mortality events in the analysis, while all other trees were labelled as survivors. A set of more than 400 candidate predictor variables were derived with the condition that the data had to be available wall-to-wall for whole Germany. These environmental predictors covered the domains of climate, soil, topography, landcover and deposition. A multiple logistic regression model with the binary response "dead or alive" was fit to the data. The most important predictors for every tree species were identified via feature selection. Prediction accuracy and model robustness were tested via leave-one-location-and-year-out cross validations (AUCs between 0.65 and 0.9). Germany-wide maps of average mortality at 1-ha resolution were derived for Norway spruce (*Picea abies*), Scots pine (*Pinus sylvestris*), European beech (*Fagus sylvatica*), penduculate+sessile oak (*Quercus robur+petraea*) and other conifer and broadleaf species pooled.

The maps provide insights into the spatio-temporal patterns of mortality and enable the derivation of summary statistics at regional scales. The cause-effect relationships from the regression models will be combined with climate scenarios and process-based forest models to predict trajectories of future forest development.

Harnessing artificial intelligence for high-resolution forest modeling and decision support

T5.24 Moving towards digital forests for a sustainable future

Werner Rammer[1]
Marc Grünig[1], Michael Reuss[1], Jonas Kerber[1], Rupert Seidl[1, 2]
[1] TUM School of Life Sciences, Ecosystem Dynamics and Forest Management Group, Technical University of Munich, Germany
[2] Berchtesgaden Nationalpark, Berchtesgaden, Germany

Abstract: The rise of remote sensing and data science led to an unprecedented wealth of forest-related data, however, primarily focusing on the current state and recent history of forests. At the same time, the urgency of climate change and evolving societal demands necessitate the adaptation of forest management practices. To assess the potential long-term impacts of forest management decisions in a no-analog future, it is important to employ high-resolution model-based projections of forest development and related ecosystem service indicators. Such projections can be integrated into decision support tools designed to assist forest managers in addressing specific challenges related to forest adaptation.

This requirement presents a dual challenge. On one hand, there is a need to cover large geographical areas to ensure wide applicability of such tools. On the other hand, it is crucial to achieve high resolution down to the individual tree level in order to accurately capture the effects of local management decisions. While high-resolution models operating at the tree or stand level typically cannot cover large areas, large-scale models like dynamic global vegetation models often lack the structural details necessary for realistic predictions. To bridge this gap, we propose a novel data-driven approach that leverages artificial intelligence techniques. The approach is built upon three key components. Firstly, detailed process-based models are employed to simulate a multitude of individual forest trajectories under diverse climate, environmental, and management scenarios. Secondly, a deep neural network is utilized to learn the specific responses of forests to environmental and management drivers using these simulations. Lastly, this "meta-model" is employed to simulate forest dynamics at high resolution across large scales. This final step requires comprehensive information on the current state of forests that can be derived from state-of-the-art remote sensing products.

The output of this modeling approach comprises multiple forest development pathways, contingent upon climate and management contexts, along with associated indicators for ecosystem services. This dataset serves as a foundational resource for decision support tools. In this contribution, we introduce our AI modeling approach and present an example application that assesses climate change adaptation strategies for Germany's forests.

Hyperspectral image reconstruction from RGB image using deep learning

T5.24 Moving towards digital forests for a sustainable future

[3] Department of Plant Science, American University of Beirut, Beirut, Lebanon

Abstract: Hyperspectral imaging is a remote sensing method that provides detailed insight into plant and tree biochemical composition (through the analysis of the electromagnetic spectrum). This makes it a powerful method for monitoring forest biodiversity. Indeed, the generated hyperspectral image can be used to classify tree/plant species (for forest inventory surveying), and assess tree health based on biodiversity indices (including NDVI for chlorophyll estimation, CRI550 for carotenoid estimation, and others). However, it requires highly expensive, complex cameras and long acquisition times. To mitigate this issue, one solution is to reconstruct spectrum data from RGB images that are much cheaper to acquire (e.g., using regular phone cameras). Multiple studies and computer vision competitions have investigated the possibility of such reconstruction. However, none have focused on plants specifically, and they are limited to the visible range only (400-700 nm). Our study uses different deep-learning models and trains them exclusively on plant datasets. The number of spectrum bands was increased, and the spectrum interval included the near-infrared range (up to 1200 nm), crucial for plant health analysis and species identification. Initial testing showed a mean average error comparable to state-of-the-art models. The results indicate a solution for plant/tree health assessment is feasible at a fraction of the cost while maintaining high accuracy. Moreover, through the application of species identification, this new method can be very helpful for forest inventory missions. Finally, the low cost and ease-of-use of our proposed method means it is highly scalable and can be used by non-experts to cover large forest areas in a relatively short amount of time.

Improved forest edge descriptions by fusing airborne laser scanning and close-range remote sensing data

T5.24 Moving towards digital forests for a sustainable future

Moritz Bruggisser[1]
Daniel Kükenbrink[1], Zuyuan Wang[1], Christian Ginzler[1], Lars T. Waser[1]
[1] Swiss Federal Research Institute WSL, Birmensdorf, Switzerland

Abstract: Forest edges represent the transition zone between the forest interior and the open countryside and provide several ecological functions. They contribute to biodiversity as habitats for plant and animal species, regulate the microclimate and the fluxes of nutrients and pollutants between surrounding agricultural areas and the forest interior.
To ensure maintenance of these edge functions, a reliable and frequent assessment of their conditions is required. Countrywide airborne laser scanning (ALS) data (15-20 points/m^2) for Switzerland, which is publicly available and will be regularly updated in the future, is ideal to monitor forest edge conservation and renaturation efforts. From the ALS data, we derive forest edge structure characteristics for entire Switzerland (total forest edge length ~187,000 km). The product comprises five metrics describing the horizontal and vertical structure of forest edges (canopy height variability, presence or absence of the shrub layer, forest edge slope, light regime information and forest façade density). These metrics are indicative for the edge structure and well interpretable.
In our ongoing study, the information content of the ALS point cloud is enhanced by combining it with mobile laser scanning (MLS) and field imagery to derive improved edge structure descriptions. The data fusion serves two goals. Since MLS provides a more detailed representation of the forest structure than ALS, particularly within lower canopy layers, we first test the feasibility to upscale highly detailed, quantitative forest edge structure attributes from MLS at the plot level to larger areas using ALS. The second goal is to evaluate the potential of the methodology for implementation in the next iteration of the Swiss National Forest Inventor (NFI), which will integrate MLS and field image acquisitions. The combined data set of ALS, MLS and field imagery allows to derive more detailed information on structure and plant diversity than ALS alone. Hence, this data fusion allows to gain valuable additional information to complement the forest edge assessment which is carried out within NFI the today (~500 plots in total comprising edges).

Machine learning of process-based models for DestinE forest digital twin

T5.24 Moving towards digital forests for a sustainable future

Matti Mõttus[1]
Heikki Astola[1], Eelis Halme[1], Francesco Minunno[2]
[1] VTT Technical Research Centre of Finland
[2] Yukatrote

Abstract: Destination Earth (DestinE) is a European Union initiative that aims to develop a digital twin of the Earth, which can simulate the Earth's systems and processes to enable informed decision-making for sustainable development. The architecture of DestinE focuses on simulating the inter-actions between natural and human-made systems using sophisticated physical models, remote sensing and in-situ data, and machine learning techniques. Using the novel high-resolution simulations of the Earth's atmosphere, oceans and land surface, a forest digital twin will allow to investigate the impact of climate change, natural hazards and human activities on the past, current and future state of the forests. To handle the unprecedented volume of observed and modeled data, and the level of detail required by the system, extensive use of advanced machine learning methods—also known as artificial intelligence (AI)—is foreseen. Currently, AI is often used as a powerful interpolation technique allowing to interpret observations and predict outcomes of physical processes at local to regional scales.

To make full use of AI in the forest science relevant to the DestinE initiative, it must be explicitly linked with physical models quantifying the temporal development of physical and biochemical variables describing a forest and its interaction with the atmosphere, hydrosphere, cryosphere and lithosphere. We present a study on how AI techniques can be applied to physical models of forest growth, productivity and reflectance in the Finnish boreal forest. We combine the large high-quality open forest data covering the whole country with Copernicus weather data and satellite imagery to demonstrate the utility of AI to retrieve the current structural and functional state of forests and predict their development over the time periods simulated by the DestinE digital twins.

Mapping of living and dead tree species in a complex forest area based on multi-temporal ALS data and CIR imagery

T5.24 Moving towards digital forests for a sustainable future

Maciej Lisiewicz[1]
Agnieszka Kamińska[1], Bartłomiej Kraszewski[1], Łukasz Kuberski[2], Kamil Pilch[2], Krzysztof Stereńczak[1]
[1] Department of Geomatics, Forest Research Institute, 3 Braci Leśnej St., Sękocin Stary 05-090, Poland
[2] Department of Natural Forests, Forest Research Institute, 6 Park Dyrekcyjny St., Białowieża 17-230, Poland

Abstract: Accurate information on the location and distribution of tree species is needed for targeted management and conservation of natural resources in different environmental contexts. This information plays a fundamental role in monitoring biodiversity, evaluating ecosystem services, and promoting sustainable forest management. Nonetheless, acquiring such data is typically a laborious and expensive process. Hence, there is a pressing demand for remote sensing techniques that can enhance inventory efficiency in a non-invasive way.

Over the past twenty years, the application of optical remote sensing has significantly advanced in the field of tree species classification. Furthermore, the integration of Airborne Laser Scanning (ALS) data holds immense promise for mapping tree species by offering a three-dimensional depiction of objects. ALS data enables the extraction of structural characteristics of trees using discrete returns or full-waveform data. This facilitates the capture of diverse tree architectures, which are influenced by variations in leaf distribution and branching patterns under varying environmental conditions.

The utilization of remotely sensed data for tree species mapping is a thriving field of research. Although certain studies rely on a single remotely sensed dataset, the mapping of tree species generally gains advantages from the integration of multiple data sources. In our study, we attempted to map tree species in a diverse study area such as the Białowieża Forest in Poland. Classification was carried out using Random Forest algorithm with the use of leaf-on and leaf-off airborne laser scanning data and CIR imagery. A total of 14 classes were distinguished, consisting of living trees such as: birch, oak, hornbeam, linden, alder, ash, maple, aspen, pine and spruce, and dead trees by class: dead pine, dead spruce, dead deciduous and snags. The highest levels of accuracies were obtained for classification based on point clouds from both seasons and including image information. Mean values of overall accuracy and kappa were equal to 82% and 0.80, respectively.

Based on the obtained results, it can be inferred that incorporating multi-temporal ALS data enables precise mapping of numerous tree species, similar to the outcomes achieved when adding information from CIR images.

Mapping the distribution of conifer and broadleaf canopies in uneven-aged mixed forests using unmanned aerial vehicle imagery and machine learning

T5.24 Moving towards digital forests for a sustainable future

Nyo Me Htun[1]
Toshiaki Owari[2], Satoshi Tsuyuki[1], Takuya Hiroshima[1]
[1] Department of Global Agricultural Sciences, Graduate School of Agricultural and Life Sciences, The University of Tokyo, Japan
[2] The University of Tokyo Hokkaido Forest, Graduate School of Agricultural and Life Sciences, The University of Tokyo, Japan

Abstract: Uneven-aged mixed forests with unique characteristics such as species diversity, stand heterogeneity, and the irregular distribution of trees, have been recognized as important for their contribution to biodiversity conservation, ecological stability, carbon sequestration, provision of ecosystem services and sustainable timber production. Recently advanced technology of integrated unmanned aerial vehicle (UAV) imagery and machine learning can generate maps, which can provide valuable spatial information for sustainable resource management. Particularly, many researchers have accepted that the applicability of integration of remote sensing dataset and semantic segmentation-based machine learning for forest management purposes such as forest type classification, individual trees identification and forest fire detection. However, there are limited studies focusing on the integrated application of UAV dataset and semantic segmentation-based machine learning algorithms for mapping tree species groups in uneven-aged mixed forests. Thus, this study aimed to explore the feasibility of UAV imagery and machine learning to describe the distribution of conifer and broadleaf canopies in an uneven-aged mixed forest through semantic segmentation-based machine learning classification models. Our study was conducted in two sub-compartments of the University of Tokyo Hokkaido Forest, northern Japan. The aerial images were acquired separately for each compartment by using different UAV platforms (DJI-Inspire 2 UAV and DJI Matrice 300 RTK UAV). We analysed the RGB information of UAV images with 512 x 512 pixels, through two machine learning models (Random Forest and U-Net). Our results showed that the validation accuracy of the U-Net model was over 80% in both sub-compartments, while the Random Forest model often failed to distinguish conifer crowns. The results from this case study indicated that the integration of UAV imagery and semantic segmentation-based U-Net model was reliable to generate the conifer and broadleaf canopy cover classification map. Moreover, our research findings show the potential of an applicable methodology for detecting dominant tree species groups in uneven-aged mixed forests.

Monitoring forest health and tree species based on satellite imagery, cloud computing and artificial intelligence

T5.24 Moving towards digital forests for a sustainable future

[3] Research fellow
[4] Associate professor

Abstract: A novel cloud-based approach was created to utilize high-resolution Sentinel-2 satellite imagery of the European Space Agency and Google Earth Engine platform. The image processing steps such as query, filtering, masking, visualizing, and analysing all took place in the cloud in order to create vegetation and water index (NDVI, NDVI change, Z NDVI, NDWI) maps and charts derived from satellite images, used for multipurpose such as land-cover surveying, tree species classification and forest disturbance detection in three Hungarian study sites. Forest disturbances include biotic (insects, fungi, virus), abiotic (fire, flood, windfall, ice break, etc.) and anthropogenic (illegal logging) forest damage types which are surveyed in Hungary on a regular basis.

Machine learning algorithms such as Random Forest, Minimum Distance Estimation, Support-Vector Machine and Gradient Boost Regression were utilized in Google Earth Engine to support land cover and tree species classification. The aim was to delineate the forests as accurately as possible, thus improving the accuracy of forest monitoring, and analysing the change in the extent of classes of tree species. Compared to the WorldCover remote sensing-based land cover map, the accuracy of methods was 70.3-80.6%. Random Forest showed the best agreement with the reference map with 80.6%.

The results indicated that the combined dataset of satellite imagery and ground-based reports provided suitable input for forest damage monitoring conducted with Google Earth Engine. The applied method successfully identified different types of forest damage on spectral index maps in the surveyed period with 78% Total Accuracy and the tree species with 82% compared to the validation set.

Open platform for point cloud processing algorithms and datasets of forest ecosystems

T5.24 Moving towards digital forests for a sustainable future

Arnadi Murtiyoso[1]
Martin Mokroš[2], Carlos Cabo[3]
[1] ETH Zürich, Switzerland
[2] Czech University of Life Sciences, Czech Republic
[3] University of Oviedo, Spain

Abstract: The use of three-dimensional point clouds to map and monitor forests have gained traction in the past years. Indeed, point clouds enable a three-dimensional representation of forests which opens the possibility to a wide array of spatial analysis and modelling. Wide range of technologies are capable of generating point clouds of forest ecosystems, varying from spaceborne through airborne to close-range. Each perspective provides data on different scales. Many studies attempt to compare them using different tools and algorithms.

In this study, we focus on close-range technologies that provide the most detailed 3D models and we propose an open platform with available processing algorithms (and their public implementations) together with an online database of existing forest point cloud datasets. The datasets and algorithms were identified in a previous work within the framework of the 3DForEcoTech COST Action. The list, guides and benchmarking are the main pillars to bring standardised solutions for a wide range of users and stakeholders within forest management and forest ecology research. Furthermore, we focused on gathering open access datasets generated by close range techniques (e.g., terrestrial laser scanning, mobile laser scanning, structure-from-motion, etc.).

The online platform was therefore envisaged as a way to integrate these findings into a modern, user friendly, and easily accessible medium for potential users. In this regard, the queryable database is planned as a one-stop gateway to facilitate interested users in accessing them, as well as a harmonised way to present them. Furthermore, a benchmarking of selected datasets and algorithms will also be conducted within the framework of a hackathon, under the aegis of the 3DForEcoTech COST Action. The results from this benchmarking hackathon will be integrated into the online platform and therefore provide further information on how each dataset and each algorithm/implementation may be useful for particular applications in forest science. The web-based database will provide users with metadata, user instructions, download instructions, as well as assessments as generated by the benchmarking process.

This work is based upon work from COST Action 3DForEcoTech, CA20118, supported by COST (European Cooperation in Science and Technology).

Performance of mobile laser scanning in forest inventories

T5.24 Moving towards digital forests for a sustainable future

Jan Feigl[1]
[1] Albert-Ludwigs-Universität Freiburg

Abstract: Forest inventories are the primary source of information about the status and growth of forest ecosystems. Even after the advent of remote sensing manual methods remain the wide spread standard. Nonetheless the use of LiDAR sensors became popular over the last decades to collect additional information. Now with the recent introduction of mobile laser scanners (MLS) arises the opportunity to push the application possibilities of LiDAR sensors in forest inventories even further.

The research project will evaluate the benefits of close-range remote sensing with a MLS for forest inventories. Therefore two classical inventory methods will be compared to MLS measurements. First an angle-count sampling is conducted manually and by MLS, because it represents an extremely fast and well established sampling method. Second several plots with a size of 1 ha are fully inventorized manually and by MLS, as full inventories may become more attractive due to technological developments in the future.

At the moment of writing this abstract no preliminary results are existing. While for the angle-count sampling it is estimated that MLS will be as efficient as the manual sampling, it is very likely to have benefits in the full inventory. MLS will probably be faster, cheaper if compared with the cumulative costs of forest workers and provide access to a large amount of data which is not gathered automatically by manual inventory. This will allow to apply inventory data to a multitude of scientific and practical questions, not only from an economic but also ecological and social perspective.

Due to their high mobility MLS make it possible for the first time to gather close-range remotes sensing data in the form of high density point clouds in a full-scale forest inventory. The research of their benefits will enable prospective scientists and practitioners to evaluate their suitability for their own projects and generate additional data in a more efficient way.

Spaceborne SAR-based detection of forest disturbance – a monitoring system for Switzerland

T5.24 Moving towards digital forests for a sustainable future

Marius Rüetschi[1]
Lars T. Waser[1], David Small[2], Christian Ginzler[1]
[1] Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Zürcherstrasse 111, 8903 Birmensdorf, Switzerland
[2] University of Zürich, Winterthurerstrasse 190, 8057 Zürich, Switzerland

Abstract: Forests provide a variety of services to society such as timber, biodiversity, and protection from natural hazards. Therefore, it is of high relevance to monitor the state of forests for adequate and sustainable management to maintain these services. Natural disturbances such as windthrows or bark beetle dispersal but also unfavourable climatic conditions, e.g. droughts, can abruptly lead to forests not being able to provide these services anymore. Remote sensing enables wide-area monitoring to detect such disturbances. Especially spaceborne Synthetic Aperture Radar (SAR) has the potential to provide data to monitor large areas at a high temporal sampling.
In the framework of this study, we develop a forest disturbance monitoring system for whole Switzerland based on Sentinel-1 (S1) SAR data. Using the full S1 constellation, a high temporal sampling is possible with data acquisition at least every three days. Based on the acquired SAR backscatter, time series are generated on the spatial scale of forest stands. Then, time series analysis methods are used to extract the moment of diverging backscatter. We assess 1) which types of disturbance and 2) at which spatial scale are possible to detect. Moreover, we analyse limiting factors such as wet snow that strongly affects SAR backscatter potentially hindering to use S1 data for disturbance detection.
The results reveal that the system mainly detects windthrows (>0.5 ha) and the detection accuracy is strongly dependent on the size of the disturbed area. Other disturbance types that are typically at smaller scales or happen more gradually than windthrows are less well detected.
S1 SAR time series show potential to monitor forest disturbance at the countrywide scale. Thus, a monitoring system based on S1 data potentially indicates disturbance-hit regions and facilitates quick and adequate forest management.

Synthetic Laserscanning data for improved area-wide forest-attribute estimation

T5.24 Moving towards digital forests for a sustainable future

Fabian Ewald Fassnacht[1]
Jannika Schäfer[2], Hannah Weiser[3], Lukas Winiwarter[4], Bernhard Höfle[3]
[1] Freie Universität Berlin

[3] Universität Heidelberg
[4] Technische Universität Wien

Abstract: Airborne laserscanning data is routinely used in an increasing number of countries to estimate key forest attributes across wide areas in the so called "area-based-approach (ABA)". Given that the ABA has reached operationality, there is an ample interest to further improve and fine-tune existing work-flows and increase their level of automatization. To achieve this, sensitivity analyses that for example lead to a better understanding of how certain environmental (e.g., topography) of technical factors (laserscanning acquisition settings, applied algorithm, number and type of reference plots) influence a given ABA work-flow are helpful. However, such sensitivity analyses are often in some way restricted by data limitations as both field data and laserscanning data acquisitions are still costly.

One way to address these limitations is synthetic laserscanning in which realistic virtual 3D-forest scenes are created and used as input to laserscanning simulation software in which for example different laserscanning aquisition settings (point frequency, scan angle, etc.) can be simulated. In this contribution we present an advanced synthetic laserscanning work-flow in which we combine the outputs of a forest growth simulator (Formind, TreeFactory), with an individual tree library containing tree models derived from terrestrial and uncrewed aerial vehicle-based laserscanner data and the laserscanning simulation software HELIOS++.

We will present the basic concept and a numerical validation of the work-flow. The validation shows that realistic laserscanning point-clouds can be simulated with the work-flow but also that space for improvement still remains. We furthermore examined, how synthetic laserscanning data can be used to increase the efficiency of the ABA to estimate aboveground biomass based on real laserscanning data by supplementing real training data with synthetic training data. Our results show that across four datasets from temperate and boreal forests, reasonable estimates for forest biomass could be obtained using only synthetic training data (r^2 between 0.67-0.70 vs. 0.72-0.79 for real data) and that if only few real training data is available, synthetic data can improve model estimates when combined with real data. This highlights some first successful application of synthetic laserscanning data for improving laserscanning-based forest inventories in the ABA.

The model-assisted estimation of timber value in a forest property using geographically balanced samples and 3D UAV data

T5.24 Moving towards digital forests for a sustainable future

[4] Natural Resources Institute Finland, Forest Inventory and Planning, Latokartanonkaari 9, 00790 Helsinki

Abstract: A common task in forestry is to determine the timber value of a forest property. While the valuation of timber in a forest property has traditionally relied on stand-level field visits, remotely sensed data acquired by an unoccupied aerial vehicle (UAV) is a potential source of auxiliary data for the valuation of timber. This is because forest properties are typically of a size that permits the efficient operation of UAVs. UAV data combined with a probability sample of field plots enable the design-based estimation of the timber value and its associated uncertainty.

We studied the estimation of timber value (€/ha) in a 40-ha forest property in Finland. We used a systematic sample of field plots (n = 160) and 3D image point cloud data collected by an UAV. We compared the efficiency of the field data-based estimator to that of a model-assisted estimator which uses both field and 3D UAV data. The sampling intensity was varied (40, 60, …, 140 plots) by subsampling the systematic sample of 160 field plots. The variances were estimated using an estimator assuming simple random sampling (SRS), and a variant of Grafström-Schelin variance estimator.

According to the estimated variances, the model-assisted estimator was more efficient than the field data-based estimator, which suggested that the sampling intensity can be reduced from 160 to 60 plots without any deterioration in precision. In the case of the MA estimator, the difference between the variance estimates computed by the SRS and Grafström-Schelin variance estimators was negligible.

We observed considerable efficiency gains when using 3D UAV data, which indicates that the use of 3D UAV data can enable a reduced field workload or improve the precision associated with the estimation of timber value in forest properties.

Three-dimensional Forest Ecosystem Monitoring and Better Understanding by Terrestrial-based Technologies - 3DForEcoTech COST Action

T5.24 Moving towards digital forests for a sustainable future

Martin Mokros[1]
[1] Czech University of Life Sciences Prague, Czech Republic

Abstract: We are witnessing rapid development in generating highly detailed three-dimensional (3D) point clouds within forest environments by close-range technologies. Terrestrial and mobile laser scanner technology can be mounted on various devices and provide accurate data about individual trees. Additionally, advancements in computational power and algorithms have allowed for processing hundreds of 2D images into 3D point clouds through photogrammetry. Sensors equipped on unmanned aerial vehicles can also provide close-range above-canopy data.
Despite the technological advancements, the application of these technologies lags behind their development. Research often focuses on evaluating a particular technology's potential rather than addressing fundamental issues. For example, researchers have yet to determine how to place TLS within different forest types to fully reconstruct research sites and detect and measure biometric variables of all trees.
Processing the 3D point cloud data is also a significant challenge. Selecting the appropriate technology and data collection approach requires careful consideration, and processing the data with available algorithms is complicated. While algorithms are available from various research groups, the complexity of processing solutions varies based on the target characteristics that researchers want to measure.
To address these challenges, a network of scientists has been established (October 2021) under the 3DForEcoTech COST Action, with over 400 scientists from 50+ countries. The goal of the network is to synchronise knowledge, develop general protocols for data acquisition, processing, and fusion for forest inventory and ecological applications, and make novel technologies available to a broader audience. By unifying efforts, the network aims to progress the application of close-range technologies and unlock their full potential for forest assessment.
In less than two years, we have created a comprehensive list of all processing solutions with detailed guidelines, and benchmarking will follow to focus on various tree parameters. Multiple state-of-the-art reviews and experiments are ongoing where we address lidar data fusion, a new era of forest inventory, point cloud processing past-present-future, occlusion and more. We have organised multiple scientific meetings, internships, training schools and more. All are available on our website: https://3dforecotech.eu/.

Understanding drought-induced spectral changes in a mid-latitude forest ecosystem

T5.24 Moving towards digital forests for a sustainable future

Beatrice Savinelli[1]
Giulia Tagliabue[1], Cinzia Panigada[1], Rodolfo Gentili[1], Roberto Colombo[1], Fabian Ewald Fassnacht[2], Emilio Padoa-Schioppa[1], Micol Rossini[1]
[1] Department of Earth and Environmental Sciences, University of Milano-Bicocca, Italy
[2] Institute of Geographical Sciences, Remote Sensing and Geoinformatics, Freie Universität Berlin, Berlin, Germany

Abstract: Forest ecosystem conservation is of crucial importance for preserving biodiversity, regulating climate patterns, and providing essential ecosystem services for human well-being. The Ticino Park temperate mixed forest represents the last remaining natural ecosystem of the Po Valley region. Recognized as a UNESCO-MAB Biosphere Reserve, this precious ecosystem has been increasingly impacted by natural and human-induced disturbances, including severe drought, exacerbated by climate change.

Remote sensing has proven to be a cost-effective tool for the indirect estimation and mapping of forest characteristics and conditions, at different spatial and temporal scale. This study aims on developing a better understanding of the relationship between drought-induced forest stress, spectral changes observed from Sentinel-2 satellite data and how these relate to functional traits and species composition. We assume that this will help to identify spectral indicators and metrics for the early detection of drought-induced forest mortality.

In 2022 summer, an extensive field campaign was carried out in the Ticino Park Forest, during which functional traits data (Leaf Area Index (LAI)) and Leaf Chlorophyll Content (LCC)) were collected within 31 forest stands. Furthermore, vascular plant species composition was analysed in 63 selected stands to characterize the different vegetation associations. We aggregated the vegetation surveys in 8 specific Syntax and calculate the corresponding Ellenberg indexes in order to ecologically characterise the sites. Moreover, to evaluate the severity and duration of drought events the Standardized Precipitation-Evapotranspiration Index (SPEI) was calculated.

Time series of Sentinel-2 images collected over the Ticino Park from 2016 to 2023 were processed to compute several vegetation indexes and derive LAI and LCC maps through the Sentinel Application Platform (SNAP) biophysical processor tool. LAI and LCC maps were validated using LAI and LCC field measurements. The temporal changes observed in the time series of the vegetation indexes and functional traits were then related to SPEI. Different from many earlier, data-driven remote sensing-based approaches to assess vegetation stress in forests, we try to actively account for expected variations in the spectral responses of forests depending on the species´ ecology and local environmental conditions.

What have been the recent trends in the development of forest ecosystems in Lithuania?

T5.24 Moving towards digital forests for a sustainable future

Daiva Tiskute-Memgaudiene[1]
Jurgita Damskienė[2], Gintautas Mozgeris[1], Melvin Adam Shor[2], Aušra Jablonskienė[2]
[1] Vytautas Magnus University
[2] State Data Agency of Lithuania

Abstract: Numerous indicators are used to describe the status of forest ecosystems. The decline of certain variables while others improve does not necessarily suggest any trends in the condition of forests. This presentation aims to introduce the results of the national condition assessment of Lithuanian forest ecosystems, based on the principles of the System of Environmental-Economic Accounting—Ecosystem Accounting by the United Nations Statistics Division. In other words, we attempted to develop an integral index to independently describe the condition of forest ecosystems over time and across different areas.

Firstly, we mapped the spatial pattern of sixteen different forest attributes at the level of forest compartments and above. These attributes included the proportions of old-growth forests, openings in the forest canopy, mixed forest stands, natural regeneration, density, growing stock volume, tree mortality, carbon stocks in living and dead biomass, forest soils, and soil properties, such as the proportions of organic and drained soils. We also considered forest edge density and the distribution of forest land in the landscape. The best available data sources, particularly data from stand-wise forest inventories covering all Lithuanian forests regardless of ownership, were used to characterize two time points: the years 2000 and 2021.

Next, all independent attributes were linearly scaled on a range of 0-1, where 0 represented the collapse of the ecosystem and 1 indicated an ideal condition. Finally, weights were assigned to all independent characteristics using the Analytical Hierarchy Process, with input from a team of experts specializing in ecology, forestry, climate change, geography, and geomatics.

The main finding was that the condition of forest ecosystems in Lithuania remained rather stable during the two decades of the current century, with some minor decline. The proportion of mixed and natural forest stands decreased; however, the volume of growing stock and the proportion of old-growth forests increased. Additionally, the rate of afforestation decelerated.

T5.25 New directions for legal context of forest ecosystem services towards 2050

Analysis of the evolution of Albanian forest legislation and its new directions in relation to ecosystem services

T5.25 New directions for legal context of forest ecosystem services towards 2050

Abdulla Diku[1]
Luljeta Mine[1], Nehat Collaku[1], Vasillaq Mine[1]
[1] Agriculture University of Tirana, Faculty of Forestry Sciences

Abstract: Forests have been performing their services in the ecosystem since they have existed. This is now a well-known and scientifically recognized fact. The importance of forests and their role in protecting the soil from erosion and degradation, preserving water resources, influencing the local microclimate, purifying the air, enriching it with oxygen, etc., are known and understood by society and different states in different ways. However, these positive impacts of forests were not defined as "ecosystem services." In different areas of the country, the many values provided by forests were mentioned separately, depending on the case (e.g., forests that protect the land from landslides, forests that provide shade for residents, travelers, or visitors, forests that maintain the freshness of water sources, etc.). The term "ecosystem services" is relatively new and did not previously exist, even in the country's forestry literature.This new concept was elaborated for our country during the elaboration of the "carbon sequestration subcomponent" under the Natural Resources Development Project.

The methodology used is based on a comparative analysis of national forest legislation, starting with the first recognized law (the Kanun of Lekë Dukagjini - mid-15th century), the first forest law (1923), the Constitution of the Republic of Albania and ending with the latest law "On Forests" approved in 2020.The purpose of this analysis is to assess how the national regulatory framework has adapted or evolved with respect to the valuation of ecosystem services provided by forests.In addition, this analysis will provide a link between the development of the national forest fund in different periods and the legal basis of those periods.This will give us a clearer understanding of the value of the regulatory framework in fulfilling the ecological functions of forests for ecosystems and communities. The results of the analysis show that the first improvement in the ecosystem services regulatory framework was associated with a commitment to implement a carbon sequestration subcomponent.Another finding is that the legal framework for ecosystem services will be further defined with the Decision of the Council of Ministers (DoCM) to be adopted in the coming months.

Keywords: ecosystem services, forest legislation.

Evolution of wildlife protection and management laws and recent trend of game derived forest byproducts in Japan

T5.25 New directions for legal context of forest ecosystem services towards 2050

Ikuo Ota[1]
Ryunosuke Fukubatake[2], Chiharu Maeda[1], Masashi Konoshima[1]
[1] University of the Ryukyus
[2] Survey Research Center Co., Ltd.

Abstract: Population of wild animals, especially deer (*Cervus nippon aplodontus*) and wild boar (*Sus scrofa leucomystax*), has been increasing for several decades in Japan. As a result, animal damages on agriculture and forestry have been expanding. The government worked to improve the related laws and promoted the effective use of hunted and trapped games. This study aims to clarify the evolution of wildlife protection and management laws and describe present status of wildlife damage prevention measures. Then the authors conducted surveys on production of forest byproducts related to wild games in several different places.

Hunting Act was first established in 1895. General rules of hunting and trapping was designated by the act. Wildlife protection area system was created in 1950 and the act was renamed as Wildlife Protection and Hunting Act in 1963. Populations of wild animals declined significantly during this period but has since been on the rise. Finally, the act was amended as Wildlife Protection and Management Act in 2014 and appropriate management of wildlife population has become an important issue.

In recent years, annual damage to crops by wild birds and animals is as high as 20 billion JPY. In addition, forestry damage is also considerable. Local governments have taken measures against animal damage by providing incentives for extermination of vermin. Central government began to promote the use of wild animals such as gibier, and many of local governments tried to facilitate such use with the help of local hunting club and entrepreneurs. In Hyogo prefecture, utilization of exterminated deer increased from 8.9% in 2016 to 26.5% in 2021. The meat in good condition is used for gibier, and the rest is sold for pet food, generating a large profit to local community. In addition, processed hides and antlers are also expected as important byproducts. This example shows the possibility of achieving both a reduction of animal damage to agriculture and forestry and revitalization of the local economy.

International Forest-Focused Policy: The Strenghts and Limits of its Efficient Creation and Implementation in Finland, Slovakia and Slovenia

T5.25 New directions for legal context of forest ecosystem services towards 2050

Lenka Haluskova[1]
Daniela Nousiainen[2], Spela Pezdevsek Malovrh[3]
[1] Technical University in Zvolen, Department of Forest Economics and Management, Slovakia
[2] University of Eastern Finland, School of Forest Sciences, Finland
[3] University of Ljubljana, Department of Forestry and Renewable Forest Resources, Slovenia

Abstract: International forest-focused policy is characterized by fragmentation, the interference of other sectors into the issue and the absence of a legally binding agreement. Within the scientific field, controversies are being held about its efficiency under national conditions. The research aims to analyse three forest-focused international processes - the United Nations Forum on Forests, Forest Europe and the European Union de facto forest policy under the national conditions of Finland, the Slovak Republic, and the Republic of Slovenia. The theoretical framework is the Policy Arrangement Approach, which defines four dimensions of the political process. For the purposes of this research, it has been modified by adding the dimension of interactions. The interactions are examined in the direction from the national to the international level and vice versa. The research is based on document analysis and interviews. International resolutions, declarations, and strategic documents were analysed to identify the main goals and outcomes of the processes. From September 2022 to March 2023, eleven interviews in Finland, fourteen in Slovakia and five in Slovenia were conducted with key domestic forest policy actors to explore their perceptions of participating in and implementing selected processes. The results show that Finland is very active at the international level. It places great emphasis on its participation in international forest policy-making. Finland participates through national delegation, a common national statement and collaboration or individual partaking of various actors. Slovakia and Slovenia are represented in the processes within their geopolitical boundaries, mainly by governmental experts on forests. The success of their participation depends on the personal skills and commitment of the individual representatives, or on them chairing the processes. An example of this is Slovakia chairing of Forest Europe, which is based on the principle of rotation. Slovenia emphasises participation in the processes with a narrower focus and does not pay attention to the global process. Implementation takes place in all three countries through the transposition of principles into legislation and strategic documents. However, it is influenced by national specificities and forestry traditions. In addition, limiting factors are general definitions opening up a wide scope for interpretation.

Just Do It! Implementation of Payments for Ecosystem Services in the Czech Republic

T5.25 New directions for legal context of forest ecosystem services towards 2050

Vilém Jarský[1]
Zuzana Dobšinská[1, 2], Zuzana Sarvašová, Marcel Riedl[1]
[1] Czech University of Life Sciences Prague, Faculty of Forestry and Wood Sciences, Czech Republic
[2] Technical University in Zvolen, Faculty of Forestry, Slovakia

Abstract: The contribution describes the process of potentially implementing payments for ecosystem services (PES) into forest management in the Czech Republic. Methodologically, the following steps were taken: 1) significant stakeholders and their efforts to advocate for direct payments to forest owners were analyzed; 2) the incorporation of their demands into conceptual and strategic documents was evaluated; and 3) the legislative process of implementing PES in forest management was analyzed. The greatest attention was paid to the legislative process. The results revealed critical points in this implementation, primarily 1) the fact that the EU does not allow notifications for "something for nothing" payments, which means mandatory payments from the state solely for forest ownership; 2) the lack of a definition for ecosystem services in the Czech Forest Act; and 3) the existing support for forest owners mentioned in the current Forest Act is not compatible with the PES principle. The aim of the National Agency for Agricultural Research of the Czech Republic project QK 23020008, titled "Payments for Ecosystem Services in Forest and Forestry" is to create a methodology for forest PES, including legislative adjustments. The presented contribution was prepared within the framework of this project.

Legal and Administrative Impacts of Climate Change on Forestry: The Case of Türkiye

T5.25 New directions for legal context of forest ecosystem services towards 2050

Üstüner Birben[1]
Gökçe Gençay[2]
[1] Çankırı Karatekin University, Faculty of Forestry, Türkiye
[2] Bartın University, Faculty of Forestry, Türkiye

Abstract: This study examines the legal and administrative impacts of climate change on the forestry sector in Türkiye. As the literature clearly states, climate change significantly affects the forestry sector, leading to changes in forestry policies and governance. The aim of this study is to assess the extent to which legal and administrative measures have been taken to address climate change in the forestry sector in Turkey and to evaluate the impact of these measures. The study was conducted using a legislative review method based on the legislation enacted in the last 20 years. Relevant legislative documents and literature were reviewed to analyze the legal regulations and administrative practices related to climate change in the forestry sector. The key findings demonstrate that Turkey has taken significant legal steps to cope with climate change in the forestry sector in recent years. The new legal regulations aim to: Strengthen forestry policies, Enhance biodiversity conservation, Improve measures against forest fires. These regulations aim to enhance the sustainability and adaptability of the forestry sector. However, the study also reveals certain weaknesses in the effectiveness of current legal regulations. It identifies gaps and challenges in the implementation and monitoring of climate change adaptation strategies. Additionally, the findings highlight the inadequate level of coordination and collaboration provided by the existing legislation. A more comprehensive and integrated approach is needed to combat climate change in the forestry sector. Strengthening legal regulations, improving forestry management and planning, and promoting research and innovation are areas that need to be developed. Furthermore, achieving more effective coordination and collaboration at the international level is seen as an important opportunity.

Legal arrangement of forest management in protected areas: persistent problem or modern challenge?

T5.25 New directions for legal context of forest ecosystem services towards 2050

Rastislav Sulek[1]
Jan Lichy[1]
[1] Technical University in Zvolen, Slovakia

Abstract: Management of non-state forests is affected by both the internal economic efficiency of non-state forest enterprises as well as the by the external restrictions which are governed, except for the nature conditions, by the regulative state measures, characteristics of business environment, and principles accepted by the whole society. When non-state forests are located within the protected areas, their economic utilization is limited due to nature protection.

In Slovakia, there is a long tradition in both nature protection as well as forestry – it is proved by the fact that 57 % of non-state forests are located within the protected areas. However, there is also competition between the conception of traditional multifunctional sustainable forestry aiming at the production of timber together with the provision of other forest ecosystem services, and conception of the strict nature protection. Thus, there is a conflict that is complicated by different ideas about issues of nature protection in forests or, vice-versa, issues of forestry in protected areas. The fundamental question is "How shall we manage forests in protected areas?", or, in many cases, even "Shall we manage forests in protected areas at all?". The one of the ways how to deal with the issues of contradictions between forest management and nature protection is to establish a set of sound legal rules that would respect legitimate property rights of forest owners together with the justified interests of the whole society caring for effective nature protection.

The objective of the paper is to identify and analyse relevant legal factors that affect the management of non-state forests within the protected areas (regulative tools), particularly (i) specific legal conditions connected to restricted forest management within the protected areas and (ii) consequent restrictions of property rights including the identification of legal possibilities of solving such restrictions.

The authors are grateful for the support of the Scientific Grant Agency of the Ministry of Education, Science, Research, and Sport of the Slovak Republic, Grant No. VEGA 1/0376/23 Economic and legal conditions of management of non-state forests within the Slovak protected areas.

New legal rules addressing societal demands for forest – Forest Act in Slovakia

T5.25 New directions for legal context of forest ecosystem services towards 2050

Martina Štěrbová[1, 2]
Zuzana Dobšinská[2], Jaroslav Šálka[2]
[1] National Forest Centre, Zvolen, Slovakia
[2] Technical University in Zvolen, Slovakia

Abstract: The Slovak forestry sector aims, based on science and forestry practise, to ensure the nature conservation in the framework of sustainable forest management. Maintaining and enhancing the biodiversity and resilience of forests is key to the sustainable provision of ecosystem services in a rapidly changing environment. The relations between nature protection and forestry are the subject of research in forestry and environmental science, while the interpretation of the achieved results can be roughly divided into two groups. On the one hand, the interpretation of these results by forestry representatives serves to support long-term sustainable and multifunctional forest management, and on the other hand, nature conservation representatives focus their attention on supporting non-intervention to protect the ecological value of the forest for the entire society. Within the individual interests of the interested parties, there should be an effort to identify the main conflicts and an attempt to resolve them to the satisfaction of both parties. Within our research, Slovak forest and environmental legislation was revised to identify and analyse controversial areas of the Forest Act and the Nature and Landscape Protection Act. Based on the results of the analysis and the conducted questionnaire survey among 20 stakeholders, a draft of the improved legislative intent of the new Forest Act was drawn up, which adequately takes into account the protection of nature and the landscape. It suggests new directions for development of forest and environmental legislation, especially in the following areas: forest protection, forest categorization, forest ecosystem services, forest management, logging and transport of wood, public access to forests, property rights, as well as state management of forest management. The goal is to ensure the provision of various and often conflicting products and services that the forest provides and the society claims their fulfilment, such as production of wood, forest fruits, recreation, protection against erosion, etc. We are leaning towards the possibility of introducing integrated forest management in Slovakia, where forest management will not be strictly separated from its protection.

THE ROLE OF ENVIRONMENTAL NGOs TOWARDS SUSTAINABLE FOREST MANAGEMENT IN LATVIA

T5.25 New directions for legal context of forest ecosystem services towards 2050

Līga Menģele-Stillere[1]

[1] Dr.iur, Head of Law Department, State Forest Service, Latvia

Abstract: Realization of economic interests in forest sector are always dynamic, but what about protection of environmental interests? Environmental NGOs according to legal regulation has rights to receive environmental information, to participate in environmental decision making and to go to court in environmental issues. Process of environmental NGO activity in forest sector will be analyzed, exploring two recent cases in Latvia: 1)microreserve court case and 2)political decision to minimize cutting diameter – Constitutional court case (not finished yet). Environmental NGOs in both of these cases actively realized their rights and in first situation it resulted in Higher Court decision placing environmental interests higher than economic interests in forest management. This can be seen as important signal for legislator and decision makers to pay more attention to environmental interests instead of doing everything for endless economic growth, which is undoubtedly important to rise welfare in less developed countries. The question is how to find balance between environmental and economic interests (social as well) towards sustainable forest management. How to realize productive dialogue between conflicting interests to reach balanced decisions in situation where producers need more forest resources, but at the same time there is high pressure for higher level of nature conservation in forest.

Main aims of this work is 1) to study the development of Environmental NGO role in protection of environmental interests in forest sector and to illustrate it by analysis of two cases, 2) to give proposals what can be done to assume balanced decisions in forest sector.

Title: UK Bioeconomy Stable Wood Production and Tenure Rights post BREXIT

T5.25 New directions for legal context of forest ecosystem services towards 2050

Prof Florin Ioras[1]
[1] Buckinghamshire New University, Queen Alexandra Road, HP11 2JZ, UK

Abstract: The UK's bioeconomy heavily relies on sustainable and secure wood production as a crucial source of raw material. This poster/presentation explores the significance of tenure rights and examines the implications of BREXIT on the UK's bioeconomy, specifically in relation to wood production and forest governance.

Secure tenure rights are vital for promoting sustainable forest management and attracting investments in the UK's forestry sector. The amended Forestry Act 1967 and the UKTR and UK FLEGT Regulations (2021)sprovide a legal framework that grants landowners secure tenure rights, ensuring their ownership and control over forested lands. This stability encourages responsible wood production and supports the bioeconomy.

Post-BREXIT, the UK has the opportunity to develop its own tailored regulatory frameworks. The Agriculture Act 2020 sets out a framework for supporting sustainable forestry practices and land management in the UK, demonstrating the government's commitment to the stability and growth of the bioeconomy.

This study will highlight specific examples of how tenure rights have influenced stable wood production in the UK bioeconomy post-BREXIT. For instance, Scotland's Forestry Strategy 2019-2029 emphasizes the importance of secure tenure rights for enabling long-term planning and investment in wood production, showcasing a commitment to sustainable forest management practices.

The implications of BREXIT on the wood supply chain and forest governance will also be explored. Changes in trade agreements and regulations may impact access to international markets and disrupt the stability of the wood supply chain. Understanding these challenges and opportunities post-BREXIT is crucial for maintaining stable wood production in the bioeconomy.

Tenure rights remain a critical component for ensuring stable wood production in the UK bioeconomy post-BREXIT. The Forestry Act 1967 and the Agriculture Act 2020 provide a foundation for secure tenure rights and sustainable forest management practices. By leveraging these legislative frameworks and carefully considering the implications of BREXIT, the UK can continue to secure stable wood production, support the bioeconomy, and uphold its commitment to sustainability.

Keywords: UK, bioeconomy, stable wood production, tenure rights, forest governance, post-BREXIT, Forestry Act 1967, Agriculture Act 2020, UKTR, UK FLEGT Regulations, sustainable forest management, trade agreements.

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

A national centre for knowledge, analysis and monitoring to prevent and mitigate forest damage

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Wiebke Neumann[1]
Jonas Rönnberg[1], Åke Olson[1], Katja Fedrowitz[1]
[1] Swedish University of Agricultural Sciences

Abstract: Forecasts on the consequences of climate change predict an increase of different types of forest damage, affecting both forest growth and biological diversity, thereby affecting goals in forestry as well as climate and biodiversity work. To meet these future challenges in a comprehensive approach and as national effort the Swedish government assigned a virtual centre at the Swedish University of Agricultural Sciences (SLU Forest Damage Centre) in 2021,. The centre is in charge to analyse, monitor and generate knowledge in order to protect forests against damage caused by different pests, pathogens, ungulate browsing, storms, fires or drought. It is a platform gathering research and environmental analysis around forest damage, and works in close collaboration with the Swedish Forest Agency and in continuous dialogue with various actors outside academia. The centre strives to be the natural first national port of call for forest damage issues in Sweden. The centre works across disciplinary boundaries, including natural and social sciences, and rest on four pillars: projects and knowledge support, research school, monitoring and analysis.

Derived from this set-up, the centre finances diverse types of basic and applied research projects, pilot studies or development projects connected to forest damage. Next, the research school is central both for knowledge development in the field and for the supply of competence within universities, research institutes, authorities and forest companies. The school collaborates closely with external stakeholders, including funding of PhD students. Moreover, the centre finances monitoring activities to reinforce and complement other ongoing monitoring activities in Swedish forests, producing additional data on forest damage and different damage agents. A major component of the centre is the analysis function, where experts on different types of forest damage collaborate closely internally and externally to investigate the risk for national pest outbreaks or damage incidents. Here, we gather experts on damage caused by insects, pathogens, wildlife, fire, drought, wind and snow as well as modelling and socioeconomic impact and consequences. Next to such risk assessments over time, a vital duty is to compile knowledge and provide support in the event of outbreaks or other incidents of forest damage.

Addressing Extreme Wildfire Events through Open Innovation Campaigns: Design and Implementation of a Challenge Design Workshop

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Alípio Torre[1]
Alexandra Xavier[1]
[1] INESCTEC, Portugal

Abstract: Extreme wildfire events (EWE) pose significant problems to forest ecosystems, human communities, and the economy and environment. Addressing these complex challenges requires innovative approaches that leverage open innovation and collective problem-solving. This paper presents the design and implementation of a co-creation-focused Challenge Design Workshop (CDW) for addressing EWE through an open innovation campaign (OIC). The workshop engaged diverse stakeholders, including local communities, forestry and fire management experts, regional authorities and policymakers, to collect and shape community problems into actionable challenges for searching for global socio-technical solutions. The goal was to directly engage the local communities of the 11 Living Labs, despite being geographically dispersed through Europe and South America, to identify problems from which to co-create challenges to divulge for the worldwide community in an open Innovation Campaign undertaken in the Fire Res project.

The structured workshop begins with collecting community problems through inquiries and community meetings by local partners. Multidisciplinary teams collaborate to transform these problems into well-defined local challenges. Trained local facilitators guided the teams and ensured a balanced representation of diverse perspectives. Globally, the problems outputted from local CDW were analysed and categorised to identify common themes related to EWE. The resulting challenges were specific, actionable, and relevant, addressing EWE across multiple geographical contexts.

Harnessing the power of OIC, the CDW created an environment where local knowledge and global expertise could converge to find global solutions—providing a platform for communities to voice their concerns and aspirations while fostering the co-creation of sustainable and practical solutions. The involvement of diverse stakeholders facilitated the development of comprehensive challenges encompassing multiple dimensions of EWE.

This paper presents the workshop's design, implementation, outcomes, challenges, and lessons learned. It emphasises the potential of engaging diverse stakeholders in open innovation practices addressing EWE and fostering new solutions. The findings highlight the importance of community engagement and integrating local knowledge for effective and context-specific solutions. The workshop framework serves as a valuable resource for initiatives tackling complex challenges related to EWE through open innovation and collective problem-solving.

An adaptive sampling and estimation method for National Forest Inventory to monitor the disturbances

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Ho Kim Trinh DUONG[1]
Olivier BOURIAUD[1, 2], Guillaume CHAUVET[3]
[1] IGN, ENSG, Laboratoire d'Inventaire Forestier, 14 rue Girardet, 54000 Nancy
[2] Ștefan cel Mare University of Suceava, Str. Universității 13, 720229 Suceava, Romania
[3] Univ Rennes, ENSAI, CNRS, IRMAR – UMR 6625, F-35000 Rennes, France

Abstract: Since the early twentieth century, National Forest Inventories (NFIs) have been implemented in many countries to quantify and describe forest resources. In the past decades, forests have experienced a rapid increase in disturbances – storms, fires, insect damages, and so on – that have strongly impacted their state. Thus, new objectives for NFIs consist in monitoring the forest where disturbances occurred, to see how the forest reacts and if management action is required to repair. However, NFI methods were mostly conceived at a time when the forests' dynamic was low, for instance with periodicities in the surveys of 5 to 10 years. During these periods no changes to the sampling design are possible, which precludes any adaptivity. However, alterations of the sampling are necessary to estimate the impact of disturbances, which are by essence not predictable, for instance, to reassess existing plots and quantify the disturbance's intensity. Adaptability, therefore, emerges as a necessary characteristic of forest surveys to allow them to sustain monitoring activities.

The French NFI is a particularly relevant case study in that it was conceived as an annual sampling with variable annual sampling intensity, thus providing capabilities to support changes in its sampling. So far, French NFI has used two-stage two-phase sampling for stratification to collect the variables of interest in the forest, especially the characteristics of the trees. Post-stratification is used to improve the precision of survey estimators with the variance reduction. This study demonstrates and presents new estimators that include all of the sampling design and estimation requirements of adaptive monitoring with improved accuracy. In particular, the estimators accommodate variable sampling intensity and post-stratification, which permits disturbance-related monitoring.

Key words: forest inventory; monitoring; disturbances; estimation; post-stratification; variance

Basinox (Pseudomonas sp.) as a potential treatment against root rot (Heterobasidion spp.) in Norway spruce in Sweden

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Dušan Sadiković[1]
Jonas Rönnberg[1]
[1] Swedish University of Agricultural Sciences, Southern Swedish Forest Research Centre, Sundsvägen 3, 23053 Alnarp, Sweden

Abstract: Heterobasidion root rot is a significant problem for the Norway spruce, leading to notable losses in various industries that rely on this tree species. It results in a decline in both the quality and quantity of wood production. For the past 30 years, Swedish forestry has utilized the fungus *Phlebiopsis gigantea*, marketed as Rotstop®S gel, to treat freshly cut Norway spruce stumps. This treatment aims to prevent spore infections by Heterobasidion spp. and reduce the damage caused by root rot.
In this study, we investigated an alternative solution using a bacterial-based product called Basinox®, which consists of *Pseudomonas* sp. We evaluated the effectiveness of Basinox® in suppressing the colonization of the pathogen in fresh tree stumps. The study involved treating 360 spruce trees located in three sites across South Sweden during commercial thinning. We assessed the application of the product through both manual and mechanical methods and examined subsequent natural infection levels in stump discs. As a positive control, we used Rotstop®S gel, which has already been established as the most effective measure against root rot.
By analyzing the presence, number, and size of *Heterobasidion* sp. colonies on harvested discs, we calculated the control efficacy and infection rates for all the treatments. Control efficacy varied across the three sites, ranging from 20% to 70%. Infection rates also differed among the sites but were statistically significant and more effective than the negative control. This study represents the first trial of the Basinox® product under natural infection conditions. Based on the varying effectiveness of both Basinox® and Rotstop®S observed across the three locations, it can be concluded that both products performed similarly during this experiment.

Keywords: Root rot*, Heterobasidion, Phlebiopsis gigantea, Pseudomonas, Picea abies,* Basinox®, RotStop®S

Climate change and extreme weather events are challenging the health of boreal forests – and some will learn it the hard way

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Markus Melin[1]
Eeva Terhonen[1], Tiina Ylioja[1], Juha Siitonen[1]
[1] Natural Resources Institute Finland (Luke), Forest Health and Biodiversity -research group

Abstract: Climate in the northern latitudes has warmed faster than the global average. While a phenomenon such as a degree of change in temperature or increase in thermal sums might sound trivial and far from everyday life, forests could not disagree more. Boreal forests have seen rapid changes caused by the progressing warming and extreme weather events in relation to their health.

Nested within the boreal zone, Finland has witnessed range expansions of forest pests and forest disturbances of the type once thought as unlikely. Yet, the degree at which the climate-induced risks are realized on the ground is dependent on the types of forest growing on them. While there are many unknowns in how climate change will affect our forests, forest health and biodiversity will go hand in hand. Unfortunately, the recent development in Finland´s forests has not only followed a path unnatural in relation to what would have been expected, but also one that – based on overwhelming evidence – is increasing their susceptibility against the changing climate and the damage agents that come along.

In this presentation, we draw together recent research on emerging damage agents and trends therein as well as data on the development of Finland´s forests, their structure and elements of diversity. We highlight the current trends and why they are undesirable, analyze the reasons behind them and take a look into the future. Finland has not experienced the types of damage that have hit Central and Eastern Europe, meaning that the country is in a position to make the necessary changes – unless it is willing to learn the hard way.

Connecting science to guidance on the ground: How do we manage riparian buffers to effectively support biodiversity?

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Eleanor Slade[1]
Jake Bicknell[2], Miklin Ationg[3], Melissa Payne[4], Matthew Struebig[2]
[1] Asian School of the Environment, Nanyang Technological University, Singapore
[2] DICE, University of Kent, UK
[3] Department of Irrigation and Drainage, Sabah, Malaysia
[4] South East Asia Rainforest Research Partnership, Sabah, Malaysia

Abstract: Riparian buffers are areas of natural, restored, or regenerating forest habitat alongside rivers. Riparian buffer strips have been proposed as a tool to help conserve freshwater biodiversity, water quality, forest biodiversity, and connectivity in oil palm plantations, with relatively little cost – and perhaps additional pest control benefits – to oil palm estates. Our recent research in Sabah has shown the importance of riparian forest buffers for supporting both terrestrial and aquatic biodiversity, and their potential to provide movement corridors for wildlife. Our results also suggest that there is little evidence of them either increasing or decreasing pest attack within the oil palm landscape. We investigated how riparian buffer width affects biodiversity, finding that wider buffers contain larger numbers of species, and that a small increase from 20m (current minimum width in Sabah) to 40m would more than double the number of species found in a buffer. However, we also found that the impact of wider buffer widths are context-specific, depending on which species are utilising the buffer, and also where it is placed in the wider landscape. For example, if the riparian buffer is linking two large forest patches a larger buffer width is recommended than if the river is running through an oil palm landscape without any connecting forest patches nearby. To aid decision-makers we have an on-going project engaging a range of stakeholders from oil palm companies, NGOs, government bodies, academics, and civil society to design a decision tree (the RiTREE – Riparain Decision Tree) that will provide guidance on recommended riparian buffer widths within a landscape to minimize biodiversity loss. This collaboration is an excellent example of how scientists and policy-makers can work together to synthesise current knowledge and make it accessible and relevant.

Drought-related calamities of European beech in Central Germany - causes, consequences, and measures (Buche-Akut)

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Joscha Hendrik Menge[1, 2]
[1] Forstliches Forschungs- und Kompetenzzentrum Gotha
[2] Georg-August-University Göttingen - Department of Silviculture and Forest Ecology of the Temperate Zones

Abstract: The joint research project "Buche-Akut" assesses the vitality decline in European beech (Fagus sylvatica L.) since 2018 in the low mountain ranges of central Germany (Lower Saxony, Saxony-Anhalt, Hesse and Thuringia).

The aim of the project is to determine possible causes of the calamities, to evaluate their consequences, and to derive recommendations for the future silvicultural treatment of E. beech forests under changed climatic conditions. Inclusion of practical knowledge was key to the project. Information and experiences regarding silvicultural management of E. beech was gathered in interviews, stakeholder forums, and comprehensive literature analyses.

The investigation of possible causes was based on both remote-sensing methods and repeated phytopathological and forest structural investigations in 50 E. beech stands with different degrees of damage:

At each site, one dominant E. beech tree and three saplings were cut and examined for pathogenic fungi and insects in a laboratory. Using semi-annual terrestrial and mobile laser scans, morphological changes in crown and branch structure were recorded, allowing a quantitative evaluation of the damage in progress over a period of three years. In addition, the vitality of each individual tree was rated visually each year as a percentage of full-foliation, following the methodology of the ICP-Forest-Monitoring.

Furthermore, a systematic sampling was conducted on a 5 km grid in E. beech forests, where tree species, DBH and vitality of E. beech was recorded at 177 plots of 500 m². Additionally, data from ICP-Forest-Monitoring and external research groups provided ground-truth for the verification of remote sensing analyses:

Using satellite data (Sentinel-2 time-series) the vitality of E. beech forests was estimated based on changes in spectral reflectance in comparison to 2017 (prior to the unprecedented drought in Central Europe). The vitality assessment was done semi-annually for the entire research area starting in 2018.

Possible causes for vitality loss were assessed retrospectively by overlaying information on stand-structure and topography derived from (repeated) airborne laser scans (ALS) and soil maps, with the satellite-based assessment of vitality. Spatially interpolated historic weather and *in-situ* weather records were used in combination with ALS to model within-stand microclimatic conditions for the investigation period.

Effects of biotic damaging agents on the wellness of our forest and how they limit the forest growth under changing climate.

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Jan Stenlid[1]

[1] Department of Forest Mycology and Plant Pathology, Swedish University of Agricultural Sciences, Box 7026, 75007 Uppsala, Sweden

Abstract: Forests are challenged by a multitude of biotic and abiotic agents that affect their health and growth. One major challenge is arrising from the fact that trees have a much longer lifespan than many of the biotic threats. With climate change trees are faced with new and potentially stressing growth conditions while pathogens and pests can disperse and develope in new areas where the environment has become conducive to their growth requirements. The presentation will discuss emergent disease and outbreaks events that have been favoured by climate change and caused major setback for for the well being of forests with particular reference to conditions in Northern Europe. Depending of the size of outbreaks, their management can face large scale practical undertakings and require active communication with the public.

How a modern portfolio theory approach to forestry can help with resilient afforestation and restructuring?

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Robert Hattersley[1]
Vadim Saraev[1]
[1] Forest Research, UK

Abstract: Trees and forests provide society with numerous valued benefits that extend beyond traditional timber supply. These include carbon sequestration for mitigating climate change, improved health and well-being, biodiversity conservation, and cultural significance, among others. In the UK and around the world many governments have set ambitious targets to expand forest cover in the near future. However, tree planting entails inherent risks. Trees are vulnerable to various hazards such as storms, pests and diseases, and drought, which are further exacerbated by climate change.

The study adapts modern portfolio theory from financial economics to the needs of forestry with multiple ecosystem services benefits and risks. We have developed a prototype model and a decision support tool to assist decision makers in achieving optimal outcomes for both future tree planting and restructuring existing forests. The model is based on the concept of diversification, recognizing that constructing portfolios of diverse assets characterised by imperfect correlations allows for a more favourable balance between benefits and risks compared to an undiversified approach. Our model integrates the best available experimental data, decision support tools, including the impacts of the latest climate change projections for the UK, and expert knowledge on trees and climate in the UK.

The main model output is the efficient portfolio frontier where each optimal portfolio differs by the relative species composition and the aggregated benefit-risk balance. The model and associated decision support tool enable decision makers to articulate their preferences regarding a wide range of benefits and risks, explore different scenarios, and select the most suitable portfolio for creating resilient and future-proof forests. In the majority of cases where multiple benefits are important the model suggests that diverse forests provide greater benefits for a given level of risk when compared to a monoculture.

How forest decision support systems can be used to mitigate forest damages in future climate

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Clara Antón Fernández[1]
Nicolas Cattaneo[1], Morgane Merlin[1]
[1] Norwegian Institute of Bioeconomy Research (NIBIO)

Abstract: Climate change poses significant challenges to forests, increasing the occurrence and severity of disturbances such as windthrows, wildfires, pests, and diseases. Effective decision-making tools are crucial for mitigating forest damages and enhancing resilience under changing climatic conditions. We explore the role of forest decision support systems (DSS) in addressing these challenges and present their potential in mitigating future climate-induced damages to forests.

We examine the key challenges associated with integrating disturbances and their interactions into decision support systems, using as motivating example the decision support systems for the high-resolution Norwegian forest resources map SR16.

How to choose right: forest resilience or vulnerability? Addressing key challenges of both approaches to learn from each other

Abstract: The on-going increase in forest disturbances demands new knowledge, data and tools to anticipate and mitigate future impacts on forests. Minimizing disturbance impacts on forests can be achieved by enhancing forest resilience and reducing vulnerability. Although resilience and vulnerability seem complementary concepts and have been used interchangeably, they underlay distinctness while they focus on different challenges. Here we aim to disentangle the relationships between resilience and vulnerability in forest social-ecological systems, identifying the strengths and weaknesses of both concepts in order to improve assessments of forests under global change. In particular, we aim to answer the following questions: (1) what are the differences between them and their respective contexts that would justify a different use? (2) which elements can resilience and vulnerability, respectively, incorporate from the other to improve assessments? First, we highlight the differences between both concepts related to their origin/background, the used methodologies, their constituent components and their relevance, and the spatiotemporal focus. Resilience has its origin in the environmental and engineering field, whereas vulnerability has a strong background in the social and policy arena. As a consequence, vulnerability is frequently more operational than resilience. In addition, resilience focus on the temporal scale (identifying predictors and mechanisms behind resilience), whereas vulnerability focuses more on the spatial scale (comparing two different study areas). Adaptive capacity and disturbances are explicitly included in vulnerability assessments; in resilience, adaptive capacity is considered a mechanism to enhance resilience, and disturbances are not intrinsically addressed. We identify the limitations and weaknesses of each concept, and we specifically discuss whether the main limitations of one approach can be addressed by the other. Based on this analysis, we conclude that resilience and vulnerability in forests shouldn't be used interchangeably, and we show a guideline to identify when is it better to use resilience or vulnerability. The comparative understanding of the existing conceptual and methodological challenges of both concepts is of paramount importance to make them simple, intelligible and straightforward. Thus, a better joint conceptualization of resilience and vulnerability will increase the effectiveness in quantifying and managing the impacts of climate change in forests.

Linking forest fire modelling and simulation with decision-support systems in Sweden

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Sara Jones[1]
Maksym Matsala[1], Emily Viola Delin[1], Narayanan Subramanian[1], Emma Holmström[1], Urban Nilsson[1], Igor Drobyshev[1]
[1] Swedish University of Agricultural Sciences, Southern Swedish Forest Research Centre, Sweden

Abstract: Forest fire is among the most important drivers of natural forest succession, shaping biodiversity, stand structure, and mediating biogeochemical cycles. Climate and land use alter regional fire regimes. In some regions, forests may exhibit more severe and frequent fire disturbances. New strategies should be developed to address future fire risks. Climate, topography and fuel properties exercise major control over fire behaviour. Among these, only vegetation structure can be manipulated in a short-term perspective to mitigate fire risks.

We explored the predictive power of vegetation data in estimating forest fire risks, relying on the ~100 fires above 10 ha in size that occurred in Sweden during 2016-2022. The model included growing stock volume of Norway spruce, Scots pine, and deciduous tree species, stand height and age, and soil moisture as independent variables. We developed a cellular automata model to simulate future fires and inform HEUREKA, a decision-support system commonly used by Swedish forest owners to guide their management decisions. Discrete soil moisture classes and proportional volume of Scots pine stand volume were important predictors. Our model predicted low forest fire susceptibility in deciduous and Norway spruce forests, and moderate forest fire susceptibility in Scots pine stands.

Near Real-Time Change Detection in Spruce Forests using Sentinel-2 Time Series

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Johannes Schumacher[1]

[1] Norwegian Institute of Bioeconomy Research (NIBIO)

Abstract: Forests play a crucial role in carbon sequestration, biodiversity conservation, and providing ecosystem services. The monitoring of forests, their changes, and their health condition is of utmost importance for effective forest management and conservation efforts. Furthermore, the ability to monitor and assess changes in forest ecosystems is essential for identifying potential threats, understanding their impacts, and implementing timely interventions.

In recent years, the availability of satellite data has revolutionized the way we monitor and assess changes in forest ecosystems. Specifically, the Sentinel-2 satellite mission provides near-real-time monitoring capabilities and offers valuable insights into forest canopy dynamics and crown appearance through its reflectance data.

This presentation focuses on the methodology for near-real-time monitoring of changes in forests related to forest damage. Specifically, we perform analyses of time series of Sentinel-2 reflectance data to detect changes in spruce forest canopies in Norway. By analysing the temporal patterns of reflectance values across different spectral bands, we can identify changes related to forest health. For example, vegetation stress caused by factors such as drought or insect infestations can result in detectable changes in the reflectance signal. Similarly, disease outbreaks or deforestation activities can also be identified through characteristic shifts or changes in trends in the reflectance values.

We aim to create a monitoring and early warning system for spruce forests that detects deviations from the expected Sentinel-2 reflectance signal, which is related to vegetation with a changing health status.

Novel developments towards a holistic risk assessment system for the European spruce bark beetle

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Abstract: European spruce bark beetle (*Ips typographus*) (ESBB) mass outbreaks have caused enormous mortality in Norway spruce (*Picea abies*) dominated Central European forests in recent decades. These climate change driven abrupt forest transformations have severe ecological and economic consequences for many European countries. Important mitigation measures include a controlled conversion of pure spruce stands into more climate-stable mixed forests. Yet, spruce will remain a relevant and viable option, particularly within its natural range, such as the mountain forests of the Alps. Therefore, effective protection and management of spruce forests based on an accurate risk assessment is urgently needed to mitigate future natural disturbances.

In the project RAWLog, funded by the Austrian Waldfonds, we work on a comprehensive risk assessment considering the relationships between abiotic, biotic as well as operational factors that influence natural disturbances. Along with storm and snow damages, drought is assessed in the model framework since it has become increasingly important as an abiotic driver of ESBB infestations. Forest accessibility and work capabilities influence both forest predisposition and the scope and response time of interventions to disturbances. Our main goal is to develop the fundamentals of a freely available practice-oriented and dynamic ESBB early warning and risk management system with high temporal and spatial resolution for entire Austria.

The development of such a model framework is supported by recent advances in remote sensing, increased data availability and innovative modeling approaches. In particular, novel methods based on Sentinel-2 time series allow for a detection of tree species proportions and forest disturbances on an annual time scale with high spatial resolution of 10 m. Furthermore, simulations of ESBB development status and tree water availability enable an increasingly accurate and daily assessment of the current forest condition. Hence, the novel system will provide crucial support for silvicultural measures and risk management in Austrian forests under climate change.

Remote sensing to monitor and mitigate forest disturbances in a changing climate

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Abstract: Historically, natural disturbances regimes have played a key role in shaping and maintaining many ecosystems. During periods of profound environmental change, disturbances also act as catalysts for ecosystem, and even biome, change.

Habitat suitability models predict that the possible distribution of tree species will shift considerably this century. These equilibrium-based models do not explicitly incorporate disturbances, leaving considerable uncertainty about the role disturbances will play in the transformation of forests globally. However, indications are that this role will be considerable, as evidence is growing that anthropogenic climate change is intensifying and accelerating several aspects of forest disturbance regimes. Increased forest disturbances can compromise a range of ecosystem services that communities have counted on locally for generations. Moreover, they may also weaken services that society as a whole counts on globally, such as the ability of forests to provide a sink for carbon in the atmosphere.

To help understand how forest disturbances are changing and to mitigate their impact on society, calls for operational forest disturbance monitoring systems are growing. In wildfire management, the use of remote sensing has a long legacy, because fire signals, be they thermal or optical, are easily picked up by satellite sensors that enable rapid mapping over large areas. Remote sensing is also used to monitor deforestation and stand-replacing harvest from the tropics to the boreal regions. Other forest disturbances, including by drought, biotic agents, wind storms, and selective and progressive logging, have proven more challenging for remote sensing-based detection and attribution. This presentation will review recent progress made in detecting and monitoring these forest disturbances by leveraging emerging analytical methods and new data streams.

Using harvester data for improved understanding of spruce root rot drivers and distribution

T5.26 New solutions for challenges in decision support for mitigating disturbances to increase forest health and resilience under climate change

Susanne Suvanto[1]

[2] Metsäteho Oy, Vantaa, Finland

Abstract: Root rot is the most devastating pathogen in coniferous forests of the northern hemisphere, leading to reduced timber quality, growth losses, control costs and increased mortality. While traditional methods for mapping root rot have been slow and laborious, automatically collected and geopositioned harvester data provides a promising source of information for improving the current level of knowledge on the root rot situation. Here, we used harvester data to (1) study the drivers of root rot and (2) map the risk of root rot in spruce stands in Finland. We built a statistical model predicting the percentage of stems affected by root rot, using an extensive set of harvester data. The data contained over 12 000 clear-cut Norway spruce stands in southern and central Finland, where presence of root rot was determined on stem-level with an algorithm based on stem-specific cutting information from harvesters. The model consisted of two parts, a fixed component describing known drivers of root rot, and a random component describing the spatial patterns in rot occurrence. The fixed part included variables describing forest stand attributes, soil and climate conditions, and proxies for the past forest management intensity. The model was then used to map root rot risk, by predicting the probability of root rot (i.e., the probability for the share of rot-affected stems to exceed a predefined threshold) using spatial data sets of the variables in the fixed part of the model, and the known locations of root rot infected stands in the harvester data set for the random part of the model. With the exceptionally large data set, the results provide an improved quantification of the relationships between root rot and its drivers and refine the current understanding on spatial distribution of rot-infected stands. This information can be used to support forest management decisions aiming to control the spread of the root-rot and to eradicate it from the currently infected areas.

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

Bottom up meets top down: Data and tools for developing forest biodiversity metrics combining in situ and remote sensing

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

Gerald Guala[1]
Healy Hamilton[2]

[2] Sustainable Forestry Initiative

Abstract: Monitoring of changes, or drivers of change, in forest biodiversity is enormously challenging. As the forestry sector increasingly embraces their critical role in achieving global conservation targets and achieving a Nature Positive economy, there is a groundswell of demand for efficient and effective forest biodiversity metrics. *In situ* biodiversity data is invaluable for establishing biodiversity composition, status, and trends, but is a financial and logistic long-term commitment. Efficiently integrating strategic biodiversity data together with dramatic improvements in remote sensing data and analysis platforms offers a path for advancing meaningful forest biodiversity metrics.

Major developments in remotely sensed data collection, curation and analysis are providing new tools and insights into forest biodiversity. Highly scalable cloud-based computational platforms supporting globally dispersed, and highly collaborative, open science are being deployed, such as the Multi-mission Algorithm and Analysis Platform (MAAP), built and supported in close collaboration between NASA and ESA. Petabytes of relevant existing remote sensing data are being migrated to fully open cloud storage where they can be used *in situ* in those platforms, thus greatly expanding access and analysis capability, especially directly in regions with the highest inherent forest biodiversity. New instruments in, or soon to be in space, and their cloud native data streams, will provide far greater capabilities to monitor forest structure, health, extent, composition and phenology with higher cadence and expediency.

For example, harmonization of lidar data from ICESat-2 and GEDI has already led to significant advances in estimating above ground biomass (AGB). MAAP is now being used to merge and compare all of the major AGB estimates and deliver regionally specific estimations for reporting. The combination of LiDAR and SAR – especially from the upcoming NISAR and BIOMASS missions - will add enormous gains in detail, depth and cadence that will transform forest monitoring.

Biodiversity data from field efforts is also rapidly advancing, with increasingly effective outcomes for tools such as e-DNA, wildlife cameras, and acoustic recorders. Future efficient and meaningful forest biodiversity metrics and monitoring will arise from a strategic integration of site-specific biodiversity data together with products and tools emerging from the remote sensing community.

Combining satellite imagery and high-resolution airborne laser scanner data to monitor forest habitat types in Natura 2000 sites

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

[3] Slovenia Forest Service, Večna pot 2, SI – 1000 Ljubljana, Slovenia
[4] University of Ljubljana, Faculty of Arts, Department of Geography, SI – 1000 Ljubljana, Slovenia

Abstract: Priority forest habitat types (FHTs) within the Natura 2000 network are of highest conservation importance in Europe. However, they often occur in smaller areas and their conservation status is not well known. In our research, we focused on the following priority FHTs: I) 9180 *Tilio–Acerion forests of slopes, screes and ravines, II) 91E0 *Alluvial forests with Alnus glutinosa and Fraxinus excelsior (*Alno-Padion, Alnion incanae, Salicion albae*), and III) 91D0 * Bog woodland (*Sphagno-piceetum*) in three Natura 2000 sites in Slovenia.

The aim of our research is to determine the suitability of remote sensing data for automatic classification and monitoring of selected FHTs. Field mapping of FHTs was carried out in 2020, giving us a good knowledge of their spatial distribution in the Natura 2000 pilot areas. The results of the field mapping were supplemented with information on site characteristics based on data from ALS.

Based on the results, we will select the input data for automatic classification of FHTs and will be the following: I) LiDAR (ALS - Airborne Laser Scanner) and II) satellite imagery (Sentinel 1 and Sentinel 2). From the LiDAR data we will compute variables describing the relief features of the sites, the structure of the vegetation and some topographic features of the areas.

The model learned and tested in three pilot areas will be applied to other selected Natura 2000 sites in Slovenia, where no field mapping has been done before. We will compare the results of FHT classification in the original three pilot areas with the results in three additional selected Natura 2000 areas. Based on the results, we will evaluate the suitability of the input data and methods used to determine the distribution and monitor the state of the forest habitat types discussed.

A set of three different forest habitat types provides a wide range of input data suitable for each FHT. Adapted input data could also allow application of the methodology to other FHTs not discussed in our research. The results of our study are the starting point for the establishment of permanent monitoring of FHTs in Natura 2000 sites in Slovenia.

Ectomycorrizal morphotypes in structural variable retention of Pinus patula Schlltdl et Cham

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

Alejandro Velazquez Martinez[1]
Ana Lucila Soto Gil[1], Jesus Perez Moreno[1], Aurelio Manuel Fierros Gonzalez[1]
[1] Colegio de Postgraduados

Abstract: One of the forest species most used in Mexico for timber harvesting is *Pinus patula*. Currently this species is under forest management in the north forests of Puebla state and in some sites, clearcut regeneration system is applied. This species, like all pine species are depending for their survival on ectomycorrhizae, given the ecophysiological importance of this symbiotic association. The aim of this work was to evaluate the effect of the clearcutting regeneration system on the structure of ectomycorrhizal communities compared with areas with variable structural tree retention of a *P. patula* forest in Chignahuapan, Puebla. Nine trees were selected within the areas of interest to obtain soil samples and to be able to extract the ectomycorrhized morphotypes, to be characterized both anatomically and its morphology. 3137 ectomycorrhized roots were counted in total, within which 33 different morphotypes were recognized. Four of them dominated more than 50% of the total relative abundance, among them *Cenococcum geophilum*. There was a negative effect on the diversity of morphotypes among the stands with forest management compared to the retention areas. Finally, it is possible to say that forest harvesting with clearcutting system has a negative impact on the diversity of ectomycorrhizae; however, the maintenance of retention areas can reduce this impact and contribute to the reestablishment of the diversity of ectomycorrhizal communities over time, as it is a diverse genetic reservoir of these communities.

Forest Diversity at Large: Sentinel-2 and Deep Learning for Tree Species Mapping with Mixed Pixel Resolution

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

Tobias Schadauer[1]
Susanne Karel[1], Markus Löw[1], Ursula Knieling[1], Kevin Kopecky[1], Christoph Bauerhansl[1], Ambros Berger[1], Stephan Gräbe[1], Lukas Winiwarter[2, 3]
[1] Department of Forest Inventory, Austrian Research Centre for Forests (BFW), Seckendorff-Gudent-Weg 8, 1130 Vienna, Austria
[2] Research Unit Photogrammetry, Department of Geodesy and Geoinformation, TU Wien, Wiedner Hauptstraße 8-10, 1040 Vienna, Austria 10
[3] Department of Basic Sciences in Engineering Sciences, University of Innsbruck, Technikerstraße 13, 6020 Innsbruck, Austria

Abstract: Accurate large-scale classification of tree species is crucial for monitoring, protecting, and managing Earth's invaluable forest ecosystems. Amongst a wide range of applications, it facilitates tracking of the geographical development of tree species in response to climate change, improves risk assessment maps for threats like bark beetle infestations or forest fires, enhances timber volume models for accurate resource estimation and is utilized by forest authorities and the local management level. Numerous studies have recognized the suitability of satellite imagery, particularly Sentinel-2 imagery, for this task.

We utilize a dense phenology Sentinel-2 time series, which offers consistent data across multiple granules, in addition to terrain and vegetation height data, to map tree species on the individual Sentinel-2 pixel level across the entire forested area in Austria. Aiming for the classification scheme to represent actual forest conditions more accurately, alongside pure tree species classes, we include mixed tree species and sparsely populated classes. Additionally, we employ synthetic data generation to enhance the training data, which was manually labeled via visual aerial photography interpretation. The models we apply are based on a residual network, tailored for time-series classification specifically, and a multilayer perceptron. Numerous studies have identified spatial autocorrelation to have a significant impact on the validation of thematic maps. We explore the effects of autocorrelation on validation by investigating two validation methods at diverse split and buffer distances: spatial split validation and a validation based on buffered ground reference probability samples provided by the National Forest Inventory (NFI). While a random training data holdout set yielded 99 % overall accuracy, the spatial split validation resulted in 74 % overall accuracy, emphasizing the importance of accounting for spatial autocorrelation when validating with holdout sets derived from polygon-based training data. The validation based on NFI data resulted in 55 % overall accuracy, 91 % post hoc pure class accuracy and 79 % accuracy when confusions in taxonomic proximity were disregarded (e.g., spruce-larch confused with spruce-beech). The significant decline in accuracy between spatial split and NFI validation highlights the disparity between polygon-based training data and ground reference forest data, especially in diverse forest areas.

Improving Neural Network Classification of Native Forest in New Zealand with Phenological Features

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

Ning Ye[1]
Justin Morgenroth[1], Cong Xu[1]
[1] School of Forestry, University of Canterbury, Christchurch, New Zealand

Abstract: Changes in vegetation Indices (VIs) over time can be used to describe the phenology, or temporal changes, in vegetation. It is unknown which of these so-called phenological features contribute most to the classification of land cover. Feature selection might be able to address this issue. In this work, phenological features were used to classify a 50 km^2 native podocarp forest in New Zealand using two-year Sentinel-2 (S-2) data (288 images) and single-date PlanetScope (PS) data. There were nine land cover classes assigned to the study area. Single-date PS and S-2 data were fused to create a base image with the same spatial resolution as PS (3.125 m/pixel) and 8 bands that contained spectral data from S-2. This fused image was used to create 30 VIs. By using time-series S-2 alone and harmonic analysis in Google Earth Engine, the phenological parameters amplitude (AMP) and phase (PH) were retrieved from these VIs. Three classification scenarios (fused bands & VIs, fused bands & phenological features, and fused bands & VIs & phenological features) were undertaken using a Neural Network for accurately classifying forests. To assess the effect of feature selection and to determine the most crucial features, Variable Selection Using Random Forest (VSURF) was performed on the three different scenarios. According to the results, VSURF could speed up the classification process while retaining a similar degree of accuracy. Phenological features improved accuracy from 90% to 94%, driven mostly by the Red-Edge Triangulated Vegetation Index-AMP&PH, Normalised Near-Infrared-PH, Greenness Index-PH, Water Body Index-PH, Normalised Difference Vegetation Index-PH, Normalised Green-PH, Red-Edge Normalised Difference Vegetation Index-PH, Leaf Chlorophyll Content-AMP, and Simple Near-Infrared and Blue Ratio-PH. These features represent variations in the canopy's morphology, biochemistry, and physiology. Overall, the results demonstrate that particular phenological characteristics can enhance the classification of native podocarp forests in New Zealand.

Mapping large European aspens using airborne lidar and image data in Finland

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

Janne Toivonen[1, 2]
Annika Kangas[1], Matti Maltamo[2], Mikko Kukkonen[1], Petteri Packalen[1]
[1] Natural Resources Institute Finland, Bioeconomy and environment, Finland
[2] University of Eastern Finland, School of Forest Sciences, Finland

Abstract: European aspen (*Populus tremula* L.) is a keystone species and pioneer in boreal forests. Despite its sparse and scattered occurrence in Northern Europe, aspen is regarded as a highly valuable species. Both living and dead aspens are important hosts for many forest-dwelling species, including birds, fungi, invertebrates and mammals. Keystone role of aspens poses requisite for the information of the abundance and occurrence of these trees at landscape level. This information is valuable in the planning and implementation of sustainable forest management and conservation. Also, the aspen occurrence in time-continuum would be informative from the landscape health and integrity point of view. The topic of this presentation is the evaluation the performance of the combined use of high pulse density (5 pulses/m^2) leaf-on ALS data and aerial images in the detection of large aspens. We define the large aspen by its diameter at breast height (DBH); analyses are repeated with different threshold values (18, 20, 22, 24 and 26 cm). The study is completed with the realistic population in Finland, which means that the portion of large aspens is very low among all the trees (approx. 0.50%). As the dataset was highly imbalanced, we adopted Synthetic Minority Oversampling Technique (SMOTE) to generate new instances of minority cases. In the best case (26 cm DBH limit), Random Forest algorithm identified 7 out of total 22 large aspens in the whole data of 33 195 trees. The most important metrics in the detection of large aspens were related to aerial images, especially near-infrared band. The importance of ALS metrics was lower. The most important ALS metrics were related to echo intensity, kurtosis of vegetation heights and lower percentiles of vegetation heights. Results of the metric importance were in line with the earlier knowledge; image and ALS intensity metrics are highly capable in the identification of broadleaved trees. SMOTE-RF outperformed the non-SMOTE-RF classification which highlights the capability of the minority oversampling technique in the case of imbalanced data.

Open spectral libraries to support forest biodiversity monitoring

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

Miina Rautiainen[1]
Aarne Hovi[1]
[1] Aalto University, School of Engineering

Abstract: Remote sensing techniques contribute to significant advances in monitoring the biodiversity of forests at large scales. New technologies, especially ones based on remote or close-range spectroscopy, are expected to offer unprecedented solutions to monitoring plant species and their traits, both remotely from aircrafts or satellites or in the field using portable sensors. Spectroscopic technologies are based on measuring how plants interact with solar radiation: different plants absorb, reflect, transmit and emit solar radiation differently throughout the electromagnetic spectrum (350–3500 nm). This interaction is determined by biochemical and structural properties of the plant organs, and is thus also indirectly linked to species. Even though the basic spectral features of plants have been known for decades, the development of new hyperspectral remote or close-range sensing methods for forests has been hindered by a limited understanding of the variations in spectral properties of different elements forming forests such as leaves, bark and forest floor. In this presentation, we summarize recent studies from Aalto University that have collected and analyzed the (hyper)spectral properties of boreal and temperate forest elements in Europe. We report intra- and interspecific variations in the spectral properties of leaves, needles, tree bark, and forest floor and peatland vegetation, and discuss their significance in biodiversity monitoring. The data sets presented are available as open spectral libraries with digital object identifiers.

Operational solutions for biodiversity monitoring and mapping in forest ecosystems

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

Sandra Luque[1]
[1] INRAE National Research Institute on Agriculture, Food & the Environment

Abstract: Maintaining and improving the integrity and biodiversity of forested ecosystems is vital for achieving the EU biodiversity strategy for 2030, Sustainable Development Goals (SDGs), and Kunming-Montreal Global Biodiversity Framework (GBF). Present data show that the tropics lost 11.1 million hectares of tree cover in 2021 (University of Maryland and available on Global Forest Watch 2022). In particular, 3.75 million hectares of loss occurred within tropical primary rainforests — areas of critical importance for carbon storage and biodiversity. We need operational solutions to tackle biodiversity challenges. Providing that biodiversity is multidimensional, there is no unique indicator to describe and/or monitor forest biodiversity. In this context, I highlight the importance to monitor forest ecosystem extent and predict forest biodiversity change and its direct and indirect drivers through the integration of state-of-the-art multi-sensor Earth Observation (EO) data, comprehensive in-situ data, and products, together with next-generation ecological models that account for uncertainty. The approach supports also, integrated efforts needed to consolidate data from in-situ and remote sensing present and future missions. This presentation will serve as an introductory background for this technical session.

Operational tools for monitoring key forest attribute layers at global scale

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

Peter Vogt[1]
Giovanni Caudullo[1]
[1] European Commission, Joint Research Centre

Abstract: Within the context of the EU action to protect and restore the world's forests (COM/2019/352), the European Commission has setup the EU Observatory on Deforestation and Forest Degradation (EUFO) to provide scientific evidence on global deforestation, forest degradation and related trade. We present an overview of the processing, layout and features of global datasets designed to monitor and quantify key forest attribute layers (FAL), addressing forest fragmentation, forest patch accounting, forest spatial pattern, and forest network coherence. The scope of the FAL is to mediate the various end-user requirements by providing an objective and tangible product composed of spatially explicit maps, intuitive quantitative indicators, and concise summary statistics.

The spatial forest coverage is derived from the Copernicus Global Land Cover dataset for the assessment year 2019. We outline the procedure of pre-processing the original Copernicus data segments into a continuous global forest mask that is compliant with the FAO forest definition. This forest mask is then analysed for the various FAL, summarising the spatial status of forest cover and its degree of forest degradation. The FAL analysis is conducted in a dual approach: first, using the original WGS84 map projection for explanatory and user-friendly visualisation on web portals and second, in equal area projection allowing statistical evaluation of the forest attribute layers. Spatially explicit maps and statistical summaries are derived for a total of 278 reporting units, comprised of 255 countries, 21 global ecological zones, the EU27, and the full global coverage. A technical report summarizes all details on the processing steps, datasets, and links to access to the resulting products. All operational tools to conduct the FAL analysis are open-source and freely available at https://forest.jrc.ec.europa.eu/en/activities/lpa/ for either interactive use in the desktop application GuidosToolbox, or for automated mass processing on Linux servers via the application GuidosToolbox Workbench.

Remote Sensing applied to Small-Scale Sustainable Forest Management for monitoring and logging detection in the Central Amazon

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

Isabel Cristina Gomes Bezerra[1]
Filipe Campos de Freitas[2], Joberto Veloso de Freitas[1], **André Luiz Alencar de Mendonça**[1], Eirie Gentil Vinhote[2]
[1] Federal University of Amazonas, Postgraduate Programme in Forestry and Environmental Sciences, Manaus, Brazil.
[2] Institute for Sustainable Agricultural and Forestry Development of the State of Amazonas, Manaus, Brazil.

Abstract: Small-Scale Sustainable Forest Management (SSFM) is a management category in the Brazilian Amazon that promotes economic, environmental, and social development while benefiting small producers. It also contributes to deforestation reduction and forest conservation. A research study was conducted to evaluate the use of satellite images for identifying forest harvesting in small-scale sustainable forest management, particularly in areas with costly access. The study focused on the municipalities of Novo Airão and Iranduba in Amazonas state.

The research utilized high-resolution satellite images from the Sentinel 2 and Planet satellites, which are freely available. Three study areas were considered, including two Areas of Effective Exploration (AEE) that underwent harvesting and one Non-Harvested Area (NHA). Images were acquired in 2016, 2018, and 2019, covering data before and after the issuance of the Operation License (OL) for forestry harvesting. Processing and radiometric correction techniques were applied to enhance image quality.

The spectral values of the images were statistically analyzed to evaluate their response in harvested and non-harvested areas, aiming to identify any differences and spectral behavior patterns. Visual analysis of the images, along with post-harvest reports, confirmed the changes resulting from logging in the study areas. The images revealed evidence of logging, such as changes in forest cover characterized by varying color and texture gaps.

Comparing the Sentinel and Planet satellite images, both proved effective in identifying small-scale logging based on changes in forest cover. However, the spectral bands of the Sentinel images did not show the same similarity as Planet bands 2 and 3 (p-value=0.6 and 0.2). This indicates that Planet images provide more refined visual and spectral results due to their superior spatial resolution.

The study demonstrated that satellite imagery can efficiently identify forest exploitation in areas of small-scale sustainable forest management. This information is crucial for monitoring and controlling management activities, thereby contributing to forest conservation and sustainable development in the Amazon region.

The Application of Near Real-Time Data for Deforestation Monitoring in Aceh Province, Indonesia: How Could It Help?

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

Benita Nathania[1]
Mirzha Hanifah[1]
[1] World Resources Institute

Abstract: Indonesia's tropical forest is the third largest after Brazil and Congo with an area of around 126 million hectares (ha) of forest cover needs to be monitored. Many forest authorities are still relying on manual and conventional methods to monitor forest areas. Therefore, there is an urgent need to have access for remote sensing data with its computing capabilities to provide forest change information at various scales, places, and times. Finer spatial and temporal resolution (near real-time) data become the default characteristics in monitoring system. This study aims to find out what are the aspects that would improve by near real time data compared to existing conventional monitoring systems. Radar Alert for Deforestation Detection (RADD) is a near real time forest disturbance alert in primary humid tropical forests, using Sentinel-1's cloud-penetrating radar sensors. RADD becomes the main tool for primary data input to enhance forest monitoring system run by Forest Management Unit (FMU) in four districts of Pelalawan in Riau province, Aceh Tamiang, Aceh Timur, and Bener Meriah in Aceh Province, Indonesia. This study shows the utilization of near-real-time deforestation alert helps FMU in five important aspects by [1] expanding their monitoring area, [2] increasing the frequency of patrols, [3] speeding up the process of determining the patrol route, [4] speeding up the process of obtaining information regarding illegal land clearing activities to be forwarded to law enforcement, and also [5] facilitating updates on forest and land cover databases as an input of official data for local governments.

The Realities of Ecosystem Services: Acknowledging the Imperfect Nature of Trees and Forests

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

Jiquan Chen[1]
Peilei Fan[1]
[1] Michigan State University

Abstract: Throughout the course of civilization, trees and forests have consistently garnered admiration from people and societies, leading to their extensive manipulation and management on a global scale. However, the utilization of forests to fulfill societal needs often took place without proper management plans, particularly prior to World War II, and persisted in many parts of the world until the end of the 20th century. The devastating losses of pristine forests in Europe, East Asia, and eastern United States have been extensively documented. Moreover, the tropical rainforests continue to face large-scale deforestation in numerous countries. Nevertheless, there has been a growing recognition of the importance of understanding and preserving trees and forests. Various initiatives have been undertaken to protect trees and forests, as well as to safeguard threatened species. Noteworthy successes include the global distribution programs for species like Metasequoia and Gingkoes, which have helped rescue them from the brink of extinction. Additionally, the establishment of reserves such as national parks and the protection of old-growth forests in the Pacific Northwest of America serve as commendable examples. Meanwhile, it is important to acknowledge that there have been other human-induced changes in trees and forests that have proven to be mistakes, and in some cases, disastrous. Regrettably, these errors have not received full recognition from the public and policy makers. Notable examples include the large-scale introduction of Scotch pine to North America, the cultivation of fast-growing Eucalyptus in Southern Asia and Africa, and the conversion of deserts into irrigated monoculture popular plantations. Considering recently developed and evolving concepts such as sustainability, ecosystem management, and ecosystem services, it is crucial to review both successful and failed cases in the context of local landscapes and societal needs. This highlights the imperfect nature of our understanding and management of trees and forests. Given the importance of these natural treasures, it is essential that the perceptions of the public and policy makers are informed by the scientific community. By incorporating scientific knowledge, we can make more informed decisions, ensuring that they align with both ecological considerations and the needs of local communities.

Understanding land use change at the landscape level using machine learning for maximizing forest ecosystem services in the Andes

T5.27 Operational tools improving forest biodiversity Monitoring from space: Finding solutions to 2030 conservation targets

Yasumasa Hirata[1]
Wei Yang[2], Kei Suzuki[3], Ethel Rubin De Celis Llanos[4], Lenin Cruyff Ventura Santos[5], Noemi Serrudo Torobeo[5], Kazuki Miyamoto[1], Tamotsu Sato[1], Shinji Sawano[1], Koji Tamai[1]

[4] National Agrarian University La Molina
[5] Peruvian National Forestry and Wildlife Service, Lima, Peru

Abstract: The Andean region maintains diverse forest ecosystems due to the variety of environments created by the great differences in elevation. These mountain ecosystems possess not only the function of producing timber and non-timber forest products, but also multiple functions, including biodiversity conservation that maintains genes, species, and ecosystems; global environment conservation that mitigates global warming and stabilizes the global climate system; landslide prevention and soil conservation that reduce surface erosion, surface collapse, and sediment runoff; and water source recharge functions that store water resources and regulate water quantity. These various functions provide various benefits (ecosystem services) to human life. Sustainable forest management is indispensable for the perpetuation of forest ecosystem functions, and for this purpose, it is important to accurately understand the current status of forests and their changes. The objective of this study is to develop a method to capture land use change at the landscape level surrounding forests using data from multiple satellite sensors using machine learning methods. The satellite data used will be Landsat satellite data and Sentinel-2 satellite data. The former has the advantage of long-term observation, while the latter has the advantage of capturing more detailed land use boundaries with higher ground resolution than the former. Therefore, we used a combination of these data and performed object-based classification using machine learning methods to identify land use change at the landscape level. In particular, from the perspective of forest ecosystem services, we proposed a method to capture the effects of new eucalyptus plantations, which use more water resources, and forest degradation and forest fires, which affect the supply of non-timber products, as trajectories in the reflectance spectrum. In order to maximize forest ecosystem services, it is necessary to identify the ecosystem services demanded by local residents and to work with them to develop afforestation, forest management, and land use allocations that do not degrade these ecosystem services. The results obtained from this method will be useful in building this consensus.

T5.28 Predicting the future of forest ecosystems from contemporary spatial patterns

Missed opportunities for growth: key determinants and limitations of radial growth in boreal forests along a latitudinal gradient

T5.28 Predicting the future of forest ecosystems from contemporary spatial patterns

Danielle Creek[1]

[3] Division of Environment and Natural Resources, Norwegian Institute of Bioeconomy Research, Ås, Norway

Abstract: The boreal zone is warming twice as fast as the global average due to climate change, with warmer spring and autumn temperatures significantly increasing the window of potential growth for boreal forests. Radial stem growth is a key indicator of tree vitality and is strongly linked to the health of a tree. Understanding the effects of climatic drivers such as temperature and moisture and photoperiod on radial growth is crucial for assessing the impacts of climate change on tree health. However, studies observing high-temporal growth responses to these rapidly changing conditions, especially in the boreal zone, remain scarce.

We analysed sub-daily radial tree growth from dendrometers for more than 200 trees of two boreal conifer species (*Picea abies* and *Pinus sylvestris*) at 10 sites along a latitudinal gradient (mean annual temperature, MAT, range from 6.8°C to 1.2°C) in Norway over two years.

Annual radial growth was positively correlated with MAT however there was large variation in the growth between individuals at each site with the role of individual tree characteristics and life history, microclimatic and soil traits explored.

As expected, growing season length (the number of days between the start and cessation of radial growth for the season) decreased with increasing latitude (from 78 to 54 days). Air temperature and photoperiod determined the start of the growing season, however most trees, irrespective of latitude, ceased growing by early August, suggesting a key role of photoperiod. We observed that the number of actual growth days (days where radial stem growth >0µm) was significantly lower across all sites, with growth only occurring on 14 to 61 days (30 to 70%) of the growing season. The number of growth days was a much better predictor of annual radial growth than growing season length.

Given that boreal trees showed radial growth only on a small percentage of possible days within a growing season and that the number of days of growth strongly determined the annual growth of an individual, our study highlights the need to better understand the key determinants tree growth at a daily level to reduce uncertainties in predictions under climate change.

Basin-wide patterns of Amazon forest sensitivity to drought

T5.28 Predicting the future of forest ecosystems from contemporary spatial patterns

Julia Valentim Tavares[1, 2]
Emanuel Gloor[2], Oliver Phillips[2], David Galbraith[2]
[1] Uppsala University
[2] University of Leeds

Abstract: Amazon rainforests face intensifying water stress due to increases in vapour pressure deficit (VPD) and changing hydrological regimes. Embolism resistance (Ψ_{50}), defined as plant capacity to resist the disruption of xylem water flow as a result of air bubble formation caused by water stress is an essential metric of tree ability to persist under dry conditions. Measurements of $_{50}$ are only available for a relatively small number of Amazon forests, representing a major challenge for understanding large-scale forest sensitivity to drought and climate change. Here we evaluate the phylogenetic basis of Ψ_{50} across Amazonian tree taxa and find a high level of phylogenetic signal, with hydraulic conservatism preserved at family level. The phylogenetic signal found in our dataset allowed us to use species composition data from more than 500 inventory forest plots distributed across Amazonia to produce the first map of basin-wide embolism resistance. The resultant spatial distributions reveals how embolism resistance vary across the largest and most biodiverse tropical forest on Earth, indicating different ability across Amazonian forests to cope with a future hotter and drier climate.

Detecting distribution of Lantana camara in western region of Nepal using remotely sensed data

T5.28 Predicting the future of forest ecosystems from contemporary spatial patterns

Deepa Sapkota[2], Narayandev Bhattarai[1]
[1] Division Forest Office Palpa
[2] Institute of Forestry, Hetauda Campus Nepal

Abstract: Remote sensing is a valuable tool for the management of invasive species. It can help to identify areas that are at risk of invasion, to track the spread of invasive species, and to monitor the impact of invasive species on native plants and animals. This study evaluates the utility of Landsat 8 Satellite data for detection, mapping and patch information extraction of the invasive weed *Lantana camara* in four district of western Terai of Nepal. Study area possess Tropical monsoon to temperate climate and major natural vegetation present in the area is *Shorea robusta* and associates species and *Pinus* in upper altitudes. Landsat 8 Operational Land Imager (OLI) satellite image of March 3 & April 19, 2022 was used to differentiate *Lantana camara* from the surrounding vegetation and other landuse using maximum likelihood classifier algorithm. The image was classified into six specific land cover classes including agriculture, urban, *Lantana camara*, forest, water-bodies, and sand/gravels/exposed soils. Out of 874991.0 hecter of the study area 47568.9 (5.44%) of area is colonizing by *Lantana camara*. The classification accuracy was assessed which give an overall accuracy of 76.27 % and overall Kappa Statistics is 0.60873. The study demonstrated the high potential for differentiation and mapping of *Lantana camara* using moderate resolution satellite imaginary at acceptable level of accuracy. The findings shows that moderate resolution satellite imaginary can contribute for planning to control *Lantana* invasion.

Ecosystem pressure-volume relationships and steady-state vegetation biomass

T5.28 Predicting the future of forest ecosystems from contemporary spatial patterns

Abstract: Water is a fundamental constituent of life, but not all water is available to life. In fact, life requires water within narrow limits of chemical potential: hence, the Dead Sea is largely dead, and the highest biomass systems occur in places with large quantities of 'free' water. To grow and reproduce, sedentary organisms must have a supply of water with a higher chemical (or water) potential than themselves. Thus, there is coordination in the water relations between organisms, communities and their environments.

The relationships between water potential and water content in plants and soil have long been of interest. However, there is increasing focus in understanding how these fundamental measures of water are linked at larger spatial and temporal scales, i.e., the scale at which land surface models operate and satellite remote sensing can provide information. Bridging the gap between fundamental tissue-level variables and ecosystem-level processes holds the potential for identifying large-scale vegetation thresholds and providing early warning signals of ecosystem change. Here we look at how these fundamental measures of water scale to landscapes and whether they can be informative of ecosystem organization over large spatial and temporal scales.

Using plot-level data from nine sites including tropical rainforest, savanna, temperate forest, and a long-term Amazonian rainforest drought experiment, we explore relationships between equilibrium vegetation water potentials and water stored in above ground biomass. The relationship between the water stored in biomass consistently scales with biomass across systems, as does the vegetation-level hydraulic capacitance, while the relative measures of water storage and hydraulic capacitance show no trend across ecosystems. Such cross-biome relationships hold promise for improving the interpretation of satellite remote sensing data.

We use this preliminary analysis to open a discussion on the extent to which community structure is fundamentally determined by the 'hydraulic environment', i.e., the supply and demand of water. Such probabilistic models are consistent with the predictable climatic distribution of natural vegetation types as first noted by Humboldt, and may lead to vegetation models that are more reliable over large spatial and temporal scales while having lower data requirements.

Estimating latitudinal patterns in stabilizing density dependence in forest communities

T5.28 Predicting the future of forest ecosystems from contemporary spatial patterns

Lisa Hülsmann[1]
Florian Hartig[2]
[1] University of Bayreuth
[2] University of Regensburg

Abstract: One of the most striking patterns in forest ecosystems is the latitudinal gradient in tree species diversity. A prominent explanation for the exceptionally high local diversity in tropical moist forests is that tropical tree communities are more strongly stabilized by specialized enemies leading to conspecific negative density dependence (CNDD). This biotic interaction is thought to prevent the dominance of individual tree species and promote coexistence. While the existence of CNDD is well established at all latitudes, there is still no conclusive evidence if and how CNDD differs between tropical and temperate forests. The few studies that have directly examined large-scale geographical variation in CNDD reported a pronounced increase in CNDD with decreasing latitude. However, these latitudinal CNDD patterns have been attributed to multiple statistical biases, including regression dilution, which are related to the use of static data and can create spurious correlations of CNDD with abundance and latitude. Here, we test several predictions arising from the hypothesis that CNDD is more influential for maintaining local tree species diversity in the tropics. To do so, we use dynamic forest inventory data from large permanent forest plots and a carefully designed analytical pipeline that aims to ensure high comparability across latitudes. Overall, our results support the idea that CNDD may stabilize diverse tropical tree communities more than temperate ones, but this stabilization appears more subtle than previously thought. Using the case of CNDD and the latitudinal gradient in local tree species diversity as an example, the presentation will outline the methodological difficulties and potential solutions associated with testing and quantifying large-scale patterns in ecological processes, such as across latitude or elevation.

Insect galls as indicators of ecosystem changes in the Mediterranean forests: comparison of patterns in fossil and contemporary data

T5.28 Predicting the future of forest ecosystems from contemporary spatial patterns

Benjamin Adroit[1]
Thomas Denk[1]
[1] Swedish Museum of Natural History, Department of Palaeobiology, Box 50007, 10405 Stockholm, Sweden

Abstract: Mediterranean forests are hotspots of biodiversity and the Mediterranean area is among the richest and most vulnerable biomes on Earth. Global Change poses a serious threat to this biodiversity and the resilience of these forests. To better understand and predict future changes in these ecosystems, paleoecological investigations are of critical importance.

Many studies focusing on temporal changes of forest biodiversity overlook one important aspect of ecosystem functioning: the interactions among living organisms influenced by the environment. The present study proposes a novel approach, integrating intensities of plant-insect interactions as indicators of forest changes over time. Plant-insect interactions play a crucial role in shaping the distribution, abundance, and diversity of both plants and insects within terrestrial ecosystems.

To investigate plant-insect interactions, a morphological guide of plant-insect interactions in the fossil record provides a useful tool to study these interactions across different ages, locations, and plant species. This method allows for direct comparisons between fossils and modern interactions, providing insights into the historical dynamics of these interactions.

We examined plant-insect interactions around the Aegean Sea including a period of 20 million years. By analyzing 2,500 fossil leaves and 4,000 contemporary samples, we observed notable changes in these interactions. The prevalence of galls on leaves showed a significant increase in regions with higher temperatures and decreased precipitation, indicating a potential shift under climate change. Additionally, our study uncovers changing associations between specific plant species and insect galls, shedding light on the evolving coevolutionary dynamics over time. By unraveling the intricate web of plant-insect interactions and their responses to changing environments, these findings provide crucial insights into the understanding and managing of Mediterranean forests in the face of Global Change.

Soil water limitations to forest temperature buffering across space and time

T5.28 Predicting the future of forest ecosystems from contemporary spatial patterns

Abstract: Forests can buffer understory microclimate and biodiversity against high temperatures. Buffering of high temperatures in forests results from a combination of canopy shading and cooling via evaporation and transpiration and varies therefore in space and time. In the context of climate change, the buffering capacity of future forests against increasingly frequent heatwaves and droughts is conditional on stable canopies and a sufficient amount of soil water. Dry soils limit evapotranspiration – the most efficient surface cooling mechanism. Up to now, we know too little about the strength of the relationship between soil moisture and temperature buffering as well as about its interaction with canopy cover, topography, geographic location and forest type. Here, we analysed temperature and soil-moisture time series of European forests investigating how day-to-day fluctuations in soil moisture drive temperature offsets, i.e., the difference between reference temperatures from daily climate reanalysis grids and temperatures inside the forest. We modelled offsets of daily maximum temperature as a function of soil moisture in interaction with canopy cover, topography and weather conditions. We found that site-specific offsets became more negative (in other words, the cooling effect was stronger) when soil moisture was higher. This relationship was also contingent on canopy cover, topographic heat load, the daily evaporative demand of the air above the canopy as well as macroclimate. In a warming macroclimate with increasing frequency of drought events, these soil-water limitations on forest buffering will become more and more critical and several forest regions risk losing their buffering capacity. Therefore, we must urgently adapt forest management practices to not only secure continuous canopy cover but also to keep the water in the soils, for example, by closing drainage ditches or adaptive thinning to prevent long-term soil water depletion from evaporative loss. We demonstrate that accounting for spatiotemporal variations in the local water balance will aid in making more realistic predictions about the buffering function of forests across landscapes and biomes and over time.

Tree species composition along environmental and disturbance gradients in tropical sub-montane forests

T5.28 Predicting the future of forest ecosystems from contemporary spatial patterns

[3] 3National Carbon Monitoring Centre, Sokoine University of Agriculture, Tanzania.

Abstract: Understanding the environmental and disturbance determinants of tree species dominance and community composition in an ecosystem, is important for informing management and conservation decisions, through maintaining or improving the existing forest composition and structure. This study was carried out to quantify the relationship between forest tree composition structure and environmental and disturbance gradients, in a tropical sub-montane forest of Eastern Usambara. Vegetation, environmental, and anthropogenic disturbance data for 58 plots across Amani and Nilo nature forest reserves were obtained. Agglomerative hierarchical cluster analysis and canonical correspondence analysis (CCA) were used to identify plant communities and analyze the influence of environmental variables and anthropogenic disturbances on tree species and community composition respectively. Four communities were identified and CCA results showed that the variation was significantly related to elevation, pH, Annual mean temperature, temperature seasonality, phosphorus nutrients and pressures from adjacent villages and roads. Likewise, environmental factors (climate, soil and topography) explained the most variation (14.5%) of tree and community composition in relation to disturbance pressure (2.5%). The large and significant variation in tree species and community patterns explained by environmental factors suggests a need for site-specific assessment of environmental properties for biodiversity conservation plans. Similarly, the intensification of human activities and associated impacts on natural environment should be minimized to maintain forest species composition patterns and communities. The findings are useful in guiding in policy interventions that focus on minimizing human disturbances in the forests and could aid in preserving and restoring the functional organization and tree species composition of the sub-tropical montane forests.

Understanding forest change from patterns along elevational gradients: Lessons from a multi-state monitoring network in the northeastern United States

T5.28 Predicting the future of forest ecosystems from contemporary spatial patterns

Martin Dovciak[1]
Jordon Tourville[1, 2], Jay Wason[3], Monica B. Berdugo[4], Michael Zarfos[1, 5]

[4] Plant Ecology and Geobotany, The Philipps University of Marburg, Germany
[5] Center for Climate and Security, Council on Strategic Risks, Washington D.C., USA

Abstract: As climate warms, tree species are expected to migrate to higher latitudes and elevations, but mixed evidence suggests that our understanding of the mechanisms driving tree migrations is still rudimentary. Since seedling establishment is required for tree migration to occur, experimental studies increasingly investigate how climate affects tree seedlings and their interactions with other organisms (e.g., non-woody plants, soil microorganisms, herbivores). Field studies along climatic gradients spanning species range limits can detect early stages of species range shifts and improve our understanding of climate-induced migrations under field conditions with many interacting factors and taxa. We used generalized linear mixed effects modelling and ordination to investigate how tree seedling recruitment, abundance, composition, diversity, and species associations with other plants and soil fungi vary from low-elevation temperate deciduous to high-elevation conifer forests in four states of the northeastern U.S. Forest plant communities were surveyed on 2,580 plots in total (each 1×1 m large), both under forest canopies and in canopy gaps. We also characterized soil depth and chemistry, microclimate, and tree root colonization by mycorrhizal fungi.

Tree seedling spatial patterns relative to conspecific adults were consistent with the early stages of upslope migration for boreal conifers (particularly in canopy gaps) but not for temperate deciduous species (regardless of canopy environment). Greater canopy tree mortality and openness in high-elevation forests supported conifer seedling establishment upslope of conspecific adults. Seedling distributions were related primarily to climate, and secondarily to edaphic conditions. Diverse tree seedling banks were associated with the high diversity of other understory plants. Tree seedling associations with other plants were more numerous in species rich low-elevation forests and less common (and more positive) in species-poor high-elevation conifer forests. The moss layer supported higher tree seedling abundance and diversity at high elevations, while the high cover of understory vascular plants had an opposite effect at all elevations. Tree seedlings formed complex interaction networks with other plants and fungi along climate-edaphic gradients, suggesting that the entire forest community needs to be considered when predicting or managing climate-induced tree migrations. Observational gradient studies play an important role in improving our understanding of climate-induced tree migrations.

Use of Satellite Imagery for Monitoring Land Cover Changes in a Taiga Region of Canada Subjected to Climate Change

T5.28 Predicting the future of forest ecosystems from contemporary spatial patterns

Armand LaRocque[1]
Abraham Olatunji[1], Brigitte Leblon[2], Manon Sorais[3], Jean-François Giroux[4]

[2] Faculty of Natural Resource Management, Lakehead University, Thunder Bay, Ontario, Canada
[3] Dalhousie University, Halifax, Nova Scotia, Canada
[4] Département des sciences biologiques, Université du Québec à Montréal (UQAM), Montréal, Québec, Canada

Abstract: Satellite imagery has become an important tool to monitor and map land cover changes. There are currently archived millions of satellite images with a nearly continuous record of global land surface data since their inception. In this study, we used Landsat optical imagery acquired in 1984-1985 and 2019-2020 and topographic variables to assess the land cover changes along the eastern coast of James Bay in Eeyou Itschee (Québec, Canada). With the 2019-2020 map, Sentinel-1 SAR imagery was also used. These images were classified by applying the Random Forests classifier. The classification overall accuracies of 93.7% and 97.9% were achieved for the 1984-1985 and 2019-2020 images, respectively.

Significant land cover changes occurred between 1984-1985 and 2019-2020. The greatest decline was observed in the bareland vegetation class. Tidal flats, shrublands, fens with very low vegetation and tundra or health cover also experienced declines. The greatest increase was observed in the burned areas. Deciduous forests, bedrock, shrub fens and muskegs also experienced an increase greater than 100% over the period.

The changes in the land cover are the result of three main factors. Firstly, there is a northward migration of forest cover and tundra vegetation, mainly in response to climate change. In addition, intolerant broadleaf forests and shrubs have replaced areas of coniferous forests due to the recent increase in wildfires. Local climate warming would also be responsible for the melting of discontinuous permafrost, causing an increase in the areas covered by muskeg. Secondly, the James Bay coast is subjected to a postglacial isostatic rebound, characterized by the rise of the land over the sea level, replacing tidal flats by marshes and various classes of terrestrial vegetation. These land cover changes impact the wildlife that inhabits or migrates through the area and indirectly on the native human communities that depend on these natural resources.

T5.29 Role of university and experimental forests in the forest education and long-term forest research

Asian network of long-term forest monitoring in university and experiment forests

T5.29 Role of university and experimental forests in the forest education and long-term forest research

[8] Hainan University

Abstract: Long-term monitoring and inventory data are important in changing environments. Many projects aim for long-term forest monitoring; however, few continue for a long term due to lack of funding and labor. Forest research organizations and university forests have an advantage in this regard. Especially university forests because they manage their own forests. The University of Tokyo Forests (UTF) has accumulated long-term monitoring data, such as meteorology and hydrology data, permanent plot data, plant and animal inventory data, and others for a long period of time. In 2016, UTF started networking with Asian university forests for long-term forest monitoring, including Seoul National University (South Korea), National Taiwan University (Taiwan), Kasetsart University (Thailand), Universiti Malaysia Sabah (Malaysia), Hainan University (China), Universitas Gadjah Mada (Indonesia), and University of Sri Jayawardenepura (Sri Lanka). These universities hold or manage university forests and research sites in different climate and vegetation zones of the Asian monsoon region. The network aimed to promote the development of long-term research field stations for stable and continuous monitoring and to establish a multilateral research cooperation network between the core institutions. Collaborative research has been done by the three research groups (RG): Climatology and hydrology, Ecology and biology, and forest management. Six plenary symposia, three plenary workshops, and two interim symposia were held. In 2019, two RG workshops focusing on hydrology and bark and ambrosia beetles were held in South Korea and Taiwan, respectively. Even during the COVID-19 pandemic, online collaboration continued. The project produced two special issues the Journal of Forest Research and the journal Water, and three books. A booklet introducing experimental watersheds and weather stations in Asian University Forests Consortium was also published.

Elevating visitor management in a protected area through visitor profiles: The case of Make it Makiling

T5.29 Role of university and experimental forests in the forest education and long-term forest research

Rogelio II Andrada[1]
Mae Belen Putian[2], Myranel Canceran[2], Angela Limpiada[2]
[1] Institute of Renewable Natural Resources, College of Forestry and Natural Resources, University of the Philippines Los Banos
[2] Makiling Center for Mountain Ecosystems, College of Forestry and Natural Resources, University of the Philippines Los Banos

Abstract: The Mount Makiling Forest Reserve (MMFR) a protected area under the management of the University of the Philippines was declared as an ASEAN heritage park in 2013 and has implemented an intensive visitor management program that is based on volunteerism among its stakeholders including the university students. The visitor management program entitled, "Make it Makiling!" is an annual activity implemented particularly during the Catholic observance of the Holy Week when daily visitors to the forest reserve average around 1,200 per day. The goal of the program includes deepening awareness and appreciation of visitors on the value of mountain ecosystems; promote ecotourism practices; ensure visitor safety and enjoyment; and encourage volunteerism in the conservation of mountain ecosystems. The study highlights conducting annual exit surveys by student volunteers to establish visitor profiles and using it as a feedback mechanism towards improving the visitor management program. Variables such as socio-demographics, motivation, preferences, perception, and suggestions were solicited through the visitor survey. The paper chronicles how the information is used to design and implement innovations every year. Specifically, improvements on interpretation materials and waste management measures were made. After four years of its conduct, organizers of "Make it Makiling!" has mainstreamed its implementation and integrated its results in planning for the program.

Filling the gap in project management competences in forestry research projects: a scoping study

T5.29 Role of university and experimental forests in the forest education and long-term forest research

César Pérez-Cruzado[1]
Yago Lestido Cardama[1], Oscar López Álvarez[1], Adela Martínez-Calvo[1], Joel Rodríguez-Ruiz[1], Manuel Francisco Marey-Pérez[1]
[1] Projects and Planification PROEPLA, University of Santiago de Compostela (USC), C/Benigno Ledo s/n, E-27002 Lugo, Spain

Abstract: Project Management (PM) is the use of specific knowledge, skills, tools and techniques to ensure the fulfillment of project objectives in scope. PM contents has been included in the last years in many University degrees related to forestry, engineering and life sciences, as well as in specific bachelor's and master's degree programmes. As the earlier study programmes usually did not include these contents, many of the researchers who are currently managing research projects has not been trained in PM. Is therefore of interest to know how researchers with different levels of knowledge in PM face the challenge of managing research projects. Another key issue is to evaluate the knowledge and us of PM tools and techniques by the different rols in the project governance structure, such as the PI, the research team, or external partners, but also by research agencies and project funding and evaluation institutions. Even though eventual knowledge gaps in PM could be filled in doctoral study programs, it is currently unknown the extent to which these contents should be covered to provide training tailored to the researcher's needs.

The main goals of this research are: 1) to know the degree of instruction received in PM, 2) the knowledge of tools and techniques of PM, and 3) the perception of importance of different PM tools and techniques by researchers, as well as the need of improvement in training in the field of forestry research by comparing to other research areas. We elaborated an online survey, which was distribured among scientists responsible of managing research projects in different areas, including forest research organizations, Universities, and research institutions. The survey was divided into three groups of questions related to: 1) the level of training in PM, 2) the level of use and knowledge of different tools and techniques of PM, and 3) the perception of importance and knowledge gaps of different tools and techniques of PM when applied to research projects.

This study raises awareness of the importance in knowledge and skills of PM, incorporating improvements in the organization of forestry research and doctoral study programs.

Learning from Talking Trees How Climate Change affects Trees and Forests

T5.29 Role of university and experimental forests in the forest education and long-term forest research

Achim Bräuning[1]
Jan-Christoph Schubert[2], Steffen Höhnle[2], Annette Debel[1], Thomas Mölg[1], Sibille Wehrmann[1]
[1] Institute of Geography, Friedrich-Alexander University Erlangen-Nürnberg, Wetterkreuz 15, 91058, Erlangen, Germany
[2] Chair of Didactics of Geography, Friedrich-Alexander-University Erlangen-Nürnberg, Regensburger Str. 160, 90478 Nürnberg, Germany

Abstract: Climate change is affecting forests, trees and ecosystems of different species in many ways. Besides, complex topographic conditions may modify the impact of climate change on forests regionally, depending on the position of an ecosystem in the luv or in the rain shadow of mountain regions or on altitude. Knowledge of students and of the general public, however, is limited on how local environmental conditions may affect the response of trees to climate conditions.

By combining climate modelling, dendroecology, and educational research, the interdisciplinary project BayTreeNet studies the local climate dynamics in Bavaria (southeast Germany) in new approach. The study area shows a complex topography, with middle and high mountain regions and dry basins between. To explain interconnections between weather situations and forest ecosystems in Bavaria, we implemented internet-connected "talking trees". Ten of those trees accessible to the public were equipped with a sap-flow sensor, electronic dendrometers and an internet-based transmission unit. School classes interpret the real-time tree responses to changing weather conditions and on-site weather data, and translate the current tree responses into simple text messages via "Twitter". All weather data, tree data, and explanatory text messages are displayed on the project Homepage https://baytreenet.de. By comparing the different activities of trees within the network, the local tree responses to current weather conditions can be related to specific weather types with specific local response patterns. Such an approach allows a deeper understanding of climate change and local ecosystem responses.

By forecasting the probable future frequency of specific weather types using a climate modelling approach, tree responses future occurrences of weather patterns can be simulated. For a better understanding of climate change impacts, the educational research will utilize climate modelling results and dendroecological findings to develop an empirically founded teaching concept. We present the main concepts, methodology and results concerning student learning progress and citizen science about climate change impacts on forest ecosystems.

Long-term monitoring sites for forest stand dynamics research and education at Seoul National University Forests, Korea

T5.29 Role of university and experimental forests in the forest education and long-term forest research

Pil Sun Park[1]
Gwanhyun Nam[1], Jong Woo Kim[1], Hyunjoong Sung[1], Hyunseok Kim[1], Sangjun Im[1]
[1] Seoul National University

Abstract: Long-term monitoring enables to detect changes in forest ecosystems and effects of forest disturbances, thus one of key activities in forest sciences. University forests are ideal sites for long-term research thanks to long-lasting researchers including professors, researchers, graduate students, and university staffs from several years to decades. Thus, many university forests are a key hub for long-term research including long-term monitoring. Seoul National University Forests consist of three regional university forests and two of them maintain long-term monitoring sites. Long-term monitoring has been conducted to understand changes in tree species composition, forest structure and disturbance effects in secondary broadleaved forests and *Pinus koraiensis* plantations in Taehwa University Forest, and an *Abies Koreana* dominant stand and riparian forests in Nambu University Forest. Permanent plots that ranged from 20 m x 20 m to 1 ha plot were established in the long-term monitoring sites. Annual monitoring includes tree species, diameter at breast height (DBH), and tree demographics (death and ingrowth). The long-term monitoring sites were used for class programs as well. Classes including forest ecology, silviculture, tree physiology, and hydrology have actively used those long-term monitoring sites. We have observed effects of disturbances on stand structural changes and different patterns of temporal changes in species composition among sites. The impact of typhoons increased with tree height in sites in plantations. Rates of changes in species composition and stand structure differed depending on stand developmental stages and elevational locations. Gap creation by windthrow at high elevations decreased tree species and increased subtree and shrub species recently. The findings provide insights into changes in forest structure and contribute to the knowledge for forest management. Long-term monitoring sites of university forests were used by researchers from various organizations, thus provide excellent basis for both domestic and international research cooperation. Maintaining long-term monitoring sites costs quite budget and efforts. Active investment and research cooperation would help to strengthen the role and function of long-term monitoring in university forests, which have contributed to education of younger generation and innovative technology in forestry.

Long-term silvicultural, ecological, and meteoro-hydrological data and research at the University of Tokyo Hokkaido Forest, northern Japan

T5.29 Role of university and experimental forests in the forest education and long-term forest research

Toshiaki Owari[1]
Nobuaki Tanaka[1], Satoshi N. Suzuki[1]
[1] The University of Tokyo Hokkaido Forest, Graduate School of Agricultural and Life Sciences, The University of Tokyo, Japan

Abstract: The University of Tokyo Hokkaido Forest (UTHF) was established in 1899, having 22,717 ha of forest in northern Japan. UTHF has collected and analyzed extensive long-term data relating silviculture, ecology, and meteoro-hydrology under an organizationally stable observation system. This paper presents the types and contents of long-term data accumulated at UTHF through forest management and monitoring, as well as research outcomes. In 1958, UTHF initiated a long-term experiment of the stand-based silvicultural management system on a business-scale. Natural forests are classified into several management types, with single-tree selection harvest as the primary silvicultural system. Each year, the UTHF staff conducts a ground forest survey for spatially explicit stand classification, field measurements of forest inventory plots, and single-tree selection for harvest. These operations have enabled the recording of stand-level information for silvicultural planning and management for over 60 years. Additionally, UTHF has recently incorporated the use of unmanned aerial vehicles to capture aerial photographs prior to each forest management planning session. To assess the effects of the silvicultural managements, UTHF has established more than 100 permanent plots within both managed and unmanaged stands. Furthermore, to understand the structure and dynamics of unmanaged forest ecosystems, UTHF established two core long-term ecological research (LTER) plots in the 1990s. The Maeyama plot covers 36.25 ha of hemiboreal forests dominated by boreal conifers and deciduous broadleaves, which is the largest forest plot in Japan. The Iwanazawa plot also covers a large area (18.75 ha) in a riparian cool temperate forest, where genetic structure and gene flow of some riparian tree species has been analyzed. Since 1914, meteorological observation has been conducted at several weather stations, revealing significant patterns of climate warming in UTHF. In 1985, four years after a massive typhoon disturbance, a gauging weir was established in the Maruyamasawa experimental watershed for evaluating the effects of forest recovery and succession on water-related ecosystem services such as low-flow and flood-flow mitigations.

Relationship between microclimate and forest canopy characteristics using lidar data

T5.29 Role of university and experimental forests in the forest education and long-term forest research

Jumi CHA[1]
Hyeyeong CHOE[1, 2]
[1] Department of Agriculture, Forestry and Bioresources, Seoul National University, Seoul 08826, Republic of Korea
[2] Research Institute for Agriculture and Life Sciences, Seoul National University, Seoul 08826, Republic of Korea

Abstract: Since the shade of trees reduces direct sunlight, lowers temperatures, and maintains moist conditions, forest canopies protect understory plants by buffering against climate change. In addition, the complexity of canopy structure creates a heterogeneous microclimate on microscopic spatiotemporal scales. Under the extreme climate condition to come, the gentle microclimates provided by canopies can act as microrefugia that serve as havens for species in unfavorable local conditions. These buffers aid to conserve ecological functions and forest biodiversity. Therefore, it is important to understand how the characteristics of forest canopies, such as cover and structure, are related to their effect on mitigating harsh climate conditions. Our study aims to (1) determine the best resolution for indicating the relationship between canopy characteristics and microclimate and (2) identify the most influential canopy characteristics. The study was conducted in the academic forest located in Gyeonggi province, South Korea. We used both UAV and Backpack LiDAR for data collection on the canopy structure and topology. A thermal imaging camera was employed to measure land surface temperature, as a proxy for microclimate. We generated data at 0.5 m, 1 m, 5 m, and 10 m resolutions to analyze the relationship between land surface temperature and canopy characteristics data, and then we identified the most significant variables. The result showed that the data at a 5 m resolution had the highest r-squared value (0.58). We could not observe a consistent pattern in the accuracy of the analysis for other resolutions. Tree crown height was the most important factor followed by canopy variance, LAI, and canopy cover. Despite the relatively low r-squared value, we found a suitable resolution to assess the relationship between land surface temperature and canopy characteristics. Further research is needed to validate the consistent results across a broader spatial context. In addition, since land surface temperature can be influenced by other climates such as wind and moisture, considering the climatic factor would also be essential.

Seedbed for Applied Silviculture: Fostering Early Scientific Training of Young Foresters for the Southwest Colombia's Forest Ecosystems

T5.29 Role of university and experimental forests in the forest education and long-term forest research

Jorge Andres Ramirez Correa[1]
Paola Andrea Torres-Andrade[1], Edilber Sebastian Guerrero[1], Diana Camila Zuñiga Buitron[1], Luisa Fernanda Macias Moreno[1], Juana Maria Mutiz Susapanta[1], Marien Vanesa Perez Joaqui[1], Jhoan Mateo Tobón Idrobo[1], Juan Manuel Perdomo Duran[1]
[1] Universidad del Cauca

Abstract: Research seedbeds have emerged as a learning strategy that allows students to address real technical problems through autonomous learning, collaborative work, and the production of scientific knowledge under the guidance of seedbed tutors. In 2018, the Seedbed for Applied Silviculture was established within the Forest Engineering program at the University of Cauca in Popayan, located in the southwestern region of Colombia with the aim to consolidate the scientific initiation of forestry students. The southwestern region of Colombia encompasses diverse natural forest ecosystems and forest plantations, offering significant research opportunities. However, it also present substantial challenges in terms of conservation and management. Currently, the seedbed consists more than 20 students at different stages of their academic careers, all engaged in research across four main lines of investigation: 1) Native species propagation for ecological restoration of degraded areas, 2) Assessment of the impacts of forest plantation establishment on flora, fauna, and landscape in cattle ranches of southwest Colombia, 3) Exploration of the dendrochronological potential of native species for hydroclimatic reconstructions and forest management planning, and 4) Silviculture, management, and wood technology of native Podocarpaceae species for their utilization in commercial timber, biomass, and pulp production. The seedbed has successfully supported the completion of nine undergraduate theses, involving a total of 15 students. Additionally, the progress of three ongoing master's theses, and the preparation of six research papers, which have been submitted to peer-reviewed journals and are currently undergoing the process of review. Engagement in the seedbed has resulted in benefits for students' academic performance, as evidenced by improved grades in their courses, increased opportunities to pursue advanced studies at the master's level, and enhanced employability. Our experience with the seedbed demonstrates that this learning approach strengthens investigative skills through collaborative work, motivating students to delve deeper into their fields of study through research, diverging from traditional formalist methodologies in classrooms.

The training and experimental forests in Estonia ─ more than 100 years of experience

T5.29 Role of university and experimental forests in the forest education and long-term forest research

Paavo Kaimre[1]
[1] Estonian University of Life Sciences, Chair of Forest and Land Management and Wood Processing Technologies

Abstract: Higher forestry education started in Estonia in 1920, when the Department of Forestry was established at the University of Tartu. It only took a year, and already the students had the opportunity to do summer courses in the university's own training forest.
The presentation gives an overview of the role of the Järvselja training and experimental forest, which is inextricably linked to higher forestry education in Estonia. The presentation is based on numerous writings written by different authors about this symbolic object of Estonian forestry. The changing role of training and experimental forests in different decades is discussed, starting from the initial concept and gradually moving today's position in forest science and education. Moreover, in addition to the academic contribution, at certain decades the training and experimental forest centre transformed to the centrum of the local community.
Using the example of the Estonian University of Life Sciences, the management and operating model of the forest centre is shortly described and analysed. Approximately 10,500 ha of forest owned by the university is managed by an independent foundation. The strengths of the symbiosis between the university and the forest centre can be highlighted as the continuity of long-term research, the preservation of experimental areas and continuous monitoring, which can unfortunately sometimes be interrupted in commercial forests.
Activities in the current century are characterized by new research directions and the establishment of modern infrastructure for this purpose, e.g. the Station for Measuring Ecosystem-Atmosphere Relations (SMEAR) and Free Air Humidity Manipulation (FAHM) experimental site.
The experimental forests serve as a micro-model of sustainable forest management, where a balance is sought between management, nature conservation, social and cultural activities. Over the course of a century, related organizations have been reorganized and generations of researchers have changed, but the goals of the partners have remained largely the same: to provide new knowledge about forests and their management.

Universitas Padjadjaran arboretum offers biodiversity resources for long-term research and education

T5.29 Role of university and experimental forests in the forest education and long-term forest research

Dina Oktavia[1]
Desty Pratiwi[1], Santi Dwi Pratiwi[2], Susanti Withaningsih[3], Joko Kusmoro[3], Budi Irawan[3], Teguh Husodo[3]
[1] Department of Transdisciplinary Sciences, Graduate School, Universitas Padjadjaran, Jl. Dipati Ukur No. 35, Bandung 40132, Indonesia
[2] Department of Geosciences, Faculty of Geological Engineering, Universitas Padjadjaran, Jl. Raya Bandung-Sumedang Km.21, Sumedang 45363, Indonesia
[3] Department of Biology, Faculty of Mathematics and Natural Sciences, Universitas Padjadjaran, Jl. Raya Bandung-Sumedang Km.21, Sumedang 45363, Indonesia)

Abstract: Higher Education Institutions (HEIs) can contribute to protecting biodiversity by undertaking conservation projects within their campuses or nearby areas. The Universitas Padjadjaran (Unpad) in West Java, Indonesia, is an example of a HEI that has established an arboretum within its main campus, covering an area of approximately 10 hectares. West Java is also one of the most biologically diverse regions in Indonesia, with a rich variety of flora and fauna. The arboretum has developed various ecosystems over the past two decades, including farmland, lakes, and forest with four springs which provide various ecosystem services. This arboretum has been found to be home to a diverse range of plant and wildlife. There are several collections of endemic plants such as *gayam* (*Inocarpus fagifer* (Parkinson ex F.A. Zorn) Fosberg), *bisbul* (*Diospyros discolor* Willd.), *kecapi* (*Sandoricum koetjape* (Burm.f.) Merr.), *lame* (*Alstonia schoolaris* (L.) R.Br. and *lobi-lobi* (*Flacourtia inermis* Roxb.). Interestingly, ten species of bamboos in Arboretum Unpad have been identified and consisted of four genus such as *Bambusa*, *Gigantochloa*, *Phyllostachys*, and *Schizostachyum.* We have documented 46 birds, 9 amphibians, 16 reptiles, and 16 butterflies. The arboretum is also as corridor for migratory for raptor groups such as crested honey buzzard (*Pernis ptilorhynchus*), Chinese sparrowhawk (*Accipiter soloensis*), crested goshawk (*Accipiter trivirgatus*). Some species as food sources for birds such as *Ficus benjamina* L., *Ficus fistulosa* Reinw. ex Blume, *Antidesma bunius* (L.) Spreng., and *Canarium indicum* L. The high biodiversity present on the campus provides an excellent opportunity for young scientists to conduct long-term research. To ensure the sustainability of such research programs, the establishment of a forest dynamic plot is crucial. Additionally, to promote biodiversity knowledge and encourage conservation efforts, ecotourism programs were provided to the public which can have a significant impact on society. Consequently, universities are not only focused on providing quality education but also on establishing a more environmentally friendly campus environment to gain a competitive advantage. It is essential to note that investing in sustainability can lead to significant cost savings for universities in the long term.

T5.30 Simulation and automation in modern forest operations

A discrete-event simulation approach to evaluate harvesting operations on steep terrain with winch-assisted mechanized felling and grapple yarding

T5.30 Simulation and automation in modern forest operations

Marco Contreras[1]
Carlos Hermosilla[1]
[1] Instituto de Bosques y Sociedad, Facultad de Ciencias Forestales y Recursos Naturales, Universidad Austral de Chile

Abstract: Harvesting operations in steep terrain in Chile are typically performed by manual felling and traditional cable yarding systems. Due to increasing concerns to improve workers' safety and productivity levels, fully mechanized operations are increasingly being adopted. In these operations, felling is performed by winch-assisted shovel loggers and yarding by skylines systems with grapple carriage. In these systems, the shovel logger is tasked with felling and bunching trees and placing piles directly under the yarding line, and shoveling piles to subsequent adjacent felling lines. We developed a discrete-event simulation approach to simulate the harvesting operation by replicating the complete work sequence of both machines. The approach requires the following inputs: i) an implicit field observation-based abstraction of the machines' work to define work cycles and the manner in which machines move throughout the harvest unit, ii) estimation of lines installation times and of machine work times for both machines, iii) digital georeferenced layers including a digital elevation model, planned felling and yarding lines containing the sequence in which machines will operate along these lines, and tree locations with volume data per tree, and iv) general parameters of both machines. The approach generates: i) digital layers including tree assignments to work positions (locations from which the machine while stationed is felling, pilling, or shoveling trees without travel), felling lines, yarding lines, and volume piled under each 5-m segments along yarding lines, and ii) shovel logger reports with estimations of work time (PMH), felled and shoveled volume (m^3), and productivity (m^3/PMH) aggregated by work position, felling line and day, and yarder reports with work time (PMH), volume (m^3), and productivity (m^3/PMH) aggregated by 5-m yarding segments, yarding line and day, and final report with productivity and operating time (PMH) required to harvest the unit. The approach was implemented as an add-in for ArcGIS Pro V2.4 and applied to a timber harvest setting in south-central Chile to show its functionality. The iterative use of the approach can be used to evaluate alternative placement and the number of felling and yarding lines as support decision-making on operational timber harvesting planning on steep slopes.

Application of mathematical models for the optimization of harvestable wood of the species Clathrotropis brunnea Amshoff.

T5.30 Simulation and automation in modern forest operations

Leidy Tatiana Bermejo Cabrera[1]
Angela Bibiana García Higuera[1]
[1] Universidad Distrital Francisco José de Caldas, Bogotá (Colombia)

Abstract: Mathematical models for timber volume optimization in Colombia are a tool that have been recently explored, given the need to promote solutions that contribute to the planning and management of timber resources, it's considered essential to promote these tools in forest management areas in order to provide information on native species of economic importance, facilitating the efficient use of resources and ensuring sustainable use.

The main objective of this research was to propose a prescriptive mathematical model based on linear programming principles for the allocation of cutting patterns, maximizing the volumetric yield of Clathrotropis brunnea logs. With the cubing data obtained in the field, a tapering model was adjusted to predict the diameter at any height of the trunk, in this way a cutting simulator was designed in MATLAB software version 9.3 that integrates in a script the mathematical modeling, where the user defines the length of the log and in an automated way the program assigns efficiently the cutting patterns according to the diametric class.

The result was the adjustment of the tapering model capable of explaining 85% of the data that make up the forest profile of the species, where the root mean square error (RMSE) was 4.02, the mean absolute error (MAE) was 2.95 and the predictive efficiency indicator was 89%.

It was possible to identify that the proposed model presents increases of up to 20% in volumetric performance. The results of this research are remarkable because they provide methodological and practical elements in the use of mathematical models as planning tools in harvesting, facilitating the analysis for trees of the same species, allowing to know before harvesting the commercial volume of individuals, the amount and types of products that are generated considering or not a market demand, with this method the subjectivity of the decision makers is eliminated and an adjustable cutting plan is provided according to the user's requirements.

Automation of the measurement process of stacked roundwood – Past milestones, current status and perspectives

T5.30 Simulation and automation in modern forest operations

Felipe De Miguel-Díez[1]
Thomas Purfürst[1]
[1] University of Freiburg, Chair of Forest Operations, Germany

Abstract: The measurement of roundwood plays a crucial role in its acquisition phase, since the volume is the basis for billing. As the costs derived from the acquisition process range approximately from 60% to 85% of the final product costs, the accuracy in this process is of utmost importance. In addition, the measurement of roundwood is a further important aspect to quantify the stored carbon (CO_2) extracted from those forest stands in the current context related to climate change.

In many countries, this process takes place in landings. Traditionally, the stack volume has been estimated using manual methods. Moreover, the real volume of stacked roundwood has been measured manually by adding the individual volume of each stacked log or estimated using conversion factors, which were calculated empirically based on statistical bases. Those statistical bases were limited due to the high costs required for collecting sufficient data. Thus, those traditional methods were costly, time-consuming and prone to provide inaccurate estimations.

However, the successive implementation of new technologies has increased the accuracy of the estimations of the gross and net volumes of the stacks as well as the efficiency of the measurement process, estimating the gross volume of the stacks in shorter periods. Whereas the photogrammetric methods have been providing reliable estimations of the gross volume as well as the stacking densities for the last years, LiDAR data-based methods have newly been developed, which also provide reliable stack volumes. 3D simulation models have recently been developed to estimate reliable and accurate specific conversion factors for each tree species and assortment based on wide statistical bases. Finally, the implementation of Artificial Intelligence in this field is currently emerging and crystallizing in new promising automatic methods for reliably estimating the gross and net volumes of the stacks.

This presentation will offer the audience a comprehensive overview of the methods currently used in Europe and America for measuring the stacked roundwood, a historical review and the perspectives and potential concerning the development of new measurement methods in the near future. Moreover, the main advantages and disadvantages of the methods will be described.

Digitalized and (semi-) automated design of cable roads by combining different sources of geospatial data and high precision mechanical analysis

T5.30 Simulation and automation in modern forest operations

Leo Bont[1]
Laura Ramstein[1], Patricia Moll[2], Janine Schweier[1]
[1] Swiss Federal Research Institute WSL, Zürcherstrasse 111, 8903 Birmensdorf, Switzerland
[2] CH 5600 Lenzburg SWITZERLAND

Abstract: Cable-based technologies have been a backbone for harvesting on steep slopes. The planning of a cable road is a complex task. It essentially comprises the definition of the start and end points of a cable road, as well as the intermediate supports. It must be ensured that the permissible forces (in particular skyline tensile forces) are not exceeded, that there is a sufficient clearance between the load path and the ground, that suitable anchor trees are found and that at the same time the number of intermediate supports is minimised as far as possible. On the other hand, for ergonomic and silvicultural reasons (work safety, damages to the forest), the skyline should be as high as possible. In practice, the search for a solution is often iterative; especially with long lines, several attempts may be necessary until a good line is found.

We will present a QGIS plugin ("Seilaplan") that assists in designing cables roads by searching automatically for the optimal cable road layout. However, it also allows a manual editing of the cable road. As the plugin is embedded in a GIS system, elevation data can easily be accessed and incorporated. Further, of particular relevance is also the integration of individual tree data and vegetation height models in order to identify suitable supports and anchor trees already in the office. The plugin is designed for Central European conditions and assumes a standing skyline (fixed anchored skyline at both ends). For the calculation of the mechanical properties of the skyline a close to catenary method is used. When testing the feasibility of the cable road, care is taken that 1) the maximum permissible stresses in the skyline are not exceeded, 2) there is a minimum distance between the load path and the ground and 3) when using a gravitational system, there is a minimum inclination in the load path. The newly developed method calculates the load path curve and the forces occurring with a high accuray.

The presented qgis plugin is a key element towards digitalization in forest operations in steep terrain and already widespread in Switzerland.

Experts' preferences for future machine systems

T5.30 Simulation and automation in modern forest operations

Rikard Lundqvist
Bosko Blagojevic[1], Ola Lindroos[2], Petrus Jönsson[3]
[1] University of Novi Sad
[2] Swedish University of Agricultural Sciences
[3] Skogforsk

Abstract: The two-machine system, with the harvester and the forwarder, have dominated the Swedish logging operations during the last four decades. There have been attempts with other systems without wide success. Technology for automation, remote operations and other energy carriers than diesel have developed significantly in other sectors recently, opening for similar development of forest machines and systems. However, which technologies and which machine systems to combine them in, have not been evaluated recently. This study aimed to map potential future machine systems on concept level for logging costs 10 years from the study's data gathering, and further to provide a basis for decisions on which system has enough potential for further evaluations with a higher level of materialization. The study was designed with a Delphi-approach, where 10 participants anonymously answered questions on a website. The participants worked with development in forest companies, a forest owners association, and a forestry research institute. The questions were about: 1) Ranking which criteria they valued the most, such as safer working environment and lower total costs, when choosing future machine systems. 2) Grading the likeliness for statements about external factors state in 10 years, such as whether they agreed or disagreed that diesel would be more available and the availability for automation would increase. 3) Ranking of a set of machine systems with different combinations of technologies. The participants responded to each set of questions two times, and saw the groups average results from the first round, before they answered the second round. The results from the study will be presented, along with interpretations and planned steps towards an increased level of materialization for the most promising machine systems.

FOMO: A forest operations annotated image dataset

T5.30 Simulation and automation in modern forest operations

Christian Höök[1]
Ola Lindroos[1], Carola Häggström[1], Omar Mendoza-Trejo[1]
[1] Dept. of Forest Biomaterials and technology, Swedish University of Agricultural Sciences, Sweden

Abstract: FOMO-AID: An annotated image dataset for forest operations

The transformation of forest operations through the integration of computational technology and machine learning promises significant increases in efficiency and innovation. Yet, the full potential of these technologies, particularly computer vision (CV), remains untapped due to the scarcity of comprehensive, annotated image datasets for algorithm training. This limitation impedes automation, reliable decision support, and innovation in forest management.

To address this challenge, we are developing the Forest Operations Machine-Optimized Annotated Image Dataset (FOMO-AID). We are advancing the field of research with our novel image annotation methodology. This method involves augmenting the StanForD communication system of forest machines with data captured by onboard cameras. These images are then processed and automatically annotated, contributing to a more comprehensive understanding of the machines' operational environment.

The FOMO-AID dataset serves as a valuable resource for training and testing CV models, encompassing a broad range of forest conditions and operations. In the spirit of open science, we aim to openly publish the FOMO-AID dataset to stimulate innovation and encourage the adoption of state-of-the-art CV technology in forest operations.

Global route planner adapted for autonomous forest regeneration of mixed tree species

T5.30 Simulation and automation in modern forest operations

Erik Arvidsson[1]
Magnus Karlberg[1], Håkan Lideskog[1], Torbjörn Lindbäck[1], Karin Hjelm[2]
[1] Luleå University of Technology, Department of Engineering Sciences and Mathematics, Sweden
[2] Swedish University of Agricultural Sciences, Southern Swedish Forest Research Centre, Sweden

Abstract: Introducing mixed species stands offers a promising solution to mitigate the risks associated with monocultures and unlock a multitude of benefits. However, the implementation of such stands presents its own set of challenges, including the need for complex management and increased costs.

One way to overcome these challenges is to introduce autonomous forest regeneration systems. Through high sensing capabilities and precise auxiliary tools, such systems will have the capabilities to manage the intricate variations within the site and incorporating mixed species stands.

Through the research presented in this paper, a specialized route planner has been developed specifically for the sequential planting of mixed tree species. Based on pre-generated maps of areal tree species distribution, this planner generates routes taking machine properties, such as seedling capacity, arm reach, and turning radius into account. These routes should enable the required autonomous regeneration work in such a way that the pre-generated species distribution is achieved with low climate footprint and still with high efficiency.

The assumption was made that the autonomous forest machine can smoothly transition between different species, and the seedlings are picked from cassettes. The machine has a limited capacity for accommodating a certain number of cassettes. Prior to executing the planting in a specific area of the stand, the machine provides information on which cassettes should be loaded.

Results show that the routes are planned so that the vehicle does not drive over sections where planting has already taken place or other no-go areas, while still being able to perform the regeneration task.

It can be concluded that the route planner developed in this research enable sustainable autonomous precision forest regeneration.

Learning forwarder trafficability from real and synthetic data

T5.30 Simulation and automation in modern forest operations

Mikael Lundbäck[1]
Arvid Fälldin[1], Erik Wallin[1], Martin Servin[1]
[1] Umeå University

Abstract: Forwarder trafficability is a function of terrain and vehicle properties. Predicting trafficability
is vital for energy efficient planning- and operator-assisting systems, as well as for remote and autonomous driving. Inaccurate or insufficient information can lead to inefficient paths, excessive fuel usage, equipment wear, and soil damages. Training trafficability models require data in a quantity hard to collect solely from in-field experiments, especially considering the need for data from situations ranging from very easy to non-traversable.

To circumvent this problem, we perform in-field system identification for a forwarder in the Nordic cut-to-length system, to obtain a calibrated multi-body dynamics simulation model traversing firm but potentially rough and blocky terrain. By letting the real-world forwarder drive in very difficult terrain, the model is able to reflect a wide range of real conditions. The model is used in simulations, where collecting large amounts of data from a variety of situations is easy, cheap, and hazard free. Using this data, a deep neural network is trained to predict trafficability in terms of attainable driving speed, energy consumption, and machine wear.

The resulting predictor model uses laser scanned terrains to efficiently produce trafficability measures with high fidelity and accuracy, e.g., depending on the vehicle's precise location, speed, heading, and weight. Trafficability on wet and weak soil is not addressed in this work. The predictor model is machine specific, but general enough for practical application in diverse terrain conditions. Our emphasis on energy consumption enables elaborate calculations of emissions, profoundly contributing to sustainable forest operations. Apart from the benefits from reduced emissions, the model can also be used to optimize extraction trail routing, which is a major contributor to the total extraction cost. Rough terrain trafficability is only part of an optimal route, but it has been neglected in previous research. We see big potential in combining our predictor model with existing route optimization methods to achieve a more complete result. By creating an open library of annotated machine data and code for preparing input terrain-data and running the trafficability model, we enable adoption of the results by others and application in existing and new software.

Optimizing Support Systems for Cut-To-Lenght Machine Operators - Current Use and Future Visions

T5.30 Simulation and automation in modern forest operations

Heli Kymäläinen[1]

[3] Metsäteho Ltd

Abstract: Cut-to-length (CTL) timber harvesting machines have information systems, assisting systems, and decision support systems to help the operators with productivity and overall operational performance. These support systems alongside machine engineering and harvest work implementation are associated with ergonomics, and they have the power to increase or decrease operators' work ability, productivity, and work fluency with exact and essential or overwhelming and irrelevant information. Timber harvesting operations have a clear demand for easing the harvesting work, lowering the threshold for beginners, and supporting professionals to longer their work careers. Gaining a deeper understanding of operators' perspectives on technical development and solutions can help address and overcome the challenges in the CTL machine development work toward automated systems. This study investigates decision-support systems currently used by operators, how they utilize them, the difficulties they encounter in their daily work, and their visions for the future support systems based on their experiences.

The study utilizes elements of the contextual interview method by interviewing operators via phone while they are actively working. This approach allows operators to connect their thoughts and experiences closely with their work, which makes it easier for participants to explain and demonstrate tasks while working. Furthermore, it prompts participants to discuss tasks or actions that they may overlook or forget to mention in a traditional interview setting. The interview questions cover topics related to current work methods, work demands, and work challenges, and the interviewees rate different future visions of technical solutions and assisting technologies on a scale of -3 to +3. The participants selected for this study are based in Finland and operate either new or relatively new machines to ensure their familiarity with the latest technological advancements. The participants' age and work experience vary.

This study highlights the operators' perspective on the future visions of the CTL machines, the development needs for automatization, and improved human-machine interaction. The research results provide insights into the operators' viewpoint regarding the effectiveness of the existing (decision) support systems and technical solutions, as well as challenges and obstacles on operational performance and productivity.

Pathfinder – A decision support tool for operational planning of integrated mechanical site preparation and planting on forest regeneration areas

T5.30 Simulation and automation in modern forest operations

Mikael Rönnqvist[1]
Patrik Flisberg[2], **Linnea Hansson**[2], Fredrik Johansson[2], Rasmus Sörensson[2], Petrus Jönsson[2]
[1] Département de génie mécanique, Université Laval, Canada
[2] Skogforsk, the Forestry Research Institute of Sweden, Sweden

Abstract: Manual planting is arduous and mechanical site preparation includes a high dose of whole-body vibrations when traversing the terrain. At the same time, there is an evident lack of skilled labor in silviculture operations in boreal forestry. Efficient regeneration methods are crucial to sustainable forestry, and in Sweden, where 99% of the planting is manual, the interest in mechanized planting is rising. Autoplant is a collaborative project among Swedish forest companies, manufacturers and researchers within silvicultural technology. The aim is to develop an integrated autonomous scarifying and planting system with high precision, low environmental impact, and a good work environment. A decision support tool, Pathfinder, was developed for the operational planning of the forest regeneration, including route planning for the machine. Pathfinder consists of two modules. The first module relies on harvester production data, digital elevation models, depth-to-water maps, soil data and so-called no-go areas for culture or nature conservation. It proposes the net area that will be subjected to scarification and planting, as well as which species to plant in different zones of the area together with desired density. The second module uses the output from the first (boundaries of the net area and plant density) together with DEM (critical slope), forcing passages (e.g., temporary bridges), and machine data (e.g., machine working width, maximum slope, loading capacity, and time for U-turns) as input. There are various factors to consider when improving route efficiency for the machines, among which minimizing the number of U-turns is crucial. A multi-step solution approach is developed to find optimal routes. The main steps include finding common directions of slope, combining shorter paths into longer and then combine them into full routes. Finally, the model suggests a set of vehicle routes considering planting and/or fuel capacity of the machine. These routes make up the overall planting solution that the machine follows, either autonomous or with an operator. The tool is tested on clearcuts throughout Sweden (3-10 ha). The results have been validated in the field both by researchers and forest owners.

Pioneering Automation in Forestry: AORO's Crane Automation Journey and Implications

T5.30 Simulation and automation in modern forest operations

Pedro La Hera[1]
Omar Mendoza-Trejo[1], Ola Lindroos[1], Håkan Lideskog[2], Torbjörn Lindbäck[2], Magnus Karlberg[2]
[1] Swedish University of Agricultural Sciences, Department of Forest Biomaterials and Technology, Sweden
[2] Department of Engineering Sciences and Mathematics, Luleå University of Technology, Sweden

Abstract: In recent years, automation technology has been transforming various industries, and now it has reached the realm of forestry with the groundbreaking development of AORO – the world's first fully unmanned forestry machine capable of performing forwarding tasks without human supervision. This achievement marks a significant milestone in the evolution of forestry operations and holds immense potential for revolutionizing the industry.

AORO is equipped with an array of sensors integrated into both the vehicle and the crane, enabling it to operate autonomously. Leveraging a range of advanced robot algorithms, including computer vision, localization, object recognition, and motion control strategies, AORO achieves full autonomy by enabling precise navigation and crane control.

In this engaging presentation, we will provide a comprehensive overview of the process involved in automating the crane of AORO, which is the culmination of nearly two decades of research. We will delve into the intricacies of the various sensors and algorithms employed to accomplish this feat. By elucidating the technical details, we aim to offer attendees a deeper understanding of the complex automation systems that underpin the functionality of forestry cranes.

To support our claims and illustrate the capabilities of AORO, we will present experimental results obtained during the development process. These results will not only serve as evidence of the progress made but also highlight the challenges encountered along the way. Moreover, we will outline the innovative solutions that were devised to overcome these obstacles, showcasing the ingenuity and adaptability of the research consortium.

Beyond the specific achievements of AORO, our presentation will address the broader implications of automation technology in the forestry industry. Drawing parallels with similar algorithms implemented in industrial setups, we will underscore the potential for automation to revolutionize forestry operations. By reducing the reliance on human intervention, automation can enhance efficiency, minimize safety risks, and optimize resource utilization. We will discuss the transformative impact that automation can have on the forestry industry, paving the way for a more sustainable and productive future.

SENSING TECHNOLOGY AND AI ALGORITHMS FOR DETECTING TREE QUALITY FEATURES AND OPTIMIZING BUCKING DURING HARVESTING OPERATIONS

T5.30 Simulation and automation in modern forest operations

Mauricio Acuna[1]
Covadonga Prendes[2], Jan Rombouts[3]
[1] Natural Resources Institute (LUKE), Finland
[2] CETEMAS, Spain
[3] OneFortyOne, Australia

Abstract: Achieving the highest value from a plantation resource is reliant on quality, timely and accurate measurement of key-value influencing tree quality features (e.g. sweep, branchiness) to support optimized stem bucking decisions. Due to the difficulties associated with the measurement of tree quality features in the field during forest inventory work, these attributes are usually excluded from optimal bucking procedures. At harvest time, in addition to diameter and length measurements, current onboard machine optimization systems rely on operator assessment of other key features like stem sweep, limb diameter, limb angle, and internal characteristics like stiffness and strength. These repeated observations, judgments and operations performed by the operators may result in reduced productivity and value losses. Emerging and new sensing technology like LiDAR, photogrammetric point clouds, and high-definition stereo imaging, represents an opportunity to leverage more accessible and affordable data collection to capture some of the factors that are currently estimated by operators with accurate measurements and improve the value recovery.

In our study, we present a non-destructive, automated methodology to optimize stem bucking based on point cloud data acquired with a mobile laser scanner (Hovermap LiDAR system), which maximizes tree value. The raw point cloud was processed with machine learning algorithms, which enabled the automatic detection of the trees in the plot as well as the estimation of diameters at different tree heights and stem sweep. This information was then used as an input to a dynamic programming bucking algorithm which optimized the value of each tree based on market and tree data. The methodology was tested on two Radiata pine plots located in South Australia, consisting of about 50 trees each. The bucking results were compared for three sets of input data: two generated from point cloud data collected with the LiDAR scanner (including and excluding sweep) and one generated from a taper equation based on manual DBH measurements. The metrics used for the comparison included total value, value per product, total volume, volume per product, and the number of logs per product.

Spur road segmentation using text-to-image synthesis for autonomous driving in forest machinery

T5.30 Simulation and automation in modern forest operations

Kengo Usui[1]
Takayuki Ito[1], Yuta Inomata[1]
[1] Forestry and Forest Products Research Institute

Abstract: Sustainable forestry operations require addressing safety and workforce challenges, leading to an interest in automation. Autonomous driving in forwarding is a key topic in forestry automation. Safe navigation along the planned path is critical for successful autonomous driving. To achieve accurate autonomous driving, it is necessary to obtain precise information in each navigation process, including sensing and path planning. However, conventional self-localization methods such as Global Navigation Satellite Systems or Simultaneous Localization and Mapping (SLAM) face limitations in a forest. Moreover, it is essential to keep redundant sensing for secure autonomous driving to avoid excessive dependence on single self-localization.

To address these challenges in autonomous driving for forestry, this study proposes a vision-based road segmentation system. The information on the road region serves not only as corrective information during path planning but also as features in SLAM, with broad applicability in autonomous driving in a forest.

The study aimed to develop a system for estimating the drivable area on a spur road using camera images to provide information for self-localization and path planning. Road detection in a forest has already been proposed by using machine learning. However, it is labor-intensive to create a dataset for segmentation. Thus, the proposed method uses text-to-image synthesis to simplify the preparation of the dataset by generating road images in a forest from text and labels. Additionally, it is easy to add the external class to the dataset using text-to-image synthesis. Therefore, the proposed method aims to estimate not only the road class but also the road-edge (buffer) class.

The results showed that the model trained on the dataset combined with the synthesized and real images achieved satisfactory accuracy of 40.8% in the intersection of union for spur road segmentation. A comparison with a dataset from a real forest indicated a 2.24-point improvement in estimation for the newly added class.

In conclusion, this study presented a method for spur road segmentation with easy dataset preparation, thereby contributing to the advancement of autonomous driving in forestry machinery.

Towards autonomous forwarding using deep learning and simulation

T5.30 Simulation and automation in modern forest operations

Arvid Fälldin[1]
Mikael Lundbäck[1], Martin Servin[1], **Erik Wallin**[1]
[1] Umeå University

Abstract: Fully autonomous forwarding is a challenge, with more imminent scenarios including operator assistance, remote-controlled machines, and semi-autonomous functions. We present several subsystems for autonomous forwarding, developed using machine learning and physics simulation,
- trafficability analysis and path planning,
- autonomous driving,
- identification of logs and high quality grasp poses, and
- crane control from snapshot camera data.

Forwarding is an energy demanding process, and repeated passages with heavy equipment can damage the soil. To avoid damage and ensure efficient use of energy, it is important with a good path planning, adapted speed, and efficient loading and unloading of logs. The collection and availability of large amounts of data is increasing in the field of forestry, opening up for autonomous solutions and efficiency improvements. This is a difficult problem though, as the forest terrain is rough, and as weather, season, obstructions, and wear present challenges in collecting and interpreting sensor-data.

Our proposed subsystems assume access to pre-scanned, high-resolution elevation maps and snapshots of log piles, captured in between crane cycles by an onboard camera. By utilizing snapshots instead of a continuous image stream in the loading task, we separate image segmentation from crane control. This removes any coupling to specific vehicle models, and greatly increases the limit on computational resources and time for the challenge of image segmentation. Log piles are normally static except at the grasp moments and given good enough grasp poses, this lack of information is not necessarily a problem.

We show how snapshot image data can be used when deploying a Reinforcement Learning agent to control the crane to grasp logs in challenging piles. Given pile RGB-D images, our grasp detection model identifies high quality grasp poses, allowing for multiple logs to be loaded in each crane cycle. Further, we show that our model is able to learn to avoid obstructions in the environment such as tree stumps or boulders. We discuss the possibility of using our model to optimize the loading task over a sequence of grasps.

Finally, we discuss how the solutions can be combined in a multi-agent forwarding system with or without a human operator in-the loop.

Will the harvester-forwarder system continue to dominate in Sweden?

T5.30 Simulation and automation in modern forest operations

Anders Rowell[1]
Rikard Lundqvist, Petrus Jönsson[1], Jussi Manner[1], Lars Eliasson[1], Ola Lindroos[2]
[1] Skogforsk, Forest Research Institute of Sweden, Uppsala, Sweden
[2] Department of Forest Biomaterials and Technology, Swedish University of Agricultural Sciences, Umeå, Sweden

Abstract: In Sweden, the cut-to-length logging system consisting of a harvester and a forwarder has dominated harvest operations since the late 80s. Its adaptability to harvesting conditions, such as tree size, terrain, and product specifications, as well as the low interdependence between the harvester and forwarder, are often quoted success factors. However, with advancements in automation, energy carriers, and remote control, emerging machine systems may challenge the supremacy of the harvester-forwarder system.

Our study will support decision-making by simulating alternative machine systems and assessing their viability for further evaluation – in a higher degree of materialization. These discreet event simulations will be conducted using the ExtendSim software. The analysis will incorporate existing productivity functions developed for harvesters and forwarders, as well as the harwarder system whenever relevant. Operating times and downtimes will be modeled using extensive datasets from harvest operations. To estimate the costs associated with each simulated system, we will collaborate closely with forest officials and machine manufacturers.

We will share the potential of the simulated systems and whether further evaluation is recommended. Our study will provide new insights and a foundation for future research and development.

T5.31 Taking advantage of technology in education

A Bibliometric Analysis of the Economics of Restoration Field

T5.31 Taking advantage of technology in education

Maria Luiza Almeida Luz[1]
Daniel Moura da Costa Teixeira[2]
[1] Laboratory of Built Environment, Inclusion, and Sustainability (LACIS), University of Brasilia, Brazil
[2] Department of Economics, University of Brasilia, Brazil

Abstract: Bibliometrics is a method for monitoring, measuring, and studying bibliographic data, and it offers valuable insights into the past, present, and future trends in academic literature. This paper presents a bibliometric analysis of the Economics of Restoration as an example of the use of bibliometrics in forest-related disciplines. The analysis focuses on co-authorship, direct citation, co-occurrence, co-citation, and bibliographic coupling networks to explore the dynamics of the Economics of Restoration. While bibliometric studies have been conducted on various topics in environmental sciences and economics, limited research has focused specifically on the Economics of Restoration field. By conducting a comprehensive bibliometric analysis using multiple databases, including Web of Science, Scopus, and Lens, key authors, documents, themes, countries, and productive journals in the field of the Economics of Restoration are identified. The analysis utilizes bibliometric maps made with VOSViewer software. Co-authorship links reveal patterns of collaboration among authors, countries, organizations, or journals, while direct citation links provide insights into the relevance of documents, authors, or journals. Co-occurrence links identify important topics addressed in publications, and co-citation and bibliographic coupling links offer valuable information about the core documents and emerging research topics within the field. The results demonstrate how the application of bibliometrics in the Economics of Restoration provides insights into the evolution of the field, from conceptual and methodological developments to addressing pressing topics such as forest and landscape restoration challenges, climate change, and land use change. Moreover, the analysis highlights advancements in economic valuations and cost-benefit analysis, emphasizing the measurement of benefits derived from restoration efforts. This bibliometric analysis serves as an example of the potential of bibliometrics in forest-related disciplines. It showcases the power of bibliometric techniques in tracking and analyzing research progress, identifying research gaps, emerging trends, and potential areas for future exploration within the field. By employing bibliometrics, policymakers, educators, and researchers in forest-related disciplines can make evidence-based decisions regarding research policies, funding allocation, and curriculum development. Ultimately, the integration of bibliometrics in forest education can facilitate evidence-based decision-making and foster the advancement of knowledge in forest-related disciplines.

Boosting Digital Skills & Competencies in Forest Education: the FOREE Erasmus+ project for digital technologies integration in forest training sector

T5.31 Taking advantage of technology in education

Alessio Surian[1]
Stefano Grigolato[2], Alessia Portaccio[1, 2], Luca Saccone[1], Marie-Charlotte Hoffmann[3], Thilo Wagner[3], Visnja Koscak[4], Martin Krondorfer[4], Dagmar Karisch-Gierer[4], Helga Pretterhofer[4], Kairit Reiman[5], Hanna Zuba-Reinsalu[5]

[3] Forestry Education Center, Landesbetrieb Wald und Holz NRW, Arnsberg, Germany
[4] Holzcluster Steiermark GmbH, Graz, Austria
[5] Adult Training Center, Luua Forestry School, Estonia

Abstract: Among the top priorities of the European Policy Agenda there is the enhancement of digital skills and competences for work and life. Indeed, digital technologies improve methods of processing, storing, and transmitting information, while contributing to the creation of knowledge and fostering progress. The forest education sector would benefit by the integration of digital technologies. However, it is important to identify first the issues and the opportunities of partial or total digitalisation, to understand the place of digital technologies in the chain of converting information into knowledge, skills, and competences and to define the ways to support the form and content of the knowledge transfer process.

The Erasmus+ 'FOREE - Boosting Digital Skills and Competencies in Forest Education' project aimed at overcoming the reservations of forestry teaching staff towards digital teaching through knowledge exchange and innovative approaches for conceptualization and implementation of e-learning formats, and at improving further the skills of combining digital learning formats and contents with on-site teaching.

Specifically, the objective of FOREE was to develop National guided pilot Train-the-Trainer course (ToT) and MOOC on blended learning models to guide the transition of the European forestry education sector from purely classroom/field-based courses into a flexible hybrid education system through the complementary use of digital learning concepts, tools and platforms and their broad application in adult forestry training courses. Additionally, the project developed an online and free-access toolbox reporting the information on the main digital tools and technologies with regards to their applicability to the forest education sector, helping the trainers to identify the best options for their teaching activities.

The FOREE Erasmus+ project consortium involved five organisations of four European countries (Italy, Estonia, Germany, Austria), including three forest education centres, one university with excellence in blended learning models and a cluster organisation with competence in digital transformation. The project's results are scalable at the European level.

Cocreating simulator based training of forest machine operators

T5.31 Taking advantage of technology in education

Carola Häggström[1]
Mathias Kristoferqvist[2]
[1] Swedish university of agricultural science, Department of forest biomaterials and technology, Sweden
[2] Swedish university of agricultural science, Department of forest resource management, Sweden

Abstract: Many Swedish forest machine training programs utilize forest machine simulators for skills training. However, these simulators don't support the training of the economical and biological effects from harvesting. Moreover, many schools lack knowledge and experience on how to utilize this training tool efficiently with the students' learning in mind. Thus, since 2016, SLU has worked together with two training schools in Sweden to develop the simulator based teaching and training and increase the skills level of the future workforce. Through an ethnographic approach, new simulator features, harvesting scenarios and classes were developed and evaluated. The classes encompassed a bland of theoretical instruction, machine simulator training, and utilization of a secondary simulator (Heureka) for the evaluation of long-term ecolocigal and economic implications of previously managed individual stands. Initially, machine instructors found the machine simulators insufficient and unnecessary, and the pupils' simulator training was restricted. Moreover, simulators were insufficient in supporting the needs of both teacher and pupil. However, by the combined coreative process, attitudes were changed, training was improved, simulator features developed, and both safety and skills were enhanced. Variations between schools and trainers resulted in checklists for successful simulator training, several simulator-training classes, and an open Swedish web-portal for forest machine simulator classes joining all forest machine training schools in the country. While improving the simulators and their usage, the education of new forest machine operators have improved and the satisfaction of both students and teachers have increased.

Conversational Agents in Forest Education: Exploring their Innovative Role in the VirtualForest Project

T5.31 Taking advantage of technology in education

Maria Del Pilar Valbuena Pérez[1]
Felipe Bravo Oviedo[1, 2], Irene Ruano Benito[1, 2], Eduardo Gómez Sanchez[3]
[1] University Institute for Research in Sustainable Forest Management (iuFOR), University of Valladolid, Avda. Madrid 57, 34004 Palencia, Spain
[2] Department of Plant Production and Forest Resources, E.T.S. of Agriculture Engineering, Universidad de Valladolid, Palencia, Spain
[3] School of Telecommunications Engineering, Universidad de Valladolid, Spain

Abstract: Despite significant progress in recent years, the forest sector is seen as a late adopter of new Information and Communication Technologies. The Erasmus+ VirtualForests project (https://virtualforests.eu/) aims to address these issues by enhancing online, distance, and blended learning in the forest sector. It specifically focuses on increasing international student access to open educational resources in a sector that is currently underrepresented in online studies.

In virtualized university courses in forestry conversational agents can play a pivotal role in assisting students. These software tools use natural language processing to interact with humans, have proven successful in many educational contexts, including tutoring and question-answering.

As part of the VirtualForests project, a conversational agent has been developed using Google Dialogflow (https://cloud.google.com/dialogflow). It serves as a teaching assistant for the distance online course "Introduction to Forestry and Natural Resources" in the Joint European master's degree on Mediterranean Forestry and Natural Resources Management (MEDFOR, www.medfor.eu). It is designed to handle concepts related to forestry activities across various topics and can answer direct questions posed by the learner. In addition to providing initial responses, it can offer more information, give examples, highlight related concepts, and engage in small talk to interact more naturally with learners.

While the use of conversational agents is not a novel concept, the approach proposed in the VirtualForests project aims to leverage their ability to mimic human interaction. This is done to increase student engagement, reduce feelings of isolation, and enhance learning outcomes. They also alleviate the instructors' burden in solving simple but frequent doubts and are available 24/7.

At present, a preliminary knowledge domain has been implemented into Dialogflow and is being tested by domain experts. Conversation logs are analyzed to refine the knowledge domain, identifying missing relevant concepts, and considering alternative question formulations. Following this, the conversational agent will be made available to actual students, and its utility assessed. A different approach being explored deals with using generative AI to create virtual agents supporting a natural conversation while always providing accurate answers.

Keywords: Conversational agents, higher education, forestry, dialogflow

Digital online platforms for peer review of teaching - from individual teacher/ing to collective university education

T5.31 Taking advantage of technology in education

Mika Rekola[1]
Niclas Sandström[2], Anne Nevgi[3]
[1] University of Helsinki, Department of forest sciences, Finland
[2] University of Helsinki, Department of education, Finland
[3] Forum4edu, Helsinki, Finland

Abstract: Digital platforms have shown their power in several sectors of society - from Facebook to Amazon and from Airbnb to LinkedIn. Today online learning and course platforms are providing home for more than 100 thousand courses. Some of the platforms, such as edX and Coursera, are university origin and provide both non-credit short courses and formal education with degrees. Others, e.g. LinkedIn, are platforms for individuals and business educators offering non-certified non-academic education.

Despite rapid increase in the number of online courses online most of higher education is still typically taken place within an individual class taught by a university teacher through a learning management system (LMS) such as Moodle or Canvas. It is clear that the potential of providing Zoom and Teams teaching was enormously untapped during COVID era. However, after all this (r)evolution some main elements of the platform economy related to higher education are still in the waiting room.

University teachers typically work alone with their courses. This is an individual and introverted approach and is dramatically contrasted to the research approach. Presumably, teaching could utilize peer-review processes similar to research and also take advantage of modern co-creating tools akin to service design. It is likely that so-called peer-review of teaching (PRT) could be efficiently managed through digital online platforms.

PRT is a system for development, review or evaluation of university teaching by colleagues or university pedagogical experts (Zeng 2020). In most studies PRT has shown to have potential and usefulness for improving teaching. Unfortunately PRT has needed a lot of administrative resources at the university level. It is this structure with extra paper work in addition to the general, introverted attitude that has been an obstacle to using PRT.

This R&D project is exploring online forest education platforms in the spirit of PRT in the following services: teaching (academic) portfolios, critical friend matching, and shared and co-created learning materials such as a handbook of forest education. Forest education lacks behind STEM and business online education. This provides an opportunity to benchmark other disciplines before piloting PRT services.

Education and Training Using Virtual Reality Technology – an application in forestry

T5.31 Taking advantage of technology in education

Francesco Neri[1]
Irene Capecchi[1], Tommaso Borghini[2], Iacopo Bernetti[1], Enrico Marchi[1], **Elena Marra**[1, 3]

[2] Department of Architecture – DIDA, University of Florence, Florence, 50121, Italy
[3] Institute of Research on Terrestrial Ecosystems (IRET), National Research Council of Italy (CNR), Sesto Fiorentino, Italy

Abstract: Forest and wood harvesting operations are one of the industrial sectors with the highest risk of accidents at work. In semi-mechanized logging operations, the great majority of accidents generally occur using chainsaws during tree felling and processing operations. These situations frequently cause serious and often fatal injuries. In many cases, the accidents occurred to badly trained and inexperienced operators, with a short employment history. One solution to reduce these harmful events is to support workers employed in this sector with training applications. This research presents a description of a training program to operate with chainsaws in tree felling and processing operations using a Virtual Reality (VR) application called ForestVRoom. VR is a useful educational tool that can integrate conventional training methods due to its potential for providing an immersive experience associated with extensible and flexible interactions. This study amplifies the existing immersive VR technology and proposes a multi-user platform to improve the interaction between participants. ForestVRoom is a collaborative symmetric VR application that bases mostly on 360° videos as content. This innovative education method was compared to the traditional theoretical lesson based on a slide show and was validated with a specific qualitative user experience questionnaire with an internal consistency and reliability evaluation. Questionnaires were administered to a sample of 45 students in undergraduate and master's degree programs at the School of Agriculture and Forestry at the University of Florence. The findings showed that the combination of traditional didactics and symmetrical collaborative VR leads to an increase in knowledge and especially in the ability to understand situations in a real forest site providing an immersive and attractive experience in a risk-free environment. In conclusion, VR training applications can improve workplace safety and advance the digitalization of forest engineering.

Education practice concerning forest observation and wooden flooring tours using VR technology

T5.31 Taking advantage of technology in education

Takashi Higashihara[1]
Yukari Sato[1], Koji Murata[2], Masanao Sato[3], Mariko Inoue[4], Miho Kojima[5]
[1] Joetsu University of Education
[2] Kyoto University
[3] Hokkaido University of Education
[4] Tama Forest Science Garden, Forestry and Forest Products Research Institute
[5] Forestry and Forest Products Research Institute

Abstract: Japan is fortunate to have a wealth of forest resources, and a significant portion of low-rise housing is constructed using wood. Students learn about forests, timber, and wooden houses in their science, technology, and home economics classes. For several years from 2020, people's movements were restricted to prevent the spread of COVID-19. As a result, students lost opportunities to witness and experience the wonders of nature and everyday life beyond the confines of school, such as observing forests and visiting model wooden houses. Therefore, we created a video teaching material that captured a tree observation garden and a room with wooden flooring rooms using a 360-degree omnidirectional camera that could record the spread of space. Furthermore, we employed a 3D printer to create multiple tree trunk models that accurately depict the local vegetation. A question about trees was presented to students along with a video recreating how the students observed trees while walking, so that students could acquire knowledge about trees while watching the video. Shooting data related to several types of wooden flooring rooms with different colors and grains were captured using virtual reality (VR) goggles and saved. By simply pressing a switch on the VR goggles, students could experience the atmosphere of various rooms with different colors and wood grains. Because of conducting lessons using our video teaching material, the students were able to recognize the expanse of the space of the forest and wooden house. Therefore, it can be postulated that using VR technology would be beneficial for understanding forests and wood.

Part of this work was supported by JSPS KAKENHI grant number 20H01740.

Evaluating the Effectiveness of AI Language Models in Generating Scientific Abstracts: An Case Study of Forest Landscape Restoration Research

T5.31 Taking advantage of technology in education

Leo Petrokofsky[1]
Gillian Petrokofsky[1, 2], **William Harvey**[1, 3]
[1] Oxford Systematic Reviews, 266 Banbury Road, Oxford,OX2 7DL, UK 2
[2] Department of Biology, University of Oxford, MansfieldRoad, Oxford, OX1 3SZ, UK
[3] School of Archaeology, University of Oxford, 36 Beaumont Street, Oxford OX1 2PG, UK 3

Abstract: Scientific abstracts play a critical role in summarising research findings and facilitating efficient dissemination of knowledge. We use well-established guidelines of CAB Abstracts, and the Collaboration for Environmental Evidence for writing informative scientific abstracts and executive summaries to test the effectiveness of different AI language models (e.g. ChatCPT, Google Bard), in generating high-quality abstracts. The test set of English language articles is drawn from a recent systematic map on Forest Landscape Restoration research. The testing also compares AI-generated English-language abstracts for reports in a range of languages (French, German, Spanish, Greek) - both academic articles and grey literature.

Criteria-informed prompts are tested in each of these AI models to generate abstracts from the main body text of the selected research. These AI-generated abstracts are cross-compared with author-generated abstracts and scored for compliance with guidelines. A series of recommendations will be produced for iterative prompts to use in order to generate the most effective scientific abstract/executive summary. This is akin to training scientists in the necessity for effective question framing for their research. This novel approach shows significant potential for improving the abstract creation process and the overall quality of scientific communication.

The results of this study will provide insights into the suitability and efficacy of AI language models in generating scientific abstracts. The findings will be helpful to students and early-career professionals, particularly those for whom English is not a first language when confronted with the necessity of preparing an executive summary or scientific abstract based on their research.

Fire Education Platform: a tool for knowledge transfer about wildfires

T5.31 Taking advantage of technology in education

Ana Catarina Sequeira[1]
Iryna Skulska[1], Renata Pacheco[1], Fabrício Fava[2], Leticia Oliveira[1], **Maria Conceição Colaço**[1]
[1] Centre for Applied Ecology "Prof. Baeta Neves" (CEABN-InBIO), School of Agriculture, University of Lisbon, 1349 - 017 Lisbon, Portugal.
[2] Research Institute in Art, Design and Society (i2ADS), Faculty of Fine Arts of the University of Porto (FBAUP), Portugal.

Abstract: Extreme wildfires pose a global threat, and the European Commission is investing considerable resources in researching and developing new models and approaches to tackle them. One of FIRE-RES project's main goals is to share knowledge, raise awareness, and engage society. Extreme wildfires are not a common or well-understood process in Europe. In order to have a common culture of risk, society needs to be aware of it, understand it, and accept it. An online tool called Fire Education Platform is being developed to address this gap, aiming to share best practices related to wildfire communication and awareness among countries.

This international multimedia tool gathers information from different countries, targeting multiple audiences (politicians, educators, students, and local communities), explores the fire culture concept and scope in Europe, analyzing topics such as the ecology of fire, fire risk, and its social dimension (oral and artistic practices, traditions and fire use by local rural communities). It will follow an interactive model, with local knowledge provided by citizens and scientists from all over Europe covering the various stages of the fire cycle. The platform will be open-access and displayed in five languages.

The platform is being developed with a common core, which includes fire culture and arts, fire news, a fire encyclopedia, and data on the FIRE-RES project written clearly and easily. The separate core includes three areas: to teach, targeted at teachers and educators; to learn, targeted at the general public; and to apply, targeted at the professional sector. Within the common core, 90 traditional tales have been retrieved so far. Most of the tales are European, though the other continents are also represented. For the collaborative design of the platform, a survey with 24 questions was launched in the 13 country partners of the project, aiming to assess the real needs of future users. The Fire Education Platform is expected to be online in 2024 and contribute to improving and fostering more and better knowledge on fire among all types of public to increase fire resilience.

Game Engines—The Newest and the Most Versatile Platforms for Forest Education: Hyrcanian Forest Use Case

T5.31 Taking advantage of technology in education

Aiding Kornejady[1]
Mohammad Karim Maghsudloo[1], Saeid Shabani[1], Luigi Lombardo[2], Sedigheh Maleki[3], Omid Rahmati[4]

[3] Postdoctoral Researcher, Dept. of Soil Science, Ferdowsi University of Mashhad, Mashhad, Iran.
[4] Soil Conservation and Watershed Management Research Department, Kurdistan Agricultural and Natural Resources Research and Education Center, AREEO, Sanandaj, Iran.

Abstract: The new era of distant education and communication prompted the scientific community to indulge more in technology and make a virtue of virtual platforms, entailing prerequisites for raising technology literacy and encouraging interdisciplinary research and cross-boundary means of education. Game engines have long been known as a platform specifically designed for game developers and gamers worldwide, whose merits remained unraveled to scientists not long ago. Here, we discussed the architecture of creating a virtual educational forest platform, without which attaining the true meaning of "Digital Twin" would be insurmountable. These steps include 1) creating the virtual replica of the physical assets of the forest site via photogrammetry, laser scanning, or just acquiring the premade and archived 3D tree scans from world-famous repositories such as Quixel Megascans; 2) coupling the previous virtual replica with the static inventory data (e.g., forest structure characteristics or silviculture prescription data collected by forestry practitioners); 3) replacing the static data with dynamic and (near)real-time data through sensors as a core process of internet of things (IoT) and generating a true digital twin of the forest, and lastly 4) embedding environmental modeling plugins to the digital twin which can enable to model and simulate specific analyses such as forest fire modeling/mapping, deforestation risk analysis, and so forth. These four steps would make the backbone of any digital twin structure, regardless of the study scope and the environment they are to be applied. Also, we showcase the tremendous merits of a game engine called Unreal Engine in making a photorealistic, live-like forest environment of an example site in the Hyrcanian Forest, fused to static data (i.e., steps 1 and 2). Furthermore, we discussed the making process of a virtual tour of a sample forest trail in northeastern Iran generated by linking several 360 panoramas captured by smartphones or professional fisheye lenses. Such interactive and responsive products can be represented in different formats such as desktop, web, and particularly as an immersive experience by VR, all designed to be simple, user-friendly, and aligned with countries with the least technological advantages.

Methodology of technology to promote experiential learning that approaches the long-term aspects of forests

T5.31 Taking advantage of technology in education

Kazuhiko W. Nakamura[1]
Akio Fujiwara[1], Kaoru Saito[2]
[1] The University of Tokyo
[2] Tokyo University Of Agriculture

Abstract: Forests contain long-term phenomena such as succession that are beyond the human scale. In applying the various technologies that are becoming increasingly popular in recent years to forest education, methodologies that approach the long-term aspects unique to forests are required. The University of Tokyo Cyberforest research project has installed and operated fixed-point cameras and microphones in forests since 1995, and has been archiving images and sounds for more than 25 years. We have considered, through a number of practical studies, methodologies for using this vast audio-visual archive to present the long-term aspects of forests beyond the human scale as part of an experiential learning approach on forest education.
The Cyberforest project began capturing 15-second video without audio every day around 11:30 a.m. in October 1995 by installing a fixed-point camera in the University of Tokyo Chichibu Forest, and added a fixed-point microphone in October 1998 to capture video with audio. In 2010, a satellite Internet connection was installed at the same location, and the operation was shifted to live audio streaming and 20-second interval time-lapse still image transmission for several hours each day. The same audio-visual distribution in this post-2010 format has been conducted at seven other locations, including the University of Tokyo Fuji Iyashinomori Woodland Study Center, the University of Tokyo Hokkaido Forest, and Shinshu University Nature Education Park in the Shiga Heights.
We have developed educational materials that represent various timescales of forests using the audio-visual live streaming and archives from these Cyberforest sites through practical researches in various types of educational situations. As a result of more than 20 times of practical research in a wide range of educational situations, including primary education, secondary education, higher education, and social education, the direction of developing educational materials that represent multiple timescales based on plant phenology was considered to be effective. In addition, since the forests presented in the visual images and sounds are essentially different from actual forests that are comprehensively perceived by the five senses, it was considered desirable for learners to have a certain experience of actual forests to compensate for the gap by their imagination.

Oppertunities for Digital Final Projects in Silviculture Education

T5.31 Taking advantage of technology in education

Marcella Windmuller-Campione[1]
[1] Department of Forest Resources, University of Minnesota

Abstract: Science and art are often two terms used to describe and define silviculture. It is critical for students to have foundational knowledge in silvics and stand dynamics. However, most silviculturists would agree the art part of silviculture comes in during the implementation of that foundational knowledge when developing and implementing silvicultural prescriptions. Incorporating nuance, creativity, and art into undergraduate and graduate education can be difficult, especially when it comes to assessment. I developed a final assignment that uses digital technologies that allow students to display their foundational knowledge (the science) while developing and implementing a silviculture prescription of their own (the art). Students use their smart phones or other methods to digitally record a 5-minute presentation. Within those 5-minutes students work through a rubric describing their site and the silvics of the species, their goals and objectives for the site, their silvicultural prescription, and link the silviculture to other ecosystem attributes (e.g. forest health, biodiversity, climate resilience). Students have shared presentation that span the gamut from working in regional forest ecosystems, to highlighting regional and international locations while on trips during the semester, to highlighting silvicultural options in video games like minecraft. Since students create their own goals and objectives, students are able to bring their perspective and think critically and often "out of the box." Additionally, the final project can be shared with family and friends provide opportunities to share what silviculture is and expanding opportunities for conversations around forest management practices.

Supporting ubiquitous learning in forestry with CHEST, a multidomain application using Linked Open Data

T5.31 Taking advantage of technology in education

Pablo García-Zarza[1]
Guillermo Vega-Gorgojo[1], Miguel L. Bote-Lorenzo[1], Juan I. Asensio-Pérez[1], José Miguel Giménez-García[1]
[1] GSIC-EMIC, Universidad de Valladolid, Spain

Abstract: The widespread use of mobile devices can help to blur the barriers that students might find between what they learn in the classroom and the world around them through ubiquitous activities. Traditionally, teachers prepare the contents for their planned learning scenarios. Major barriers for this approach are the authoring effort and the difficulties to reuse content from other contexts. These limitations can be addressed with Linked Open Data (LOD), a federated database of interlinked sources from multiple domains such as forestry. Notable examples of LOD sources include Wikidata and DBpedia. However, accessing and managing LOD need expertise on semantic technologies, uncommon to most user groups (including teachers). We propose CHEST to address these challenges.

CHEST is a multidomain platform that exploits LOD sources to support ubiquitous learning situations. CHEST includes map-based user interfaces for teachers and learners with different capabilities that can be used in web, Android, and iOS devices. Forest domain teachers using CHEST can annotate as LOD features such as trees, author learning tasks associated to a feature (e.g., which is the species of this tree?), or create itineraries. They also explore available information coming for a variety of sources such as OpenStreetMap and Wikidata, allowing them to reuse existing environmental data and thus reduce the authoring effort. For example, if the leaf type of a tree is annotated in OpenStreetMap we can obtain information about it in Wikidata to enrich the tree's description. Teachers can supply meaning to the tasks thought the itineraries. In the itinerary they must pick the trees that they students should visit, and they can select learning tasks (generated by other teachers or on the fly using templates and available information) or add their own tasks. Students can follow the itinerary and carry out the learning tasks proposed by their teachers.

With CHEST prototype we have proven the possibility of using forestry data generated by the OpenStreetMap community, combined with information from other repositories, for educational purposes. As future work we want to use information from forestry repositories that research groups are translating into LOD to automatically generate more meaningful learning tasks.

Teaching and training in silviculture: a case-study in Brasov, Romania

T5.31 Taking advantage of technology in education

Valeriu-Norocel Nicolescu[1]
[1] Transylvania University of Brasov, Faculty of Silviculture and Forest Engineering, Brasov, Romania

Abstract: Silviculture has always been a major discipline in the forestry curricula throughout the world. This is also the case of Romania, where the first forestry school established in the second half of the 19th century considered Silviculture as a genuine milestone in the foresters' curriculum so dedicated this discipline a large amount of both teaching and practicals hours.

The same situation was encountered in the Faculty of Silviculture and Forest Engineering, part of Transylvania University of Brasov. It was established in 1948, as a continuation of the Faculty of Forestry within the Polytechnic School of Bucharest, founded in 1923. Since its early ages, the discipline of Silviculture in Brasov was dedicated two terms (full 3rd year of study, in a 5-year B.Sc. course), with 3 hours of teaching + 3 hours of practicals/project per semester (*Forest Biology* in semester I, *Silvicultural interventions* in semester II). This situation has changed dramatically since the application of Bologna system in Romania (2005/2006 academic year), the number of hours per semester (second in year 2 and first in year 3) for Bachelor degree (240 ECTS) being reduced to 2 (teaching) + 2 (practicals/project). Consequently, a lecture derived from the previous Silviculture course (Special Silviculture, showing the practical application of silvicultural interventions by forest formations) is taught in the 2-year (first semester) of the Master course (120 ECTS), with 2 hours of teaching and 2 hours of practicals.

Currently, the Silviculture lecture is facing the same challenges as in other parts of the world: allocation of similar time budgets as purely classroom-based disciplines, limiting drastically the use of field tours as part of teaching process, increasing diversity of students (both B.Sc. and M.Sc., many of them from high schools and professions not related to the Forestry field), limited staff at forest district level, with less time for apprentice training, making very difficult the planning and conducting of field tours and hosting students.

The remote-distance teaching, forcibly used during the pandemic, is definitely not a solution in Silviculture - students need a hands-on training in order to achieve the desired level of practical knowledge and experience in this field.

Training the Next Generation of Logging Equipment Operators with Forest Machine Simulators

T5.31 Taking advantage of technology in education

Nopparat Kaakkurivaara[1]
Tomi Kaakkurivaara[1]
[1] Kasetsart University

Abstract: A forest harvester simulator is a specialized software that aims to train individuals who operate forest harvesting equipment. The program creates a virtual environment that accurately replicates the experience of operating the equipment, with realistic graphics and physics models. The main objective of this simulator is to provide a safe and cost-effective training method for operators before they operate the equipment in real-world conditions. By using the simulator, operators can develop their skills, reduce the risk of accidents and equipment breakdowns, and increase productivity.

However, despite the many benefits of forest machine simulators, their use is still limited in some countries like Thailand due to the high cost of the technology. To make the simulators more widely available, ongoing efforts are being made to explore low-cost or open-source simulator technology. To address this gap, a recent study introduced a basic simulator into Thailand's circumstances.

The study aimed to achieve two objectives. Firstly, it compared the learning outcomes of simulator-trained operators, including factors such as the learning curve, biofeedback (pulse and temperature), and productivity. Secondly, it examined the effect of personnel parameters on the learning outcomes, including factors such as professional versus unprofessional backgrounds, male versus female operators, and gaming experience versus inexperience.

The Ponsse basic simulator was utilized to provide training for the candidates. The simulator offered a variety of forest stands and species to simulate real-life logging operations. The candidates were divided into four sub-groups based on their knowledge or experience in logging operations and their experience with simulation gaming. Prior to the training, all candidates received a brief introduction to the simulator. To evaluate the effectiveness of the simulator training, the performance of the candidates was measured and compared between groups. The performance metrics evaluated included productivity, error rates, and completion times. Additionally, surveys were conducted with the candidates before and after the training to assess their perception of the effectiveness of the training. The surveys included questions about their confidence, perceived competence, and satisfaction with the training. A detailed description of the measuring procedures, methods, and results will be presented at the conference.

What is the effect of forest education on knowledge and management decisions?

T5.31 Taking advantage of technology in education

Rikard Jakobsson[1]
Erika Olofsson[1]
[1] Department of Forestry and Wood Technology, Linnaeus University, Sweden

Abstract: An underlying assumption for providing forest education is that it produces impact. This is perfectly reasonable and matches our experience. However, how this impact is manifested in knowledge level, attitudes and subsequent measures in forestry is rarely investigated and quantified. This is an important area to investigate not only since education needs to be evaluated but also since knowledge and information are profound parts for forest owners to contribute to achieving the forest policy goals as well as societal goals for climate and health, where forestry plays a significant role.

Linnaeus University has since 2001 conducted courses for forest owners and other interested, and a total of over 5 000 people have attended one of the courses, Sustainable Small-scale Forestry. The course set-up has been adapted to distance with physical meetings in the forest combined with own studies and written submissions. The effect of these academic courses on forest owners' knowledge and management decisions has never been studied. Course evaluations are certainly carried out, but these have limitations in that they represent an indirect way of examining knowledge acquisition, where the participants indicate the perceived knowledge acquisition, quality, and usefulness of the course.

We investigated participants' factual and self-assessed knowledge levels, attitudes, and measures in forestry before and after the course using both quantifiable and open-ended questions.

The results showed an increased ability to elucidate solutions to silvicultural examples in planting, pre-commercial thinning, and overall forest management. The self-experienced knowledge level decreased for areas where the students were exposed to new knowledge. Also, there was an inclination to shift forestry measures, but a more significant impact occurred in decision-making with more mindful decisions.

T5.32 Teaching and training in silviculture: contemporary challenges and future prospects

Blended learning in academic forest education: experiences after educating 5 000 forest owners

T5.32 Teaching and training in silviculture: contemporary challenges and future prospects

Rikard Jakobsson[1]
Erika Olofsson[1]
[1] Linnaeus University

Abstract: Private forest owners own 60% of the European forests. However, little adapted academic education has been offered for them; traditionally, it has served the need of the State to manage its forest and the need of companies to buy timber. In 2001 academic courses for forest owners started at Linnaeus University in Sweden. The number of students, their performance and continuing studies are of interest to forest owners, employers, educators and society but were never compiled. This is a follow-up of some aspects of 22 years of education.

Since many potential students already worked, studied, or were even retired, some part-time distance-based approach was assumed to fit the student group's needs and was tried. The courses were conducted as blended learning courses with excursions, lectures in- and outdoor and field-based homework in a digital learning platform, providing terminology and science in forest mensuration, ecology, silviculture, growth and yield and economics and has been used by several forest companies in further education.

In the first year, 112 students registered (37% women), and 46% completed the introductory course. By autumn 2022, more than 5 000 students had attended the courses, almost 50% being women. Over the years, the courses have been developed with continuation courses with a continuation rate of 75% for introductory courses and extended to programs of two and three years of length full-time.

The courses serve as an example of how academic education can be organised and implemented in a forest education system addressing the need of the forest sector for an educated workforce. From a societal point of view, as a concept of Life-long learning, the courses are an example of opening new knowledge fields and careers. Forest owners are introduced to forest management, bringing terminology, networks, and competence. Future development includes courses for European forest owners.

EVOLUTION OF SILVICULTURE EDUCATION IN CENTRAL MEXICO

T5.32 Teaching and training in silviculture: contemporary challenges and future prospects

Patricia Hernández-de La Rosa[1]
Alejandro Velázquez-Martínez[1]
[1] Colegio de Postgraduados

Abstract: Silviculture education originated in central Mexico approximately 90 years ago, with the establishment of the first School where a BS degree was offered. Curricula and field practices focused on temperate pine-oak forests. At the beginning, around 1930, the fundamentals were adapted from schools founded in the United States with a philosophy focused exclusively in wood production. This stage lasted approximately 40 years, mainly training undergraduate students in the only existing school. Later, in the decade of the 80's of the 20th century, and in accordance with global policy and trends on sustainability, the teaching philosophy evolved to multi-objective forestry, which spread with the establishment of forestry careers in the north of Mexico. At the same time, in central Mexico, the first graduate program related to forestry sciences was founded, offering a course in advanced silviculture, focused on ecological and quantitative fundamentals in the application of silvicultural practices, although the emphasis remained on timber production. Currently, there have been changes in the focus Silviculture orientation aligning with international trends, forestry education and research policies in the country, as well as regional demands for the different species under management. New teaching trends consider multi-purpose Silviculture and Silviculture with emphasis on ecological principles. Nowadays, student´s demand for forestry courses, and particularly for both Master Science and Ph.D. students, along with other forestry professionals, not only include forest goods, but also multiple ecosystem services. This is also evident in the forested areas of northern Mexico, where existing large areas with temperate forests, and in the south, where the evolution of the teaching of tropical forest silviculture requires a particular approach.

Handbook for teaching and learning forest sciences in colleges and universities

T5.32 Teaching and training in silviculture: contemporary challenges and future prospects

Anne Nevgi[1]
Mika Rekola[2], Niclas Sandström[1]
[1] University of Helsinki, Faculty of Educational Sciences, Department of Education
[2] University of Helsinki, Faculty of Agriculture and Forestry, Department of Forest Sciences

Abstract: Universities around the world are responding to the challenges of globalisation, the spread of higher education to increasingly diverse groups of students and the growing demands placed on them by national governments. The quality of teaching and teaching excellence are factors with which universities compete to attract the best students to their degree programmes (French & O'Leary, 2017). This global competition for the best students also applies to forestry education. Universities provide pedagogical training for their teachers to support their development in teaching excellence.

Pedagogical training requires textbooks and for academics, professors and senior lecturers, there are many textbooks about teaching and learning in colleges and universities (e.g. Biggs & Tang, 2009; Lindblom-Ylänne & Nevgi, 2009; Marshall,Fry & Ketteridge, 2014; Moore, Risquez & Walsh, 2007). There are some handbooks for teaching and learning a specific discipline such as geography (Walkington, Hill & Dyer, 2019), business education (Thomsen et al., 2021), and political science (Ishiyama, Miller & Simon, 2015). However, to our knowledge, there is no handbook or textbook for the educators of forestry and forest sciences in colleges and universities.

The editors of the *Handbook of teaching and learning forest sciences* are Anne Nevgi, Mika Rekola, and Niclas Sandström (alphabetical order). The topics of the *Handbook* may include the following areas: Challenges of Forest education, Developing and designing curriculum and courses of forest sciences, Educational technology, digital platforms and artificial intelligence in teaching and learning, Teaching subject areas (specific teaching methods for subjects), In-class teaching techniques, and Developing teaching competency of forest educators.

The timeline for the editing and writing of the Handbook and developing the interactive website will be 2-3 years starting from autumn term 2023. Handbook will be published as an e-book with links to an interactive website, and as a physical book. In the session, the organisation of the Handbook will be presented, and how the Handbook and it's interactive website can be used in self-study, in peer review of teaching, in developing and planning one's own teaching, and in pedagogical training.

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

An approach to model natural forest regeneration using commonly available data.

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Andreas Sommerfeld[1]
Matthias Schmidt[1]
[1] The Northwest German Forest Research Institute, Department of Forest Growth Growth and Risk Modelling

Abstract: Forests are one of the most essential ecosystems and are therefore crucial for human wellbeing. Changes within the climate and disturbance system are causing increasing uncertainties for forest development. Yet, the variability of the initial stages of forest development, the forest regeneration phase, remains high. Trees are characterized by a high life expectancy and individual forest development phases can often last for decades. These life history traits lead to a high vulnerability of forests, as environmental conditions can change significantly in global change during the same period. Therefore, the forest regeneration phase, which is the developmental phase with the highest adaptive capacity of forest ecosystems, is of critical importance. Nevertheless, our understanding of the interaction of environmental conditions and the quantification of effect sizes leading to successful natural regeneration remains insufficient.

We developed a statistical model to estimate regenerative success using data commonly available for larger forestry companies. Specifically, we combined wall-to-wall site classification data composed of soil moisture, nutrient supply, tree species shares and volumes with in-depth data on local tree parameters such as mean quadratic diameter, stand basal area, and crown projection. We used a Generalized Additive Model (GAM) to analyze the occurrence and density of natural regeneration. The GAM allowed us to model any non-linear relationships and specifically we used a GAM implementation that is able to model so-called "compositional data". By doing so, we were able to model the occurrence of different regeneration tree species simultaneously. This approach allowed us to consider the dependencies between the co-occurrence of several tree species within one regeneration plot.

A regeneration model, which is generally applicable while using readily available parameters, enables forestry companies to guide large-scale planning of natural regeneration. For forest science regeneration models are able to inform primary forest growth and biomass models to better estimate current and future regeneration potentials and possible forest development trajectories. Regeneration models enables a climate-adapted and resource-efficient way of steering tree species composition and thus the shape of future forests.

Bayesian calibration of process-based model PREBAS using multi-source data

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Ritika Srinet[1, 2]
Francessco Minunno[1, 2], Xianglin Tian[1, 3], Mika Aurela[4], Harri Mäkinen[5], Daesung Lee[5], Mikko Peltoniemi[5], Annikki Mäkelä[1, 2]
[1] Department of Forest Sciences, University of Helsinki, Latokartanonkaari 7, Helsinki 00014, Finland
[2] Institute for Atmospheric and Earth System Research / Forest Sciences, Faculty of Agriculture and Forestry, University of Helsinki, Helsinki 00014, Finland
[3] College of Forestry, Northwest A&F University, Yangling 712100, China
[4] Finnish Meteorological Institute, Helsinki, 00560, Finland
[5] Natural Resources Institute Finland (Luke), Latokartanonkaari 9, Helsinki, Finland

Abstract: Process-based models simulate the ecosystem carbon dynamics based on plant physiological and ecological processes. These models are extensively being used for quantification of forest fluxes and stand dynamics and assess the possible future changes in forests associated with changing climate. However, the simulations from these models require information on physiological, structural, and functional traits for model parameterization. The uncertainties in the parameter estimates have a significant effect on the accuracy of model output. Hence, the calibration of the process-based model parameters is crucial to make model outputs comply with measurements. The present study focuses on the calibration of PREBAS, which is a coupled model consisting of two modules, PRELES - a canopy photosynthesis model for estimating gross primary productivity (GPP) and a simplified water balance and CROBAS - a tree growth model. PREBAS was calibrated using extensive multi-source dataset including multi-temporal forest stand structure data from permanent growth and yield experiments, national forest inventory data, foliage and stem biomass data from the old growth, uneven-aged forest, and multi-site GPP and evapotranspiration data from Eddy covariance (EC) sites across Finland. The daily meteorological input was prepared from CRU JRA V2.1 forcings dataset which was bias-corrected using the spatially downscaled girded weather observations from meteorological stations, whereas for EC sites, the meteorological data from EC towers were used. Bayesian calibration of model parameters was carried out for three species, Scots pine (Pinus sylvestris L.), Norway spruce (Picea abies [L.] H. Karst.) and silver birch (Betula pendula L.). The Bayesian calibration effectively reduced the uncertainty of PREBAS parameters and predictions. On comparing the posterior distributions of the parameters, major changes were observed in the CROBAS parameter estimates, whereas PRELES parameter estimates did not diverge much from the prior. This was also reflected by the higher improvements in the simulated forest structural variables and biomasses, against smaller improvements in simulated fluxes. The study emphasised on the importance of the comprehensive, multi-source data covering a wide range of climatic conditions, forest structures, development stages, and management practices for model calibration, which allows to increase the reliability and robustness of PREBAS for its application in regional simulations.

Carbon stocks in tropical forests: disentangling the response of forest structural components to environmental drivers across spatial scales

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Pauline Depoortere[1]
David Bauman[2], Adeline Fayolle[1], Jean-François Bastin[1]
[1] TERRA Teaching and Research Centre, Gembloux Agro Bio-Tech, Université de Liège
[2] French National Research Institute for Sustainable Development (IRD)

Abstract: The critical role of tropical forests in the global carbon cycle is well-known. Yet, there remain uncertainties regarding the spatial distribution of forest aboveground carbon stocks (AGC) substantially limiting our potential to develop relevant conservation and restoration strategies for these ecosystems. In particular, the lack of convincing relationships between forest AGC and its environmental drivers represents an unstated and major source of uncertainty. In this study, we hypothesize that this lack of consensus results from the omission of a key concept in forest ecology: the AGC of a forest community is not a single entity but the product of distinct forest structural components (e.g. basal area, mean quadratic diameter, stem density and wood density weighted by basal area) each responding differently, and sometimes antagonistically, to environmental drivers (e.g. climate, soil properties and topography). Gathering forest inventories from 606 plots across three tropical regions (i.e. South America, Asia and Africa), we studied the influence of environmental drivers on several forest structural components and AGC, using linear regressions and controlling for spatial autocorrelation in model residuals. In addition, we tested the influence of the climate data sources by testing the sensitivity of the results to different climate datasets (e.g.WorldClim, ERA5, CHIRPS and TRMM). Preliminary results unveil significant and strong relationships between environmental drivers and each forest structural component (with an average RMSE of 18%), whereas no or weak environmental influence was identified on AGC (with an average RMSE of 34%). It confirms the hypothesis that the link between environmental drivers and forest AGC is indirect through specific and antagonistic relationships between environment and each forest structural component. Interestingly, we identified a strong influence (with an average RMSE of 8,2%) of soil properties (i.e. clay content and pH) and topography (i.e. elevation and slope) on the wood density weighted by basal area. These results highlight the necessity to study the drivers of forest structural components across tropical regions to understand the spatial distribution of tropical forest AGC. This research provides key insights for future studies on forest AGC drivers as well as conservation-restauration strategies.

Characterizing structural complexity and dynamics of birch stands using UAVLiDAR and field inventories

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Arthur Vander Linden
Lorna Zeoli[1], Jean-François Bastin[1], Tom De Mil[1], Hugues Claessens[1]
[1] Forest Is Life, TERRA Teaching and Research Centre, Gembloux Agro-Bio Tech, University of Liège, Passage des déportés 2, 5030 Gembloux, Belgium

Abstract: Among the numerous consequences of global changes, the loss of resilience in european temperate forests could lead to significant ecological and economic disaster. Currently, many tree species of sylvicultural and heritage importance, such as European beech (Fagus sylvatica), are no longer suited to their current site conditions, and this situation will only worsen in the future. It is therefore urgent to identify new resilient tree species with high sylvicultural potential in order to adapt forest composition to global changes. Among these species, birch (Betula pendula Roth.) shows promising characteristics for the future forest diversification from an ecological and economical point of view. However, we still lack a deep understanding of the functioning of this species, especially key informations that would enable the development of its silviculture. In this study, we combined trunk-centric field inventories with threedimensional canopy data acquired through UAV-LiDAR to characterize the structural complexity and dynamics of the stand. We examined individual trees, analyzing their morphology, foliage, crowns, and trunks, and then aggregated the information at the stand level to characterize the influence of stand structure on individual growth monitoring with high resolution automatic point dendrometers. Through this research, we have highlighted certain autoecological specificities of this species that will enhance silvicultural recommendations for future plantations or stand enrichments. By adapting silvicultural standards to this fast-growing pioneer species, we have the opportunity to develop a more close-tonature forestry approach with low initial investment requirements, while benefiting from high-quality wood with a great potential for woodworking purposes.

Contribution of Three-North Afforestation Program to forest greening in Northern China during 1978-2022

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Xiao Zheng[1]
[1] CAS Key Laboratory of Forest Ecology and Management, Institute of Applied Ecology, Chinese Academy of Sciences

Abstract: In response to land degradation in arid and semi-arid regions, China has launched the world's most ambitious afforestation project, known as Three-North Afforestation Program (TNAP, 1978–2050), which also known as "Protective Forest Project", was designed to increase forest coverages for protecting agriculture, reducing soil erosion, and controlling desertification over an area of 42% of China. However, temporal-spatial variation patterns and potential causes of forest greening are not well understood in Northern China, and it is not clear whether forest greening (area and quality) is due to climate change or engineering contributions. Here, we extracted the forest increase area using multi-source remote sensing data and analyzed whether it is consistent with climate change. In addition, the temporal-spatial variation patterns of forest quality were analyzed. Then, combined with the climate data, the relationship between forest quality change, climate change, and TNAP was analyzed. The forest area shows an overall increasing trend from 1978 to 2020, among which, the increase in forest area from 1978 to 2000 is mainly contributed by TNAP, while from 2000 to 2020, it is mainly a combination of climate change and TNAP. The quality change of the forest mainly shows a decrease first and then an increase; among which, 65% were related to TNAP and 35% to climate change. The above results highlight that the TNAP plays a crucial role in forest greening in Northern China. While climate change's role in forest greening in Northern China is relatively weak, it cannot be ignored.

Developing a site index model of sugi planted forests using time series digital crown height models derived from aerial photograph and airborne LiDAR

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Yasushi Mitsuda[1]
Satoshi Ito[1]
[1] Faculty of Agriculture, University of Miyazaki, Japan

Abstract: A site index prediction model for sugi (*Cryptomeria japonica*) planted forests was developed using tree height growth data calculated as the difference between time series digital crown height models (DCHMs). The study was conducted at the Tano Forest Science Station, University of Miyazaki, Japan. The data sources included digital surface model (DSM) and digital terrain model (DTM) derived from airborne LiDAR data captured in 2013, as well as a DSM derived from a digital aerial photograph taken in 2016. DCHMs were developed at a resolution of 0.5 meters for both 2013 and 2016 within the sugi planted forests. The DCHMs were then resampled at a resolution of 20 meters using local maximum filtering to produce dominant tree height maps. The difference in dominant tree height between the two years, at a resolution of 20 meters, was calculated as the dominant tree height growth distribution map for the period of 2013 to 2016. Topographic factors such as solar radiation index, wetness index, and topographic exposure index were computed using the DTM resampled at 20-meter resolution. A model combining the site index prediction model and the height curve model was parameterized using dominant tree height growth, stand age (derived from a forest map), and topographic factors. The estimated parameters indicated that the site index was higher in areas with lower solar radiation, higher wetness, and lower topographic exposure. This study utilized spatial big data, specifically DSMs and DTM, which allowed for a broader examination of the relationship between site index and topographic factors compared to traditional data sources (e.g., sampling plot surveys). As a result, a robust model was developed to predict site index for a specific site using topographic factors and dominant tree height for specific ages at that site. Finally, the effect of climate change on predicting site index and dominant height growth was assessed by comparing the model's predictions with actual tree growth data obtained from stem analysis.

Environment-induced growth changes in forests of Finland revisited

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Helena Henttonen[1]
Pekka Nöjd[1], **Harri Mäkinen**[1]
[1] Natural Resources Institute Finland

Abstract: After a rising trend from the beginning of 1970s, during which the overall annual growth of the forests of Finland increased by more than 70 %, a recent reduction has been observed. We analyzed the development of annual growth, focusing on the component not explainable by changes in growing stock or forest structure.

The data originate from the Finnish National Forest Inventories. We developed models predicting periodic (5 years) annual volume increments per hectare with properties of the trees and the stands as predictor variables. Deviations from model-predicted values in large areas were interpreted to be induced by environmental variation. The development was analyzed separately for three species groups: Scots pine, Norway spruce and broadleaves.

We observed a rising growth trend not explainable by forest structure. The species groups produced rather a similar pattern in different parts of Finland: from the 1960s to mid-1990s, measured volume increment was mainly below the model-predicted level, thereafter above it. During the current century, the difference between measured and predicted annual volume increment has shown a downward trend for Scots pine. For Norway spruce, the difference of measured and predicted growth has continued to increase in southern Finland but shows little change in the north. For broadleaved species, a recent increase was detected as well, though not as large as for Norway spruce. The geographical pattern of the environment-induced growth component was described in more detail via maps using a 75 km × 75 km grid. The key question is: are we witnessing a turning point of the long increasing growth trend, or are the recent years just a temporary downturn, a part of natural variation.

Forest dynamics and demographic processes in the largest primeval beech forest of Europe

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Jonas Stillhard[1]
Lukas Heiland[2], Roman Flury[1], Meinrad Abegg[1], Lisa Hülsmann[2], Martina L. Hobi[1]
[1] Swiss Federal Research Institute WSL, Zürcherstrasse 111, 8903 Birmensdorf, Switzerland
[2] Ecosystem Analysis and Simulateion (EASI) Lab, University of Bayreuth, 95447 Bayreuth, Germany.

Abstract: Forests dominated by European beech (*Fagus sylvatica*) are known for their pronounced continuity and a small-scale disturbance regime. At larger spatial scales, this results in an ecosystem which is in steady state, while at smaller spatial scales considerable dynamics can be observed. It is assumed that the continuity of species composition in this ecosystem relies on the crown plasticity, shade tolerance, and longevity of beech, and that these traits allow beech to outcompete other species such as maple (*Acer* sp.). However, the main demographic processes recruitment, growth, and mortality reflecting these traits and their contribution to the long-term structural dynamics of these forests are not well understood.

Here, we analyse two datasets with different spatial and temporal resolution, both gathered in the primeval beech forest of Uholka-Shyrokyi Luh, the largest remnant of primeval beech forests, to gain insight into the dynamics of beech forests in the absence of anthropogenic influences. First, we investigate the structural and compositional changes using kernel smooths, capturing the small-scale dynamics of structural attributes such as basal area and tree density. Subsequently, we analyse the influence of both competition and disturbances on the demographic processes using spatially explicit species-specific models for recruitment, growth and mortality. Finally, we assess the contribution of the demographic processes to beech dominance using a three-stage Lotka-Volterra-type model. This allows us to shed light on the feedbacks between forest structure, demographic processes and compositional changes at different spatial scales in primeval beech forests.

Forest ecosystem resilience evaluation using time-series NFI plots and remote sensing data stack

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Yong Pang[1]
Tao Yu[1]
[1] Chinese Acaemy of Forestry

Abstract: The state of forest resilience could substantially change as a result of climate change and disturbance. It is challenging to characterize the resilience of forest ecosystem. Here we intend to develop an indicator system for the evaluation of forest ecosystem resilience. Through the 9 repeat cycles of NFI plots, both the individual tree and the plot level factors are analyzed. Tree level growth trajectory, stand level parameters and its environment factors are analyzed with the consideration for stand natural development, management activity, and disturbance agents. Then the 35 years Landsat remote sensing data stack is built according the stand development and disturbance events. Both the pixel level and forest stand level are compared. The results in the typical forests of China will be investigated. As an arising topic, this preliminary result will provide a feasible way for the forest ecosystem resilience evaluation.

Identification of tree heights in the Chiquitano Dry Forest using UAV LiDAR technology

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Oswaldo Maillard[1]
[1] Fundación para la Conservación del Bosque Chiquitano (FCBC), Santa Cruz, Bolivia

Abstract: Annually, the areas affected by fires in Bolivia range from 1.1 to 9.2 million hectares with a total of 24 million hectares impacted in the last 21 years. Restoring the ecological functionality of ecosystems degraded by forest fires is a high priority in the country to reverse the loss of biodiversity and carbon storage. One of the regions most impacted by fires in the country is the Chiquitano Dry Forest, a transition zone between the Amazon rainforest and the dry forests of the Chaco and Cerrado. In recent years, satellite monitoring in combination with field information has been fundamental to understand how regeneration processes occur in this forest. One of the field tools to perform these analyses is the use of LiDAR technology that has been implemented in the Unmanned Aerial Vehicle (UAV). In this study, field inspections were conducted in an area located in the Boque Chiquitano, in which three plots of permanent vegetation of 20x50m were installed and woody individuals with DBH diameters>2.5 cm at breast height (1.3 m) were measured. Two of the plots had some type of disturbance (fire, cattle, selective extraction) and one had no recent disturbance. These plots were overflown by a DJI Matrice 300 RTK UAV with a Zenmuse L1 LiDAR sensor attached. The results obtained show that the data obtained by the LiDAR sensor allows the identification of tree heights, helping in the evaluation of large extensions of wooded areas that require a lot of field effort to make the measurements. However, the methodologies used in this study underestimate the total number of trees in the plots, the size of the crowns and do not obtain real diameters. A possible explanation for this is that many trees are infected by vines and that the vegetation in the lower stratum is dense, confounding the tree diameters. The tools for classifying the information obtained by the LiDAR sensor still need to be further improved.

Recreating structurally realistic tree maps with airborne laser scanning and ground measurements

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Joel Kostensalo[1]
Lauri Mehtätalo[1], Sakari Tuominen[1], Petteri Packalen[1], **Mari Myllymäki**[1]
[1] Natural Resources Institute Finland (Luke)

Abstract: The estimation of forest attributes representing aspects of structural biodiversity from vast areas is difficult not only because of the lack of agreement on what constitutes a structurally diverse forest, but also due to difficulties regarding the detection of small trees. However, there is a consensus that a structurally diverse forest should have large variation in tree size (i.e., height and diameter), as well as some clustering of trees, as regular tree pattern is typical for managed forests. We developed a framework for building structurally representative tree maps using airborne laser scanning data which were corrected based on a limited number of ground measurements using data from two locations in Finland. In the proposed method, an individual tree detection algorithm is optimized so that the number of undetected trees and false detections is minimized. The ground measurements are then used to train models for the number and location of undetected trees and false detections. This model can then be applied to other areas in the proximity of the ground measurements to build tree maps, with the location, height, and diameter for each tree. The methodology was shown to reproduce the species-specific numbers of trees and size distributions as well as the spatial pattern of the trees with sufficient accuracy for practical use in large-scale mapping of forest attributes. For species detection additional spectral data was used.

Spatially explicit modeling of nonlinear growth patterns in plantation forests over broad geographic scales

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Jacob Bukoski[1]
Susan Cook-Patton[2], Jeffrey Vincent[3]
[1] College of Forestry, Oregon State University, USA
[2] Global Science, The Nature Conservancy, USA
[3] Nicholas School of the Environment, Duke University, USA

Abstract: Spatially explicit models that account for nonlinear patterns in forest growth are critical for managing forest values that depend on stand age, such as forest product yields or carbon sequestration rates. Process-based models account for nonlinear growth patterns but tend to be coarse in spatial resolution and computationally expensive to run. Conversely, empirical models can account for variation at finer spatial resolutions but are generally limited to linear rates over distinct time spans to date. In this talk, we present an empirical nonlinear growth modeling approach that accounts for spatial variation at 1 x 1 km spatial resolution and is applicable across broad geographic scales (all low- and middle-income countries). Using a global dataset of thousands of observations of aboveground biomass stocks and stand age in monoculture plantations, we map nonlinear growth patterns for distinct plantation types at 1x1 km spatial resolution. Specifically, we use statistical models and a large raster stack of climatic, edaphic, and topographic variables to estimate, for each pixel, localized growth parameters necessary to predict aboveground biomass for each plantation type at any given stand age. Our modeling thus represents a data-driven approach that accounts for spatial variation in key constraints on forest growth and is applicable at relatively fine spatial scales. Potential applications of our modeling approach include mapping spatial variation in optimal rotation lengths across landscapes or tracking of carbon sequestration at finer temporal and spatial resolutions. However, key challenges exist for improving, extending, and validating our models, including the incorporation of remotely sensed data products, future climate projections, and the influence of management factors. In addition to presenting our growth modeling approach, we will discuss these challenges and potential opportunities to overcome them.

Spatio-Temporal Analysis of Forest Inventories: Challenges and Approaches for Modelling Ingrowth Dynamics

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Roman Flury[1]
Jeanne Portier[1], Brigitte Rohner[1], Esther Thürig[1], Golo Stadelmann[1]
[1] Forest Resources and Management, Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Switzerland

Abstract: National Forest Inventories (NFIs) are crucial in monitoring forests and their ecosystem services in many countries. Such inventories have evolved over the years, adapting sampling strategies to address new threats and advancing monitoring devices. This study uses statistical spatio-temporal methods to analyze data from complete and ongoing forest inventory cycles in Switzerland, specifically focusing on ingrowth within forests. In the Swiss NFI, ingrowth is defined as trees that meet the caliper threshold of at least 12cm diameter at breast height (dbh) between two consecutive inventories. Our analysis includes the spatio-temporal modeling of the number, the tree species and the dbh of ingrowth trees based on roughly 5’500 plots that have been measured since 1983.

We use multivariate spatio-temporal modeling techniques based on the realization of a stochastic process. In this context, we examine the difficulties of applying these models to the Swiss NFI data, particularly the fundamental change in sampling periods after the third inventory cycle, when serial sampling changed to continuous sampling with 1/9 of the plots remeasured every year. In addition, the assumptions of these models, such as translation and rotation invariance, and their implications are discussed in more detail. Moreover, we emphasize computational burdens and bottlenecks resulting from the increasing size of NFI datasets. The findings shed light on the intricacies of forest ingrowth processes in space and time and offer valuable insights for sustainable forest management. Furthermore, with this study, we contribute to the broader field of analyzing NFI data since these models can be adapted, for example, to other demographic processes such as mortality or growth.

Study on single tree survival model of mixed stands of Larix olgensis based on mixed effect model and survival analysis method

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Chunming Li[1]
huiru zhang[1]
[1] the chinese academy of forestry

Abstract: Accurate prediction of tree mortality is a very important part of forest growth and

yield model system. Constructing a tree survival model based on mixed effect model and survival analysis method can improve the precision of tree mortality model. Taking the data of 20 sample plots of mixed stands of *Larix olgensis*, *Abies nephrolepis* and *Picea jazoensis* in Wangqing Forestry Bureau of Jilin Province, northeastern China as the example, the tree mortality and survival model was constructed based on 6 parameter distribution models of survival analysis method (exponential distribution, Weibull distribution, log-normal distribution, log-Logistic distribution, Gompertz distribution, Gamma distribution), stand factor and site factor were added into the model as covariates. The sample plot's random effect was considered and compared with the simulation effect of the traditional model. With the increase of initial DBH, the risk of tree mortality decreased and the survival rate increased; with the increase of BAL, the risk of mortality increased and the survival rate decreased; with the increase of stand density per hectare, the probability of tree mortality increased and the survival rate decreased; the good-fitness of Weibull distribution model was the best; compared with the fixed effect model, the simulation accuracy of Weibull distribution model was greatly improved after considering the sample plot's random effect, and reached a very significant degree. In forest management, if we want to improve the survival rate of trees, we should adopt scientific and reasonable management methods and management time to avoid excessive stand density.

The role of microclimate for predicting forest regeneration

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Lisa Hülsmann[1]
Leonie Gass[1], Wibke Richter[1]
[1] University of Bayreuth

Abstract: Forest microclimate is a topic of increasing scientific attention because of its importance for local biodiversity, global change impacts on forest ecosystems, and the interactive effects between forest canopy and regeneration. One of the expected outcomes of increased consideration of microclimates is improved predictability of ecosystems, particularly of species occurrences and responses to climate change. Nevertheless, relatively little is known to date about the extent to which microclimate products derived from topographic, biological, and macroclimatic variables improve the predictability of forest dynamics. Here, we assess the degree to which predictions of forest regeneration – a crucial process for species distributions and forest composition with a high potential to be sensitive to microclimatic effects – can be improved by accounting for sub-canopy microclimate temperatures from European forests. To this end, we fit species-specific regeneration models with data of small trees from national forest inventories and quantify how much variation in tree regeneration is explained by microclimatic temperature offsets in addition to macroclimatic variables. Our results provide an indication of the usefulness of gridded microclimatic products that integrate many environmental variables for projections of forest dynamics and whether it is necessary to consider feedbacks between large and small trees, not only in terms of seed production but also in terms of structural feedbacks manifested by microclimatic variation.

Visualizing big forestry data with Forest Explorer

T5.33 Temporal, spatial and big data - Challenges for modelling climate change impacts on forest tree and stand growth

Guillermo Vega-Gorgojo[1, 2]
Felipe Bravo[1], Cristóbal Ordóñez[1], José M. Giménez-García[2]

[2] Group of Intelligent and Cooperative Systems, Universidad de Valladolid, Spain

Abstract: Forestry sciences heavily rely on data collection to facilitate sustainable forest management and research activities. To achieve this, permanent and extensive data recording systems, such as land cover maps and forest inventories, are employed. However, these datasets are typically isolated and consist of disparate data types, which poses challenges for their integration. To address this issue and deal with the variety challenge of Big Data, Linked Open Data and Semantic Web technologies are particularly well-suited. In the EU project Cross-Forest (https://crossforest.eu/), we have published a comprehensive Linked Open Data resource encompassing the contents of forest inventories and land cover maps from Spain and Portugal, henceforth the Cross-Forest dataset. It can be accessed through the SPARQL endpoint at https://crossforest.gsic.uva.es/sparql/, although this is not very convenient for target users from the forestry domain. To support this user group we propose Forest Explorer, a web application providing an interactive map for easily browsing the contents of the Cross-Forest dataset. The application is available at https://forestexplorer.gsic.uva.es/ and only requires a device with a web browser (including desktop computers, tablets, and mobile phones). The application includes panning and zoom controls for navigating to the area of interest. Depending on the zoom level, the amount of detail is adjusted: first aggregated inventory data per region, then land cover patches, plots, and finally trees as the user zooms in. Forest Explorer further empowers users with various customizable controls to tailor the displayed information, including taxa filters so as to obtain information about specific species, genera, families or classes, as desired. The application allows a professional usage, as well as a more casual one for scientific disseminators, data scientists, or citizens. Over 11,500 users have already employed Forest Explorer thus far. The application has been featured multiple times in the media, describing potential uses, impacts and opportunities for management. A technical description of Forest Explorer can be found in [1].

[2] Natsional′nyy Universytet Bioresursiv I Pryrodokorystuvannya Ukrayiny

Abstract: Historically forest management in countries of Northern Eurasia (mostly comprising territories of the former Soviet Union) was oriented on estimation and regulation of the resource groups of ecosystem functions and services of forests. Transition to Sustainable Forest Management (SFM) in conditions of rapid climate change requires urgent analysis and reconsideration of some background principles, tools and technologies of forest management, and consequently modification (in some cases developing new) forest information systems based on major principles of applied systems analysis. The major requirements to such systems are i*nter alia* 1) ability to provide continuous operative monitoring of all forest ecosystem functions and services, part of which are not defined by current forest inventories and monitoring now; 2) early detection of changes in forest ecosystems, particularly of their resilience/ vulnerability due to impacts of new climates; 3) immediate use of new knowledge in practical forest management; and 4) permanent process of education and training of forest professionals and decision makers. Ideally, the major goal of such a process is development of unified national information spaces on forests and forest management, i.e. system integration of basic components of national forest inventories, forest monitoring and economic inventories. In essence, the ideal pattern of such a transformation should be nationally oriented models of local forest monitoring is based on integration of multi-remote sensing and ground data, and realized, for instance, in a form of Integrated Land Information System.

Implementation of such systems over vast areas of NE requires political will, understanding new needs by policy makers, availability of resources, and substantial time. However, there are important urgent problems, consideration of which would also serve as preliminary steps of future development of the mentioned systems, such as analysis and selection of optimal systems of forest management in accordance with changing functional destination of forests and local interactions between ecosystem services; modification and harmonization of forest related primary and derivative indicators used in different fields of knowledge; new methodologies and forms of development empirical and “semi-empirical” modelling systems connecting remote sensing and ground measurement; others. The presentation considers potential links with European research on the topic..

Advancing forest inventorying and monitoring in a time of rapid global change: A case study from Switzerland

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Ross Shackleton[1]
Marco Ferretti[1]
[1] Swiss Federal Research Institute (WSL), Zürcherstrasse 111, Birmensdorf, Switzerland

Abstract: Global environmental change issues are rapidly affecting forests, and currently, in most countries' forest inventorying and monitoring (IM) initiatives face many limitations and challenges which hinder scientific understanding, the development of timely policy responses and leads to the suboptimal use of resources. To address the gaps and challenges of current IM, there is an urgent need for a "new age" of advanced forest inventorying and monitoring (AIM) in Europe that incorporates novel tools and technologies and collaboratively integrates different ongoing systems, especially at increased temporal resolutions. In this talk, we introduce the Advanced Inventorying and Monitoring for Swiss Forests (SwissAIM) initiative, which was collaboratively developed over the past three years. This can be used as a useful case study to guide the development of AIM across other regions of Europe and even more broadly across the globe.

SwissAIM will build upon and promote synergies between existing IM programs (e.g. national forest inventory - NFI, ICP Forests Level I, and biodiversity-focused initiatives), incorporate minimally invasive and destructive measurements, and draw on novel tools and technologies. This will aid with timely reporting of forest conditions and changes, and lead to a better understanding of forest processes and dynamics which ideally will help to guide timely policy and management decisions. We will present four main steps undertaken in the development of SwissAIM, including: (i) developing a vision and long-term strategy, (ii) designing the system, by collaboratively identifying research questions, survey and plot design options as well as variables and methods of interest to different stakeholders, (iii) prototyping the design and methods, and, (iv) promoting collaborative governance and engagement. We will also present some key messages and lessons that emerged through designing SwissAIM, which could be useful for others developing AIM programs in Europe.

Blending satellite, process modelling and ground observations for regular updates of European forest carbon dynamics

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

[6] European Forest Institute (EFI), Finland

Abstract: Europe's forests play a major role in the continent's climate change mitigation plans, and also provide many other benefits to society. Systems are needed to accurately monitor forest dynamics and carbon cycling (and changes therein) to underlie both science and policy. Here we present a novel approach for such a forest monitoring system that combines high-resolution remote sensing of forest disturbances with process-based modelling to provide a spatially and temporally consistent pan-European assessment of forest carbon cycling over the last two decades. Recent advances in disturbance detection mean that it is now possible to quantify forest disturbance occurrence, intensity and agent at 30 m resolution annually based on the Landsat archive across the European continent. We use this information to force a process-based demographic forest model, LPJ-GUESS, with prescribed harvest and disturbances, constraining what has hitherto been the most uncertain part of modelled forest dynamics. Initialising LPJ-GUESS with actual forest structure based on forest age and composition information derived from national forest inventories ensures that the model results represent the observed structure of European forests. Using the model as a link between these two strong observational constraints and the wider body of forest process understanding, we are able to calculate the unobserved carbon fluxes with a much higher degree of confidence than previously possible at this scale. Key output variables include net exchange of carbon between the forest and the atmosphere, forest growth rate and tree mortality rates. Potential future improvements would include incorporating ground-based information on growth, harvest and mortality, which would further constrain the modelled dynamics whilst maintaining pan-European consistency. Our approach can be applied operationally for regular updates and can contribute to the wider effort to assemble a continental-scale forest monitoring system, as well as having the potential for application in other regions and ecosystems of the world.

Drivers of forest biomass change in Europe and Russia

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Dmitry Schepaschenko[1]
Ian McCallum[1], Florian Kraxner[1]
[1] International Institute for Applied Systems Analysis (IIASA)

Abstract: Forest biomass stock and change are important indicators of ecosystems health, biodiversity, climate change adaptation and the success of mitigation efforts, among others. Remote sensing instruments and data processing techniques have improved significantly over the recent decade. However, validation of changes and identification of drivers observed changes are often not properly quantified. We use well established tool (Geo-Wiki.org) for visual interpretation of very high resolution imagery and vegetation indices to confirm changes in biomass reported by several remote sensing-based products, incl. CCI Biomass and to sort out the drivers of changes, incl. natural regrowth, forest management (planting, thinning, harvesting), natural disturbances (fires, pests, wind, flooding) and land use change. A stratified random sample was made based on a number of land cover, forest and biomass change maps. This makes it possible to estimate the area of changes associated with one or another driver at regional scale. We will present to which extend biomass change can be confirmed by visual interpretation of very high resolution imagery and Sentinel-2 time series, as well as drivers of biomass change in Europe and Russia for 2010-2020.

The work is supported by the Horizon Europe EYE-CLIMA project (101081395) and the European Space Agency IFBN/GEO-TREES project (4000114425/15/NL/FF/gp).

From litter to soil carbon - harmonizing soil carbon stock estimates for a common European forest monitoring system

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Claudia Guidi[1]
Nathalie Cools[2], Heleen Deroo[2], Jari Liski[3], Toni Viskari[3], Robert Jandl[4], Markus Didion[1]
[1] Swiss Federal Institute for Forest, Snow and Landscape Research WSL, CH-8903 Birmensdorf, Switzerland
[2] Research Institute for Nature and Forest (INBO), 9500 Geraardsbergen, Belgium
[3] Finnish Meteorological Institute, Helsinki, 00101, Finland
[4] Austrian Forest Research Center, A-1131 Vienna, Austria

Abstract: Forest soils are a major, but challenging to estimate, C reservoir. In a context of global changes, monitoring and predicting possible changes in soil C stocks in forest ecosystems is essential. Improving the estimation of soil C responses to forest management practices and climate would help decision-makers to frame appropriate climate mitigation strategies. However, accurate field observations of litter-derived C inputs are particularly scarce at large scales and different methods are used to obtain such estimates e.g. in National Forest Inventories (NFIs). Within the EU-funded project PathFinder, our study aims to derive European-wide harmonized soil C inputs and stock estimates since 1990s, and further develop the current estimation methodology.

Here, we use observations of litterfall and deadwood production from plots in the pan-European forest monitoring network of the "International Co-operative Programme on Assessment and Monitoring of Air Pollution Effects on Forests" (i.e. ICP forests). Litterfall and deadwood observations, together with repeated stand inventory data, are used to improve current regional allometric functions by biogeographical regions and forest types. For validation purposes: (i) harmonized estimates of soil C inputs are compared with independent net primary production (NPP) estimates from MODIS, and (ii) historic changes in soil C stocks simulated with the model Yasso20 are compared with measured soil C stock changes from additional ICP forest sites.

Overall, this study will provide a harmonized framework for estimating and reporting changes in soil C stocks in European forests, which can be applied in NFIs for predicting soil C stock changes in response to different scenarios of forest management and climate.

Global estimation of forest biomass: a review study

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Emanuele Papucci[1]
Cornelia Roberge[1], Ruben Valbuena[1], Göran Ståhl[1]
[1] Department of Forest Resource Management, Swedish University of Agricultural Sciences, 901 83 Umeå, Sweden

Abstract: Accurate estimates of aboveground forest biomass (AGB) and carbon stocks are increasingly demanded for enhancing our understanding of the global carbon cycle related to climate change. Mapping and estimation often go hand-in-hand, using techniques such as model-assisted or model-based inference. In this context, many projects across numerous countries continue to face challenges in obtaining accurate AGB estimates. Further, the studies tend to report contradicting results, thus implicitly highlighting the many sources of uncertainty that affect results from this type of large-area survey. The purpose of this study was to review large-area AGB surveys conducted around the globe between 1993 and 2023 from the point of view of the methodologies used in various parts of the assessment schemes. As a basis for the review, we propose ideal methodological standards for different parts of a comprehensive AGB survey. It should be noted that fulfilling all parts of our standards is probably impossible in practice, and thus the standards should mainly be seen as a tool for identifying which parts of large-area AGB surveys tend to be more problematic than others. In the standards, we make a distinction between surveys adopting design-based inference (through model-assisted estimation) and surveys adopting model-based inference. The standards comprise a set of criteria. For each criterion, we specify indicators of quality and reliability. Examples of criteria are the properties of the remotely sensed data used, properties of the field data used, the statistical procedures applied, and the methods adopted for quality assurance and quality control. For each criterion, we grade the studies from 1 to 5 ("poor", "fair", "good", "excellent", and "outstanding", respectively), and summarise the results across all studies for each criterion. We do not reveal our grading of individual studies but use the overall results for identifying what parts of surveys tend to be more problematic than others, and for discussing what developments would be relevant from the point of view of enhancing the overall quality of large-area AGB surveys.

Is the regression to the mean in remote sensing inventories a problem for forest planning?

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Patrik Ulvdal[1]
Lars Sängstuvall[1], Göran Ståhl[1], Ljusk Ola Eriksson[2], Karin Öhman[1]
[1] Department of Forest Resource Management, Swedish University of Agricultural Sciences
[2] Department of Southern Swedish Forest Research Centre, Swedish University of Agricultural Sciences

Abstract: Information about the forest resource is needed to make decisions about future forest management. Traditionally, this information has mainly been gathered in the field. However, as improved sensors have emerged, remote sensing has become a commonly used technique for forest inventory. One of the most important changes this has meant for forestry is the availability of spatially detailed wall-to-wall maps of forest attributes. For example, wide-scale airborne laser scanning campaigns have been performed in some countries, and satellite-based systems like the Sentinel-2 continuously produce multispectral images on the continental scale. Estimates from these remote sensing inventories are of varying quality. However, they have the strengths that they are objective by nature, produce similar data for large areas, and provide a clearer error structure compared to traditional forest inventories in operational use. On the other hand, a profound weakness with model-based inventories is the regression to the mean, i.e., estimates for small attributes are overestimated while estimates for large attributes are underestimated. For example, small trees will be estimated to be taller than they are in reality and vice-versa. Such errors could lead to problems in making implementable forest management plans. In this study, we will address this topic by quantifying the risk of suboptimality in both economic and ecological terms from basing decisions about forest management on remotely sensed information. We evaluate forest planning performance for two inventory methods (airborne laser scanning and satellite imagery) in a business-as-usual scenario extended with concerns towards biodiversity values and carbon sinks. The results will provide insights into the effect of the regression to the mean for the benefit of the development of new remote sensing techniques and planning models. The results may also provide knowledge for the upcoming European Union processes regarding large-scale forest monitoring with remote sensing.

Mapping and estimation platform for EU wide forest monitoring with integrated field and remotely sensed data

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Jukka Miettinen[1]
Radim Adolt[2], Mari Myllymäki[3], Laura Sirro[1], Lauri Seitsonen[1], Johannes Breidenbach[4]

[2] Forest Management Institute, Czech Republic
[3] Natural Resources Institute Finland, Finland
[4] Norwegian Institute of Bioeconomy Research, Norway

Abstract: The HorizonEurope project PathFinder (https://pathfinder-heu.eu/) will provide tools and design participatory processes for supporting evidence-based policies in the EU that foster synergies between forest-based bioeconomy and biodiversity. One of the objectives of the project is to develop a mapping and estimation platform for EU-wide forest monitoring based on integrated use of field and remotely sensed data. Here we present the main components and key functionalities of the platform.

The amount of data available for forest monitoring has been rapidly increasing over the past ten years. The influx of 10-30 m resolution satellite imagery (e.g. Sentinels and Landsats) and supporting Earth Observation (EO) based products (e.g. Copernicus pan-European forest High Resolution Layers), together with the growing amount of field measurements result in massive volumes of data. The only way to take full advantage of the synergies that the datasets offer is to utilize Big Data storage and processing approaches with effective inter-platform connections.

The PathFinder processing platform maximizes the use of existing components, linking them into a connected system of components allowing integrated use of field data with remotely sensed data and auxiliary datasets. Key components of the platform include:

1. Pre-processing of satellite and other auxiliary datasets.
2. Database of harmonized NFI field datasets
3. Extraction of remote sensing and auxiliary variables for field plots, ensuring the compliance with data restrictions such as secret plot coordinates.
4. Creation of high-resolution forest attribute maps integrating remote sensing and field data.
5. Estimation of forest statistics using NFI field data as the only source of information and in combination with wall-to-wall auxiliaries (typically products of EO data analysis) with the nFIESTA (new Forest Inventory ESTimation and Analysis) tool developed in the H2020 project DIABOLO.
6. Distribution of harmonized results through dedicated distribution channels (e.g. FISE).

The platform concept allows flexibility in the execution of each of the main components. Many of the components can be run in multiple platforms allowing to maximize the benefits of individual platforms. Similarly, the platform offers several models and estimators for forest attribute map creation and forest statistics estimation, and implementation of new ones.

MoniFun - Co-creating a blueprint of a harmonised European Forest Multifunctionality Monitoring System

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Abstract: The Horizon Europe project MoniFun will co-create—via an interdisciplinary, multi-actor approach—a blueprint for a harmonised European Forest Multifunctionality Monitoring System (EFMMS) that consolidates fragmented qualitative and quantitative information on forest multifunctionality into a comprehensive, interoperable system integrating existing platforms and data sources with innovative tools, to fulfil the needs of diverse stakeholders, policies, certification schemes and society. After mapping information needs, experts from different fields of forest multifunctionality will co-create harmonised indicators on thematic areas (forest resources in Europe; forests & climate change; forests & biodiversity; forests & society). Routines using partners' data will be developed and validated to: a) combine field plot (national forest inventories) and remote sensing (Copernicus) data to map forest multifunctionality; b) use artificial intelligence to monitor rapid changes in forests in real time; c) produce harmonised statistical estimates with accuracy and granularity meeting information needs; d) nowcast and forecast ecosystem services related to resilience needs under climate and halting biodiversity loss over various timespans; and e) feed the Forest Information System for Europe.

The main output of MoniFun will be a technical description of EFMMS, including recommendations for governance and funding. Financial support to third parties will be used to validate developed methods and analyse the possible of use of blockchain to augment information from existing public databases. MoniFun will share data, knowledge and tools with relevant related Horizon-projects. EFMMS will support the successful planning, implementation and evaluation of forest-related EU

policy objectives, including those of the New Forest Strategy, European Green Deal, Biodiversity Strategy, Bioeconomy Strategy, Fit for 55 Package, and Renewable Energy Directive.

Monitoring European forest condition in near real-time

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Allan Buras[1]
Anja Rammig[1]
[1] Technical University of Munich, School of Life Sciences, Land Surface-Atmosphere Interactions, 85354 Freising, Germany

Abstract: Climate-change induced forest decline is a major challenge for European forestry. In particular, recent extreme drought events as in 2018 and 2022 have resulted in widespread growth decline, tree die-back, and calamities. In order to timely react to emerging forest decline, foresters require up-to-date information on the condition of their forests. While ground-based forest inventories provide a high level of detail with regards to forest condition, the information typically comes at annual resolution with a delay of several months and is only representative for local sample plots. In contrast, remote sensing data deliver information on canopy reflectance in near real-time and across space, thus rendering a promising avenue for providing timely information on forests' condition.

Under this framework, we here present the European Forest Condition Monitor (EFCM). The EFCM is based on MODIS-NDVI and allows for visualizing and downloading information on the relative canopy greenness of any forest patch in Europe for any date since January 2001. The sensitivity of the EFCM to changes in forest condition is exemplified using case studies related to late-frost induced defoliation, drought-induced growth reduction, forest fire, and flood-induced dieback. Moreover, we show how EFCM data can be used to assess tree-species specific drought vulnerability providing valuable information for forest practitioners in context of managing the climate resilience of European forests.

Remaining methodological constraints of the EFCM are highlighted, resulting in a prospective for further refinement of existing and upcoming forest monitoring platforms. Here, particular emphasis is given to the implementation of freely available, high-resolution satellite images (e.g. Sentinel 2) and additional vegetation indices (e.g. NDMI, NDRE) that have rendered valuable for monitoring forest decline but also come along with computational challenges due to the vast amount of pixels that need to be processed on European scale. In conclusion, we present an existing and freely available European forest monitoring platform and provide suggestions for the further development of a pan-European forest condition monitoring.

Operational forest monitoring across Europe using Earth observation

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Cornelius Senf[1]
Alba Viana-Soto[1], Wanda De Keersmaecker[2], Ruben Van De Kerchove[2]
[1] Technical University of Munich
[2] Flemish Institute for Technological Research (VITO)

Abstract: Forests cover more than 30% of Europe's land area and provide important services to society. Recent climate events have led to likely unprecedented episodes of natural disturbances, rising questions regarding the resilience of Europe's forests to climate change. Yet, there is a lack of comprehensive data on forest state and change across Europe, which has resulted in a call for developing a pan-European forest monitoring system. Within the Horizon Europe ForestPaths project we aim at approaching this ambitious goal by creating a (i) a new forest disturbance monitoring system and (ii) a set of base layers on forest structure and composition, both based on Earth observation data. The forest disturbance monitoring system is based on the analysis of annual Landsat time series processed consistently for all of Europe at 30 m spatial grain and covering all years since 1985. Different approaches for detecting disturbances are benchmarked with initial results showing substantial improvement compared to past datasets. A novel agent attribution approach further allows for attributing disturbances to either natural (i.e., wind, fire, bark beetle) or human (i.e., harvest) causes. Mapping base layers on forest structure and composition will be achieved by integrating dense time series from Sentinel-1 and Sentinel-2 with air- and spaceborne LiDAR data. Initial tests from Belgium suggest a high potential of this new approach for mapping key structural features (i.e., height, density, vertical diversity) and composition (e.g., leading species). Our approaches serve as a first step towards an operational Earth observation forest monitoring system across Europe.

Overview of the main challenges for comprehensive forest monitoring in Europe

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Yasmin Imparato Maximo[1]
Jo Van Brusselen[1], Pieter Johannes Verkerk[1]
[1] European Forest Institute, Yliopistokatu 6B, 80100 Joensuu, Finland

Abstract: Comprehensive forest monitoring systems are crucial for supporting effective forest management and policy development and target setting. The new European Union (EU) Forest Strategy for 2030 calls for the development of an EU-wide integrated forest monitoring framework. This framework should address the patchiness of the current inventory systems, which includes national, EU, and international initiatives, expand the scope and overcome other challenges related to the systems currently in place. To identify the main challenges in developing a comprehensive forest monitoring for Europe, we reviewed more than 60 scientific papers, books, reports, and legislation and identified over a hundred issues that represent obstacles to harmonization and a holistic European system. Subsequently, we classified these issues into problem categories, which represent the main challenges for forest monitoring in Europe: (i) comparability: since most national forest inventory systems are developed independently, their definitions, time coverage, plot density, or resolution often differ in a way that data are not easily comparable, and datasets need harmonization to achieve the necessary comparability (ii) quality: assessment quality may differ between indicators within a forest inventory, or for the same indicator between forest inventories. This is influenced by differences in plot measurements, plot density or the number of plots over an area, and to which extent earth observation is included in the methodology (iii) transparency, accessibility, and dissemination: access to forest inventory data is mostly limited across European countries, including restrictions on in-situ plot data availability. The disseminated data is often expressed in a format that poses challenges in terms of usability and interpretation for different types of users (iv) indicator coverage: national forest information systems often lack a holistic approach and topics such as biodiversity and bioeconomy are not sufficiently covered. The development of comprehensive EU-wide forest monitoring and information system(s) has multiple motivations and is undoubtedly part of an ongoing political debate. Several ongoing projects are actively working towards addressing these obstacles. As the aforementioned problems differ in terms of their drivers, significance, and impacts, it is vital for the success of initiatives aimed at developing harmonization approaches to address solutions across all problem categories.

Pan-European, large-scale, long-term and harmonized – ICP Forests as a model for future international forest monitoring?

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Marco Ferretti[1]
Kai Schwärzel[2], Alexa Michel[2]
[1] Swiss Federal Institute for Forest, Snow and Landscape Research, Zürcherstrasse 111, 8903 Birmensdorf, Switzerland
[2] Thünen Institute of Forest Ecosystems, Alfred-Möller-Str. 1, Haus 41/42, 16225 Eberswalde, Germany

Abstract: Context. European forests represent an invaluable asset for wood production, biodiversity conservation and to combat climate change. While National Forest Inventories (NFIs) are important to periodically evaluate the condition of European forests, they may be limited in terms of international focus, temporal resolution, range of attributes covered, and data accessibility. These are exactly the areas where the International Co-operative Programme on Assessment and Monitoring of Air Pollution Effects on Forests (ICP Forests) has had its strengths for almost 40 years. By reviewing the main achievements of the program, here we show how it is relevant and useful to several European policy initiatives and discuss areas of future improvement.

Methods. Launched in 1985, ICP Forests includes now 42 Countries in Europe and beyond. It is based on a multi-level monitoring concept with a probabilistic component (ca. 6000 Level I plots) and an intensive, case-study oriented component (ca. 600 Level II plots). The two components are linked by a common set of attributes. Methods adopted by the ICP Forests are internationally standardized, regularly reviewed and updated, cover all ecosystem compartments, include comprehensive Quality Assurance/Quality Control, and permit annual reporting.

Main results and conclusion. Results can be considered in terms of scientific achievements and program's governance. In terms of science, ICP Forests was successful in detecting and reporting spatio-temporal changes in forest condition (in terms of forest health, growth, nutrition, biodiversity) and identifying their relationship with biotic (e.g. pests, diseases) and abiotic (e.g. climate, air pollution) drivers. In terms of governance, since its establishment ICP Forests adopted a model combining a bottom-up approach (with Expert Panels dealing with scientific evidence and methodologies) and a top-down decision-making mechanism (the Task Force, where all Countries are represented). Overall, this model was resilient during the dramatic political changes that happened in Europe since the 1990s, and was able to demonstrate over the past 40 years that harmonized international forest monitoring is possible and feasible. For the above reasons, while there are areas where considerable improvement is necessary, we consider ICP Forests as a useful model for future forest monitoring in Europe and beyond.

PathFinder:Towards an Integrated and Consistent European LULUCF Monitoring and Policy Pathway Assessment Framework

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Johannes Breidenbach[1]
Johannes Schumacher[1], Rasmus Astrup[1]
[1] NIBIO - Norwegian Institute of Bioeconomy Research

Abstract: PathFinder will develop and demonstrate an integrated forest monitoring and pathway assessment system. This system will allow a consistent EU greenhouse gas reporting of the LULUCF sector, while at the same time, combine such monitoring capability with advanced pathway assessment to help plan the essential policy and implementation steps towards achieving the policy targets.

The PathFinder project is funded under Horizon Europe framework (no. 101056907) from 2022 to 2026. The PathFinder consortium consists of 24 partners including JRC and EEA, and is coordinated by NIBIO.

PathFinder combines the use of field and remotely sensed data for high-resolution mapping and precisely estimating forest attributes. The cooperation of the largest forest monitoring organizations operating in the EU, i.e., national forest inventories (NFIs) and the network installed under ICP Forests, provides a rich data base of harmonized ground truth information which will be complemented by a field survey of consistently assessed field monitoring sites. Advanced measurement devices will provide an audio-visual digital twin including genetic properties of the consistently monitored forest for maximum transparency and interoperability of new data. The analysis of combined databases will improve our understanding of fluxes among carbon pools and the development of biodiversity indicators.

The forest information of the monitoring system will feed into a scenario framework that forecasts outcomes of forest management alternatives. The scenario framework utilizes a wall-to-wall approach combining forest management, land-use, cross-sectoral demands, and climate impacts to forecast future forests. The scenarios facilitate trade-off analysis of forest ecosystem services and are potential alleys in the pathway assessment.

More information can be found under https://pathfinder-heu.eu/ and by following @EUPathFinder (twitter).

First results of the PathFinder project will be presented:
- The design of a consistent European field survey optimized for remote sensing applications.
- Advanced field plots that are assessed with various proximal sensors.
- Pan-European 10-meter-resolution forest attribute maps combining NFI and Copernicus satellite data.
- An estimation system that turns fine-resolution maps into relaible estimates.
- An analysis platform for communication the results.
- The forecasting system that supports today's decisions by predicting their future impact.

- Policy pathways that minimize trade-offs and maximize synergies among forest ecosystem services.

Potentials of National Forest Inventories for Annual Reporting: The case of Sweden

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Cornelia Roberge[1]
Hans Petersson[1], Alex Appiah Mensah[1], Per-Erik Wikberg[1], Jörgen Wallerman[1], Magnus Ekström[1, 2], Anton Grafström[1], Göran Ståhl[1]
[1] Department of Forest Resource Management, Swedish University of Agricultural Sciences, SE – 901 83, Umeå.
[2] Department of Statistics, Umeå School of Business, Economics and Statistics, Umeå University, Umeå, Sweden

Abstract: Many national forest inventories (NFIs) in European countries rely on a combination of permanent and temporary field samples to gather information about the state and changes in forests. Normally the full sample is not measured each year. Rather, it is covered over intervals ranging between approximately 5 and 10 years. Estimates are typically reported as moving averages or average annual changes for the period between two consecutive measurements.

For current reporting on Land-Use, Land-Use Change and Forestry (LULUCF) in climate reporting for Sweden, a five-year re-inventory cycle is used. Data between consecutive measurements are interpolated and data for the most recent years are extrapolated for this reporting.

To fulfil upcoming requirements for forest accounts (FA) in Eurostat's proposal for amending Regulation (EU) 691/2011 on European environmental accounts, member states will need to supply annual estimates of standing stock, increment and drain for calendar years. These estimates can then be used for the interpolation of LULUCF climate reporting data and thus make for better cohesion in estimates reported within LULUCF and FA.

To meet the need for annual estimates, remote sensing (RS) data and different model-assumptions will be needed. We evaluate a solution involving:

1) Updating plot level information using normal growth models, applying ordinary mortality functions. Average annual growth multiplied by estimated annual growth index (from bore core measurements on temporary sample) is added to previous measurements per year since inventory.

2) Detecting harvesting activities, predicting harvested volumes and the remaining volumes on plots by continuous monitoring using Sentinel-2 satellite images with high temporal resolution.

This approach is expected to greatly reduce the bias when using the full five-year-panel, in comparison to ignoring the growth and harvest in estimating with full panel in spite of time difference. Potential improvements of sampling error by utilizing full sample means introducing model errors in growth and harvest volume predictions. These are also assessed. The possibility to combine the full sample with model assisted estimation may open up statistics production for both smaller areas and more narrow time-frames and will be compared to using only most recent inventory data.

Preserving European Forests: The Vital Role of Seed Monitoring in the Face of Climate Crisis

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Iris Oberklammer[1]
Mario Pesendorfer[1], Georg Gratzer[1]
[1] University of Natural Resources and Life Sciences, Vienna

Abstract: The 3 Billion Trees Pledge of the European Green Deal 2030 combined with an increase in disturbances and the trend for assisted migration results in high demand for tree seeds. Many of the required species show masting behaviour, intermittent seed production with high spatial synchrony. While this phenomenon is well understood in some species, we lack information on reproduction in many forest species. Monitoring their seed production will result in an increased understanding of their biology and the drivers underlying masting behaviour. In addition to increasing biological understanding, monitoring is important to plan seed harvesting and resource allocation within nurseries. Furthermore, it has effects on the number and diversity of seedlings available for forest managers, thus limiting their choices when reacting to disturbance events. Here, we discuss several monitoring concepts and investigate criteria that optimize the trade-off between effort and information gained. Monitoring of seed production within a coherent and consistent European framework would ultimately enable the prediction of annual seed production.

Project FORWARDS: The ForestWard Observatory to Secure the Resilience of European Forests

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Ruben Valbuena[1]

[9] Fondazione ICONS, Italy.
[10] Thünen Institute of Forest Ecosystems, Germany.

Abstract: Climate change has already had a harmful impact on forest ecosystems in various parts of the world. For this reason, the EU-funded FORWARDS project will prototype the ForestWard Observatory, a pan-European monitoring and evaluation tool that will help in demonstrating the impact of climate change on forests, guiding decision-making for practical forests management.

By developing the ForestWard Observatory and promoting Climate-Smart Forestry and biodiversity restoration, FORWARDS will reconcile the current divide between forest information obtained from the ground and from satellites incorporating timely and detailed information on European forests' vulnerability to data on climate change impacts.

The project will gather and apply information from existing networks and also establish a novel network of pilot sites testing climate-smart forestry and biodiversity restoration practices. The knowledge resulting from the research will be employed to inform relevant stakeholders of best practices, to secure the long-term resilience of European forests.

The European Forest Information Network (EFINET): toward a forest monitoring system based on remote sensing and ground data integration

Abstract: Forests are a primary ecosystem in Europe and play a crucial role in citizen health and human wellbeing, representing a cornerstone to climate change adaptation and mitigation. However, Europe lacks a unified, and comprehensive forest monitoring system that integrate ground and remote sensing data sources. Currently, ground-based surveys from national forest inventories (NFIs) are the main data source for official statistics. Despite its valuable contribution, ground data alone presents some limitations due to cost, standardization issues, infrequent updates, and data access restrictions. Meanwhile, the increasing availability of remote sensing data combined with advances in cloud computing enables the use of sophisticated algorithms over large areas, opening new possibilities for generating comprehensive and up-to-date information on forest structures and dynamics in Europe.

To harness this potential, the European Forest Institute provided funding for the European Forest Information Network (EFINET) project, which aims to prototype a European forest monitoring system based on the integration of ground and remote sensing data. EFINET focused on the adaption of existing and the development of new methods in five representative large study areas: Bialowieza Forest (Poland), Tuscany (Italy), Canton of Grisons (Switzerland), Vindelaven Juhtatdahka biosphere reserve (Sweden), and the whole of Nederland. Airborne Laser Scanning derived metrics were used as reference data, due to their previously demonstrated strong correlation with several forest variables of interest, as canopy cover, diameter at breast height, tree height, basal area,

biomass, growing stock volume, carbon content, and their changes over time due to disturbances. Then, temporal patterns derived from Landsat data were employed to establish a comprehensive set of predictors for estimating forest 3D metrics. These predictors were then used to generate spatially-explicit estimates of forest disturbances and forest structure variables – complementary to NFI estimates.

Our results reveal that forest height metrics can be predicted through automatic analysis of remote sensing imagery with high accuracy, which is crucial from a European forest monitoring system perspective. Our approach provides indeed a core component of a fully integrated forest monitoring system, which will ultimately bring together the spatial consistency and temporal frequency of remote sensing with the fidelity of ground-based observations.

Towards a global forest map implementing the FAO FRA land-use definition

T5.34 The new age of forest monitoring: A common European forest monitoring system in a global perspective

Timothée Stassin[1, 2]
Adolfo Kindgard[2], Simon Besnard[1], Diego Marcos[3], Robert Masolele[4], Xavier de Lamo[2], Erik Lindquist[2], Anssi Pekkarinen[2], Martin Herold[1, 4]

[2] Food and Agriculture Organization of the United Nations, Rome, Italy
[3] Inria, University of Montpellier, Montpellier, France
[4] Wageningen University and Research, Wageningen, the Netherlands

Abstract: The Food and Agriculture Organization of the United Nations (FAO) performs global Forest Resources Assessments (FRA) regularly at the request of and in collaboration with member countries since 1946. The most recent assessment (FRA 2020), examines forest resources, their management, and use in 236 countries and territories. Forest area and change is a key variable in FRA, particularly to support countries reporting on 'Life on Land' indicators - 15.1.1 and 15.2.1 of Sustainable Development Goals (SDGs) and the Nationally Determined Contributions (NDCs) to the Paris Agreement. For the FRA purpose, the FAO implements a harmonized definition of forest as land use, in contrast to common land-cover definitions. Moreover, the FRA forest land-use definition is implemented in the recent European Union Deforestation-Free Regulation (EUDR).

The FAO national reports provided by national correspondents for the FRA are mostly tabular data and aggregated estimates. A participatory global Remote Sensing Survey (FRA 2020 RSS) was conducted with the aim of improving estimates of forest area and change at global and regional levels by taking advantage of the increased availability of satellite imagery. The result is a unique dataset of satellite images consistently analyzed at 400 000 sample locations by more than 800 trained local experts from 126 countries and territories.

While the RSS provided quality interpretations at sample locations for regional and global analysis, the survey has not provided spatially explicit information on forest distribution. We will present here how Artificial Intelligence (AI) models trained on the RSS dataset can be leveraged to fill this gap. A first forest land-use map for different continents inferred from a model with over 90% overall accuracy will be showcased. The challenges paired with mimicking the human photointerpretation process with an AI model will be discussed, including accuracy assessment, feature selection, model architecture, and model training strategy. We will further present how these models trained and deployed on the FAO SEPAL cloud-computing platform can assist countries in developing their own forest maps using sample data.

T5.35 The next generation of forest decision support systems for tackling today’s and future challenges!

Accounting for economic and environmental impacts of farm afforestation

T5.35 The next generation of forest decision support systems for tackling today's and future challenges!

Mary Ryan[1, 2]
Cathal O'Donoghue[2], Kevin Kilcline[1], Tom Houlihan[1], Niall Farrelly[1], Jane Stout[3]
[1] Teagasc
[2] University of Galway
[3] Trinity College Dublin

Abstract: With the prevalence of often mis- or partially-informed political debates on the composition and management of future forests, there is an immediate need to provide policy, industry, and research/extension stakeholders with decision support systems (DSS) that go beyond traditional forest production to account for multifunctional outputs. As a largely agricultural country that provides substantial government subsidies to incentivise land use change to forestry, Ireland presents an interesting case-study of broadening an existing forest growth/economic DSS to facilitate life-cycle analysis of the economic (private) as well as environmental and social (public) impacts of different scenarios for land-use change in relation to both the long-term impact of new forest types and the potential to mitigate emissions from superseded agricultural enterprises, with regard to the provision of timber and non-timber life-cycle ecosystem services. Building on considerable cross-country modelling experience, the modelling approach adopted in this paper interacts timber and management considerations with soil type, policy subsidies and increasing carbon prices to provide quantitative values for the private (farmer's) life-cycle return to planting conifers and broadleaves in different agricultural contexts, but also quantifies the social/public (carbon) return for both land uses, along with bioeconomy inputs: roundwood and biomass production and flows to harvested wood products (HWP). The carbon impact is estimated using National Inventory Report methodologies and valued using government shadow prices for carbon. These economic and carbon values will be aggregated to develop life-cycle scorecards with different values for different soils, species types and management practices (e.g. thin/no-thin). An expert-based forest biodiversity scorecard will also be developed by the multi-disciplinary team, which will allow for the tabulation of quantitative economic and carbon impacts against tabulated qualitative forest biodiversity scores. As agricultural soils, land use and efficiencies vary widely and based on the dearth of micro-modelling of the agriculture/forestry land use change uvovered in a systematic review, farm/forest scale modelling is required to reflect the heterogeneity in land-use change decisions. Combining existing and new model components, the outputs of this challenging modelling framework should provide useful discussion points for other researchers, along with important topical information for a wide range of stakeholders.

A novel interactive multiobjective optimization method for group decision making in climate-smart forestry

T5.35 The next generation of forest decision support systems for tackling today's and future challenges!

Juuso Pajasmaa[1]
Bhupinder Singh Saini[1], Babooshka Shavazipour[1], Jari Vauhkonen@uef.fi[2], Kaisa Miettinen[1]
[1] University of Jyvaskyla, Faculty of Information Technology, P.O. Box 35 (Agora), FI-40014 University of Jyvaskyla, Finland
[2] University of Eastern Finland, School of Forest Sciences, Yliopistokatu 6 (P.O. Box 111), 80101 Joensuu, Finland

Abstract: Although storing carbon in forest trees, soils, and wood products is a straightforward way to mitigate climate change, decisions to do so depend on the preferences of the forest owners. For example, economic objectives typically conflict with environmental benefits and climate mitigation. Traditional forest management tools cannot support simultaneous consideration of climate and other environmental benefits and individual objectives (called climate-smart forestry). Climate-smart forestry can also be hindered by lack of awareness, communication, and collaboration between forest owners to have large enough areas for climate impact. Therefore, there is an acute need for a group decision support tool enabling climate-smart forest landscape planning where multiple forest owners can balance between various individual objective functions alongside some collective objective functions (e.g., climate and environmental ones), and different holding sizes are involved. The tool must be designed to increase the forest owners' awareness and support trade-off analyses and collaboration among them to find consensus plans for climate-smart forestry.

To address this crucial gap, in this study, we propose a novel interactive multiobjective optimization method enabling different forest owners to provide their preferences for both their individual and collective objective functions and support them in finding consensus plans that benefit both individual and collective objective functions. We demonstrate the usability of the proposed approach as a group decision support tool with a case study of climate-smart forest planning. We show in the pilot study how multiple forest owners with various holding sizes were supported in finding a consensus solution with the proposed method.

Adaptation strategies timeline for conservation and sustainable use of forest resources under uncertainty climate change.

T5.35 The next generation of forest decision support systems for tackling today's and future challenges!

Katsuhiro Nakao[1]
Haruka Tsunetaka[1], Wataru Murakami[1]
[1] Forestry and Forest Products Research Institute, Japan

Abstract: The purpose of this research is to establish a timeline for implementing adaptation strategies that support the sustainable conservation and utilization of forest resources in the face of uncertain future conditions. By doing so, it seeks to determine the optimal timing for implementing adaptation measures and identify irreversible tipping points. The study focuses on a 250 km^2 area in northern Kyushu, Japan, including cities, rice paddies, and forests. Using climate scenarios and concentration pathways, the research projected forest stand growth and landslide risk for the 2030s, 2050s, and 2080s. Models estimated forest stand growth and the frequency of heavy rainfall events causing landslides. Based on the outcomes, five land-use maps were created: two for timber production and landslide reduction, two for balanced objectives, and one representing the current state. Modifying land use according to each map was considered as adaptation measure. However, implementing such measures faced limitations due to factors like the need to protect areas with high biodiversity, depletion of social and human resources resulting from population decline, and restricted transportation due to aging infrastructure. The evaluated the extent of achievement towards the optimal adaptation measures by considering these limiting factors and assessed the tipping point when the level of achievement dropped below 25%. The time period at which this tipping point occurred was recorded. The findings indicated that tree height growth patterns would change in various parts of the target area starting from the 2030s, but only a limited number of locations were expected to experience growth decline. On the other hand, landslide risks were projected to increase in certain areas of the target region from the 2050s onwards. As for both growth and landslide risk projections, the uncertainty associated with climate scenarios and RCPs amplified from the 2050s onwards. The decreasing effectiveness of adaptation measures and the growing uncertainty towards the later part of the period suggest that early implementation of adaptation measures may yield better results.

An interactive decision support tool for sustainable robust forest harvest planning

T5.35 The next generation of forest decision support systems for tackling today's and future challenges!

[2] Department of Mathematics and Statistics, University of Jyvaskyla, P.O. Box 35 (MaD), FI-40014 University of Jyväskylä, Finland
[3] Skogforsk, The Forestry Research Institute of Sweden, Uppsala Science Park, 75183 Uppsala, Sweden

Abstract: Sustainable forest management involves decision-making problems with multiple conflicting objective functions (e.g., economic, environmental, and social), multiple periods, and different sources of uncertainty. We have designed an interactive decision support tool prototype for sustainable, robust forest harvest scheduling in multiple periods. A novel multi-scenario multi-objective mixed-integer optimization problem has been formulated and solved, providing support for forest planners to study the existing trade-offs between demand satisfactions for multiple assortments in different planning periods. Besides, an intuitive robust analysis to study the outcomes variations caused by uncertainty and find a robust schedule in tactical forest planning problems has been proposed. The prototype's usability has been examined with a case study of forest harvest planning with 250 stands, three assortments (pine, spruce, deciduous trees), and a twelve-month harvest planning horizon.

Ecosystem-based Adaptation and Changemaking to Shape, Protect and Maintain the Resilience of Tomorrow's Forests

T5.35 The next generation of forest decision support systems for tackling today's and future challenges!

Alexia Stokes[1]
[1] INRAE

Abstract: In the Horizon Europe project, *eco2adapt*, we will develop the Ecosystem-based Adaptation (EbA) framework, derived from Nature-Based Solutions (NBS), that harnesses biodiversity and ecosystem services to reduce vulnerability and build social-ecological resilience to climate change. We will work in Living Labs in Europe and China, located in climate hotspots, and adopt a cutting-edge Decision Theatre approach to investigate how forest managers integrate disturbance and vulnerability into decision-making. Scenarios of how disturbance affects forest dynamics and ecosystem services at a landscape scale will be derived through modelling, and in Living Labs, stakeholders will learn how their choices affect ecosystem services in neighbouring forests. We will combine interdisciplinary knowledge from scientists and stakeholders in Europe and China to understand perception and provide incentivization for adopting EbA solutions, through local capacity-building and national policy plans. Through the same Decision Theatre methodology, we will use a capacity building approach to create and promote innovative technical, economic and governance mechanisms at a regional level. Semantic technology will be applied to create a knowledge base for hosting FAIR data and creating a SmartPhone Application (named the OneForest ToolBox) that allows users to access and add data concerning climate-resilient species, provenances, mixtures, management techniques and ecosystem services, whilst taking into account future uncertainties about climate and societal changes. We also provide a suite of cutting-edge tools to monitor vulnerability and resilience (including invasive species and above-and belowground biodiversity), at all levels of society – from the citizen to the policy-maker. By including tailored communication to all levels of society, we will reach out to a broad audience that has the capacity to cause positive change.

Environmental, safety and economic benefits of two-stage trucking in harvesting operations, introducing a decision-supporting tool

T5.35 The next generation of forest decision support systems for tackling today's and future challenges!

Robert Radics[1]
Muhammad Umar[1], Karen Bayne[2]
[1] Lincoln University, Lincoln, New Zealand
[2] Scion Forest Research, New Zealand

Abstract: The authors aimed to provide a decision support tool to optimise transportation and roading decisions by considering economic, social, and environmental factors. Two-stage trucking uses capable off-road vehicles to transport logs to roads that highway trucks can use. That solution is beneficial since it needs less roading and smaller landing sites and decreases erosion. The trade-off is the potentially higher cost due to the additional downloading and uploading of vehicles. Therefore, a multiattribute decision-supporting tool helps find the best solution by harvesting sites.
Based on semi-structured interviews with forest owners, forest management companies, harvesting crews and transportation companies, the key factors: terrain, existing road network, specific challenges of the roads, the total mass of logs from the harvest, erosion risk, multiple woodlots and harvests served by one super-skid, and the landing site distance from the all-season road.
Interviewees found economic and environmental benefits of two-stage trucking compared to one-stage trucking, mainly from the less roading and smaller landing sites. Generally, the steeper the terrain, the more benefits the two-stage trucking. Two-stage trucking can reduce roading by 30%. Sediment traps need to be emptied less frequently, which indicates less erosion from logging operations and infrastructure construction. The well-organised two-stage trucking operations reduced operation waste and improved safety. The number of incidents was significantly reduced reported by forest management companies.
Following the interviews, several time studies were conducted at harvesting sites to establish the logistic-economic model and identify the critical variables, distributions, and best-fitting regressions. Their probability distribution represented essential factors and outputs to make the model adaptable to various environments. The challenging terrain, lack of forestry roads, smaller woodlot, and longer transportation distance on an all-season road make two-stage trucking beneficial compared to one-stage trucking.
The designed integrated logistic-economic model asks for a reduced set of inputs (terrain -1-5 scale-, total wood mass, existing roads -yes/no-, distance from mill and distance from an all-season road) from the users.

Integrated Decision Support Systems for delivery of ecosystem services based on EU forest policies (DSS4ES): New COST Action CA22141 project

T5.35 The next generation of forest decision support systems for tackling today's and future challenges!

Jan Kaspar[1]
Emin Baskent[1, 2], Ola Eriksson[3], Harald Vacik[4]
[1] Faculty of Forestry and Wood Sciences CZU Prague
[2] Emeritus Prof., Faculty of Forestry, KTU
[3] Department of Forest Resource Management SLU
[4] Institute of Silviculture BOKU Vienna

Abstract: The role of digital technologies continuing to enhance the sustainability of value chains grounded in renewable resources has been well acknowledged. Within these technologies, the advanced DSS with embedded Operations Research techniques has proven to be indispensable tools for the long-term sustainable production of forest products and conservation of services. In this context, new COST Action has been started in 2023. The main aim of this Action is to establish a research network for facilitating the conceptualization and development of new methodological approaches of the next generation of DSS covering the relations between forest, forest landscape management and stakeholders of the landscape. The emphasis is on screening, evaluating, and proposing decision-making tools and methods. There are five focal points of the Action: 1) data and knowledge, for gathering and utilization of forest characterization; 2) models and methods, for design of DSS; 3) user perspective, for processes involving stakeholders; 4) DSS integration of various ES; 5) governance**,** for approaches of translating results into practice. The results of the Action will support holistic landscape planning approaches, which enhance sustainable forest management, considering a full range of ES, and address the policies and regulations across Europe. In this respect, an integrated DSS for sustainable provision of multiple ES at landscape scale includes support for the provision of resources for bio-based economic activities. The concept, structure and the process of the Action and opportunities for joining the network will be presented in interactive way for engaging the audience.

Modelling forests as social-ecological systems - A systematic comparison of agent-based approaches

T5.35 The next generation of forest decision support systems for tackling today's and future challenges!

Hanna Ekström[1, 2]
Nils Droste[1], Mark Brady[2, 3]
[1] Department of Political Science, Lund University, Sweden
[2] Centre for Environmental and Climate Science, Lund University, Sweden
[3] AgriFood Economics Centre, Department of Economics, Swedish University of Agricultural Sciences, Sweden

Abstract: Forests play a substantial role for a multitude of nature's contribution to people: in relation to biodiversity loss, climate change mitigation and adaptation, water availability, timber production, local ecological knowledge, and recreational values. This wide range calls for appropriately complex approaches to capture human behaviour in forest systems. Starting from a social-ecological system understanding, we perform a systematic comparison of agent-based models that can be used for understanding human-nature interactions in such systems. In contrast to traditional decision support system, agent-based approaches are developed to explicitly model heterogeneous agents. This study highlights strengths and areas for development of agent-based approaches as forest decision support systems. We find that out of 31 reviewed models, only 10 approaches include a direct representation of interactions between social actors and forests. Our comparison highlights three main angles for further development: i) calibration and validation of agent-based approaches include workshops, surveys, remote sensing and field measurements but robust methodological standards are still lacking, ii) agent learning and the dynamics of such feedback loops are emerging in computational science but are not yet fully implemented in social-ecological systems approaches, iii) coupling to ecological models such as dynamic vegetation models or species distribution models is only implemented in a few forerunner models. Based on this comparative overview, we present and discuss four agent-based model frameworks that are situated along these development frontiers: CRAFTY, FLAME, CORMAS, SOSIEL and PALM. These involve direct interaction among and between social and ecological systems, dynamic representation of processes, and a flexible design that allows for adjustments beyond their original purpose.

Key words: ABM, forest management, decision, model choice, complex adaptive system

Optimal Locations of Mass Timber Manufacturing Facilities within the Wood Supply Network in the United States

T5.35 The next generation of forest decision support systems for tackling today's and future challenges!

Vaibhav Kumar
Prakash Nepal[1], Richard D. Bergman[1], Neelam C. Poudyal[2]
[1] USDA Forest Service, Forest Products Laboratory, Madison, WI 53726, USA
[2] School of Natural Resources, University of Tennessee, Knoxville, TN 37996 USA

Abstract: Mass timber building materials are becoming more popular worldwide due to their many benefits, including their low carbon footprint, potential lower construction costs, and ability to support sustainable development. Despite growing popularity, facilities manufacturing mass timber are still limited in the United States. Users mostly rely on imported mass timber, primarily from Europe, which is economically and environmentally inefficient. It is therefore crucial to establish a regional supply chain network of domestic mass timber industry. By integrating factors on demand and supply side of mass timber, such as regional mass timber demand forecasts, raw material availability, transportation networks, sawmill capacity, the cost of acquiring raw materials, and labor force availability, this study aims to identify optimal locations for new mass timber manufacturing facilities within the conterminous United States. Our GIS-integrated mathematical optimization foundation uses information about North American road networks, forest ownership, mill locations, and an estimate of mass timber demand based on city population densities to find optimal locations for both softwood and hardwood mass timber manufacturing facilities. Our study aims to create an ideal network between timber suppliers (sawmills), new mass timber manufacturing facilities, and timber growers by considering supply chain networks and the anticipated demand for mass timber in US regions. Findings will be useful in informing forestry stakeholders on the viability of mass timber manufacturing and regional development planners regarding ideal sites for strategic investment on mass timber industry.
Keywords: Mass Timber, Supply Chain Network, Manufacturing Facilities, Timber Supply, Softwood/Hardwood Sawmill

PixSim: Enhancing high-resolution large-scale forest simulations

T5.35 The next generation of forest decision support systems for tackling today's and future challenges!

Nicolas Cattaneo[1]
Clara Antón Fernández[1], Rasmus Astrup[1]
[1] Norwegian Institute for Bioeconomy Research (NIBIO), Division of Forest and Forest Resources, Høgskoleveien 8, 1433 Ås, Norway.

Abstract: PixSim is a flexible, cross-platform, open-source stand level forest growth simulator designed to operate at the pixel level using high-resolution wall-to-wall forest resource maps. It addresses the need to adapt forest growth simulators to modern remote sensing-based forest inventories, offering forest scientists and managers a powerful tool to enhance forest management strategies and decision-making processes. By operating at the pixel level, PixSim enables improved spatial resolution and captures intra-stand variability, which is often overlooked in stand-level simulators. Implemented in the R programming language, PixSim offers minimal package dependencies, provides flexibility and scalability, and has been optimized for high-resolution large-scale simulations, ensuring efficient computation. The simulator's flexibility and open-source nature facilitate the incorporation of management modules and the inclusion of climate change scenarios in simulations.

Potentials and limitations of adaptive management and the resilience concept for real-world decision making in forestry.

T5.35 The next generation of forest decision support systems for tackling today's and future challenges!

Simon Reinhold[1]
[1] Freiburg University

Abstract: The transformation of our ecosystems due to global change is characterized by complexity and dynamics, subject to rapid change and disturbance. Foresters need to integrate deeper uncertainties and a wider scope of ecosystem services and stakeholder interests into their silvicultural considerations. A vast body of theoretical knowledge on adaptive management and the resilience concept with its different scopes for forest ecosystems already exist. Yet real-world examples for adaptive forest management and widely accepted implications of managing for resilience are not established yet. But what are the obstacles that prevent these theoretical concepts from becoming on-the-ground solutions for forest stewards and nature conservationists?

The trend in forest sciences goes towards viewing forests as complex, adaptive and open socio-ecological systems rather than something that can be steered with a command-and-control approach. Forest ecosystems are complex, have emergent properties and are capable of ecosystem learning and responding to impacts with resilience.

Nevertheless, little attention has been put on forester's perception of forest ecosystems and the bias in their decision-making in this complex and ontologically uncertain environment. Our hypothesis is that some of the needed prerequisites for adaptive management, namely experimenting, advanced monitoring and data availability and interregional networking as well as communication with stakeholders are hindered by structural limitations in the communication with science and superordinate hierarchical levels.

On my poster I will present some preliminary results from a series of qualitative interviews with German forest managers that specifically target their perception of uncertainty and their personal obstacles for incorporating adaptive management into their decision making. Findings will be presented in two categories: a more general, theoretical framework on the hierarchical, temporal and spatial environment that foresters centre their decisions around and more concrete problems like management tools or organisational institutions that foresters would need to improve for effective and future-oriented, uncertainty-sensitive decision making.

Supply and Demand of Local Forest Cultural Ecosystem Services based on Human Activity using Agent-Based Modelling

T5.35 The next generation of forest decision support systems for tackling today's and future challenges!

Jang-Hwan Jo[1]
Moongi Choi[2]
[1] Department of Forest Sciences and Landscape Architecture, Institute of Life Science and Natural Resources, Wonkwang University, Iksan, Republic of Korea
[2] Department of Geography, The University of Utah, Salt Lake City, USA

Abstract: Efforts to quantify ecosystem services (ES) from supply and demand perspectives and incorporate them into environmental policies have been implemented. Among these efforts, the estimation of ES supply often reflects the features or capacities of the ecosystem related to the target ES, regardless of whether humans actually consume the ES. Demand is often estimated from a macro perspective using various data, such as social media and consumption patterns, assuming that humans consume ES supply. However, few studies have estimated ES at the micro spatial scale or individual level, considering the direct activities of humans. In particular, for cultural ecosystem services (ES), micro-scale human activities such as hiking and tourism play a significant role in determining supply and demand, compared to provisioning, regulating, and supporting ES. Therefore, if the existing macro-level methods are used to estimate cultural ES, there is a possibility of underestimation or overestimation. Thus, this study presents a new methodology to estimate cultural ES scores from the perspectives of supply and demand at an individual scale, considering individual human activities and assessing the mismatch. We utilized spatial data on mountain trails to estimate the supply ES score and conducted a viewshed analysis. We employed agent-based modeling (ABM) to simulate individual hiking activities and quantify their potential exposure to ES for the demand ES score. Our approach yielded a more detailed cultural ES supply score than traditional map-based approaches. By considering the number of hikers and their actual moving patterns, we achieved more accurate results for the supply-demand mismatch at an individual level. This methodology enables the examination of supply-demand mismatches in cultural services across various scenarios at an independent scale. The findings of this study offer implications for establishing effective policies that balance the supply and demand of cultural services in real-world contexts.

T5.36 Towards a global observatory of forest dynamics

A global map of disturbance patterns across the world's forests

T5.36 Towards a global observatory of forest dynamics

Abstract: The patterns left by disturbances on forest landscapes are the result of a complex combination of factors, involving the causal agents, the pre-disturbance state of the forest and the broader environmental context. Characterising these patterns and understanding their distribution is therefore necessary for understanding the processes governing forest dynamics and how they can shape future forests. However, despite the increasing richness of ground and remotely sensed forest observations, we have limited knowledge on how forest disturbances differ structurally across the world. Here, we combine patch-level quantifications of disturbance structure, calculated from Landsat-derived tree cover loss data recorded between 2002 and 2014, to categorise and map forest disturbance patterns at the global scale. Based on metrics reflecting magnitude, shape complexity and spatiotemporal clustering, four patterns could be identified: i) small-isolated patches, the most abundant type, ii) clustered patches, prevailing in fragmented and sparsely treed forests, as well as in the dense intact forests of the Amazon, iii) complex patches, preponderant both in number and coverage, and iv) large-multi-year patches, the least abundant but most dominating spatially. In terms of counts, these patterns occurred in consistent proportions across all forested biomes. However, in terms of aggregated areas, the large-multiyear patterns were the most prominent in the fire-prone boreal and Mediterranean forests, while the complex patterns were as much dominating as the large-multiyear patterns in the heavily harvested forests across the Tropics and temperate regions. The disturbance patterns identified will provide a strong basis for elucidating the causal agents and for projecting potential trajectories of forest recovery.

Abundance of Northern Hemisphere tree species shrinks in the warm and arid regions of their climatic niche

Abstract: Long-term forest inventories provide an important data source due to their wide spatial extents covering large environmental gradients and detailed information on forest structure, composition and demography. These characteristics allow forest inventories to quantify a wide spectrum of indices from changes in forest dynamics to multifunctionality and give them a fundamental role in understanding the impacts of global change on forests. We analysed Northern Hemisphere forests with national forest inventories from Europe and North America, to quantify changes in tree species abundance across Northern Hemisphere forests in recent decades (1985-2019). For our analyses, we considered more than two million measured trees from 73 widely-distributed species on more than 126000 forest inventory plots. We found a generalised abundance decrease across the different regions of the species' climatic niche. However, when comparing changes in abundance within species, we observed that declines occur mainly in the warm and arid regions of their climatic niche, even adjusting for stand development. This result was also supported by quantifying the relationship between climate-driven abundance changes and species' climatic

niches. Our results imply an ongoing shift in abundance optimum of Northern Hemisphere tree species towards the cold and wet regions of their climatic niche but that might not be sufficient to track climate change for most species. We provide information on species-specific changes in abundance that must be taken into account when designing planting, management and conservation plans in the face of increasing climate change impacts.

AfriTRON: Challenges and Opportunities of Monitoring Africa's Closed-Canopy Tropical Forests

T5.36 Towards a global observatory of forest dynamics

Simon Lewis[1, 2]
Bonaventure Sonke[3], Corneille Ewango[4], Ifo Suspense Averti[5], Alfred Ngomanda[6], Vincent Medjibe[7], Wannes Hubau[8], Aida Cuni-Sanchez[9], Declan Cooper[2], AfriTRON Consortium[10]

[8] University of Gent, Belgium
[9] University of Life Science, Norway
[10] 36 Institutions worldwide, but mostly in African countries

Abstract: Africa is home to the second largest block of closed-canopy tropical forest on Earth. Africa's forests play a major role in the global carbon cycle, being a major carbon sink in intact forests and a major source from deforestation and degradation. They distribute water to the Sahel and Nile headwaters contributing to maintaining agriculture that sustains 300 million rural people. In terms of biodiversity they are home to our closest living relatives, and are centres of mammal diversity. Yet we know very little about these forests and how they function in our rapidly changing Earth system. To help address this the African Tropical Rainforest Observatory Network, AfriTRON, has been established since 2009 (Lewis et al. 2009, Nature; www.afritron.net) to collect and collate standarised permanent plot inventory data across closed-canopy tropical forests in Africa, monitoring all trees >=10 cm diameter in plots, and periodically re-visiting them to assess tree growth, mortality and changes in carbon stocks. There are now ~500 locations with data across 14 countries spanning central, west and east Africa. Here we present the latest results from the AfriTRON network on the changing dynamics, carbon balance, and impacts of drought, temperature and elevated carbon dioxide concentrations on these forests. We then highlight the opportunities for understanding and better managing these forests, if the AfriTRON network obtains funds to continue recensuses and fill-in data gaps spatially, and the challenges faced by African scientists in doing science on the continent, including of making data not only open, but open and fair. We highlight that any 'global observatory' will be limited by the limitations of the most difficult to sample major forested regions of Earth. The world's second largest block of tropical forest is one of those, so a focus on Africa to build any global observatory is a must.

Building a global airborne laser scanning database to capture the 3D structure and dynamics of the world's forests

T5.36 Towards a global observatory of forest dynamics

Tommaso Jucker[1]
Fabian Jörg Fischer[1], Ricardo Dal'Agnol da Silva, Laura Duncanson, Jérôme Chave, David Coomes, Grégoire Vincent, Sassan Saatchi, Samuel Favrichon, CanopyScapes consortium
[1] University of Bristol

Abstract: Forest ecosystems vary enormously in the 3D structure of their canopies due to differences in the height, crown architecture, density and size distribution of their trees. Capturing this spectrum of structural diversity and complexity is essential to understanding the role that forests play in regulating both carbon and water cycling on land, as well as their ability to provide habitat for biodiversity and regulate local microclimatic conditions. When it comes to large-scale mapping forest canopy structure, airborne laser scanning (ALS, also known as LiDAR) is widely considered the gold standard due to its ability to generate accurate, high-resolution canopy height models (CHMs) and digital terrain models (DTMs) of entire landscapes. However, acquiring ALS data remains expensive and access to data is often limited to a small number of sites surveyed on a project-by-project basis. To overcome this hurdle, we compiled the first global ALS database of forests, including data acquired at >10,000 locations across the world and spanning all major forest types on Earth. The database will be hosted online, allowing users to explore the location of the individual ALS datasets on a map, query key aspect of their metadata (e.g., acquisition date, flight parameters, sensor specification, data contributors), and download analysis-ready CHMs and DEMs for those ALS datasets that are open access. In doing so these data will feed directly into numerous areas of ecological research, as well as providing crucial cal/val data for forest biomass mapping efforts, satellite data fusion and integration with land surface models – ushering in a new era of canopy science and discovery.

Building the AfriMont network to study Africa's montane forests

T5.36 Towards a global observatory of forest dynamics

Aida Cuni-Sanchez[1]
Martin Sullivan[2]
[1] Norwegian University of Life Sciences, Ås, Norway
[2] Department of Natural Sciences, Manchester Metropolitan University, Manchester, UK

Abstract: Until recently, carbon stocks in African montane forests were poorly known, with insufficient data to generate an old-growth specific default value in the latest IPCC guidelines. To address this knowledge gap, we formed the AfriMont network, bringing together over fifty researchers who had established inventory plots in montane forests. We found that African montane forests on average stored 149 Mg C ha^{-1}, comparable to lowland African forests and greater than forests in tropical America. This ground-based data is especially valuable as remote sensing data related poorly to field measurements in our topographically complex mountain sites. We discuss experiences from building the network, and the challenges for sustaining it to monitor forest dynamics.

Ecological insights unveiled: half a century of research at Stillberg, a high-elevation afforestation in the Swiss Alps

T5.36 Towards a global observatory of forest dynamics

Esther R. Frei[1, 2, 3, 4]
Alessandra Bottero[1, 2, 3, 4], Arthur Gessler[4, 5, 6], Andreas Rigling[4, 6], Frank Krumm[4, 5], Peter Bebi[2, 3, 4]
[1] shared first authorship
[2] WSL Institute for Snow and Avalanche Research SLF, Davos, Switzerland
[3] Climate Change, Extremes and Natural Hazards in Alpine Regions Research Centre CERC, Davos, Switzerland
[4] SwissForestLab, Birmensdorf, Switzerland
[5] Swiss Federal Institute for Forest Snow and Landscape Research WSL, Birmensdorf, Switzerland
[6] Department of Environmental Systems Science, ETH Zurich, Zurich, Switzerland

Abstract: The catastrophic avalanche winter of 1950/51 devastated large areas of protective forests in Switzerland, raising questions about causes of such damage and the implementation of preventive measures for the future. Consequently, the high elevation afforestation Stillberg was established in the treeline ecotone near Davos in the eastern Swiss Alps. The experiment aimed to investigate methods for regrowing avalanche-damaged forests and developing sustainable measures to reduce avalanche risk. Since 2016, the site is integrated into the European Long-term Ecosystem Research network (eLTER).

In 1975, a total of 92’000 seedlings of *Larix decidua*, *Pinus mugo* ssp. *uncinata*, and *Pinus cembra* were planted along an altitudinal gradient at and above the current treeline (2075 to 2230 m a.s.l.). Annual monitoring of tree survival, growth, and vitality was conducted from 1975 to 1995, with additional assessments in 2005 and 2015. Meteorological parameters have also been continuously measured, alongside the documentation of microsite features such as solar radiation and snowmelt date.

During the initial 15 years after establishment, mortality rates were highest. Snowmelt date emerged as the most important factor influencing the mortality of all tree species, while elevation strongly affected growth during the first three decades. Pathogenic snow fungi were the primary agents of mortality of *P. cembra* saplings. Over time, the relative importance of different environmental variables for tree health and growth changed, leading to a *L. decidua*-dominated forest where competition and facilitation became crucial processes in recent years. Over the course of half a century of research at the Stillberg research site, a wealth of data has been collected, which have recently been made available as open research data. These datasets can contribute to transdisciplinary syntheses exploring ecosystem processes and the impact of climate change in mountain regions. In the face of climate change, new questions arise about suitable management strategies to adapt high-elevation forests to future climatic conditions without compromising the multiple ecosystem services they provide. As a result, the site is currently used as one of five demo sites in the EU-funded project FORWARDS, which aims at prototyping a future European observatory for climate change impacts on forests.

Land-use change effects on habitat availability and genetic diversity of tropical trees

T5.36 Towards a global observatory of forest dynamics

Laura Moro[1]
Robert Muscarella[1], Pascal Milesi[1]
[1] Uppsala University

Abstract: Land-use change presents major threats to biodiversity with impacts typically outpacing those from climate change. Habitat loss and fragmentation, key features of land-use change, can have direct and indirect consequences on plant species including reduced size and connectivity between populations, and reduction of genetic diversity. In Puerto Rico, for example, forest cover dramatically increased from ~6% in the early 1900's up to ~55% today. We quantified the impacts of land-use change on the area and configuration of suitable habitat patches for 267 native tree species in Puerto Rico to understand how land-use dynamics have affected their current geographic distributions, population sizes and genetic diversity.

We built species distribution models (SDMs) for all native tree species in Puerto Rico (N=267) based on current geographic distribution and abiotic conditions. We then combined SDMs with available data on land-use change (based on historical aerial photos from the 1930s, 1950s, and 1970s, combined with more recent satellite imagery) to estimate habitat availability through time. We used Plot based data from the Forest Inventory and Analysis (FIA) Program of the US Forest Service to estimate current population sizes and forest cover. Our results provide species-specific information on (i) the areal extent (km2) of climatically suitable habitat at different time points, (ii) fragmentation indices of suitable habitat at different time points and (iii) species responses to land-use change according to their life history strategies and phenotypic traits.

Overall, 223 species gained and 44 species lost suitable habitat during the time period analyzed. Species-specific responses varied and depended on species' life-history strategies, phenotypic traits, and general habitat association. To more comprehensively assess both the short- and long-term effects of land-use change, we will integrate this information with population genetic data. We will use a comparative genomics approach to determine how land-use change has influenced patterns of genetic diversity for a focal set of 20 tree species with diverse life-history strategies and climatic associations. This will allow a broader understanding of the implications of habitat recovery for forest genetic resources.

Monitoring tree growth and mortality in central Africa

T5.36 Towards a global observatory of forest dynamics

Abstract: Tree growth and mortality are two central processes in mixed and structurally complex moist tropical forests. Accurate estimates of the variables needed to model them remain sparse and scattered though. It remains thus difficult to predict forest evolution at a local scale and build reliable management plans. To fill this gap, from 2009 and up to now, we have annually monitored up to 21,000 trees belonging to 42 species exploited for timber production in Central Africa. To this end, we set up a particular sampling scheme. We sampled tree individuals without establishing plots, while ensuring that at least 20 trees were measured per species, site and logging history. With this data, we successfully provided new species-specific estimates of diameter increments and mortality rates, and we could investigate the relationships between tree growth, tree size and logging history. The resulting estimates can be used to provide more accurate forest projections (e.g. with matrix population models) and draw up sustainable management plans. Yet, the within and between-site variability were substantial, and further long-term data should be collected in different sites to predict tree growth and especially tree mortality with accuracy under different ecological conditions. The pros and cons of our monitoring systems will next be discussed and compared to other approaches used to monitor forest dynamics.

Quantifying European forest harvest regimes – a realistic representation of forest management for large-scale models

Abstract: The majority of forests globally are impacted by human activities and Europe in particular has a long history of intensive forest use. Harvesting of wood is one of the key processes of forest management, altering forest dynamics from tree recruitment to growth and mortality. This makes accounting for it crucial in any large-scale analysis of forest ecosystems. Yet, the representation of harvests in large-scale models is typically far from realistic, as the true management regimes – a realization of decisions made by individual forest owners – are not well described by simple rules or even by formal management guidelines. Here, our goal was to use field-based forest inventories to characterize European forest harvest regimes, implement these in the demographic vegetation model LPJ-GUESS and assess the effect on carbon dynamics. We quantified harvest regimes in 11 countries based on forest inventory plots (in total over 180 000 plots). Harvest regimes were described in terms of frequency and intensity of harvest events, and their relationship with potential drivers of harvest were quantified, considering pre-harvest forest structure, growth conditions, natural disturbances and variables relating to the policy environment, harvest costs and management goals. The results reveal notable variation in harvest regimes across Europe, with differences

between the countries, but also finer-scale variation within country borders. The results were then used to implement empirically-based harvest regimes in LPJ-GUESS, deriving harvest probability and intensity from the patterns observed in the data. The quantification of the current harvesting regimes across Europe provides much needed detail and fidelity in our understanding of the contemporary forest management practices, and implementation in vegetation modelling brings the model simulations closer to what is happening in forests in reality. This enables both improved assessments of continental-scale carbon dynamics and a realistic reference to which potential future forest management regimes can be compared to.

The Power of Plots: tracking Earth's tropical forests one tree at a time

T5.36 Towards a global observatory of forest dynamics

Oliver Phillips[1]
[1] University of Leeds

Abstract: Tropical forests, Earth's most precious ecosystems, are changing as never before. Meanwhile, careful, long-term measurements are essential to know how, where and why. The tropical forest carbon sink and its changing dynamics - which we only know about because of thousands of plot-level measurements - have consequences for policies intended to stabilize Earth's climate. Can we rely on tropical forests to keep on helping us? One thing is for sure, if we don't look, we won't know. Meanwhile, the people making the necessary measurements are among the most disadvantaged in global science. The large investments being made in remote sensing, machine learning, and open data initiatives have potential to help, but they also risk exacerbating the structural inequalities in global forest monitoring where thousands of key workers on the ground are already helping to make big data science possible, science that is largely led by others.

Our challenge is therefore huge - to unite researchers across the world to understand the ecology of tropical forests, their sensitivity to climate change and how they may help to slow it, while simultaneously making the research process much more equitable. ForestPlots.net aims to bring communities together to support sustainable, equitable and reliable long-term monitoring of Earth's most critical ecosystems and create a shared scientific picture of their health.

In this talk I will first briefly touch on the key findings from our tropical ground monitoring. I will then especially explore the scientific, practical and ethical challenges that we face, as we try to ensure that both the production and the use of forest data becomes more equitable, that the many less-visible colleagues who contribute vital work receive real recognition, and that we build fair, long-term collaboration across national, economic and cultural divides.

Towards a global understanding of tree mortality

T5.36 Towards a global observatory of forest dynamics

Abstract: Rates of tree mortality are increasing in many regions, with implications for forests and climate. Yet how and why these trends vary globally remains unknown. Developing a comprehensive assessment of global tree mortality will require systematically integrating data from ground-based long-term forest monitoring with large-scale remote sensing. Here, we summarise data from more than half a million forest monitoring plots from 88 countries and five continents and discuss the potential to use these to estimate tree mortality trends globally. Our survey shows that the area monitored increased rapidly from 1960 and has remained steady since 2000. Our data also shows large regions with limited ground-based information on tree mortality, especially the tropics and Asia. The integration of existing forest inventories with remote sensing and modelling can potentially fill those gaps, but this requires development of methods and legally binding agreements enabling seamless flows of information from the field to global assessments of tree mortality. Finally, a truly global monitoring effort must promote fair collaborations, transferring funding to and empowering scientists from less wealthy regions. Increasing interest in forests as a natural climate solution, the advancement of new technologies and world-wide connectivity means that now a global monitoring system of tree mortality is not just urgently needed, but also possible.

Unity makes strength: accelerating tropical forest science and building capacity through a global alliance of research networks

Abstract: Tropical forests contribute to approximately 70% of the world's forest carbon sink and support more than half the known species on Earth. Despite their global significance, our empirical understanding of the structure and functioning of tropical forests remains hindered due to the limited availability of field-based observations across environmental, disturbance, and successional gradients. While several international research networks have made significant contributions to tropical forest science over the past decades, none of them offer a comprehensive pantropical perspective on the dynamics of these critical ecosystems.

Here, we introduce the Alliance for Tropical Forest Science (ATFS), a new pantropical partnership that aims to accelerate research and build the scientific capacity necessary to improve understanding of how tropical forests function and to predict their responses to future environmental changes. The ATFS brings together 12 international tropical forest plot networks that manage 11,680 forest plots across 57 countries. We present the main objectives of the alliance and share the experience from the Tropical Forest Mortality Working Group (ATFS–MWG). We discuss the main challenges and showcase recent advancements in multi-network data harmonization and capacity building, along with preliminary results from the first multi-network study aiming to identify the primary drivers of tree mortality and associated carbon losses across the world's tropical forests.

As climate changes, assembling the disciplinary expertise, data, and scientific capacity across tropical forests is critical to resolving the underlying drivers of forest dynamics as well as informing the policy initiatives necessary to stop further global temperature increases and biodiversity losses.

Using a tree ring network to detect tropical forest responses to global change

Abstract: Introduction. Tropical forests and woodlands are key components of the global carbon cycle, and have a large potential to help mitigating climate change. Their ability to sequester carbon is likely diminished by increasing droughts. Yet, little is known how droughts affect wood production at pantropical scale. A new tropical tree-ring network helps filling this gap.

Questions. We answered the following research questions. (1) To what extent is tree stem growth reduced during drought years, and does this differ across droughts caused by low precipitation, high vapour pressure deficit (VPD) or high climatic water deficit (CWD)? (2) Is there evidence for lagged effects of droughts on tree growth, and – if so – how strong or persistent are these? (3) To what extent is variation in drought effects explained by mean climate?

Methods. We used a pantropical network of 477 tree-ring chronologies (https://tropicaltreeringnetwork.org/) from (sub-)tropical latitudes, comprising 150 species, 35 plant families and > 10,000 trees. For each chronology, we used gridded climate data to identify the 10% driest years (since 1930) in terms of seasonal precipitation, VPD and CWD.

Results. (1) Tree-growth responses during drought years were highly variable, but mostly negative. At pantropical level, growth declines during drought years were very small: ~ -3% (dry season) and ~ -2% (wet season). These values were very similar across drought types. Growth declines during dry-season droughts were significantly larger for Gymnosperms than Angiosperms. (2) During the two years following droughts, pantropical growth anomalies returned to values close to zero (-1 to +1 %). Thus, we did not find evidence for lagged effects of droughts. (3) Growth declines during drought years were stronger in hotter and more arid areas, but ample local variation in responses remained.

Discussion. Tropical tree-growth sensitivity to droughts is highly variable, overall small in magnitude and short in duration. Nevertheless, mild drought responses in terms of tree growth may still cause elevated levels of tree mortality. Under climate change, we expect drought impacts on growth and mortality to aggravate due to warming, VPD rise and increasing drought frequency and intensity.
