FORESTS & SOCIETY TOWARDS 2050

STOCKHOLM 2024

26th WORLD CONGRESS IUFRO

FORESTS & SOCIETY TOWARDS 2050

Stockholm, Sweden
23–29 June 2024

IUFRO World Congresses are among the largest global forest-related events. They attract more than 4000 participants, including representatives from academia, governments, industry, NGOs and civil society, from all world regions.

IUFRO World Congresses are interdisciplinary and integrative in scientific content. They are a forum for scientists and stakeholders to discuss technical and societal issues of forest-related research, policy-making and management. For the host countries and partner organizations, IUFRO World Congresses offer a global stage for showcasing their region and activities.

The first IUFRO congress took place in 1893, one year after the foundation of IUFRO. Since then, congresses have usually been held every five years in different parts of the world. The congress in plenary session is also the general assembly of the members of IUFRO.

Congress Scientific Committee

Chair:
Elena Paoletti (Chair, Italy)

Members:
Teresa Fonseca (Division 1, Portugal)
Marjana Westergren (Division 2, Slovenia)

Abstract: The rehabilitation of forest areas is not new to Malaysia as forest replanting activities have been carried out throughout the country for years to meet the demand for woody and nonwoody products as well as to nurture degraded forestland. Thus it is important for a soil to be evaluated to ascertain the degree to which rehabilitation activities have succeeded in restoring forest health, particularly in sustaining soil quality in rehabilitated forests. This review article aims to provide a corpus of information for forest managers and related agencies who work closely with forestry. The aim is to provide an overview on the importance of soil quality in measuring the success of forest rehabilitation programs. Research articles on the evaluation of soil properties at selected rehabilitated forests in Peninsular Malaysia were included in the review. The impact of forest rehabilitation in relation to soil properties comprising soil compaction, moisture, acidity, macronutrients, cation exchange capacity, microbial count, microbial enzymatic activity, and microbial biomass is discussed. Natural forest is used as a benchmark to see the effect of forest rehabilitation programs. Our review indicates that rehabilitated forests that were established earlier and have gone through a longer period of time have better soil quality compared to the soil of forests established later. This shows that rehabilitated forests are able to restore their soil quality and achieve fertility on par with natural forests, if given longer periods of time for recovery. Soil quality analyses should be done regularly to measure the extent of success in rehabilitation programs. Evaluation of forest soil quality should not neglect any of the three important aspects of soil physical, In short, it is important to select appropriate parameters to evaluate soil quality so that one can gain a clear picture of current soil conditions to ensure proper actions can then be taken to restore the condition of problematic soils to its optimum level.

Restoration and in situ conservation of native species the Atacama Desert, Chile

The Scientific Committee - Potpourri session
José Andres Hernández Cartes[1]
Ismael Jimenez[1], Leonardo Cifuentes[1]
[1] Instituto Forestal de Chile

Abstract: The decade 2021-2030 has been defined as the era of ecosystem restoration. In accordance with Chile's international commitments, committing itself by 2030 to the afforestation of 200,000 ha with at least 70,000 ha of native species, the sustainable management and recovery of 200,000 ha of native forests, and the application of the National Landscape Restoration Plan which includes 1 million ha under restoration processes by 2030. These commitments at the level of adaptation to climate change and biodiversity conservation represent a huge challenge for Chile in terms of governance, implementation and long-term monitoring.

For Chile to achieve restoration goals in the coming decades, studies have identified bottlenecks that prevent the country from meeting these challenges, which include: insufficient stock and supply of seeds for the production of native plants and the need for production protocols; and the need for innovative plantation designs of native species that allow improving the deficient results in the establishment phase.

The vegetation of the arid zones of Chile plays a fundamental role in the persistence and functioning of the Mediterranean ecosystems, it is the most threatened part of the country under a scenario of global climate change, a phenomenon that accelerates the processes of desertification and erosion, affecting the populations of rare, endemic and restricted-distribution species. The native flora of the Atacama region consists of 980 species of native vascular plants, of which 9.6% are in the Endangered (EP, 26 species) or Vulnerable (VU, 68 species) category.

The objective of the study is the conservation of endemic native shrub species (10 species) and cacti (4 species) with some degree of conservation danger, through the implementation of a landscape-scale restoration plan that covers an area of 60 ha.

In a first stage, seed collections were carried out and propagation protocols were generated for the target species. The individuals were established in land with a natural distribution and irrigated by means of a technical drip irrigation system. Irrigation was calculated by analyzing the historical rainfall of the study site. After 1 year of establishing the individuals in the field, there is an average of 85% survival.

"Adjusting land use patterns in agriculture with value chains from fast-growing economic trees in a new transformed agroforestry system"

The Scientific Committee - Potpourri session

Kitipong Tangkit
Aerwadee Premashthira[1], Warayost Lamaisie[1], Nopparat Kaakurivaara[1], Chakrit Na Takuathung[1], Trairat Neimsuwan[1], Narinthorn Jumwong[1], Ponthep Meunpong[1]
[1] Corresponding Author

Abstract: Efforts to promote commercial economic plantation in countries with conflicting land use policies that are not hostile to agriculture have long worked with agroforestry systems. The introduction of the concept of changing the word economic tree to a new name for the economic plant has not been concretely successful when the slow growth of economic trees is an obstacle to solving the problems of smallholder farmers.

But the problem of agricultural crops such as crops grown in developing countries with short-term harvests is always pressured by market prices and production factors and is a burden that the government must directly support the price both direct and indirect.

The idea of building a fast-growing economic timber agroforestry system for farmers is a challenge as to what model can lead smallholder farmers to create stability in the short, medium, and long term. The experiment introduced fast-growing plants, such as eucalyptus, to develop and improve activities within the value chain that work together with primitive crops. Changing the cultivation behavior deeply rooted in the cultural system is challenging. Consistently improving the outcomes in activities within the value chain may be the key to success in helping smallholder farmers overcome lifestyle imbalances and reduce short-term crop input debt. Very well with the economic tree that was renamed in the original name of the bio-based economic plant.

"Delineation of Groundwater Potential Zones in Una District, Himachal Pradesh Using Analytic Hierarchy Process (AHP) and Geospatial Analysis"

The Scientific Committee - Potpourri session

Mohd Hussnain[1]
DR Bhardwaj[1]
[1] Dr YS Parmar University of Horticulture and Forestry, Nauni, Solan, Himachal Pradesh. 173230.

Abstract: Human activities and ecosystems cannot exist without groundwater, which plays a crucial role in supporting human activities and sustaining ecosystems. However, its availability and quality are increasingly threatened by a variety of factors, such as population growth, climate change, and anthropogenic activities. It is vital to identify and delineate groundwater potential zones in order to ensure sustainable management and use. Geospatial analysis and Analytic Hierarchy Process are used to investigate potential groundwater zones in the Una district in Himachal Pradesh. Analytic Hierarchy Processes are multicriteria decision-making techniques that evaluate different factors affecting potential groundwater zones and assign weights based on their relative importance to each parameter. The research methodology involves the selection of thematic maps of geomorphology, lithology, soil, lineament, drainage, land use, slope, aspect, and rainfall. A geospatial tool in ArcGIS software was used to convert these maps into raster data by utilizing Survey of India toposheet data, SRTM DEM data, and Liss III data of Resourcesat-2A satellite imagery. Moreover, these datasets were subject to predetermined scores and weights in the decision-making process. A comprehensive groundwater potential zone map was developed by integrating a variety of datasets, such as topographic maps, satellite images, rainfall data, soil data, and land use/land cover data. The anticipated groundwater zones obtained were classified into five categories: Very poor covering 1% (17.85 km^2) of the total area; Poor 7 % (114.89 km^2); Fair 30% (453.76 km^2); Good 36% (548.06 km^2) and Excellent 26 % (392.78 km^2). The validation process involved obtaining open well yield data and referring to the Central Ground Water Report from 2021-2022 for comparative analysis and verification. Researchers have provided insight into how groundwater managers and policymakers can develop strategies and plans that address the spatial heterogeneity of groundwater potential zones in future water management plans.

Keywords: Groundwater potential zone, Geospatial analysis, Analytic Hierarchy Process, remote sensing.

A Bayesian network model to disentangle the effects of stand and climate factors on tree mortality of Chinese fir plantation

The Scientific Committee - Potpourri session
Yihang Jiang[1]
Xiongqing Zhang[1], Zhen Wang[1], Jianguo Zhang[1]
[1] Research Institute of Forestry, Chinese Academy of Forestry

Abstract: Tree mortality is a complex process that not only needs to consider the impact of various factors on tree mortality, such as stand and climate factors, but also considers the uncertainty and link the various long-term effects of the factors to each other. In this study, based on the long-term spacing trials of Chinese fir in four regions of southern China, Bayesian network was used to model tree mortality in response to stand and climate factors, as well as comparing with logistic regression and random forest methods. The results showed that Bayesian network had the highest accuracy in predicting tree mortality. In addition, Bayesian network could automatically find the dependency relationship between data and provide a theoretical framework for modeling uncertainty by using probabilistic calculus and underlying graph structure. Sensitivity analysis showed high importance of RD for survival rate among stand factors, and the most relevant of MAT among climate factors, whereas stand structure (Gini) was ranked as less important. In addition, tree mortality increased with the increase of AP, N, age and Gini coefficient, but decreased with the increase of RD, MAT and WMMT. Moreover, climate factors also affected stand variables, and there was a certain interaction between stand variables. The results will provide insights into forest management of Chinese fir plantation under the background of global climate change in the future.

A framework for considering justice aspects in integrated wildfire risk management

The Scientific Committee - Potpourri session
Claudia Berchtold[1]

[2] International Institute for Applied Systems Analysis (IIASA), Population and Just Societies Program
[3] Forest Science and Technology Centre of Catalonia (CTFC)

Abstract: Throughout history, ecosystems and societies have adapted to wildfires, but there is increasing evidence that anthropogenic climate change as well as socioeconomic development are altering the dynamics of extreme wildfire events, leading to increasing wildfire risk globally. With this increasing wildfire risk, inequalities may escalate, leading to potential new conflicts in wildfire risk management (WFRM). Managing these growing risks in increasingly complex governance settings raises important equity concerns; in particular, what is perceived as just in terms of outcomes of and processes in WFRM. Building on the environmental justice literature, we develop a framework for identifying and categorizing along the WFRM cycle (prevention, preparedness, response, and recovery & adaptation) crucial and generally applicable aspects of distributional, procedural, and restorative justice. We argue that policy and decision makers should proactively consider all three justice aspects within collaborative governance policy processes to successfully innovate integrated WFRM strategies that respond to equity concerns.

A framework for indicators of recreational values in forests

The Scientific Committee - Potpourri session

Peter Fredman[1]
Anders Sirén[2], Carl Lehto[3], Anders Lindhagen[3], Marcus Hedblom[3]
[1] Mid-Sweden University
[2] Universidad Amawtay Wasi Ecuador
[3] Swedish University of Agricultural Sciences

Abstract: Tourism and recreational activities are important ecosystem services that forests provide and they continue to grow. Seventy percent of Europe's forests are available for public recreation and about six percent are primarily designated or managed for public recreation. The intensity of recreational use can be measured in million visits per year, providing an indication of how important forest are for recreational purposes. There are however several challenges to monitor and measure social values in forests. Many countries have difficulties to report valid data according to the Ministerial Conference on the Protection of Forests in Europe (FOREST EUROPE). A state-of-the-art report of social indicators in forestry in North European countries by the Nordic Council of Ministers concludes that there is a need for further development of social indicators for sustainable forest use, but a major problem in most countries is a serious shortage of reliable data about forest recreation. The current study will help to fills these knowledge gaps. The objective of this study is to develop a framework for indicators of recreational values in Sweden. It was set up as a literature-based pilot study, supported by the National Board of Forestry, where 165 documents (peer-reviewed scientific articles, reports, policy-papers etc.) were identified and analyzed through a snowball approach.

Conceptually, we propose a two-dimensional framework. The first dimension is defined as either a potential or a realized value. Recreational potentials of a forest depend primarily on the forest's characteristics, but also on the influence of the surrounding environment, the existence of recreational infrastructure and the location of the forest. The realized value is the perceived experience qualities and actual use by recreationists. The second dimension captures whether the indicator measures the recreational value provided by a specific forest, or the value enjoyed by a specific user. The study also identifies several factors that may have a significant impact on recreational values – in a positive or negative way – but have not been sufficiently studied to be suggested as indicators based on current knowledge.

A new approach to ecosystem restoration: opportunities in sugarcane plantation landscapes

The Scientific Committee - Potpourri session
Giulio Brossi Santoro[1]
Pedro Henrique Santin Brancalion[1], Vinicius Moura Costa[1], Paulo Guilherme Molin[2]
[1] University of São Paulo - ESALQ
[2] Federal University of São Carlos - UFSCar

Abstract: The interest and need for ecosystem restoration increased greatly worldwide in the past years mostly targeting highly diverse regions such as the brazilian Atlantic Forest. However, land availability can be a main challenge since local landscapes consist of complex land use mosaics. Thus, increasing the efficiency of large agricultural systems such as sugarcane, can free up marginal areas and create opportunity for restoration. This work sought to find restoration opportunities by identifying and quantifying marginal areas of mechanized sugarcane production (Short Line Areas – SLA). The SLA consist on regions of short sugarcane planting lines where production costs are higher than the profits. We trained regression models using supervised machine learning algorithms to quantify the SLA in São Paulo state (Brazil) assessing two SLA thresholds: 50 and 100 meters. The models were based on 120 agricultural landscapes of 25 km² sampled throughout the state (total of 7,553), in which the SLA were manually mapped and explanatory variables that could be correlated with the presence of such regions were calculated (mean slope; drainage density; percentage of sugarcane cover, and landscape metrics applied to the crop fields). Finally, the estimates were used to investigate the potential contribution for reducing the state's deficit of legally preserved areas. The best models were created by the Random Forest algorithm. Model performance for each threshold (50 and 100 meters, respectively) was assessed using the Coefficient of Determination (0.451 and 0.634), Mean Absolute Error (0.252 e 0.932) and the Root Mean Squared Error (0.323 e 1.195). Estimates for the entire state were 174.19 km² of SLA considering the 100-meter threshold; and 39.78 km² for the 50-meter threshold. Overall, the use of SLA to reduce the state deficit of legally preserved areas can mitigate from 0.43 up to 4.83% of the total deficit. Investigating SLA showed potential to create new restoration opportunities, especially in complex landscapes. These regions can still be addressed considering incentives for voluntary commitments; corroborating the efforts, commitments, policies and projects of ecological restoration encouraged by the UN Decade of Ecosystem Restoration.

A scoping review on determinants of financial institutions' engagement in biodiversity conservation

The Scientific Committee - Potpourri session

Qian Liu[1]
Charlotte Marie Süring[1], Bo Jellesmark Thorsen[1, 2], Thomas Lundhede[1, 2]
[1] Department of Food and Resource Economics, University of Copenhagen, Rolighedsvej 23, 1958 Frederiksberg, Copenhagen, Denmark
[2] Centre for Macroecology, Evolution and Climate, University of Copenhagen, Denmark

Abstract: Scaling up investments and finance for ecosystem conservation is recognized as an urgent and crucial response to combat biodiversity loss. Financial institutions (FIs) are now recognized as vital sources and catalysts in this endeavor, given their potential to mobilize and allocate financial resources, driving transformative action through meaningful dialogues with their stakeholders. However, voluntary investments by FIs in biodiversity conservation remain limited. We expect the role of FIs in biodiversity finance within agricultural-environmental policy frameworks to be contingent upon their motives, barriers, and available financial tools. Despite some attempts at summarizing the state of research in the grey literature, a comprehensive scoping review is lacking. To address this gap, we conduct a review of scientific literature to identify the determinants of FIs' engagement in biodiversity activities. This includes examining the contextual conditions and extent of FIs' investments in biodiversity conservation, including the challenge of assessing the measurable biodiversity outcomes resulting from such engagements. Our study defines FIs as banks, insurance companies, pension funds, and mutual funds. Specifically, we provide overviews of existing studies, encompassing publication patterns, countries, and study types, summarizing the settings, contexts, and scales of conducted research. Additionally, we explore FIs' motives for investing in biodiversity conservation, the facilitating or inhibiting conditions for their conservation activities, and the characteristics of their direct and portfolio-based biodiversity investments. Comparative analyses among different types of FIs encompass financial motivations, obstacles, tools, geographical money flows, portfolio characteristics, investment sectors, and project features. By addressing the research gap in biodiversity finance, this paper proposes enhancements in research and policy to align with the EU's biodiversity strategy for 2030 and the global biodiversity 2050 Vision and goals.

A spatial framework for investment allocation under tree-planting policies: Outcomes for costs, land use, and human equity

The Scientific Committee - Potpourri session
Madisen Fuller[1]
Justin Baker[1], Zoey Roberts[2], Greg Latta[2]
[1] North Carolina State University
[2] University of Idaho

Abstract: Forest expansion, or the establishment of trees on land without current or historic tree cover, has significant potential as a GHG mitigation strategy, particularly in temporal and boreal regions where forest management and timber production could provide additional value to forest expansion efforts. There is great potential for economic gains from forest expansion, but there are challenges in ensuring the best outcomes. Capturing the dynamics of forest expansion is multifaceted and relies on ecological (i.e., soil and water qualities) and economic (i.e., timber markets, implementation costs) conditions, which need to be considered when implementing forest expansion investments. Failing to account for these factors will result in inefficient use of resources for planting and lower CO_2 benefits per dollar of investment. This paper assesses simulated changes in the spatial distribution of tree planting and additional forest carbon storage on alternative land use types under different incentive structures. We develop a spatially explicit resource allocation optimization framework to assess trade-offs between multiple policy structures. We combine estimates on planting costs and potential, current land utilization, forest yields, and demographic indicators to build a forest expansion optimization framework in the contiguous United States. We compare estimated CO_2 sequestration, cost efficiency, land use change, and spatial allocation of investments under policies that seek to maximize CO_2 storage over different time horizons and budgets. Lastly, we consider a policy design that prioritizes tree planting in communities with a higher relative proportion of disadvantaged populations to understand the cost and CO_2 implications of efficiency vs. equity considerations. Preliminary projections estimate total forest expansion to be between 17.94 and 28.14 million acres, a range of 393.9 to 662.8 million tons of CO_2, and the cost of expansion ranges from $11.19 to $26.63 per ton of CO_2. We find the highest expansion and CO_2 storage in scenarios with higher budget expenditures and longer simulation periods, but the cost per ton of CO_2 increases with the budget due to higher marginal abatement costs and opportunity costs of land. These outcomes are shown to be highly sensitive to spatially explicit economic and ecological conditions, as well as incentive structure specifications.

A survey of Swedish hardwood sawmills

The Scientific Committee - Potpourri session

Grace Jones[1]
Charlotte Egman[2], Erika Olofsson[2]
[1] Teagasc, Forestry Development Department, Ireland
[2] Linnaeus University, Department of Forestry and Wood Technology, Sweden

Abstract: Swedish forestry could benefit from maintaining a greater proportion of broadleaved species in the otherwise conifer-dominated stands, since greater species diversity may improve forest resilience to disturbances. Furthermore, the demand for Swedish roundwood is predicted to continue increasing, with many projects and studies now focused on hardwood utilization. Despite a growing interest in broadleaved tree species, in recent years the number of hardwood sawmills has been declining and there is limited information about their locations and capacity.

In this work, 21 hardwood sawmills were surveyed to identify mill locations and details about their log inputs. Questions related to species and volumes used, where raw material was sourced from, and what end products were manufactured. Additional questions were asked about their most significant threats and opportunities and their level of optimism regarding the future of hardwood sawmilling in Sweden.

Survey respondents mainly processed oak and birch, approximately 87,000 and 42,000 m^3sub/year, respectively (combined totals for all sawmills). The beech, alder and ash volumes were in the 1,000s of m^3sub/year. All the participating hardwood sawmills were located in southern and central Sweden. The sawmills produced a range of products, including sawn timber, flooring, tabletops, fine joinery, matches and toothpicks. Most of the birch volume was used for furniture components, while oak was widely used to restore or refurbish buildings and in public outdoor environments.

The surveyed sawmills were small and source most of their inputs from nearby suppliers. Few sawmills were importing raw materials, and where imports did occur, they were generally for oak. Common issues identified when importing wood included: unreliable wood quality, high transport costs and a desire to support local suppliers.

The sawmills were optimistic about their future and the Swedish hardwood sawmilling industry. As the mills are small, they have greater flexibility and can make decisions faster, which was perceived as a competitive advantage. Sweden has a continuing demand for hardwood timber, which may encourage forest managers to invest more in broadleaved tree species.

A Systematic Literature Review on European Forest Nature Conservation Politics: Avenues for Research and Theory Development

The Scientific Committee - Potpourri session
Antonio Basilicata[1]
Metodi Sotirov[1]
[1] University of Freiburg, Chair of Forest and Environmental Policy, Germany

Abstract: Even though basic scientific knowledge on the importance of biodiversity and its conservation have been known for decades, the related issues are perceived differently by states and other actors in Europe. At the same time, numerous biodiversity indicators are showing negative trends and especially forest ecosystems are increasingly affected by biodiversity degradation. In the European Union (EU), many efforts have been taken to maintain biodiversity in forests. For instance, recent political developments such as the new EU strategies on forests and biodiversity or the proposal for an EU Nature Restoration Law aim at improving the ecological transformation of society and economy. However, to achieve these ambitious policy targets coherently, forest nature conservation policymakers must consider a multitude of involved actors, sectors and conflicts. The fragmentation of interests and values of stakeholders becomes not only apparent on the EU level but also within member states, especially in federalist countries like Germany. Consequently, the myriad of actors and their either complementary or conflicting interests pose a challenge for nature conservation policymaking and implementation. To capture this complex conglomerate, forest nature conservation needs to be also informed by social and political sciences.

This systematic literature review addresses knowledge gaps in forest nature conservation politics by focusing on conflicts and challenges, their typologies, as well as relevant actor groups and policy sectors in the EU and Germany. Hence, the review is guided by the following two research questions: What are the relevant policy sectors and actors that influence nature conservation politics both in the EU and Germany? What are the main conflicts and types of conflicts regarding nature conservation politics in the EU and Germany? Furthermore, the review will conduct a meta-analysis for identifying theories on policy change and actor networks as well as existing research gaps in these frameworks, aiming at theory development. In order to facilitate the reporting of results from the review, and thus increase reliability and validity, the PRISMA statement is used. The findings of the study provide new avenues for research on forest nature conservation politics and identify opportunities for syntheses of policy change theories.

Adapting the Tasmanian forest practices system to climate change

The Scientific Committee - Potpourri session
Amelia Koch[1]
[1] Forest Practices Authority

Abstract: Given the increasing risk to production forests posed by climate change, the regulator of forestry in Tasmania, Australia, initiated a project to explore the ways the forest industry could adapt to climate change. The first stage of the project involved seeking feedback from local scientific experts on the expected impacts of climate change on Tasmanian production forests and potential adaptation options. Broad themes covered were carbon, forest vigour and condition, fire, soils, water, biodiversity and weeds, pests and diseases. The 52 responses were distilled into 75 potential adaptation options which varied greatly in importance and achievability. The second stage of the project was to convene a practitioner workshop to explore 'what climate change adaptation options could the forest industry start to progress?' Prior to the workshop the 30 people invited were given the background report from Stage 1 and asked to rank all adaptation options for importance and achievability. During the workshop 23 participant-identified discussions were had which aimed to identify practical actions to achieve the potential adaptation options. The third stage of the project used the information from the workshop and expert review to develop a list of targeted actions where the regulator of forestry has a direct or supporting role. Given limited resources, each action was assessed for importance and achievability, the result of which was used to identify a list of ten priority actions. These actions include reviewing the effectiveness of current erosion control measures, developing new spatial layers for planners to use and promoting research that will inform future management. This prioritisation process will be repeated regularly to ensure continual progress and to account for changes in priorities and resources.

Adaptive Natura 2000 forest conservation concepts in a climate change hotspot region

The Scientific Committee - Potpourri session
Anja Bindewald[1]
Axel Buschmann[1], **Ina Aufderheide**[1]
[1] Forest Research Institute Baden-Wuerttemberg (FVA), Department of Forest Nature Conservation

Abstract: Climate change is inevitably leading to changes in forest structures and species communities - including the death of many trees, sparse forest structures where non-native invasive plants may become established, shift of protected species distribution, and the increased spread of pests and insects that further threaten forest biodiversity. These conditions pose a challenge to protected forest areas, such as those inside Special Areas of Conservation (SAC) as part of the Natura 2000 network. The SAC have been established under the EU Habitats Directive, which aims to preserve or restore favourable conservation status of habitat types as well as animal and plant species listed in the Directive's annexes. To date, however, there is limited knowledge about the impacts of climate change on characteristic tree and herbaceous plant species in protected forest areas. Therefore, we assess the current state of forest habitat types inside several SAC in the climate change hotspot region Upper Rhine in Germany to detect possible changes that have already occurred due to ongoing global warming. To this end, we collect data on characteristic plant species and forest health condition in 2023 and 2024 by assessing heat- and drought-induced damage to tree stands in different beech and oak dominated forest habitat types in three SAC. Based on the results, we discuss the development and implementation of measures to compensate for climate-induced losses of protected forest habitats. Furthermore, we discuss the appropriateness of habitat definitions and assessment criteria under current and expected future climate conditions and develop conservation objectives that consider the vulnerability of these forest habitat types and adaptive management measures. Our results may also be relevant to other hotspot regions that are (will be) facing similar climatic conditions.

Advances in forest variable modelling using LiDAR technology: insights from a tree breeding trial in North-West Spain

The Scientific Committee - Potpourri session
Elena Pérez[1]
Elena Canga[1], **Covadonga Prendes**[1], Rafael Navarro-Cerrillo[2], Juan Majada[1], Ricardo Alía[3]
[1] CETEMAS
[2] Universidad de Córdoba
[3] Forest Sciences Institute, ICIFOR-INIA, CSIC, Madrid 28040. Spain

Abstract: Forest variable modelling from LiDAR (Light Detection and Ranging) data has revolutionized our understanding of forest ecosystems and their dynamics. By utilizing the three-dimensional data collected from airborne and/or terrestrial LiDAR sensors, researchers and forest managers can accurately estimate numerous forest variables, such as tree height, canopy density, biomass, and species diversity, which have many applications in a wide range of fields of study, including tree breeding trials.

This study was performed in a *Pinus pinaster* tree breeding trial and aimed to use LiDAR data to select the family/meta-population of this species that is best adapted to the conditions of North-West Spain. For this purpose, two types of point clouds were used: (i) terrestrial, collected with a handheld scanner, and (ii) aerial, collected with a UAV-LiDAR system. The terrestrial point cloud was used to determine tree positions and measure diameter-at-breast-height and total height of each tree, while the aerial point cloud was used to calculate a set of variables associated with vegetation structure (height, coverage, crown characteristics, etc.) at the single tree level. From these data, two models were fitted to estimate volume and biomass fractions using statistical techniques. Based on this, the differences between families/meta-populations for these two variables were analysed.

The study's general results revealed significant differences in volume and biomass among the *P. pinaster*families/meta-populations assessed. Specifically, certain *P. pinaster* families exhibited higher volume and biomass, indicating a potential influence on forest productivity and carbon storage capacity. The integration of LiDAR technology provided accurate and detailed measurements, underscoring the importance of considering genetic differences in *P. pinaster* families for effective forest management and conservation efforts.

In conclusion, the study using LiDAR data successfully quantified the differences in volume and biomass among various *P. pinaster* families/meta-populations. This reinforces the crucial role of LiDAR-based forest variable modelling in guiding informed decision making for forest management and conservation strategies.

Advancing forest resilience to global changes: a pan-canadian application of the functional complex network approach

The Scientific Committee - Potpourri session
Olivier Villemaire-Côté[1]
Charles Nock[2], Kevin Solarik[3], Brad Pinno[2], Christian Messier[1]
[1] Université du Québec en Outaouais, Institut des Sciences de la Forêt Tempérée, Canada
[2] University of Alberta, Department of Renewable Resources, Canada
[3] National Council for Air and Stream Improvement, Canada

Abstract: Global changes pose significant threats to the resilience and sustainability of forests worldwide. While climate-smart forestry and adaptive silviculture have been proposed and applied to address these challenges, they fail to adequately tackle growing social, economic, and environmental uncertainties associated with global changes.

To address these limitations, our approach embraces a comprehensive framework that recognizes forests as complex adaptive systems. It incorporates essential elements such as uncertainty, non-linearity, thresholds, and cross-scales hierarchies. Our strategy involves functionally diverse plantations as insurance against global changes. Additionally, we emphasize the utilization of functional diversity, redundancy and connectivity to increase resilience at both stand and landscape scales. To confront potential future climates, we consider assisted migration to introduce new functional traits and genes. By employing network theory, we describe the spatial connectivity of forest stands. Furthermore, we acknowledge the significance of self-regulation forces within forest ecosystems to effectively address the threats of global changes. This enables us to identify key stands in the landscape where interventions should be prioritized to promote forest resilience.

To validate this approach, we have initiated a large-scale study in collaboration with multiple universities, First Nations, industries, and governmental and non-governmental organizations, encompassing diverse forested biomes across Canada. This study involves a comparison between the functional complex network approach, business-as-usual practices, and climate-smart forestry under various future climate and disturbance scenarios. Moreover, we are diligently evaluating the socio-economic and governance implications associated with implementing both climate-smart and functional complex approaches. To ensure a holistic perspective, we actively engage social scientists, First Nations, and other collaborators in the development of realistic and socially acceptable management scenarios.

Through this project, we aim to bring the functional complex network approach into the real world, equipping forest managers with the necessary tools to determine appropriate actions and locations within the forest landscape to enhance resilience in the face of global changes. Our ultimate goal is to contribute to a paradigm shift in forest management and public perception, transforming it from an extractivist viewpoint to one where forest management actively contributes to increasing the resilience of forests to the uncertainties brought about by global changes.

Advancing Transformative Stakeholder Engagement for Inclusive Forest Restoration Processes.

The Scientific Committee - Potpourri session
Marie Vaney
Alba Granados Agüero[1], **Nina Horstmann**[1]
[1] Prospex Institute

Abstract: The importance of addressing conflict around forest restoration is now firmly recognised as imperative for success in the field. So is the inclusive involvement of stakeholders in the restoration process. However, the adoption of both practices still faces challenges, also with respect to the will and readiness of forest restoration teams to do so. The experience of the EU Horizon 2020 SUPERB project offers unique insights into how twelve such teams across Europe are being encouraged and empowered to recognise and tackle conflict with and among their different stakeholders through close engagement with the latter.

SUPERB stands for *Systemic solutions for upscaling of urgent ecosystem restoration for forest related biodiversity and ecosystem services*. It is a four-year research and innovation project that runs until December 2025 and aims to develop, test and upscale effective restoration solutions in twelve diverse European forest areas. This work is embedded in an innovative framework of continuously engaging a broad range of stakeholders. As part of this framework, inclusive stakeholder engagement is advanced as a tool for identifying and dealing collaboratively with conflict to enable effective, sustainable and socially beneficial restoration outcomes. The present study discusses and assesses SUPERB's hands-on efforts to work with the project's restoration teams to mainstream such use of stakeholder engagement at the local level.

The study's central methodology is participatory research, conducted by the authors as the SUPERB partner responsible for guiding and supporting the design and implementation of the project's stakeholder engagement activities. The study draws on the direct experience of the authors working on this task. It also makes use of related project reports and feedback from the forest area partners and stakeholders involved. The study concludes that to effectively coach forest restoration teams to take on conflict through inclusive stakeholder engagement it is crucial to introduce this co-creative approach at a pace that fits each team's context and experience.

This abstract is complementary to the one submitted to T4.6 by O'Brien and Begemann. If choosing between the two, please kindly prioritise the latter.

Advocating for Forestry as a Topic in High School Curriculum

The Scientific Committee - Potpourri session

Jilian Princess Bathan[1, 2]
Dr. Leonida Bugayong[1]
[1] University of the Philippines Open University
[2] Department of Environment and Natural Resources

Abstract: The Philippines has lost about 32% of its forest cover between 1990 and 2015, according to the World Bank. Many Filipinos are aware of the alarming rate of deforestation in the country, but forestry continues to be underappreciated and undervalued. One of the prevailing causes is a lack of education and awareness. This study aimed to establish a basis for high school education to include the topic of forests in the junior high school curriculum. This zeroes in on the significance of engaging the youth to protect, conserve, and manage our forests and be future stewards capable of influencing our planet's sustainability. The K to 12 Science Curriculum of the Philippines' Department of Education and the Angeles City Science High School's (ACSHS) Most Essential Learning Competencies (MELCS) for Environmental Science were analyzed and compared with other schools in Angeles City, Pampanga. These show that forest education is significantly lacking in the junior high school curriculum, with the K to 12 Science program not having any substantive forestry-related content. An online survey was conducted to determine the knowledge gap on forestry among 164 Grade 7 students, four Science teachers, and 56 alumni of ACSHS. The survey determined the respondents' knowledge on forestry and whether their behaviors take into account the current state of the Philippine forests. Data were analyzed using simple descriptive statistics. The respondents all acknowledged the importance of incorporating forestry as a topic in high school, as supported by the results obtained. The study highlights the need for intentional school activities where students can better appreciate what forests are, the ecosystem services that they provide, and the importance of participating in the protection and conservation of this undervalued natural resource. Examples of learning activities include viewing online modules and writing essays about forests, and projects such as establishing school nurseries for native tree species, tree planting, visiting protected forest areas to identify forest flora and fauna and learn about forest ecosystem protection and conservation. This study can inform policy makers to include the topic on forests in the high school curriculum to educate future generations about addressing forestry challenges.

An integrated approach for the sustainable management of forested islands of South Korea: Typology and ecosystem service mapping

The Scientific Committee - Potpourri session
Jang-Hwan Jo[1]
Emily Marie Lim[2], Deogkyu Kwon[1], Young-Gyun Son[2], Chanwoo Park[3]
[1] Department of Forest Sciences and Landscape Architecture, Institute of Environmental Science, Wonkwang University, Republic of Korea
[2] Graduate School of Environmental Studies, Seoul National University, Republic of Korea
[3] Warm-Temperate and Subtropical Forest Research Center, Jeju-do, Republic of Korea

Abstract: The efficient implementation of sustainable island forest management policies requires classifying them based on specific criteria and establishing a consistent management system for the forested island types identified. Through two expert Delphi analyses, a list of ecosystem services and key ecological and socio-economic factors relevant to the management of forested islands were elicited. Using these results, a typology of forested islands was established: (type 1) connected islands with high natural vegetation cover [n=156]; (type 2) connected islands with moderate natural vegetation cover [n=16]; (type 3) connected islands with low natural vegetation cover [n=60], (type 4) unconnected islands with high natural vegetation cover [n=1,810]; (type 5) disconnected islands with moderate natural vegetation cover [n=108]; and (type 6) disconnected islands with low natural vegetation cover [n=302]. An AHP analysis conducted with forest experts enabled the identification of priority ecosystem services to be considered for the management of each island type. In areas where islands are connected, provisioning services (natural resources, medicinal plants, etc.) were considered to have greater importance than regulating services (erosion prevention) and supporting services (species diversity). In areas where islands are disconnected/isolated, especially those that lack natural vegetation, regulating services (erosion prevention) were prioritized for management to achieve ecosystem conservation goals. In particular, type 3 islands require urgent management to increase ecosystem resilience as being connected to the mainland makes island forest ecosystems vulnerable to anthropogenic impacts and invasive alien species, which may lead to disturbances to island forest ecosystems. To illustrate the application of the classification system, the land use scoring method was carried out on a forested island corresponding to type 3. The spatial distribution of prioritized ecosystem services revealed mismatches between the supply and demand of erosion prevention, freshwater supply, and habitat provision services. The results of this study are twofold—a classification framework that categorizes forested islands based on ecological and socioeconomic factors is proposed, and key island ecosystem services to be prioritized in future management are identified for each island type. The results can be used as evidence to guide island development and management policies to sustain flows of key ecosystem services.

Analysis of Land Use and Land Cover Change in the Forest Zone of Nigeria

The Scientific Committee - Potpourri session
Olaniran Thompson[1]
[1] Department of Agricultural and Resource Economics, Federal University of Technology, P. M. B. 704, Akure, Ondo State, Nigeria

Abstract: Land-cover change has many environmental, physical, and socioeconomic significances. Therefore, the study investigated the consequence of Land Use/Land Cover (LULC) change on vegetation indices in the forest zone of Nigeria between 1989 and 2019 (30 years). Multistage sampling technique was used to sample three states which are Ekiti, Edo and Ondo State. In each state, three communities were purposively selected for the study, making 18 communities in the forest zones of Nigeria that was used for the study. Image processing and Geographical Information System (GIS) analysis was carried out. The result revealed that in the freshwater swamp Agricultural Ecological Zone (AEZ) of the forest zone, there was declining in areas covered by dense vegetation (69.17%) and wetland receded by 98.19% in the last 30 years. The built-up land and agricultural land increase by 152.71% and 21.18% respectively in the last 30 years. In the rainforest zone AEZ of the forest zone, there was 1689.43% increase in areas covered by sparse vegetation against 50.94% decline in dense vegetation. The study recommends that government and Non-Governmental Organizations (NGOs) should assist in formulating environmental policies that will protect the ecosystem in the study area.

Analyzing the dynamics of forest gaps in the Białowieża Forest (2015-2022) - a comparative study utilizing multitemporal data analysis of ALS and DAP

The Scientific Committee - Potpourri session

Miłosz Mielcarek[1, 2]
Sylwia Kurpiewska[1], Kacper Guderski[1], Dorota Dobrowolska[3], Ewa Zin[4], Łukasz Kuberski[4], Krzysztof Stereńczak[1]

Abstract: Gaps play an important role in ecological processes occurring in forest ecosystems, influencing forest structure, particularly in mature stands and old-growth forests. Gaps can affect tree growth, regeneration success, and contribute to the maintenance and enhancement of biodiversity. The ability to spatially characterize gaps (size, location) and track their temporal changes would be highly valuable for multifunctional and sustainable forest management, especially in forest planning and silviculture.

Modern remote sensing systems have opened up new possibilities for tree biometrics and the assessment of forest structure properties. Remote sensing technologies that provide continuous spatial information based on three-dimensional data, such as Airborne Laser Scanning (ALS) and Digital Aerial Photogrammetry (DAP), have gained much interest in last decades. Digital Surface Models generated using ALS and DAP data provide a detailed and accurate representation of the land surface and objects within a given area and provide valuable information about the characteristics of trees and stands.

The aim of the research was to determine the dynamics of gaps in the Białowieża Forest District from 2015 to 2022 using airborne laser scanning data and high-resolution aerial imagery. In addition, a comprehensive comparison was made between the utilization of ALS point clouds and image-derived Point Clouds (IPC) for spatial characterisation of gaps.

The results obtained confirm that the structural changes in the forest stands of the Białowieża Forest District are very dynamic. Moreover, the analyses carried out show that the number of gaps detected based on ALS data was significantly higher compared to the data from DAP (for data collected in the same year). It is worth noting that the largest differences in the number of gaps detected occur for small gaps (under 5 acres). Furthermore, ALS data better represent the shape of the gaps. The knowledge gained from the analysis can be valuable for the management of the Białowieża Forest area and the development of forest management concepts that resemble natural processes.

Are forests in protected areas more or less prone to climate-change induced disturbances?

[2] Universitat Autònoma Barcelona, 08193 Cerdanyola del Vallès, Spain
[3] Technische Universität München, Germany

Abstract: Disturbances are an essential component of forest dynamics influencing tree mortality, growth and regeneration and, ultimately, shaping species composition and forest structure. Yet, while disturbances induced by forest management can be planned, unpredictable shifts in the regime of disturbances associated to climate change (e.g., wildfires, drought, pest outbreaks), may threaten forest conservation. Therefore, characterizing the disturbance regime is crucial to assess forest resilience. In this line, there is still a debate whether forests in protected and non-protected areas may differ in their disturbance regime, with some voices alleging that reduced forest management in protected areas makes them more prone to other disturbance types or forest decay episodes. Here we analyze the disturbance regime of Catalonian forests from 1986 to 2020 in and outside of Natura 2000 areas (40% and 60% of forests, respectively), distinguishing between two types of severe disturbances (wildfires and other disturbance types including forest harvesting), and events of lower intensity, likely associated to drought-induced forest decay. For this study, we combined different data sources: i) the National Forest Inventory, ii) historical land-use maps, iii) a remote sensing-based map of disturbances across Europe (1986-2020) and, iv) the monitoring of forest decay episodes (2012-2020). From 1986 to 2020, severe disturbances affected 19% of the forest surface in Catalonia, a trend similar to the overall 17% of Europe's forest area disturbed for the same period. Yet, while wildfires accounted for 7% of all disturbances in Europe, they represented 48% in Catalonia. Occurrence of disturbances in unprotected areas almost doubled that in protected areas (17.1% vs 9.2%, respectively), with a similar proportion in the occurrence of wildfires, other types of disturbances and forest decay episodes, regardless of the protection status. Overall, our results stress the disproportionate importance of wildfires in shaping forest landscapes in Mediterranean-type regions in comparison to harvesting activities, while they also refute that those forests included in protected areas (i.e., Natura 2000) are more prone to suffer the effects of climate-change disturbances. This research benefited from the EU projects RESONATE (GAP-101000574) and wildE (GAP-101081251).

Assessing Primary Vegetation Recovery from Earthquake-Induced Landslide Scars in Japan's Boreal Forests: RTK-UAV Approach

The Scientific Committee - Potpourri session

Yasutaka Nakata[1]
Masato Hayamizu[2], Nobuo Ishiyama[2]
[1] Graduate School of Life and Environmental Sciences, Kyoto Prefectural University
[2] Forestry Research Institute, Hokkaido Research Organization

Abstract: Globally, post-disturbance site formation is caused by large-scale natural disturbances. In such areas, it is necessary to restore vegetation rapidly as it regulates the outflow of sediment and water. However, the relationship between post-disturbance site vegetation recovery and environmental factors has not yet been elucidated. This study aimed to estimate the environmental factors affecting early vegetation recovery after large-scale disturbances (i.e., earthquakes). We used a novel analysis of multidimensional high-definition earth surface data derived from real-time kinematic unmanned aerial vehicles (RTK-UAVs) with high positioning accuracy to reveal primary vegetation recovery conditions, accounting for ground surface changes and environmental information of earthquake-induced landslide scars in Japan's boreal forests. A vegetation survey was conducted to understand the species composition and coverage that had recovered from earthquake-induced landslide scar in Japan's boreal forests. The herbaceous species *Petasites japonicus* subsp. *giganteus* and the woody introduced species *Larix kaempferi* were identified as the dominant species that help restore vegetation, with high frequency and plant coverage in the primary succession of the landslide scar. The reproductive characteristics of these pioneer species suggest that they have an advantage for establishment and growth, particularly on landslide scars with substantial topsoil dynamics. An optimal generalized linear model was used, which considered the distance from the vegetation inside and outside the landslide scars, ground surface change, inclination angle, annual amount of solar radiation, and the local region as explanatory variables. The ideal environmental conditions for vegetation recovery are summarized as follows: 1) Maximum biological legacy preserved inside and outside landslide scars. 2) Vegetation recovery expected in stable areas with little erosion and accumulation. 3) Vegetation recovery expected on slopes other than steep slopes or those with extremely high amounts of sunlight. The vegetation recovery conditions and RTK-UAV remote-sensing techniques used in this study can be applied to vegetation restoration zoning plans immediately after a disaster in similar environments.

Assessing the suitability of under-represented tree species for forest management – an example using economic return and biodiversity indicators

The Scientific Committee - Potpourri session
Benjamin Gang[1]
Logan Bingham[1], Elizabeth Gosling[1], Thomas Knoke[1]
[1] Technical University of Munich, Institute of Forest Management

Abstract: A shifting focus in forest management from timber production to resilience and multifunctionality in the face of changing disturbance regimes might entail altering the species composition of forests. Although the conifers Douglas fir (*Pseudotsuga menziesii*) and silver fir (*Abies alba*) currently comprise only a small proportion of Central European forests, the prospect of widespread planting of these species as a climate adaptation measure is currently widely debated by forest managers. To inform this debate objective assessments of the multi-functional value of these species is required.

Here, we introduce Pareto frontiers to objectively assess the value of tree species under competing objectives and considering uncertaion future. Using these frontiers, we explore trade-offs between financial performance and biodiversity aspects of German tree species portfolios with and without these currently rare conifers. We compare several potential biodiversity indicators (related to herbivores, saproxylic beetles, and deadwood decomposition rates) that can be derived from standard forest inventory data.

Our results indicate that optimizing the biodiversity indicators generates gradual decreases in financial performance at first, but after an inflection point soil rent declines sharply. Portfolios excluding Douglas and silver fir achieved comparable biodiversity levels, but much weaker financial performance, than portfolios that included these conifers. Our novel approach of generating Pareto frontiers that integrate uncertainty can offer useful insights into ecosystem services trade-offs in contexts where risk is unequally distributed across management alternatives.

AUTOMATIC CHARACTERIZATION OF FOREST STANDS USING A HANDHELD SCANNER: FROM POINT CLOUDS TO VALUABLE INFORMATION FOR FOREST MANAGERS.

The Scientific Committee - Potpourri session

Covadonga Prendes Pérez[1]
Carlos Cabo Gómez[2], Celestino Ordoñez Galán[2], Elena Canga Líbano[1]
[1] Forest and Wood Technology Research Centre Foundation (CETEMAS), Pumarabule s/n, 33936 Carbayin, Asturias, Spain
[2] Department of Mining Exploitation and Prospecting, University of Oviedo, 33600 Mieres, Asturias, Spain

Abstract: Optimizing forest management practices for sustainability requires accurate and reliable information about available resources. Traditional inventory methods fall short in meeting the information needs for sustainable multipurpose management. In this regard, although terrestrial laser scanning has improved data collection efficiency, the development of automated tools for variable extraction from 3D point clouds is still necessary. By utilizing these tools, forest managers can streamline workflows and make informed decisions, thus contributing to sustainable forest management practices.

In this work, we present an example of automatic characterization of a forest stand through the processing of 3D point clouds captured with a handheld scanner. The processing is carried out automatically through a two-step mathematical algorithm. First, the algorithm calculates essential geometric variables that characterize the trees: diameters of sections along the stem, coordinates of section centres (XYZ) and total tree height. Second, it uses these variables to estimate stem shape variables, specifically maximum sagitta, sinuosity and lean of each tree.
The characterization was conducted in a Pinus pinaster breeding plot, where the algorithm calculated variables with only a small error range. That is, the approach demonstrated its robustness in estimating section centres, which are crucial for calculating shape parameters. The results obtained highlight the approach's effectiveness as an efficient alternative to traditional inventories which can automatically provide useful information for forest managers.

The approach presented here has direct applications in forest planning tasks, namely providing relevant information about forest stands which serves as the basis for informed decision-making in a wide range of tasks such as resource estimation, silviculture treatment simulations according to different scenarios, tree breeding and habitat characterization.

Bat sonotype as a novel insight into the congo basin rainforest dynamic

The Scientific Committee - Potpourri session
Yoba Alenga

Abstract: Tropical forest ecosystems are undergoing an exponential regression of their surface areas with subsequent habitat loss and fragmentation. The effects of such disturbances on bats are quite significant, even leading to a decline in populations. In order to ensure the maintenance of bat populations, it is thus important to preserve their habitats. This involves highlighting preferential habitats but also factors related to their foraging sites.

We have combined acoustic surveys and capture-mark-recapture methods to study relationships between bats and their preferred habitats and also to identify functional role of bats captured or recorded in their habitat. A total of 42 bats were captured, belonging to 13 species, including 5 species of frugivorous bats and 8 insectivorous bats.

The frugivorous bats - namely the species *Scotonycteris bergmansi*, *Casinycteris arginnis*, *Myonycteris torquata* and *Epomops franqueti* - were associated with dispersal of 16 plant species in the Yangambi Man and Biosphere Reserve (*Aidia micrantha*, *Allanblackia floribunda*, *Anonidium mannii*, *Barteria nigritana*, *Canarium schweinfurthii*, *Coelocaryon preussi*, *Dacryodes edulis*, *Mammea africana*, *Maranthes glabra*, *Microdesmis yanfungana*, *Musanga cecropioides*, *Pycnanthus angolensis*, *Staudtia gabonensis*, *Strombosia grandifolia*, *Strombosiopsis tetrandra* and *Panda oleosa*) while the species *Megaloglossus woermanni* ensures the pollination of the species *Maranthes glabra*.

Acoustic monitoring revealed the presence of 11 sonotypes namely of the following species: *Chaerephon pumilus*, *Macronycteris gigas*, *Macronycteris vittatus*, *Doryrhina cyclops*, *Rhinolophus fumigatus*, *Neoromicia nana*/*Scotophilus dinganii*, *Pipistrellus nanulus*, *Pipistrellus rueppellii*, *Nycteris arge*, *Myotis bocagii* and *Glauconycteris superba*.

The type of habitat (primary forest) significantly increases the foraging activity of bats. A medium to high density of the understorey and a medium opening of the canopy have a significant influence on bat activity and call structure. Complementarity of acoustic monitoring and capture is crucial to understand the mechanisms governing aggregation of bats assemblages in order to assess their activity and the ecosystem services they provide.

Beyond the timber legality regime: insights and implications for the newly emerging forest-risk commodity regime

The Scientific Committee - Potpourri session
Laila Berning[1]
Metodi Sotirov[1], Ahmad Maryudi[2], Andita Aulia Pratama[1, 2], Dwi Laraswati[2]
[1] The University of Freiburg
[2] Universitas Gadjah Mada

Abstract: Illegal and unsustainable land use are the key drivers of global deforestation and forest degradation. Timber supply chains are regulated through a complex of demand- and supply-side private and public policy and governance mechanisms under the transnational timber legality regime. To address regulatory gaps in not regulating transnational agricultural commodity supply chains, the European Union, United Kingdom, and United States started developing new demand-side trade rules to address agricultural expansion as the most important driver of deforestation. These new legislative initiatives to regulate agricultural forest risk commodity (FRC) supply chains build on experiences with designing, implementing, and enforcing timber legality policies. We analyse these policy changes by drawing on regulatory governance scholarship and Bernstein and Cashores (2012) four pathways of global influence theoretical framework. Our results show shortcomings in formally designed synergies between state-sanctioned trade rules (e.g., EU Timber Regulation, US Lacey Act Amendment) institutionalizing timber legality norms in hard law and market incentives in the form of development-cooperation based free trade agreements (i.e., Forest Law Enforcement Governance and Trade Voluntary Partnership Agreements) and voluntary private regulation (i.e., forest sustainability certification). Our results challenge assumed win-win synergies of policy and governance mechanisms seeking to deliver on social, environmental, and economic goals and contribute to research on the design of smart policy mixes under the newly emerging forest-risk commodity regime.

Biodiversity Assessment of Gums, Resins, and Associated tree species in Arid and Semi-Arid Lands of Northern Kenya.

The Scientific Committee - Potpourri session
Collins Masinde[1]
Solomon Kipkoech[1], Gladys Rutto[1], Jonah Kiprop[1]
[1] Kenya Forestry Research Institute

Abstract: Anthropogenic activities, especially unsustainable harvesting of tree resources and degradation, cause a decline in biodiversity in Arid and semi-arid lands (ASALs). ASALs cover 80% of Kenya’s landmass and support 36% of the population. Besides, they support 70% of the livestock and 90% of wildlife. In response, robust biodiversity loss exists, overexploitation of gums and resins tree species, and climate and land use changes, besides the emergence of invasive species. This review investigated the composition, diversity, distribution and occurrence of gums and resins and associated species in ASALs of Northern Kenya. It also explored the best conservation strategies for gums and resins-producing species by mapping their distribution which is important economic resources in these regions. Our research findings indicated a lower Simpson's biodiversity index for Mid-Tana (0.08) and Sabarwawa (0.07) landscapes. No significant differences were found using the Hutcheson t-test p-value 0.006687. Plant communities in both landscapes are sparsely diverse, Sabarwawa (0.0698) and Mid-Tana (0.08658). Results from the ß-diversity indicated a moderate species turnover process indicating a high similarity in species composition. Four gums and resins-producing species were noted: *Boswellia neglecta*, *Commiphora holtziana*, *Vachellia senegal* and *Vachellia seyal*. The relative frequency of gums and resin species was equally higher in Mid-Tana, 23.13%, compared to Sabarwawa, 22.22%. A strong positive correlation existed between gums and resins species richness and low and mid-lower altitudinal gradients. Findings from our study can provide a baseline regarding biodiversity conservation in arid and semi-arid landscapes. Notably, elevation influences the occurrence of gums and resin-producing tree species, thus, a critical factor in the growth of these species. These species are alternative sources of livelihood for theDry eco-regions and require sustainable management.

Biological Invasion by Acacia longifolia (Andrews) Willd. and Environmental Susceptibility in Temperate Regions. Determinants and Impacts in Centre-We

The Scientific Committee - Potpourri session
Jorge Luis Oliveira-Costa[1]
Rui Ferreira de Figueiredo[1, 2], Vânia R. Pivello[1, 3]
[1] Center of Studies in Geography and Spatial Planning (CEGOT), Portugal
[2] Department of Geography and Tourism, Centre of Studies in Geography and Spatial Planning (CEGOT), University of Coimbra (Portugal);
[3] Department of Ecology, Institute of Biosciences (IB), University of São Paulo - USP (Brazil);

Abstract: This communication aimed to: (i) define and map the global and local cores (Portugal and Brazil) invaded by Acacia longifolia; (ii) identify its impacts on coastal ecosystems; (iii) understand the relationships between the patterns and processes responsible for the proliferation and invasion of this species; (iv) and, finally, this information pretend to be a support to the future evaluation of the distribution patterns and ecological processes of the species to develop national and transnational Invasive Alien Species management. Acacia longifolia is a coastal shrub native to Australia, and shows significant invasive potential. It was introduced first in Portugal at the end of the 19th century, about a century before it was brought to Brazil. We did a global analysis of the invasive species dynamics (regarding its invasibility/invasiveness), focusing on areas invaded by the species with different natural and socio-ecological characteristics. Considering that total eradication in the short-medium term is technically unfeasible, more pragmatic management solutions are required whose adaptation to local realities greatly benefits from these global analyses.

Biopesticide potential of Melia volkensii?

The Scientific Committee - Potpourri session
Victor Jaoko[1]
Jackson Mulatya[1]
[1] Kenya Forestry Research Institute

Abstract: The fall armyworm, *Spodoptera frugiperda,* and red flour beetle, *Tribolium castaneum* are insect pests of economic importance that have a negative impact on maize production and stored grains, respectively. The continued use of synthetic insecticides has been reported to cause undesirable effects and negative consequences on the environment, human and other non-target organisms leading to renewed interest in botanical pesticides as a safer alternative. In this study, we employed a bioactivity-guided strategy to isolate and identify insect antifeedants from *Melia volkensii,* an indigenous tree species native to drylands of East Africa. Laboratory screening of methanolic extracts from the bark, leaves, nuts and pulp showed that *M. volkensii* nuts and pulp extracts had higher antifeedant activity against fall armyworm and red flour beetle. Further fractionation of the nut and pulp extracts was done using solvents of increasing polarity. Biotesting of the solvent fractions showed that antifeedant activity was retained in the dichloromethane fraction, which was subsequently purified using column chromatography. The respective chromatographic subfractions were tested against the insects to identify bioactive fractions. The bioactive nut subfractions were subjected to preparative-HPLC and preparative-TLC to yield pure toosendanin. Recrystallization of the bioactive fraction from pulp yielded pure salanninolide. The limonoid compounds were positively identified using LC-MS and NMR spectroscopy. This study provides new leads for development of insect control compounds and shows that *M. volkensii* extracts could be incorporated in integrated pest management.

Bird diversity in old hinoki plantations with multi-layered canopy structure

The Scientific Committee - Potpourri session
Ryoko Hirata[1]
Suzune Nishi[1], Satoshi Ito[1]
[1] University of Miyazaki

Abstract: Forests with a complex vertical structure (stratification) have high biodiversity including rich forest bird populations. However, there is still little knowledge about whether multi-layer forests with single conifer species can contribute to biodiversity conservation same as that consisting of multiple species (conifer and broadleaf). We investigated bird species diversity in old hinoki (*Chamaecyparis obtusa*) plantations in southern Japan, and evaluated the contributions of multi-layered canopy structure of different species composition to bird species diversity conservation.

The field survey was conducted in four forest stands: a two-layered old plantation (TC) dominated by hinoki (106-year-old canopy trees and 28-year-old understory trees), a well-developed multi-layered mixed stand (MW) consisting of old hinoki (100-year-old) canopy trees with a well-developed understory of large broadleaf trees, a developing multi-layered mixed stand (MD) with old hinoki (100-year-old) canopy trees and less developed understory of sparsely distributing broadleaf saplings, and a 99-year-old semi-natural evergreen broad-leaved forest (SB).

The broad-leaved forest (SB) had high bird diversity during both the breeding and wintering seasons, showing small seasonal and annual variations in diversity. The well-developed multi-layered mixed stand (MW) showed a trend in bird diversity similar to that of the broad-leaved forest (SB). The developing mixed stand (MD) had lower bird diversity than developed mixed stand (MW) and greater seasonal and annual variations in diversity. In the two-layered stand (TC), the bird diversity was similar to that of the developing mixed stand (MD).

We concluded that the single-species and two-layered hinoki plantation (TC) investigated in this study less contributed to bird diversity than the well-developed multi-layered mixed plantation (MW), but had a similar level of contribution as the developing mixed plantation (MD), suggesting an importance of the richness of food resources.

Blossom, place to read, shade and friend: Accounting for social and cultural values of trees outside of woodland in peri-urban and rural environments

The Scientific Committee - Potpourri session

Beth Brockett[1]
Jen Clements[1]
[1] Forest Research

Abstract: Trees outside of woodlands and forests (ToW) represent a large percentage of tree cover in some countries. Recent research from England has found that 4.3% of land area is covered by ToW, compared to 14.6% covered by woodlands. For many people ToW are their main interaction with trees of any kind. This project sought to better understand the range of social and cultural values different publics associate with ToW, especially in less-studied peri-urban and rural settings. An interdisciplinary social science approach also collaborated with ecologist colleagues and drew on insights from the arts and the humanities. This led to a holistic understanding of how social and cultural values intersect with and are influenced and informed by other ways of viewing ToW. The results led to the development and testing of a theoretical framework for public values around TOW and illustrated how we might identify and measure this range of values. Our findings have implications for how we plan, establish, manage and care for this vital resource, as distinct from woodland trees. Enabling us to better account for social and cultural values as we balance goals, risks and trade-offs for ToW within policy and practice.

Bridging the human-nature divide in Forest Growth Models for Indigenous Forest Landscapes: taking the cases of Central India and Southwest USA.

The Scientific Committee - Potpourri session

Alark Saxena[1]
[1] Northern Arizona University, Flagstaff, AZ, USA

Abstract: Ecological models such as Forest Growth Models are central to decision-making for the scientific management of forest landscapes. However, applying these models to Indigenous Forest landscapes reveals a theoretical gap in knowledge. Current models inadequately represent Indigenous Forest landscapes that are characterized by complex adaptive social-ecological systems. Models fail to systematically integrate human interactions that influence ecological dynamics. These inabilities increase the human-nature divide in forestry science and often produce unwanted surprises. From a management perspective, Indigenous decision-making needs are inadequately met in these models. At the same time, there is a risk of losing traditional ecological knowledge (TEK) as the altered natural resource management regimes based on current science have created barriers to transfer TEK to future generations. Thus, there is a critical need to develop models that are theoretically capable of dealing with social-ecological systems, bridging the human-nature divide, responding to Indigenous communities' needs, and supporting TEK conservation. Based on my ongoing research with indigenous communities, I will demonstrate the development of integrated social-ecological models using participatory modeling and process-based modeling approaches that model indigenous communities' interactions with specific forest species in two contrasting landscapes. I take the example of Tendu (*Diospyros melanoxylon)* in Central India used by Gond Communities for *bidi* (local cigarette) making and Emory Oak (*Quercus emoryi)* central to the culture of White Mountain Apache in the Southwestern United States. Based on the current model development process, I will discuss how these models can become boundary objects that can be used for Knowledge Co-production, bridge the human-nature divide, empower Indigenous community decision-making for their landscapes, and preserve TEK for the sustainability of Indigenous Forest Landscapes.

Burn them all? – Analysis of the current forest bioenergy dispute

The Scientific Committee - Potpourri session

Daniela Nousiainen[1]
[1] School of Forest Sciences, University of Eastern Finland, Finland

Abstract: The intention of the EU to replace fossil fuels with renewable energy sources is one of the reasons for the increased demand for (not only) European forests. The newest Renewable Energy Directive sets up the share of the renewable energy goal for 2030 to be 40%. Another current EU renewable energy policies have the ambition to reach the share of renewable energy to 45% by 2030 (e.g. REPowerEU). There has been a heated debate about these ambitions for over a decade. Various actors present their attitudes and opinions about forest bioenergy in many newspaper articles, statements, opinion papers, letters and the forms of petitions or protests. This study focuses on the current forest bioenergy debate that often happens on different online channels and platforms applying the discourse analysis principles. It aims to analyse over 100 newspaper articles, statements and petitions to explore various actors' perceptions of the EU forest bioenergy. The analysis of the written sources is complemented by the information obtained through interviews with eight actors. These actors were selected due to their active participation in the public debate related to EU forest bioenergy. The main objective of the study is to analyse all the material to describe the discourse and determine bridges and barriers among the actors concerning forest bioenergy. It also explores the perceptions and opinions of actors about each other and the effect of the dispute on the actors' activities. It also analyses the actors' opinions about various actors' participation in the dispute. The results of the study will provide a piece of information for further facilitation of the forest bioenergy discussion and negotiations and this way to support the related policy-making. The results can also be taken into account when preparing a communication strategy for individual actors. The poster will present the pre-results of the ongoing study analysis.

Can science solve conflicts on managing forests for multiple Ecosystem services use?

The Scientific Committee - Potpourri session

Ján Matúš Urbančík[1]
Zuzana Dobšinská[1], Jaroslav Šálka[1]
[1] Technical University in Zvolen, Department of forest economics and management, Slovakia

Abstract: Knowledge transfer has received increasing attention by scientists and policy makers especially in ecosystem services provision and related trade-offs between them. It is a complex process, which depends on decision makers´ ability to convince all relevant actors to accept scientific solutions for existing problems. In this way, it can help resolve conflicts in forest use and protection. The aim of the presentation is to analyse four different knowledge transfer processes in Slovakia using the RIU model (Böcher and Krott, 2016). The RIU model enables to identify which phase - research, integration, or utilization - is crucial for the overall success. We also included power analysis for deeper understanding of stakeholders´ relations. The main research methods are document analysis and semi-structured interviews. We conducted case studies on various governance levels (local, regional, national, international) to create a complex overview of different situations, guidelines, recommendations, and identified success factors. Results show that changes in political leadership can initiate changes of knowledge transfer process dynamics. Involving relevant stakeholders facilitates the acceptance of results and helps to prevent future forest use conflicts. The effect of a skilled facilitator and powerful actors or actors´ groups are crucial. Knowledge transfer differs, depending on whether it takes place at a local, regional, national, or international level, in our case it even required multi-level governance.

Carbon footprint and impacts of mechanized timber harvesting operations in the Northeastern United States

The Scientific Committee - Potpourri session
Ashish Alex[1]
Anil Raj Kizha[1], Alex Kunathu George[2], Libin Thaikkattil Louis[3]
[1] School of Forest Resources, 5755 Nutting Hall, University of Maine Orono, ME 04469, USA
[2] 203 Freer Science Hall, Paul Smith's College, New York - 12970, USA
[3] University of Maine Fort Kent, 23 University Drive, Fort Kent, ME 04743 USA

Abstract: The US economy targets to achieve net-zero carbon emissions by 2050. Sustainably managed forests are considered a net sink rather than a source of carbon. Logging contributes remarkably to the carbon footprint of sustainable forest management. Estimating the carbon footprint of logging operations is essential to minimize the environmental impacts of the industry. The objectives of the study were to quantify and compare the carbon footprint (kgCO 2 eq) of predominant mechanized timber harvesting methods such as whole-tree (WT), cut-to-length (CTL), and hybrid-cut-to-length (Hyb. CTL) in the Northeastern USA. Life cycle assessment (LCA) was done using SimaPro software and allied database (USLCI and USEI), adhering to ISO 14040 and 14044 standards. TRACI (Tool for reduction and assessment of chemicals and other environmental impacts) v 2.1 was used for impact assessment. The system boundary was from tree stump to mill gate and the functional unit was 1 tonne of round wood. The input variables were the quantity of fuel (liter tonne -1) and lubricants (engine oil, grease, hydraulic oil, and antifreeze (kg tonne -1) obtained from the logging companies/contractors in the region. The data required to do the analysis was obtained from the logging companies. The preliminary result showed that the average global warming potential was highest for the WT (11.57 kgCO 2 eq), followed by Hyb. CTL (11.09 kgCO 2 eq) and CTL (9.91 kgCO 2 eq). A similar trend was observed for smog. Ozone depletion potential was highest for Hyb. CTL, followed by WT and CTL. These results could help forest managers to make informed decisions while selecting the harvest method, considering the carbon footprint in the forest industry's pursuit of carbon neutrality. As the green economy is gaining importance, information on the carbon footprint of the forest supply chain is necessary to ensure the sustainability of active forest management activities.

Carbon Sequestration and GHG Emissions from Cacao (Theobroma cacao L.) Cropping Systems in Davao Oriental Philippines

The Scientific Committee - Potpourri session

[5] Ateneo De Davao University

Abstract: Cacao (*Theobroma cacao* L.) is a high value crop grown as monoculture or intercropped with coconut in countryside of the Philippines to maximize economic gains, however, carbon sequestration potentials and GHG emission are not realized for climate change mitigation. This research assessed carbon and GHG in cacao farms from Davao Oriental in Mindanao Island. Three cropping systems were selected: monocrop cacao, monocrop coconut, intercrop cacao and coconut across three municipalities (Mati, Lupon, Caraga) in the region. Carbon measurement was based on crop biometrics, laboratory analysis, and allometric equations. Estimated mean carbon sequestration from four carbon pools in intercropping, mono-coconut, and mono-cacao were 110-, 109-, and 22-tons ha^{-1}, respectively. Cacao in intercrop system contributes only ≈4% of the carbon stocks due to smaller stem diameter, younger age, and soil management practices. Rate of annual biomass accumulation aboveground generated was higher in monocrop coconut than intercropping and monocrop cacao ranging from 08-0.91 tons ha^{-1} yearly. Major drivers in carbon sequestration were soil management, spacing, farm management and biodiversity. Higher GHG emissions were obtained from mono-crop or intercrop cacao where 50% emissions were added when cacao is incorporated as understory. High sources of emissions were from residue and fertilizer application for cacao management. Conversion of deforestation areas into intercropping can potentially add 340,344 tons of additional carbon wins across four target provinces in five-year period. Potential carbon stocks that can be saved from averted deforestation is estimated at 1.4M tons in five years. The presence of natural ecosystems adjacent intercropping farms indicates environmental benefits like canopy layering, biodiversification, soil improvement, and creating possible corridor for wildlife. Capacitating farmers to promote carbon conservation and improvement of extension services will sustain ecosystem services while improving income. Substantial reduction in GHG emissions can be achieved if carbon wins can be integrated as part of the farming practices.

Challenges in forest commons between traditional and new uses of forests: a Q methodology study applied to an Alpine case

The Scientific Committee - Potpourri session
Giacomo Pagot[1]
Paola Gatto[1]
[1] Università degli studi di Padova

Abstract: Interest for forests as providers of multiple ecosystem services, including several regulating and cultural services, is rapidly emerging in industrialized Countries, putting new pressure on forests and their managers and owners and requiring a more holistic forest management approach.

The present study is set in the northern Italian Alps, specifically in the Dolomites, where there is a centuries-old tradition of forest commons, formed by descendants of the original indigenous communities, that collectively own and manage large areas of forests and pastureland. Forest commons in such context are similar to indigenous communities of in tropical Countries or North America, but, as opposed to those, are not well studied in Europe. As other forest owners, these forest commons are now facing new societal demands for recreational uses, which are challenging their traditional approach to forest management, mostly focused on timber production. In our study area, there are 15 forest commons, that own more than 80% of the forest area (ca 20000 ha) and a similar surface of pastureland.

We aim to explore if, and how, the commoners, via their democratically elected leaders, perceive this new role as providers of ecosystem services, especially recreation. Currently, there is little knowledge on these specific types of owners. We interviewed 13, out of a total of 15, leaders of forest commons in the area and used Q methodology to explore the main viewpoints among them. Q methodology aims at analyzing human subjectivity in the form of preferences, beliefs and viewpoints. A standard set of statements representing the possible positions on the topic of forest for recreation is sorted by each respondent according to their agreement with such statements. Factor analysis is than applied to allow the reduction of the results to few key factors that summarize the main viewpoints of the respondents.

Our results aim to highlight the change of perspectives occurring in the interviewed leaders and cast light on the relevant role forest commons will play in the future as providers of recreation and other ecosystem services in the Alps.

Challenges of satellite data integration with risk-related factors for an information platform accounting for uncertainty

The Scientific Committee - Potpourri session
Marco Piragnolo[1]

Abstract: Earth observation data are trending at a growing rate of exponential proportions. New investments on space technology have resulted in more platforms and sensors looking down at our Earth. Both public and private space agencies are growing their data production, removing the gap between what was once “large data” and is now “big data”. Earth observation truly matches the multiple “V”s of big data - it is varied, comes at high velocity, with large volumes and with data of different veracity. The latter is the focus addressed in this note, as we describe the challenges of using down-stream products from satellite imagery together with other factors that concur to provide risk indicators , such as climate forecasts on a short and long term. Each measure intrinsically contains a degree of error and this must be propagated to the final products and clearly provided along with the required products. Products from satellite imagery and other means of survey cover a specific spatial and time range. If we take land cover as an example, accuracy metrics are estimated by ground truth acquisition at specific locations and time, using more reliable means, such as higher resolution imagery or in-situ knowledge. Each category of land cover must have a minimum number of test sites to provide a matrix of hits and misses and final per-class metrics, such as omission / commission errors, precision/recall etc. This part, i.e. spatialized information on uncertainty and reliability, is often overlooked, and not given enough highlight on the downstream products. We present and discuss here a proof-of-concept of a geodata platform that integrates maps with predicted flooded areas in the Sundarbans mangrove forest, from sea level rise (SLR) values estimated from IPCC forecasts. A digital elevation model (DEM) is used accounting for different degrees of confidence that depend on DEM accuracy. The resulting loss of land cover categories was mapped via remote sensing imagery (Landsat), using classification and accuracy assessment with ground key points, providing uncertainty information to the user accessing the platform.

Challenges of trees and forests managment alongside the railway lines

The Scientific Committee - Potpourri session
Szymon Bijak[1]
Michał Orzechowski[1], Zuzanna Sałamacha[1], Łukasz Kwaśny[1], Karol Bronisz[1]
[1] Warsaw University of Life Sciences

Abstract: Railway traffic is extremely vulnerable to the dangers caused by the vegetation growing along the railway lines. Trees, or their parts (especially branches), as well as shrubs are very often a causing factor of the more or less serious railway accidents and incidents resulting in delays of various duration. We analysed causes of the occurences that had been recorded by the railway services in Poland during recent years to elaborate the critical conditions (dimensions, health status, age, species or others) that enhance the risk of the vegetation-caused railway accident. This is the first stage of the elaboration of the tool that enable to manage and maintain the vegetation growing alongside the railway lines to limit the danger of the accidents.

Characteristics of Tree-Based Interventions in a Uganda Refugee Settlement

The Scientific Committee - Potpourri session
Sarah Juster[1]
John Munsell[1]
[1] Virginia Polytechnic Institute and State University

Abstract: Refugee displacement represents a global environmental challenge. Loss of tree cover is particularly concerning in areas where refugees and hosts heavily depend upon tree products—especially fuelwood and shelter-building poles. Tree-Based Interventions (TBIs) are increasingly promoted in refugee settings to reduce tree cover loss while improving the well-being of refugees and hosts. Examples of TBIs include agroforestry, community woodlots, farmer-managed natural regeneration, and tree conservation through promoting improved cookstove technology. The environmental and social benefits of TBIs in refugee settings are apparent, but their distinct characteristics are less understood. This research analyzes and synthesizes the similarities and differences of TBIs promoted by four non-governmental organizations (NGOs) within the Imvepi refugee settlement of northwest Uganda. Four NGOs are chosen as case studies due to the diversity of their offered services. These range from the distribution of tree seedlings to refugee and host households and encouraging the use of fuel-efficient stoves, to planting food forests at local schools and hospitals. Imvepi—which hosts nearly 65,000 mostly South Sudanese refugees—enables deep analysis of the scale, mission, and resources of each case NGO. Data will be collected in the form of semi-structured interviews with administrative and local NGO staff between May and July, 2023. Data will also be drawn from TBI site visits and the review of NGO reports and documents. A qualitative scenario decision support tool will be developed based on synthesized TBI characteristics to guide the selection of TBIs across a variety of displacement settings. TBIs are a valuable facet of NGOs focused on the welfare of refugees, hosts, and surrounding landscapes, yet TBIs differ based on the guiding philosophies and resources of a given NGO. This study explores similarities and differences across TBIs and synthesizes the range of TBI characteristics and activities into a single framework that can apply in varying displacement contexts.

Community Forests as an Innovative Approach to Promoting Rural Prosperity in the United States

Abstract: Forests in the United States support livelihoods, protect environmental quality, and provide a broad range of other social and ecological benefits. Yet, their moderate market returns and provision of nonmarket goods and services that often go uncompensated can make them susceptible to degradation through overexploitation and conversion to more profitable land uses. Community forests (CFs) are a hybrid forest governance approach that enable community members and other key stakeholders cooperatively to manage local forests to produce a range of benefits. CFs have been proposed and established as a potentially promising approach to redress the imbalances between social and ecological forest benefits, and limited market returns and development pressures—issues particularly important in rural areas. However, there is limited empirical data on CFs' current status, trends, characteristics, or outcomes in the U.S., and what characteristics and conditions lead to enhanced forest retention, ecosystem services provision, profitability, and community well-being.

Our extensive research has enhanced understanding of community forests to generate and practical and policy insights for their establishment and support as an innovative approach to forest conservation and rural prosperity in the U.S. First, we conducted an inventory to characterize the broad diversity of community forests in the U.S. Second, we conducted detailed case studies using in-depth site visits and interviews of managers and stakeholders for 18 community forests across a broad range of geographies and ownerships. Results indicate a wide variety of goals and objectives, governance mechanisms, acquisition methods, financial models, outcomes, and community benefits. This talk will explore how and under what circumstances these may lead to enhanced economic opportunities and conservation successes and discuss policy implications. In particular, we explore the various financial models used and implications for financial sustainability.

Could continuous cover forestry on drained peatlands increase the carbon sink of Finnish forests?

The Scientific Committee - Potpourri session

[2] Norwegian University of Life Sciences NMBU

Abstract: Land-based mitigation measures are needed to achieve climate targets. One option is mitigation of currently high greenhouse gas (GHG) emissions of nutrient-rich drained peatland forest soils. Continuous cover forestry (CCF) has been proposed as a measure to manage this GHG emission source; however, its emission reduction potential and impact on timber production at regional and national scale have not been analysed.

To quantify the potential emission reduction, we simulated four management scenarios for Finnish forests: (i) clearcutting of nutrient-rich drained peatlands replaced by selection harvesting (CCF) and (ii) the current prevailing forest management regime (BAU), and both at two harvest levels, namely (i) the mean annual harvesting (2016–2018) and (ii) the maximum sustainable yield. The simulations were conducted with a forest simulator (MELA) coupled with hydrological model (SpaFHy), soil C model (Yasso07) and empirical GHG exchange models.

Simulations showed that the management scenario (CCF) that avoided clear-cutting on nutrient-rich drained peatlands produced approximately 1 Tg CO_2 eq. higher carbon sinks annually compared to the BAU at equal harvest level for Finland. This emission reduction can be attributed to the maintenance of higher biomass sink and to the mitigation of soil emissions from nutrient-rich drained peatland sites.

Could Developing Countries Achieve Industrial Sustainable Development? —— Take China's Forestry Industrial Policy as an Example

The Scientific Committee - Potpourri session
Yulan Sun[1]
[1] Fujian Agriculture and Forestry University

Abstract: Developed countries have achieved sustainable forest industrial development to realize the forest Kuznets curve. China as the largest population developing countries, its industrial policy is help to realize industrial sustainable development since 2003. As a result, this paper first uses the text mining method to analyze China's forestry policy discourse and use PMC-Index method to measure policy effectiveness. The results show that: (1) To realize forestry sustainable industry is that develop industrial ecology in process industry such as wood process industry, paper industry, and develop ecological industry such as non-timber product, woody food and oil, under-forest product.(2)The policy general belongs to acceptable, the actor, namely, policy subject and object are poor of all first variable. (3) The evaluation is perfect that it is about paper industry and camellia industry. (4) The central government is focused on ecological construction while the sub-government concentrates on ecological construction and economic development.

Current trends in the management of Portuguese community forest areas

The Scientific Committee - Potpourri session
Iryna Skulska[1]
Ana Catrina Sequeira[1], Vanda Acácio[1], Renata Pacheco[1], Francisco Castro Rego[1], **Maria Conceição Colaço**[1]
[1] Centre for Applied Ecology "Prof. Baeta Neves" (CEABN/InBIO), School of Agriculture, University of Lisbon, Tapada da Ajuda 1349-017 Lisbon, Portugal

Abstract: The Portuguese community lands ─baldios─ have hundreds of years of history. Since its beginnings, local rural populations have used these lands for their subsistence, which led to a progressive landscape change. This process created the local economic and social characteristics of the baldios. At the beginning of the last century, most baldios were nationalized by the State and were rapidly afforested. After the 1974 April Revolution, these territories were returned to their traditional owners ─local rural communities─ giving rise to the starting of their management and governance decentralization process. Currently, the Portuguese community forest areas occupy more than half a million hectares and are organized into more than 1100 units. Different stakeholders, such as commoners (baldios owners), Forest Services, and local authorities, are involved in their management. Their natural resources provide important support for the development of the rural economy. However, the current state and dynamics of the management processes of these lands are not sufficiently analyzed. In addition, there is almost no information about the baldios of the Portuguese Atlantic islands of Azores and Madeira.

In 2022, a round table was organized to discuss community-based forest management in Portugal. This event has contributed to updating information on Portuguese baldios and highlighted ongoing changes and current problems. Among the topics discussed were: (1) The development, potential, and challenges in the management of baldios of Azores and Madeira; (2) The legislative framework of the forest regime, its impact on the management of baldios forest areas, and the need for its reform; (3) The main risks influencing the quality of forest management in baldios; (4) New management models such as clusters of baldios; (5) and, Forest certification of community forest areas and the valuation of their ecosystem services.

This presentation at the IUFRO congress aims to discuss at the international level the topics above mentioned and to elaborate on the adequate steps to improve the management and value of the Portuguese community forest areas.

Design and synthesis of novel urushiol derivatives from the sap of lacquer (Toxicodendron vernicifluum) and evaluation of their anticancer properties

The Scientific Committee - Potpourri session
Hao Zhou[1]
chengzhang wang[1]
[1] Institute of Chemical Industry of Forest Products, Chinese Academy of Forestry

Abstract: Urushiol, isolated from the sap of lacquer (Toxicodendron vernicifluum), is a natural alkyl phenolic compound that is a privileged structure in drug discovery, especially in the design of protein kinase inhibitors, and exhibits potent cytotoxicity against a variety of human cancer cell lines [11-12]. Structurally, urushiol contains an o-dihydroxybenzene (catechol) coupled with an unsaturated 15-carbon alkyl side chain, which makes urushiol susceptible to oxidation and polymerization, thus negatively affecting its anti-cancer activity. Intriguingly, urushiol also possesses significant inhibitory activity against HDACs and is structurally similar to SAHA, as it has a linker and a CAP region. However, urushiol does not contain a ZBG, a region that had been shown to be critical for the inhibitory activity in conventional HDAC inhibitors.

In this study, we designed and synthesized 11 novel urushiol-based HDAC inhibitors for cancer therapy. Specifically, we introduced a ZBG group by adding a hydroxamic acid group to the alkyl side chain and blocked oxidative polymerization by replacing the alkyl side chain with a methylene acetal. We also introduced different pharmacophoric groups to the 15-carbon alkyl side chain or benzene ring of urushiol to increase its inhibitory potency. It has been demonstrated that the synthesized compounds 1 –11 inhibit class I HDAC1/2/8 strongly, but not class II HDACs (HDAC6). Compounds 1-11 exhibited inhibitory activities against HDAC1/2 with IC50 of 50.1-240.17 nM, and against HDAC8 with IC50 of 16.11-41.15 nM in vitro, while against HDAC6 with IC50 of 1409.59 nM.Consistent with the in vitro assay, strong antiproliferation activity was observed in multiple cancer cell lines. six compounds showed superior in vitro anti-proliferative activity against four human cancer cell lines (A2780, HT-29, MDA-MB-231, and HepG2 with IC50= 2.31-5.13 μM) than SAHA. Analysis of acetylation levels revealed that the synthesized compounds only caused an increase in the acetylation of histone H3, but not α-tubulin. Furthermore, we demonstrated that our compounds regulated multiple tumor-related biological processes, including cell apoptosis and the cell cycle. Their administration led to MDA-MB-231 cells remarkable apoptosis and cell cycle arrest in the G2/M phase. Together with their favorable ADMET and drug-like properties, these urushiol-based compounds are promising anticancer agents.

Determinants of Forest Dependence in the Forest Communities of Southwest Nigeria.

The Scientific Committee - Potpourri session
Olaniran Thompson[1]
[1] Department of Agricultural and Resource Economics, Federal University of Technology, P. M. B. 704, Akure, Ondo State, Nigeria

Abstract: This study examined the factors influencing forest dependence among households living in the forest communities of Southwest, Nigeria. Primary data was used for the study and multi-stage sampling technique was used to select 147 household living in the forest communities in Ekiti and Ondo State in the Southwest Nigeria. Data were collected using questionnaire while descriptive statistics and Tobit regression model were used for analysing data collected. Most (81.63%) of the households' sampled were males, 78.23% were married and the mean age of the respondents was 45.2 years. The average household size of the respondents was seven. The result shows that large proportion (97.28%) of the households give high priority to the provisioning and physical benefits of the forest such as supply of firewood, medicinal plants and farming activities more than the regulating, cultural and supporting benefits. The Tobit regression model shows that the factors that positively influence forest dependence were length of stay, dependency ratio, farm size and gender (male) while age, non-forest income, distance to nearest forest and credit facilities exerted negative influence. Therefore, the study recommends that medium- and long-term credit should be made available to forest households and empowerment programs should also be designed for them in forest communities to create employment aside forestry related ones to ensure successful forest rehabilitation scheme in Nigeria.

Determinants of soil field-saturated hydraulic conductivity across sub-Saharan Africa: texture and beyond

The Scientific Committee - Potpourri session
Aida Bargués Tobella[1]
Leigh Ann Winowiecki[2], Douglas Sheil[3, 4], Tor Gunnar Vågen[2]
[1] Department of Forest Ecology and Management, Swedish University of Agricultural Sciences (SLU). Umeå, Sweden
[2] World Agroforestry (ICRAF). Nairobi, Kenya
[3] Forest Ecology and Forest Management Group, Wageningen University & Research. Wageningen, The Netherlands
[4] Center for International Forestry Research (CIFOR). Kota Bogor, Indonesia

Abstract: Soil infiltration is critical for water security and related ecosystem services. This infiltration, the ability of soils to absorb water at their surface, is controlled by the soil hydraulic conductivity. Despite recent efforts in assembling measurements of soil hydraulic conductivity, global databases and derived pedotransfer functions remain biased towards agricultural soils and lack coverage in the tropics. Here, we present soil infiltration measurements and other indicators of soil and land health collected systematically in 3573 plots from 83 100 km^2 sites across 19 countries in sub-Saharan Africa. We use these data to (a) determine field-saturated hydraulic conductivity (K_{fs}); (b) characterize K_{fs} at these locations; and (c) explore which variables best explain the variation in K_{fs}. Our results show that sand content, soil organic carbon (SOC) and woody vegetation cover had a positive relationship with K_{fs}, whereas grazing intensity and soil pH had a negative relationship. Our findings highlight that, despite soil texture being important, structure also plays a critical role in determining K_{fs}. These results indicate considerable potential to improve soil hydrological functioning through management and restoration practices that target soil structure. Promoting vegetation cover, particularly that of woody vegetation, enhancing SOC content, limiting animal stocking, and preventing soil erosion can increase K_{fs}. This evidence provides the basis to guide and design sustainable land management practices and restoration interventions for improved water security and soil health under a changing climate with more extreme weather. Our dataset expands existing regional and global databases of soil hydraulic properties, improving coverage for Africa and providing field data for underrepresented soils and land uses, including forests and woodlands. As such, we envision that our dataset can contribute to improved understanding and prediction of soil hydraulic properties and to improved Earth system and land surface models.

Developing silvopastoral system management

The Scientific Committee - Potpourri session
Najeeb Alsubhi[1]
Rahmah Jrais[1, 2]
[1] National Center for Vegetation Cover Development and Combating Desertification
[2] King Khalid University

Abstract: Silvopastural system is one of the effective sustainable management practices of forests, which integrates trees, livestock and pastures on the same land. Silvopastural system assists to achieve several benefits for both forests and rangelands sectors such as managing forest fires, increasing forest land fertility, controlling grazing and promoting biological diversity and wildlife habitat. As well as, enhancing rural communities' incomes which leads to limited migration. This study will be conducted in 15 sites of nine forests in southern and southwestern Saudi Arabia, two hectares per site. It aims to identify the effectiveness of silvopastural system in the region, and to determine the awareness level among the local communities in order to achieve sustainable management of forests and rangelands. Preliminary results will be obtained in the first quarter of 2024, thus there is a high potential for minimizing wildfires and negative human practices on vegetation cover, such as logging and overgrazing. On the contrary, maximizing animal production and income. Finally, this study will be accomplished by mid-2025, and its outputs will contribute to illustrating the optimal mechanism through which silvopastural system can be applied at a large scale around the country.

Development paths for Vietnamese forest and wood sector

The Scientific Committee - Potpourri session
Nguyễn Bảo Ngoc[1]

[1] Research Institute of Forest Industry, Vietnamese Academy of Forest Sciences, Vietnam
[2] Vietnam National University of Forestry, College of Wood Industry and Interior Design, Vietnam
[3] University of Eastern Finland, Faculty of Science, Forestry and Engineering, Finland
[4] Natural Resources Institute Finland, Production systems, Finland

Abstract: Vietnam has a forest area of almost 15 million hectares of which 4.6 mill. hectares are plantations. However, only planted production forests (3.6 mill. ha, mostly acacia) are used for timber production, while logging is prohibited in natural forests. There are two million forest owners, and the mean area of privately owned stands is less than two hectares. Almost half of the plantation forests are owned by private people or communities. Plantation forests are managed by regimes aiming at pulpwood production, but logging and timber transportation have a low level of mechanization. Sawmills suffer from sawlog quality variations and inappropriate log dimensions, which results in poor sawn timber yield and challenges in productivity and profitability. This setup restricts the willingness to invest in modern saw milling capacity, while the forest resources and lumber demand of the furniture producers suggest doing so. Consequently, most harvested roundwood (>30 mill. m^3/a) is chipped and exported to Chinese pulp mills, while the extensive furniture sector relies on imported wood. Sawn timber made of Vietnamese roundwood ends up in low value applications. The country aims at developing local use of domestic timber. Here we map the pathways to develop Vietnamese forest and woodworking sectors towards a higher degree of self-sufficiency. The results, based on SWOT analysis, show that the opportunities in the forest-based livelihoods and industrial value chains should be more clearly highlighted and communicated to citizens and decision makers. The plantation forest resources allow much greater sawlog production than now. There are also risks, such as a higher probability of windfalls, associated with prolonging the rotation time of plantation forests to increase the saw log yield. Vietnamese woodworking industries, as well as public sector, are highly committed to develop the forest management and industrial, value adding processing of domestic wood towards an agile, modern, and low-risk market player and investment environment. The production philosophy should be shifted from production push to market pull, which requires better management and networking of the numerous micro scale producers, as well as integration of the large industrial producers more tightly in the forestry-wood product value chain development.

Did Lithuania manage to reach an agreement on its forests? The effect of National Agreement on Forests on conflicts in Lithuanian forest sector.

The Scientific Committee - Potpourri session

Ekaterina Makrickiene[1]
Gintautas Mozgeris[1]
[1] Vytautas Magnus University, Faculty of Forest Sciences and Ecology, Department of Forest Sciences, Lithuania

Abstract: Forests have always played an important role in Lithuania's landscape, economy, and society. While the variety of ecosystem services provided by forests and the trade-offs between those services are preconditions for forest-related conflicts in many countries, in Lithuania, the conflicts are further exacerbated by the transition from a planned to a market economy, the "greening" of society's mindset, and the resurgence of private forest ownership.

The need to establish a consensus on the future direction of Lithuanian forest policy led to an unprecedented decision to organize a National Agreement on Forests (NAF): a co-creation process in which all stakeholder groups would be equally involved. The process lasted from mid-2021 to late 2022 and included both discussions and document preparation. The aim was to create a robust National Forest Programme for Lithuania and to resolve the most contentious conflicts.

In our research, we evaluated the NAF as a National Forest Programme using MCPFE criteria and assessed its effectiveness as a tool for resolving conflicts in Lithuania's forest sector. Although the NAF was recognized as an important step toward improving forest governance in Lithuania, thanks to its broad participation and representation of various interests, agreements were not reached on three out of the nine topics discussed. This may lead to a deepening of the respective conflicts in the future.

Distribution of Diaporthe species in native and invasive woody Fabaceae plants in Lithuania

The Scientific Committee - Potpourri session
Dovilė Čepukoit[1]
Daiva Burokienė[1]
[1] Nature Research Centre, Laboratory of Plant Pathology, Lithuania

Abstract: *Diaporthe* spp. are widespread plant pathogens and have a broad range of hosts, including naturally growing trees. In this study 206 fungal cultures of the species *Diaporthe oncostoma* were studied. They were isolated from *Fabaceae* family plants *Lupinus polyphyllus* Lindl, *Robinia pseudoacacia* L., *Sarothamnus scoparius* (L.) W. D. J. Koch (*Cytisus scoparius* (L.) Link), which are included in the list of invasive plants in Lithuania. During the research, a total of 149 plants were collected throughout the territory of the country. In total, five loci that were used for MLSA were analysed: the internal transcribed spacer (ITS) region (primers ITS1/ITS4; White et al., 1990), the translation elongation factor 1-α (*tef1*) gene (EF1-728F/EF1-986R), the actin (*act*) gene (ACT-512F/ACT-783R), part of the calmodulin (*cal*) gene (CAL-228F/CAL737R (Carbone & Kohn, 1999) and part of the beta-tubulin (*tub*) gene (Bt-2a/BT-2b; Glass, Donaldson, 1995).

Diversifying tree species within our forests to increase resilience – an interdisciplinary approach.

Abstract: Humans, as integral parts of social-ecological systems, can anticipate change and, through adaptive management, influence forest resilience to help ensure both current and future forests deliver a wide range of ecosystem services. A system's resilience is its capacity to absorb or withstand perturbations, essentially maintaining structure and functions. When resilience is enhanced, systems are more likely to tolerate disturbance events.

An increase in tree species diversity is often suggested as a method to increase the resilience of forests to disease and climate change. Current guidance on diversification focusses on the silvicultural requirements of tree species mixes. However, to gain the maximum benefit from the range of ecosystem services delivered by diversification an interdisciplinary understanding of diversification is required.

Here we used an interdisciplinary approach, focussing on forests dominated by *Pinus sylvestris* (Scots Pine) or *Picea sitchensis* (Sitka Spruce), but with an interest in all forest types, to address four challenges associated with species diversification of forests. First, we used interviews and focus groups to assess how forest managers and other stakeholders understand forest diversity (at different scales), and what their ambitions are in relation to resilient future forests. Second, we used DNA techniques to assess how an increase in tree species diversity influenced the leaf microbiome. We assessed if the microbial diversity increased when tree species diversity increased and whether this provided additional biological control against pathogen infections. Third, we collated records of the biodiversity associated with Scots pine or Sitka spruce and identified which other tree species will also host these species. We used this data to assess how diversification of the forest provides greater support for biodiversity and ecosystem functioning. Fourth, we assessed how to implement diversification. Using bright spot analyses, case studies and literature reviews we assessed how continuous forest cover, natural regeneration and planting of novel species increased species diversity. Throughout, the project interacted with forest managers to ensure the results were relevant and practical and liaised with them over how to communicate the results.

Diversity of Woody Species and Biomass Carbon Stock in Response to Exclosure Age in Central Dry Lowlands of Ethiopia

The Scientific Committee - Potpourri session
TEMIMA MUHAMMED[1]
Fikrey Tewolde[2], Bethel Shefine[2]
[1] Wollo University
[2] Debre Birhan University

Abstract: Empirical evidence on the potential of area exclosure in the restoration of severely degraded lands is crucially important. Thus, a study was conducted to examine the influence of exclosure age on vegetation structure, diversity, and biomass carbon stock in the central dry lowland of Ethiopia. Exclosures of 5, 15, >20 years old, and adjacent open grazing land were selected. Data on vegetation were collected using 20 × 20 m sampling quadrats which were laid along parallel transect lines. The result showed that 17 woody species which represent 9 families were recorded at exclosures and open grazing lands. Shannon-Wiener (*H'*) diversity index ranged from 0.74 (open grazing land) to 2.12 (middle age exclosure). Shannon evenness (*E*) index was higher in the middle age exclosure (0.80). Woody species basal area and tree density significantly ($p < 0.05$) increased with increasing exclosure age. The Aboveground woody biomass significantly ($p < 0.05$) varied from 12.60 (open grazing land) to 68.61 Mg ha-1 (middle age exclosure). Similarly, the aboveground biomass (AGB) carbon stocked was significantly ($p < 0.05$) higher in the middle (32 Mg ha-1) and old age exclosures (31 Mg ha-1). This study indicated that exclusion can restore the degraded vegetation and sequester and stock more atmospheric carbon dioxide in the aboveground biomass. Therefore, open degraded grazing land of the lowland areas can be restored into a promising stage through area exclosure land use management.

Keywords: *Acacia species, Biomass, Degraded landscape, Grazing land, Woody species, Vegetation structure*.

Do Forest Carbon Programs Align with the Needs and Values of Indigenous Communities in the United States?

The Scientific Committee - Potpourri session
Stephanie Chizmar[1]
Michelle Baumflek[1], Gregory Frey[1], Tatyana Ruseva[2], Tammy Kowalczyk[2], **Rajan Parajuli**[3]
[1] United States Forest Service Southern Research Station
[2] Appalachian State University
[3] North Carolina State University

Abstract: While forest carbon programs incentivize management that enhances carbon sequestration and storage on forestlands, it is unclear how existing and proposed carbon programs align with the varied cultural values and forest management preferences of Indigenous peoples and communities in the United States. Moreover, it is also uncertain if and how the evolving forest carbon programs incorporate cultural values and Indigenous forest management practices into their protocols for carbon projects. This study uses a mixed-methods approach to assess the compatibility of forest carbon programs with forests managed by Indigenous communities and their members. More specifically, we systematically review the scientific literature as well as documentation published by forest carbon program developers and registries in the United States to analyze information related to participation and interest in forest carbon programs and protocols for forest carbon projects on lands managed by Indigenous communities and members. We synthesize findings from the literature to identify opportunities and barriers to participation in carbon programs and the compatibility of existing and proposed carbon programs with the values and needs of Indigenous communities and members.

Further, we plan to complement the review with a case-study analysis of the United States South, a 13-state region ranging from Virginia to Texas. We will use a participatory action research (PAR) approach to engage Indigenous communities in the region and related stakeholders on forest carbon programs and their preferences for research activities, including a discussion-based workshop. Utilizing the input collected, we will facilitate the workshop to foster discussion and co-production of knowledge, and future research questions and objectives. The PAR approach utilized in this study establishes a long-term framework for engagement with Indigenous communities to ensure that they have autonomy over research activities and that their cultural values and preferences are fully acknowledged, respected, and integrated in research and practices pertaining to forest carbon programs. The developed framework, which we see as a main contribution, may be adapted for future forestry research initiatives with Indigenous peoples.

Do individual PES buyers care about additionality and free-riding? A choice experiment

The Scientific Committee - Potpourri session
Oliver Frings[1]
Jens Abildtrup[1], Claire Montagné-Huck[1], Salomé Gorel[2], Anne Stenger[3]
[1] University of Lorraine, University of Strasbourg, AgroParisTech, CNRS, INRAE, BETA, 54000 Nancy, France
[2] University of Rennes 1, IODE, INRAE, SMART, 35000 Rennes, France
[3] University of Strasbourg, University of Lorraine, AgroParisTech, CNRS, INRAE, BETA, 67000 Strasbourg, France

Abstract: Based on a survey of the French population, this study investigates consumer preferences for forest ecosystem services (FES) provision towards efficiency and equity in the context of additionality, and differences in willingness to pay (WTP) for FES between a tax-based and a donation-based payments for ecosystem services (PES) scheme. We show that consumers prefer equity to strict additionality adherence, with this preference being significantly stronger among females. However, consumer preferences are heterogeneous and respondents with a closer connection to the forest express the opposite preference. Regarding WTP, we find no systematic difference between the two payment vehicles, but significantly different WTP depending on how respondents perceive the aspect of potential free-riding: When respondents considered that non-contributors would also benefit from a PES scheme, a small group showed a lower WTP, while a larger proportion showed a significantly higher WTP. We thus find a pronounced altruistic attitude of French society towards FES provision. We conclude by discussing the role of altruism in PES, the dilemma posed by the partial incompatibility of additionality and equity, both from an economic and legal perspective, and the environmental impact of environmental credits when credit buyers do not account for additionality.

Do Trichoderma treatments affect the Asian chestnut gall wasp (Dryocosmus kuriphilus) and its natural enemy?

The Scientific Committee - Potpourri session
Matteo Bracalini[1]
Alessandra Benigno[1], Chiara Aglietti[1], Salvatore Moricca[1], **Tiziana Panzavolta**[1]
[1] Department of Agriculture, Food, Environment and Forestry, University of Florence, Italy

Abstract: Fungi of the genus *Trichoderma* are beneficial microorganisms with multiple positive effects on plants. They may promote plant growth and improve plant health through the stimulation of plant defense responses to various pests, such as fungi, nematodes, and insects. Although these beneficial fungi have been mainly investigated for their antimycotic properties, recent studies focus on their effectiveness also against insect pests. Indeed, some *Trichoderma* species affect insects directly, through the parasitization or the production of bioactive compounds with insecticidal, repellent, or antifeedant effects. *Trichoderma* may also act indirectly, for example by mycoparasitizing insect-symbiotic fungi or stimulating the plant in producing defense compounds and even volatiles attractive to pests' natural enemies.

Considering the growing demand for eco-friendly tools to control plant parasites, an increase in the use of *Trichoderma*-based products is expected. Therefore, it is critical to understand the multiple, yet unexplored, interactions between *Trichoderma* and plant parasites. In this regard, a novel case study is represented by chestnut groves, where *Trichoderma* treatments may contribute to the control of numerous fungal diseases, but at the same time, they may affect the main chestnut insect pest, the Asian chestnut gall wasp (ACGW) and its natural enemy, *Torymus sinensis*. This hymenopteran parasitoid has been largely employed in Italy and other European countries in ACGW biological control, generally with good results.

In this study, two chestnut groves were treated by endotherapy with the BITE® tool in June. Trees were injected with a conidial suspension (1 x 10^7 conidia/mL) of *Trichoderma* spp. (*T. viride*, *T. atroviride* e *T. harzianum*). Three types of samples were collected before and after the treatment, both on treated and control trees: buds and ACGW withered galls in winter; ACGW fresh galls in June. In the laboratory, buds and galls were counted and dissected to verify the presence and health status of the ACGW and *T. sinensis*. Results indicate that the treatment did not have direct negative effects on *T. sinensis,* as its mortality percentages on treated and untreated chestnuts were not statistically different. The hypothesis that *Trichoderma* fungi, by their endophytic properties, affected ACGW and *T. sinensis* interactions is discussed.

Dynamic modelling of social-ecological resilience in two forest harvesting systems.

The Scientific Committee - Potpourri session

Lesly Elizabeth Solis Mendoza[1]
Leopoldo Galicia Sarmiento[1]
[1] Institute of Geography, National Autonomous University of Mexico (UNAM)

Abstract: Forest harvesting is currently one of the main drivers of local change that has impacts on the structure, ecological functions and ecosystem services provided by forests around the world. The concept of resilience has become a key concept for natural resource use and resolution of socio-ecological conflicts arising from ecosystem management practices. Conceptualising and measuring resilience remains a challenge. We propose the operationalisation (propose a measurement framework and apply it to a case study) of resilience for social-ecological systems under forest harvesting in Mexico. The main results are the identification of the social and biophysical structural elements of the forest SES model; we describe three dynamic feedbacks: governance (social processes), ecosystem services (ecological processes) and forest management (social-ecological processes); we analyse the effects of drivers of change and propose a social-ecological resilience strategy based on the literature review. We find that climate change can reduce species richness and diversity and negatively affect soil properties, which triggers a positive feedback process that reduces the possibilities for diversification of economic activities. The adaptive response is to implement mixed forest plantations and nurseries with native and quality plants as an alternative to cope with climate change. On the other hand, globalised markets favour the intensification and specialisation of timber production, thus reducing the conservation of other resources and diversification of economic activities. Among the main adaptive capacities, they should promote multipurpose forest use to maintain harvesting and safeguard other ecosystem services simultaneously. This work identified elements that promote ecosystem resilience such as polycentric governance, the maintenance of biodiversity and the control of slowly changing variables such as the recycling of nutrients in forest soils.

Economic valuation of landscape and biocultural heritage: an alternative for conservation and restoration

The Scientific Committee - Potpourri session

Huascar Camacho[1]
[1] Escuela de Ciencias Forestales Universidad Mayor de San Simon

Abstract: In the current context, the conservation and restoration of the landscape and biocultural heritage have become imperative to guarantee the sustainability of natural and cultural resources. This research focuses on exploring economic valuation as an alternative to promote the conservation and restoration of these assets.

The main objective of this study was to evaluate the feasibility and effectiveness of economic valuation methods in the context of landscape and biocultural heritage. To achieve this, different economic valuation approaches were applied, such as the travel cost method and the contingent valuation method.

The results obtained revealed that economic valuation can be an effective tool to assign monetary values to the benefits provided by landscape and biocultural heritage. By applying these methods, it was possible to determine the society's willingness to pay for the conservation and restoration of these assets, which provides valuable information for decision-making.

In addition, key factors that influence the economic valuation of landscape and biocultural heritage were identified, such as the degree of deterioration, accessibility, the perception of benefits and the level of public awareness. These factors can have a significant impact on the effectiveness of conservation and restoration policies.

In conclusion, the economic valuation of landscape and biocultural heritage offers a solid alternative for conservation and restoration, by providing a quantitative basis for decision-making and promoting the proper allocation of resources. However, a multidisciplinary approach and the active participation of all stakeholders is required to ensure the effective integration of economic values in the planning and management of landscape and biocultural heritage.

This study highlights the importance of considering economic aspects in conservation and restoration, which can contribute to greater awareness and support for the protection of these valuable assets.

EFFECT OF SUCCESSIONAL CLASS IN COMPETITION AMONG TREES

The Scientific Committee - Potpourri session
Franciele Alba Da Silva[1]
Gabriel Agostini Orso[1], João Paulo Madi Sardo[1], Allan Libano Pelissari[1], Afonso Figueiredo Filho[1], Sebastião do Amaral Machado[1]
[1] UFPR

Abstract: Competition indices are frequently used in single-tree models, especially in natural forests. Although there is a wide variety of competition indices developed over time, there is currently no consensus as to which index or which group of indices is the most appropriate. Furthermore, each competition index varies according to the number of neighbours or the area selected to compose it. This makes an accurate estimate of diametric increment even more difficult. However, these indices do not consider characteristics such as species or successional group of the target tree or neighboring trees, nor the quantification of this relationship for each species or group. We aimed to adapt a distance-dependent and an independent index to incorporate the successional group and quantify the influence of each group on diametric growth in a fragment of a mixed rainforest located in Paraná state. We tested BAL and Tomé & Burkhart competition indices. The successional group was added by including a parameter for each combination of target and neighbor tree. The pioneer, secondary, and climax groups were defined, in addition to a group for exotic species. The adapted indices identified the most influential groups among themselves. Exotic species most influence the growth of other individuals, followed by neighboring trees in the same successional group. This effect was better observed in the distance-dependent index, which restricts the neighborhood of each target tree by approximately 3.5 times, compared to the distance-independent index.

Effects of natural and anthropogenic factors on mammal distribution in Htamanthi Wildlife Sanctuary, Myanmar

The Scientific Committee - Potpourri session
Byung Bae Park[1]
Si Ho Han[1, 2], Myo Min Latt[1, 3]
[1] Department of Environment and Forest Resources, Chungnam National University, Republic of Korea
[2] Kasuya Research Forest, Kyushu University, Sasaguri, Fukuoka, Japan
[3] Department of Natural Resources Management, University of Forestry and Environmental Science, Yezin, National Unity Government of the Republic of the Union of Myanmar

Abstract: Assessing and monitoring wildlife is crucial for biodiversity conservation and protected area management. This study aimed to investigate the potential effects of physical environmental features on the distribution of mammal species at both community and individual levels in Htamanthi Wildlife Sanctuary, Myanmar. From 2014 to 2019, camera trap surveys and ranger patrols were conducted. Data analysis focused on mammal records within individual grid cells (4 km x 4 km). Using a negative binomial generalized linear model, we identified the key predictors contributing to the richness of different mammal species communities and the distribution of mammal species communities. Results indicate that the distance from gold mining activities, the protected area boundary, main streams, old timber roads, villages, and slope were important factors influencing the richness of mammal species communities. Additionally, the distance from gold mining activities, main streams, old timber roads, and villages played significant roles in explaining the of mammal species distribution. Distance from main streams emerged as a major determinant of species richness in different mammal communities, except for large body-sized mammals, omnivores, and insectivores. Slope significantly influenced the richness of medium-sized mammals and insectivorous species. Anthropogenic factors also played a role, as distance from villages affected the richness of insectivorous and primate species communities. At the individual species level, Asian palm civets, clouded leopards, guars, leopards, red muntjaks, and wild boars were more frequently detected near main streams. Tigers and boars were more abundant away from gold mines. Red muntjaks and clouded leopards showed higher distribution around old timber roads. Events involving tigers, leopards, and wild boars increased closer to villages. The distance from the protected area boundary affected leopard distribution. Elevation influenced leopard and sambar distributions, while slope gradient influenced Asian palm civet, red muntjak, sambar, and elephant distributions. These findings emphasize the importance of considering natural and anthropogenic factors

in wildlife assessment and management. Understanding the environmental features that influence mammal distribution can inform effective conservation strategies and preserve biodiversity in protected
areas.

Effects of wood ash application on seedling growth and soil properties in a young Cryptomeria japonica forest, Japan

The Scientific Committee - Potpourri session
Tsuyoshi Yamada[1]

[1] Forestry and Forest Products Research Institute
[2] Tohoku Institute of Technology
[3] Chugoku Lumber Co., Ltd

Abstract: Wood ash application in forests is effective for promoting tree growth in organic soils of regions with cool temperatures such as Scandinavia and North America. However, data regarding wood ash application to forest soils in temperate zones are still lacking. Extensive research is required to elucidate how this application affects tree growth and forest soils to ensure its effectiveness and the sustainable site productivity. Although the amounts of wood ash generated from biomass power plants have increased since the introduction of the feed-in-tariff in Japan, majority of the wood ash containing some nutrients is not effectively utilized. To elucidate the effects of wood ash application on tree growth and soil properties in temperate forests, we investigated the growth of sugi cedar (*Cryptomeria japonica*) seedlings and the variations in soil properties after treatment in a forest located in Kumamoto Prefecture, southwest Japan.

After applying 5 Mg ha^{-1} of wood ash, soil pH and concentrations of exchangeable base cations, such as calcium, magnesium, and potassium, tended to increase in surface soils, demonstrating the effects of liming and recharging exchangeable cations. Conversely, the increase in pH and concentrations of exchangeable cations in the subsoils, and in concentrations of total carbon and nitrogen in surface and subsoils were unclear by the application of wood ash. Moreover, the sugi cedar seedlings in the treated plot grew either as much as or less than those in the control one. No significant differences in the gene copy number of bacteria and fungi were observed between the both of the plots. These data suggest that the effects of wood ash application on forest soils are limited to surface soil, and it is difficult to promote seedling growth using this treatment without including nitrogen. Therefore, for promoting tree growth and maintaining site productivity, wood ash should be performed in combination with nitrogen fertilizer, avoiding areas affected by high precipitation and steep slopes to prevent nutrient loss.

EFFICACY OF Hura crepitans TREE EXTRACTS AS BIO-PRESERVATIVE AGAINST WOOD BIO-DETERIORATIVE AGENTS

The Scientific Committee - Potpourri session

Lawrence Olanipekun Aguda[1]
Olusola Samuel Areo[1], Babatunde Ajayi[2], Oluwaseun Yetunde Aguda[3]
[1] Department of Forest Products Development and Utilization, Forestry Research Institute of Nigeria.
[2] Department of Forestry and Wood Technology, Federal University of Technology Akure.
[3] Bio-medicinal Research Centre, Forestry Research Institute of Nigeria.

Abstract: The use of plant-based, eco-friendly and environmentally sustainable preservatives for wood protection as an alternative to synthetic preservatives has great potential. Extracts from the back, leaves, roots, seeds and the wood of *Hura crepitans* tree were used to treat five less suspectible wood species. Distilled water, ethanol, toluene and ethanol-toluene were used for the extraction. Chemical analysis of the extracts were carried out using Gas Chromatography-Mass Spectrometry (GC-MS) after derivation using N,O bis (trimethyl silyl) acetamide. More than one hundred and eighty compounds were identified from the extracts. The main groups of compounds identified from extracts are fatty acids, hydrocarbons, phenolics, sterols, sterol ketones, sterol esters and waxes. Extracts obtained were concentrated using rotary evaporator before they were used to treat the five susceptible species at 12% (weight/weight) retention level. The samples were weighed, labelled and treated by deep soaking in the concentrated extracts for 72hrs. Treated samples were removed, weighed to determine the level of retention before drained and oven dried at 60^0C for 48hrs until a constant weight was achieved. The sample were weighed before taken to timber graveyard for six months. Another set of untreated wood samples was weighed and taken to the timber graveyard for the same number of months to serve as control. Visual assessment was carried out weekly during this period to determine the rate of attack. After six months the experiment was terminated and samples were removed, cleaned and oven dried for 18hrs at 60^0C. After conditioning to equilibrium moisture content (EMC) of 12%, samples were cleaned of soil debris before the final weight was taken and the percentage weight loss for individual test samples were determined. The results was analyzed using factorial experimental design to determine the level of significance. It was observed that the extracts improved the resistance of these susceptible wood species to bio-degradation more than 75% when compared with the controls. It was also observed that extracts gotten using ethanol-toluene were more potent when compared with other extracts. It can be concluded that the extracts from *Hura crepitans* trees contribute greatly to the protection of wood against bio-degradation agents.

Efficiency Measurement of Ecological Conservation and Restoration from the Perspective of Multi-objective and Multi-factor Analysis

The Scientific Committee - Potpourri session
Yue Ren
Yukun Cao[1], Shaopeng Zhang[1]
[1] Department of Forestry Economics and Management, Northeast Forestry University, Harbin, Heilongjiang Province, China

Abstract: This paper proposes an ecological protection and restoration assessment theoretical framework based on multi-objective outputs and multi-factor inputs from the perspective of ecological efficiency evaluation. The Super-Efficiency SBM model was used to measure the social and economic effects of ecological resource consumption transformation in Heilongjiang Province, China from 2006 to 2019, and the standard deviation ellipse method and convergence analysis method were used to evaluate and test the impact on regional sustainable development. The results show that the stability of land use structure is insufficient, the conversion rate of resource consumption is low, and the mean ecological efficiency of the region is only 0.343, which belongs to the non-effective ecological efficiency region. The investment in forestry ecological restoration funds has a significant impact on the efficiency of ecological resource transformation, and the implementation of the Chinese ecological restoration project of mountain-river-forest-farmland-lake-grassland promotes the improvement of the ecological efficiency level of the community of life.The spatial distribution pattern of the ecological efficiency center of gravity is unstable. In the main years when forestry investment increased, the center of gravity of ecological efficiency showed a large movement range. This article proposes the following suggestions: improve the social and economic development level of regions with low ecological efficiency through technology transfer and diffusion and experience imitation in environmental regulation, and ultimately make the ecological efficiency of different regions converge to the same steady-state level. The focus should be on local conditions to reduce resource consumption intensity and improve the efficiency of fund utilization, form a comprehensive and systematic ecological environment governance system through reasonable enhancement of regional environmental regulation, increased investment in technological progress and ecological protection and restoration funds. This study is helpful to provide a basis for promoting the coordinated development of the social, economic and ecological aspects of the community of life and for evaluating the social and economic effectiveness of global ecological protection and restoration.

Enhancing resistance against decay and improving fire safety of Cross Laminated Timber (CLT)

The Scientific Committee - Potpourri session
Joris Van Acker[1]
Xiuping Jiang[1], Marcy Durimel[1], Liselotte De Ligne[1], Bogdan Parakhonskiy[1, 2], Andre Skirtach[2], Jan Van den Bulcke[1]
[1] UGent-Woodlab, Laboratory of Wood Technology, Ghent University
[2] Ghent University, Research Group Nano-Biotechnology, Department of Biotechnology

Abstract: Bio-based building products are considered key in our future socio-economic environment, since they are a very relevant nature-based solution (NbS) to climate change. The statement of President von der Leyen (European commission) to turn the construction sector into a carbon sink is critical in this respect: bio-based materials should be used on a larger and more targeted scale in the future. The long-term use of materials is therefore very important since we need to improve the lifespan of renewable materials to increase its carbon sink potential.

Hence wood is increasingly considered as a main building material. Service life aspects are critical in relation to the EU Construction Products Regulation (CPR). Traditional treatments to protect against fungal decay and the impact of fire are not always performing adequately and often environmental impact has been an important consideration. The option to enhance wood properties using innovative technologies can be combined with better definition of the expectations and requirements. Besides focusing on combined innovative treatments of the wood matrix, also envelope treatments similar to the use of coatings are envisaged. CLT has become a commodity construction product for green building and hence options are explored to cover alongside standard product use also enhanced performance based on material properties and a range of technology tools. Enhanced performance is often related to fire safety and extending service life under conditions with more risk of longer time of wetness, use classes 2 and even 3 according to EN 335.

Since CLT is often based on wood species with some refractory properties in relation to impregnation. Impregnation and penetration of active components is valid for many fire and decay protection methods of solid wood. Pathways for liquid transport have been explored using micro-CT scanning. The performance of treatments using different water-based treating solutions can be linked to the ability to reach anatomical structures.

Environmental Human Right Defenders – Change Agents at the Crossroads of Biodiversity, Climate Change and Cultural Heritage

The Scientific Committee - Potpourri session
Torsten Krause[1]
Fariborz Zelli[1]
[1] Lund University

Abstract: Environmental human rights defenders (EHRD) fight for political, social and environmental rights alike, while often facing intimidation and violence for their work and activism. This paper summarises first results from a new inter-disciplinary project where we investigate with qualitative methods to what extent EHRD serve as important agents of change for the management of forests in the global South.

We first develop an overarching conceptual understanding of EHRD that can be applied to different political and regional contexts. We then establish a theoretical framework to identify major socio-environmental discourses that underlie the motivations and goals of EHRD, their understandings of forest ecosystems and the ecological and social crises they seek to address.

We apply this conceptual and theoretical framework tothree regional study areas in forested areas in post-conflict Colombia. The country has become the most dangerous country worldwide for EHRD with more than 400 killings recorded since 2016. Colombia has also undergone a recent governmental change with a considerable shift in both rhetoric and laws towards EHRD protection.

In addition to the EHRD themselves, we include the groups and communities they belong to or represent - and we scrutinize the degree of political legitimacy the EHRD have as defenders of forested habitats and leaders within and beyond these groups.

Altogether, our analysis is guided by the following research questions:

1. Which major motivations, goals and underlying discourses inform EHRD and their understandings of the cultural, biocultural and climate change crises they seek to address?
2. Which practices and strategies do EHRD employ tostrengthen their leadership and legitimacy and topursue their goals?
3. Which successes and obstacles – including implications for their vulnerability and the vulnerability of the forest ecosystems they seek to defend – have EHRD faced in Colombia since the signing of the peace agreement in 2016?
4. Which lessons can be learned with a view to supporting and protecting EHRD and forest ecosystems in Colombia across scales?

Our expected findings seek to contribute to better understanding and supporting different groups of EHRD, through informing international and Colombian policy makers, civil society organizations and academics.

Erwinia leaf blight and dieback disease on Eucalyptus Species in Western Kenya: A New Threat to Commercial Growing of Eucalyptus in Kenya

The Scientific Committee - Potpourri session
Beryn Otieno[1]
Jane Njuguna[1], Emmanuel Makatiani[1], Joseph Machua[1]
[1] Kenya Forestry Research Institute

Abstract: Eucalypts are the most preferred plantation species in Africa and account for half of tree plantations in East Africa. Their growth has faced challenges of insect pest invasions mostly emanating from their native habitats in the Australopacific region. Important diseases such as canker (*Chrysoporthe cubensis*), rust (*Puccinia psidii*) and Ceratocystis wilt (*Ceratocystis fimbriata*) have also been identified on eucalypts. Reports indicate that the occurrence of bacterial pathogens on eucalypts started in the early 1980s, with minor incidence, becoming more expressive from the mid-2000s with outbreaks of *Rasltonia solanacearum* and *Xanthomonas* spp. Eucalypts in community nurseries in Western Kenya have been attacked by a new disease which is not recorded in their area of origin. The Disease is quickly spreading with incidences upto 100% observed in nurseries and plantations (upto 60%). Symptoms on infected seedlings from nursery and field observations at Migori in Western Kenya, included water soaked lesions on the leaf parenchyma, blights, die back and mortality of seedlings and saplings. Isolation and culturing of the pathogen was carried out using standard laboratory techniques identified the causative agent identified to be bacteria. Bacterial colony morphology was studied on standard media and their shape, elevation, colour and diameter described.

Preliminary laboratory studies report point to the gram negative *Erwinia* species as the potential cause of the observed symptoms on eucalyptus seedlings. This disease could pose serious threat to the productivity of commercial plantations of Eucalyptus and related species in Western Kenya. For appropriate management of the disease detailed genetic characterization of the specific bacterial strains responsible for the disease is being undertaken in the laboratory. We recommend testing of conventional bactericides for quick management of the disease in nurseries together with frequent surveillance to map out the spread and factors predisposing seedlings to the infection by the bacteria.

Key words: Erwinia, Eucalyptus seedlings, commercial plantations, genetic characterization

Estimating Above Ground Biomass of Dry Afromontane Forests with Remote Sensing Imagery and Machine Learning Models

The Scientific Committee - Potpourri session
Abrha Megos Meressa[1]
Meley Mekonen Rannestad[1]
[1] Norwegian University of Life Sciences (NMBU)

Abstract: The application of remote sensing imagery and machine learning algorithms for analysing various characteristics of vegetation has gained significant popularity due to the increasing availability of satellite data and cloud-based computing in recent years. In this study, we utilize Multispectral band reflectance data extracted from Landsat 8 and Sentinel-2B satellites, along with seven vegetation indices, to estimate the above-ground biomass (AGB) of dry Afromontane Forest in Northern Ethiopia. By employing a comprehensive set of machine learning models, including Light Gradient Boosting Machines (Light GBM), Extreme Gradient Boosting Machine (XGBM), Random Forest (RF), and Structure Vector Machine (SVM), we aim to accurately estimate the AGB of the mentioned forest region. Additionally, we employ simpler regression-based machine learning models with regularization techniques to identify robust patterns in the data, prevent overfitting, and improve the generalization capabilities of the models. The models' performance is evaluated and compared based on their prediction accuracy using metrics such as mean absolute error (MAE), root mean square error (RMSE), and cross-validated root mean square error (CV-RMSE). The findings of this study indicate that the tuning of hyperparameters in gradient boosting models significantly enhances their predictive performance compared to the simpler regression-based machine learning models. On the other hand, models without tuned hyperparameters tend to suffer from overfitting. Notably, Light GBM and XGBM with hyperparameter tuning exhibit lower RMSE values and superior predictive capabilities compared to regular GBM, which is more susceptible to overfitting. The predictions generated by these optimized models demonstrate higher accuracy and stability in comparison to conventional gradient boosting machines, RF, SVM, Lasso, and Ridge models. The utilization of machine learning models and the insights derived from this research hold great relevance for forest conservation and management decisions, particularly in developing countries where financial constraints and security impediments limit the feasibility of field surveys and data collection.

Europe's Forest Sink Obsession

The Scientific Committee - Potpourri session

Abstract: The focus on the net carbon uptake in the forest dominates the European decision to reverse the declining land carbon sink. This decision has been made, however, without considering the consequences for the circular bioeconomy. Moreover, since the benefits of the circular bioeconomy are only indirectly recorded as "*reduced emissions"*, and not as forest benefits, the benefits of forest use are not even acknowledged. LULUCF (Land Use, Land Use Change and Forestry) accounting thus fails to balance LULUCF emissions/removals with the forest-based substitution effects recorded in sectors. The focus on carbon sequestration in standing forests is likewise disassociated from the past century's experience with forest use. Several Member states have managed to continuously increase the annual forest increment, harvest ever larger amounts of forest, and, simultaneously, to increase net forest removals, leading to a continuous increase in forest carbon stocks. Closer scrutiny suggests *avoided emissions*, the *net flux in forest-based emissions/removals ("net removals*"), and *renewed forest growth*, provide important contributions to the global carbon budget. Reducing forest use intensity (i.e., raising the forest reference level, FRL) may thus conflict with forest-based climate change mitigation strategies. Moreover, micro-level incentives in the EU LULUCF policy framework may be incompatible with the private and public sector investment goals which could otherwise underpin forest growth potential. Failing to encourage the kind of forest investment momentum required to achieve genuine progress, the current emphasis on reforestation and protection has provided only marginal contributions to the European forest carbon budget. Though significantly greater contributions are routinely provided by Managed Forest Lands (MFL), these remain under-mobilized and even heavily restricted in the LULUCF policy framework. A more strategic approach is therefore required to strike a balance between the need for protected, biodiverse-rich forest environments, on the one hand, and promoting societal and investment interest in the many benefits (mitigation, adaptation, human livelihood, consumption, etc.) forests and forest-based resources can provide.

Evaluation of forest biodiversity using a machine learning technique in Mt. Gariwang, South Korea

The Scientific Committee - Potpourri session

[3] Department of Forestry, Environment, and System, Kookmin University

Abstract: Forest fragmentation, degradation and climate change are major causes of rapid biodiversity loss. In biodiversity conservation strategy, it is essential to develop indicators to reasonably compare and evaluate biodiversity between/among regions. The purpose of this study is to develop quantitative and objective biodiversity indicators and to suggest evaluation methodology using machine learning techniques. In order to achieve this research purpose, this study was conducted on five forest types of Mt. Gariwang in South Korea. A total of 60 plots (20×20m2) were surveyed for woody and herbaceous plants. Taxonomic, phylogenetic, and functional diversity factors were calculated using plant data. In addition, abiotic factors such as topography (i.e., elevation, slope, topography position index, topography wetness index), climate (i.e., mean annual temperature and precipitation), and normalized difference vegetation index (NDVI) factors were used as explanatory variables to estimate biodiversity factors. RandomForest as a machine learning approach was used to analyze the relative importance of each abiotic factor on the biodiversity factors of plant groups such as total, woody, and herbaceous plants. Machine learning techniques are used to reasonably estimate the aggregation and selection of biodiversity indicators. As a result, elevation was the main variable to evaluate the biodiversity of Mt. Gariwang, including both woody and herbaceous plants. Moreover, climate factors showed high importance values for the total and herbaceous plants. On the other hand, woody plants are controlled mainly by topography and NDVI factors. The results of the study suggest that when calculating forest biodiversity indicators, it is necessary to separately analyze woody and herbaceous plants. In addition, our study emphasizes that it is essential quantitatively to calculate biodiversity indicators for sustainable ecosystem conservation. Finally, this study is significant in that it selected objective indicators by using machine learning analysis between forest monitoring data and spatial data.

Evaluation of the temporality of occupations in Permanent Preservation Areas in the state of São Paulo

Vinicius Moura Costa[1]
Felipe Rosafa Gavioli[2], **Giulio Brossi Santoro**[1], Paulo Guilherme Molin[2]
[1] University of São Paulo
[2] Federal University of São Carlos

Abstract: The current brazilian environmental law (nº 12.651/2012) defines legally preserved areas (LPA) for native vegetation in both rural and urban lands. Different types of LPA target specific situations such as springs and river buffers, hilltops or very steep regions. However, it was the approval of the previous environmental law (7511/1986) that increased LPA sizes according to each situation and therefore major adjustments should have occurred to meet legal requirements. São Paulo state environmental agency uses a temporal principle to define whether the LPA must be restored. In another words, if the current LPA anthropic land use consist on buildings, the landowner is exempted of performing adjustments as long as it was built before the implementation of the law (1986). Thus, the goal of this work was to estimate how much of each LPA type in the state of São Paulo was considered to be regular due to the temporal principle. Land use and land cover data from MapBiomas, as well as LPA polygons from the Brazilian Foundation for Sustainable Development (FBDS) and the Secretary of Infrastructure and Environment of the State of São Paulo (SIMA), were used for the analysis. Land use classes were reclassified to Natural Formations, Agriculture and Livestock, Anthropized Areas, and Water Bodies. The Anthropized Areas class, which is entitled to temporal regularization, is composed by Urban Infrastructure, Mining, Other non-vegetated areas, and Aquaculture. Results showed that LPA in São Paulo state sum up to 29,337 km². In 2020, around 52.36% of the total amount had native vegetation, while 47.64% were degraded, with 40% being occupied by agricultural uses since 1985. Only 0.82% of the degraded LPA can be considered regular using the temporal principle as they were built/occupied since 1985. In 2020, 4.71% of the degraded LPA had native vegetation in 1985, showing a vegetation net increase of 1,606 km² in LPA. Finally, these results can be highly relevant for public administration and for the state environmental agency since it points out LPA exempted of regularization.

Evidence of natural hybridization between Pinus brutia and P. halepensis in regenerating planted forests

[3] Institute Institute of Evolution, University of Haifa, Haifa, Israel

Abstract: Interspecific hybridization increases genetic diversity, which is essential for coping with changing environments. Hybrid zones, occur naturally in overlapping habitats of closely related species, can be artificially established during afforestation. Interspecific hybridization can promote sustainability in man-made forests, particularly in regions facing degradation due to climate change. However, there is limited evidence of hybridization during forest regeneration. Here, we studied the frequency of *Pinus brutia* Ten. x *P. halepensis* Mill. hybridization at three stages of the forest regeneration process in five planted forests: seeds before dispersal, emerged seedlings, and recruited seedlings at the end of the dry season. We found hybrids on *P. brutia*, but not on *P. halepensis* trees, due to asynchronous flowering phenology. Using 94 single-nucleotide polymorphism (SNP) markers, we demonstrated that all stages included hybrids, most of which were hybrids of advanced generations. The hybrid proportions increased from 4.7±2.1 to 8.2±1.4, and to 21.6±6.4 percent, from seeds to emerged seedlings, and to recruited seedlings stages, respectively. The increased hybrid ratio implies an advantage of hybrids over *P. brutia* during forest regeneration. To test this hypothesis, we measured seedling growth rate and morphological traits under semi-controlled conditions and found that the hybrid seedlings exhibited selected traits of the two parental species, which may contribute to the fitness and survival of the hybrids during the dry season in the forest. This study highlights the potential contribution of hybrids to sustainable-planted forests and contributes to the understanding of the genetic changes that occur during the regeneration of man-made forests

Finnish Forest Happiness

The Scientific Committee - Potpourri session

Syamili Manoj Santhi[1]
Tuomo Takala[1], Aino Korrensalo[1, 2], Jukka Tikkanen[1], Eeva-Stiina Tuittila[1]
[1] School of Forest Sciences, University of Eastern Finland, Yliopistokatu 2, FI-80100 Joensuu, Finland
[2] Natural Resources Institute Finland, Yliopistokatu 6 B, FI- 80100 Joensuu, Finland

Abstract: Humans have a symbiotic relationship with forests which has evolved over time. This intricate relationship has a profound impact on human well-being, which is widely acknowledged as a key indicator of national prosperity. One crucial aspect of human well-being is experiencing happiness. There is an indication that happiness benefits from spending time in green spaces that have been linked to reduced stress levels measured at the physiological level. However, the previous works have not adequately addressed forest-specific happiness that has broader societal implications.

In this study, we aim to understand the concept of 'Forest Happiness' from the world's happiest nation by exploring the sociocultural values and experiences associated with forests in Finland. We developed a multilingual (Finnish, Swedish, English) web-based questionnaire survey based on the existing knowledge of social values associated with Finnish forests. The questionnaire with open-ended and closed questions covers topics related to the aspects of the forest that make people happy, how people perceive forest happiness and forest-related issues that may decrease perceived happiness. Data analysis combines qualitative content analysis with multivariate techniques.

After less than two months since the launching of the survey around 808 responses were collected. From the preliminary analysis, it appeared that about 63% of the respondents reported that they would be considerably unhappier without their relationship with forests. Above 55% associated social values such as silence and tranquillity, space and freedom, contact with nature, scents, sounds, colours and shapes of the forests as their most preferred Finnish forest features which made them happy. However, 50% of the respondents reported that the Finnish forests can occasionally decrease their happiness due to factors like clearcutting, changes in land use, intensive forest management activities and littering. In the further analysis of this data, we aim to identify the main types of forest happiness in Finland.

Overall, the results show that Finnish forests have a profound impact on experienced happiness. Beyond the perceived attractiveness of the Finnish forests, the people value the serenity and liberation they experience in the forests. Addressing specific forest management issues is essential for maintaining and amplifying Finnish forest happiness.

Fir beetles (Pityokteines vorontzovi and P. curvidens) associated fungi and their functional roles

The Scientific Committee - Potpourri session
Sifat Munim Tanin[1]
Peter H. W. Biedermann[1]
[1] Chair for Forest Entomology and Protection, University of Freiburg, Stegen-Wittental, Germany

Abstract: The role of bark beetle associated fungal symbionts in tree mortality, potentially through nutrient provision and protection, has long been acknowledged. A few bark beetle species (*Pityokteines vorontzovi, P. spinedens, P. curvidens*) recently emerged as threats to drought-stressed fir (*Abies alba*) stands in some parts of Europe. The fungal associates of these fir bark beetles remain poorly studied, however, and there are no studies on their functional roles for the beetles.

In this study, the fungal community associated with two common fir beetles (*P. vorontzovi* and *P. curvidens*) were investigated in the Black Forest region of Southern Germany. Using isolations from emerging adults, we identified 30 fungal species and subsequently focused on five core symbiotic fungi (*Geosmithia sp, Ophiostoma piceae, Cladosporium oxysporum, Penicillium bialowiezense, and Graphilbum fragrans*) to assess the attractiveness of these fungal volatiles to these beetles. Employing a novel behavioral bioassay, the responses of fir beetles to the volatiles and gustatory cues of the selected fungi were examined. We found that beetles responding to fungal volatiles also exhibited a significant preference for boring into media colonized by three putative fungal mutualists (*Geosmithia sp, Ophiostoma piceae, and Cladosporium oxysporum*). This behavior suggests the beetles' recognition of specific fungal nutrients and/or detoxification products of plant-defensive compounds. Building upon these findings, our ongoing research aims to elucidate the potential benefits that fungi confer to fir beetles.

Forest-based land reform partnerships in rural development and the sustenance of timber markets. Learning from two South African cases

The Scientific Committee - Potpourri session
Ratsodo Phillip Tshidzumba[1, 2]
Paxie Wanangwa Chirwa[1]
[1] University of Pretoria, Department of Plant Science,
[2] Fort Cox Agriculture and Forestry Training Institute, Department of Forestry and Natural Resource Management, South Africa

Abstract: In South Africa, although implementation of government and forestry industry's embraced forest-based land reform partnership governance models, rural development and community beneficiaries' access to timber or wood products markets independently remain a challenge. This study assessed the perception of community beneficiaries on the sales and leaseback and community managed enterprise forest-based land reform public-private partnership (FBLR PPP) models on the provision of wood product end-use alternative. Two communities (Amabomvini and Cata) were purposefully selected for the study, in which 140 and 175 household beneficiaries were randomly sampled, respectively. Focus group discussions were also conducted with key informants from both communities' registered legal entities. The chi-square results showed a significant ($p \leq 0.001$) relationship between the household beneficiaries' responses regarding the recommendation of pulp and paper and fuelwood as preferred wood products end-use alternatives from both communities. Binary logistic regression analysis revealed that household beneficiaries who are not educated are significantly less likely to influence wood usage for building material ($p \leq 0.038$) and sawn timber ($p \leq 0.033$) compared to those who are educated, respectively. Most household beneficiaries in Amabomvini recommended pulp and paper (63.6%), while those from Cata community (84.6%) recommended fuelwood. Additionally, the study shows that the provision of wood product market for the community-managed enterprises would be vital for the sustainability of their forest-based business. Furthermore, prioritizing access roads could assist in construction of new or nested markets for timber products trade and improving their well-being and socioeconomic status. This would ensure that community beneficiaries value the economic role forest, forest products and the significance of strengthening community governance structures in an endeavour to reduce conflicts amongst beneficiaries. Most importantly, government support towards strengthening of community beneficiaries' institutional arrangement or governance of the legal entities is critical to create an enabling environment for the community beneficiaries.

From event to regime, disruptive affections in postwildfire landscapes.

The Scientific Committee - Potpourri session

Pepa Morán Núñez[1]
[1] DUTP, Department of Urbanism, Territory and Landscape. Polytechnical University of Catalonia UPC

Abstract: Wildfires are the main disturbance affecting the Mediterranean area (Pyne,1997; Pausas, Vallejo et al.2003). The fire regime has changed mainly due to climate and human activity. (Marlon et al. 2008; Pausas and Keeley 2009). The international community specialized in wildfire management recognizes the inability to solve and deal with the problem strictly from the field of emergencies. The classic prevention model is being questioned, since it is not an issue of extinction capacity or economic resources destined to extinction, but an issue of landscape's ability to integrate and modulate disturbances.

The relationship between the severity of wildfires and human agency calls into question wildfires as a matter alien to society that falls on it, but rather as a matter of social and political responsibility (Latour, 2017) Going deeper into what is perceived or what is communicated as disruptive broadens the pre-established limits by entering the field of the affective. Postwildfire images that describe landscape a few days after the fire allow us to perceive the sublime, which disturbs and connects us with feelings beyond reason, which are in the realm of the material and the sensitive.

Risk communication recognizes that risk images have the capacity to convey to people the emotional consequences of natural hazards, in addition to stimulating the risk experience. John Dewey describes that the perception of change transforms the observer into a participant. Representation has the capacity to transmit an aesthetic and emotional experience transforming the observer into a participant. The representation that transmits an aesthetic experience of postwildfire landscapes in different temporalities, beyond the "0" day, transcends the dualistic positioning of the creative or destructive and redefines the disturbance. The aesthetic experience allows us, through affection, to recognize capacities beyond appearance and the standards of beauty, incorporating the disruptive. The representation of the operability of the disturbances and certain intrinsic aspects of it, such as transformability, have the capacity to transmit affect, generating a disruptive aesthetic experience that integrates the disturbance in postwildfire landscapes.

Fungi Among Us: Fungal Hitchhikers and Animal Couriers

The Scientific Committee - Potpourri session
Marta Belka[1]
Kathrin Blumenstein[2]
[1] Department of Forest Entomology and Pathology, Faculty of Forestry and Wood Technology, Poznań University of Life Sciences, Poland
[2] Chair of Pathology of Trees, Institute of Forestry, Faculty of Environment and Natural Resources, University of Freiburg, Bertoldstr. 17, 79098 Freiburg, Germany

Abstract: Fungi are extremely important decomposers, symbionts, pathogens, and a food source in various ecosystems. While many fungal species rely on wind, water, or direct contact for dispersal, the spread of fungi by animals is often overlooked. Animals, including mammals, birds, insects, and arthropods, have been found to serve as effective carriers, facilitating their dispersal over large distances and across diverse habitats. Fungal dispersal can contribute to promoting biodiversity and ecosystem resilience. For instance, mycorrhizal fungi play a vital role in nutrient cycling and plant growth, and their dispersal by animals can enhance plant community composition and ecosystem functioning. This can profoundly impact wildlife.

Understanding the mechanisms and patterns of fungal spread by animals is crucial for both conservation efforts and ecosystem management. By identifying the key animal species involved in fungal dispersal, their movement patterns, and ecological interactions, targeted interventions can be developed to mitigate the spread of harmful fungal pathogens or promote the establishment of beneficial fungal symbioses.

Investigating the impact of environmental changes, such as habitat fragmentation or climate change, on fungal-animal interactions, can provide insights into potential alterations in fungal dispersal dynamics and disease transmission patterns.

This study summarizes the current understanding of fungal dissemination by different groups of animals, highlighting the mechanisms involved, the ecological implications, and potential impacts on forest health.

Governing by Numbers: Actors, power and technocratic forest governance in Cameroon

The Scientific Committee - Potpourri session
Sandrine ANDONG[1, 2]
Patrice BIGOMBE LOGO[2, 3]
[1] Institute of International Relations of Cameroon, University of Yaoundé 2 (IRIC-UY2)
[2] FOREQUAL Research projet
[3] University of Yaoundé 2 (UY2)

Abstract: International relations in the forest sector of the Congo Basin are a field where collaboration between North-South actors reveals a permanent power struggle. This game is even more visible within the implementation processes of international forest governance instruments such as the Voluntary Partnership Agreement on Forest Law Enforcement, Governance and Trade (VPA-FLEGT). In Cameroon, the implementation and the success of the VPA-FLEGT were conditional on the operationalization of an advanced version of the *Independent Forest Monitoring* (IFM)-type system, namely SIGIF-II. Within the framework of the VPA-FLEGT process, IFM-II should, on the one hand, guarantee the timber tracking and, on the another hand ensure the storage, analysis and archiving of all forest-related information in order to contribute to better monitoring the production and the marketing of legal timber produced in Cameroon. From the public policy analysis perspective, this article aims to analyse the agenda setting and the developing process of the IFM-II as an instrument of technocratic governance of forests in Cameroon. Its proposes to map the main North-South actors involved and their interests vis-à-vis the IFM-II project, and then questions the problem of inequalities underlying the strategies of domination and resistance between these actors. We mobilise the Advocacy Coalition Framework (ACF) to understand what underlies the game, strategic and political actions of actors in the political conflict that drives the IFM technocratic reform process. We argue that (i) the IFM-II developping process has induced formal and informal interests that actors involved are keen to preserve at the expense of the effective implementation of this instrument; (ii) the politicisation of the IFM-II project has resurfaced various resentments of (neo)colonial and imperialist inequalities in a North-South power struggle between the European Union and the Cameroonian Government in the forest sector and (iii) finally that, the elaboration and the validation of this data management tool and the tensions generated reveal a new form of confrontation that shifts the globalization of tropical forest governance from the modalities of access to forest resources to the norms of production and control of data on these resources.

Keywords : *International relations, data governance, forest policy, inequalities, domination, resistance*

Hcanopy, a new site index to describe mature and irregular forests productivity: the case of old growth beech stands

The Scientific Committee - Potpourri session
Marie-Pierre Tasseroul[1]
Philippe Lejeune[1], Hugues Claessens[1], Hugues Titeux[2]
[1] Forest is Life, Terra research center, Gembloux Agro-Bio Tech, Université de Liège, Gembloux, Belgium
[2] Earth and Life Institute, Université catholique de Louvain, Louvain-La-Neuve, Belgium

Abstract: Forests of Western Europe have long been shaped by economic considerations, far removed from the way natural ecosystem's function. Monocultures, regular stands, and the promotion of a few commercially interesting species are all choices that have influenced forest management in the past. In the 21st century, the full force of global change is making those involved in forestry rethink their approach to silviculture. In response to these changes, continuous cover forestry regeneration has been encouraged, using natural regeneration, and leading progressively to uneven-aged stands. Although this type of stand offers greater forest resilience, it is difficult to characterise, particularly in terms of productivity. Indeed, most of the indicators in the literature have been calculated for even-aged, often planted, and homogeneous stands, far from the definition we have given to the resilient forest of tomorrow.

In this context, we developed a new indicator to assess the productivity level of these uneven-aged stands using a variable that is stable over time: the maximum canopy height (Hcanopy). The aim of this study was twofold:

(1) To identify the dendrometric parameter, based on easily available remote sensing data, that best represents stand productivity and allows for stands comparison, provided that the canopy consists of mature trees.

(2) To assess which ecological parameters influenced the value of this indicator.

We focused on beech (*Fagus sylvatica*), and especially on mature and uneven-aged beech stands in old-growth temperate forests of Western Europe. These forests were divided into polygons characterized by homogeneous abiotic conditions. For each polygon, topographic, soil, climate and silvicultural data were extracted from raster layers, to analyse their effect on Hcanopy.

The analysis shows that the average maximum canopy height (Hcanopy), corresponding to the average height of the ten tallest trees per hectare, is the best indicator to describe the productivity level of this type of stand. The value of this indicator, calculated for each polygon were highly and significantly different between forest site types. A multivariate analysis is currently underway and should identify the variables that most influence Hcanopy.

Heterogeneity matters: The impact of forest heterogeneity and tree diversity on predation pressure of pest insects in semi-natural boreal forests

The Scientific Committee - Potpourri session

Fredrika Wrethling[1]
Christer Björkman[1], Maartje Klapwijk[1]
[1] Swedish University of Agricultural Sciences, Department of Ecology, Sweden

Abstract: Plant diversity favours top-down control of pest insects from natural enemies in agricultural environments. Accordingly, tree species diversity has been expected to benefit top-down control of pest insects in forests as well. However, results concerning pest suppression by natural enemies are not unequivocal, and studies about the importance of mixing tree species in forestry for pest control show differing results. Even forests with low tree diversity have been shown to maintain a high degree of habitat heterogeneity, providing niches for natural enemies. To date, there are few experimental studies in semi-natural boreal forests about the underlying mechanisms of natural regulation of pest insects.

Previous studies of the pest insect *Neodiprion sertifer,* a specialist herbivore on *Pinus sylvestris*, has shown that forest heterogeneity is a better determinant of predation pressure than tree species diversity. Therefore, we investigated the relationship between forest heterogeneity, tree species diversity, and the predation pressure of *N. sertifer* as a specialist herbivore together with plasticine models as a proxy for generalist herbivores. We measured a wide range of heterogeneity factors in mixed forests and monoculture forests in semi-natural boreal forests in central Sweden. Larvae of *N. sertifer* and plasticine models were placed out on experimental trees, and around each experimental tree we measured tree species diversity and structure, type and structure of understory, structures of dead wood and boulders, and presence of ants.

Our results showed that tree species diversity did not increase predation pressure at stand level. However, ant presence, tree and understory structures, dead wood and the presence of boulders did affect predation pressure directly or indirectly within the stands. We conclude that local heterogeneity is more important than tree diversity at stand level, and that the influence of boulders on the outcome of predator-prey interactions is underemphasized. Future studies are needed to investigate the impact of heterogeneity, and especially boulders, on arthropod predator-prey interactions, which would allow assessing their contribution to overall ecological processes.

Identification of wood by-products use patterns in Slovakia

The Scientific Committee - Potpourri session
Ján Parobek[1]
Martin Moravčík[2], Hubert Paluš[1], Miroslav Kovalčík[2], Michal Dzian[1]
[1] Technical University in Zvolen
[2] National Forest Centre

Abstract: Renewable resources, considered inevitable part of the issue of the circular economy, are increasingly recognized as a key factor in environmental protection, sustainable development, and economic prosperity. The circular economy emphasizes the utilisation of wood resources and reutilisation of these resources and waste streams into value added products. Successful implementation of wood utilisation in various industry sectors serves as a driving force for building a sustainable society. The analysis of wood flows takes into account not only the utilisation of wood as a material, but also by-products and waste generated by the production to be used as inputs for further uses in construction, wood processing or energy sectors. The study deals with the analysis of actual wood use patterns in Slovakia with a focus on wood by-products management following the wood cascading principles. The obtained data are the basis for the calculation of a cascading coefficient to optimise the use of wood in the whole chain of its processing and utilisation. At the present time, the most important producer of wood by-products is the sawmilling industry, consuming approximately 40% of the total volume of industrial wood used in Slovakia. Moreover, the results describe some specific wood flows focused on possibilities of using wood by-products and recycled wood for the production of products with a higher added value.

Ilyonectria and Dactylonectria species from Pinus radiata in New Zealand

The Scientific Committee - Potpourri session
Rebecca McDougal[1]
Kiryn Dobbie[1], Vageesha Neththikumara[1], Darryl Herron[1], Gayathri Vaidyanathan[1, 2]

[2] AgResearch Grasslands, Private Bag 11008, Palmerston North 4442, New Zealand

Abstract: *Ilyonectria* and *Dactylonectria* species have been associated with diseases in agricultural, horticultural and forestry crops causing cankers, root rots and black foot disease (BFD). These genera are ubiquitous and are found in soil, plant roots or woody tissues, and can act at saprobes, endophytes, or weak and latent pathogens. They have *Cylindrocarpon*-like anamorphs and produce conidia that are spread through soil and water. Many species produce chlamydospores allowing them to survive in the soil for extended periods of time. Species in these genera have been associated with severely reduced yields and crop losses. *Dactylonectria* and *Ilyonectria* species have been identified from diseased *Pinus radiata* submitted to Scion's Forest Health Reference Laboratory (FHRL). These samples were showing symptoms of root rot and most often sampled from nurseries or from recently planted stands. A delimiting study was carried out to determine what *Ilyonectria* and *Dactylonectria* species are associated with symptomatic *P. radiata*. Using ITS 1/4, only four of the 19 isolates studied aligned phylogenetically with currently described species. The remaining 15 isolates could be separated into six distinct phylogenetic clades. Three further gene regions were used to determine how these isolates might be related to known *Ilyonectria* species. However, our analysis revealed that the isolates were phylogenetically distinct from the known *Ilyonectria* species we used in this study. Further validation and descriptions of new species is being undertaken to improve our understanding of distribution, host associations, and pathogenicity to *P. radiata* and other forestry and horticultural hosts.

Impact of non-native tree species in Europe on soil properties and biodiversity: a review

The Scientific Committee - Potpourri session

Abstract: In the context of global change, the integration of non-native tree (NNT) species into European forestry is lively debated. While native tree species are increasingly limited by higher frequencies of hot drought spells, previous forest services such as protection in mountainous areas or wood production are questioned. One option is to integrate more drought-resistant tree species – among them NNTs – in our stressed forests, another is to do without NNTs and accepting a loss of growth, i.e. a reduction in wood production.

The ecological consequences of increasing use or spread of NNTs in European forests are highly uncertain, as the scientific evidence is either constraint to results from case studies with limited spatial extent, or concerns global assessments that lack focus on European NNTs. For both cases, generalisations on European NNTs are challenging to draw. Therefore, we compiled data on the

impacts of seven important NNTs (*Acacia dealbata*, *Ailanthus altissima*, *Eucalyptus globulus*, *Prunus serotina*, *Pseudotsuga menziesii*, *Quercus rubra*, *Robinia pseudoacacia*) on physical and chemical soil properties and diversity attributes in Europe, and summarised commonalities and differences.

From a total of 103 publications considered, studies on diversity attributes were overall more frequent than studies on soil properties. The effects on soil properties varied greatly among tree species and depended on the respective soil property. Overall, increasing (45%) and decreasing (45%) impacts on soil occurred with similar frequency. In contrast, decreasing impacts on biodiversity were much more frequent (66%) than increasing ones (24%). Species phylogenetically distant from European tree species, such as *Acacia dealbata*, *Eucalyptus globulus* and *Ailanthus altissima*, showed the strongest decreasing impacts on biodiversity. Our results suggest that forest managers should be cautious in using NNTs, as a majority of NNT stands host fewer species when compared with native tree species or ecosystems, likely reflected in changes in biotic interactions and ecosystem functions. The high variability of impacts suggests that individual NNTs should be assessed separately, but NNTs that lack European relatives should be used with particular caution.

Impacts of COVID-19 Pandemic on Private Forest Landowners in the Southern United States: Challenges and Opportunities

The Scientific Committee - Potpourri session

Ana Cubas-Baez[1]
Rajan Parajuli[1], Erin Sills[1], Iain Burnett[1]
[1] North Carolina State University

Abstract: The Southern United States (or simply "the U.S. South") includes 13 southeastern states from Virginia to Texas and contains approximately 100 million hectares of the most dynamic, diverse, and productive forestlands in the nation; responsible for about 60% of national timber production. As with the rest of the economy, the forestry sector in the U.S. South was disrupted by COVID-19. The pandemic interrupted the production and supply chains of manufacturing industries. For example, it produced an increase in the price of Southern softwood composite lumber, mainly caused by labor shortages and stay-at-home policies. However, the average saw timber prices were lower in 2020 compared to previous years. The pandemic also increased demand for finished wood products (for example, packaging and shipping materials for online shopping). However, this did not mean higher prices for standing timber. Since around 87% of the forestland in the U.S. South is privately owned, the pandemic may have shaped the future of forestry in the region by changing landowners' objectives, approaches, and plans related to forest management along with new challenges and opportunities. This research aims to evaluate the impacts of the COVID-19 pandemic on private forest landowners and to explore the challenges and opportunities in post-pandemic forest management in the Southern United States. We will collect data from a sample of private forest landowners in 13 states in the U.S. South with a survey instrument that elicited information about the COVID-19 impacts, forestland revenues, communications networks and education, forest management, and landowners' future plans for forest management. Our survey instrument is designed to reveal both contemporaneous and lasting impacts of the pandemic. We will evaluate the impacts of COVID-19 from a comparison of landowners considering variables such as location, size of land, and ownership. We will also develop models of landowner decisions to adopt new approaches and practices of forest management. The findings from this study will provide insights into the severity of COVID-19's impacts on several aspects of forest management to identify which effects of the pandemic were fleeting and which were more long-lasting to learn lessons toward a more robust forest-based rural economy.

Implementation Gaps and Challenges in Sokshing Forest Land leasing Policy: A Case Study in Bhutan's Forestry Sector

The Scientific Committee - Potpourri session

Ratan Gurung[1]
Kazuhiro Harada[2]
[1] PhD student at Graduate School of Bioagricultural Sciences, Nagoya University, Japan
[2] Professor at Graduate School of Bioagricultural Sciences, Nagoya University, Japan

Abstract: For centuries, sokshing (leaflitter forest) has been an integral part of rural livelihood in Bhutan, serving as the indigenous knowledge system for sustainable forest resource management. The farming community utilizes sokshing by collecting leaflitter as cattle bedding material, which is then combined with cattle excreta to produce farmyard manure. In 2007, Bhutan's Land Act resulted in the nationalization of sokshing land, deleting the legal household ownership records and mandating the leasing of reverted sokshing from rural areas to agriculture-dependent households. Thus, this research focuses on the implementation of the sokshing forest land leasing policy in Bhutan, aiming to assess the extent of policy adoption and its impact on forest management practices. To examine policy implementation, interviews were conducted with various policy actors at the national, regional, and local levels, including government officials, non-governmental organizations, traditional leaders, and local communities. A combination of qualitative and quantitative methods, such as interviews, surveys, and analysis of policy documents and field data, was employed in this study. The findings reveal prevalent deficits in the implementation of the sokshing leasing policy within Bhutan's forestry sector. Notably, none of the farmers have received leasehold titles for sokshing land, leading to concerns among local communities regarding ownership rights. Poor implementation of the 2007 land act and a lack of clarity regarding land property rights contribute to this ambiguity. The study identifies a lack of intersectoral coordination and communication, inadequate institutional and financial capacity, and insufficient sensitization and awareness of leasing procedures as the main barriers to sokshing lease implementation. Therefore, addressing this ambiguity and ensuring effective implementation of the sokshing lease policy necessitates improved communication and coordination among government units and stakeholders, allocation of sufficient resources, and the harmonization of policies and legal frameworks. By implementing the formulated policies, stakeholders can mitigate the concerns and challenges surrounding sokshing lease, fostering a more sustainable and inclusive approach to forest resource management in Bhutan.

In vitro Regeneration of Thick Walled Edible Bamboo Species (Dendrocalamus asper) from Seed Originated Explants

The Scientific Committee - Potpourri session
Md Aktar Hossain[1]
Nuren Tabassum[2], **Md Mahbubur Rahman**[1], Waheeda Pervin[1], Bayezid Mahmood Khan[2], Nusrat Sultana[1]
[1] Bangladesh Forest Research Institute, Chittagong - 4000, Bangladesh
[2] Institute of Forestry and Environmental Sciences, University of Chittagong, Chittagong - 4331, Bangladesh

Abstract: *Dendrocalamus asper* known as rough bamboo, giant or sweet bamboo is a thick walled tropical bamboo grown commercially in China, Thailand and Malaysia mainly for edible shoots and structural construction. However, there was no report on growing of this bamboo species for edible shoot production or any other purposes in Bangladesh. The present research project has therefore been carried out to develop efficient in vitro regeneration protocol for this bamboo species from seed originated explants. Deglumed seeds of *D. asper* were surface sterilized with 0.1% $HgCl_2$ for 0, 5, 10, 15 or 20 min and germinated in vitro in MS media without any PGRs. Germinated shoots were cultured in MS media supplemented with four concentrations (0, 1, 3 and 5 mg/L) of BAP in liquid media for shoot generation. Newly generated shoots were then cultured in semi-solid MS medium supplemented with 0, 1, 3 and 5 mg/L BAP combined with 1mg/L or 2 mg/L Kinetin for shoot multiplication. Disinfection time of seed with 0.1% $HgCl_2$ significantly enhanced the germination percentage of *D. asper* seeds in the MS media. The concentration of BAP suggestively affected the duration of shoot induction, rate of shoot proliferation and the number and growth of shoots in both the liquid and solid media. MS medium supplemented with 3mg/L BAP in combination with 1mg/L Kn showed the maximum shoot proliferation. Increasing the number of shoot from 1 to 5 in the bunch used as explants also significantly increased average number of shoots in explants cultured in the media supplemented with 3 mg/L BAP and 1 mg/L Kn. In vitro generated shoots were elongated in the MS media supplemented with 2 mg/L GA_3. The highest percent of root induction and maximum number of root per shoot was recorded from half-strength MS media supplemented with 2mg/L IBA. Survival rate after 30 days was 90 in the greenhouse environments.

Indigenous and Small-scale Natural Resource Management in the Great Lakes Region of the United States

The Scientific Committee - Potpourri session

Emily Huff[1]
Antoinette Shirley[1], Kristin Floress[2]
[1] Michigan State University
[2] USDA Forest Service

Abstract: This presentation will review small-scale and indigenous natural resource management trends in the Great Lakes region of the United States. Drawing from in-depth semi-structured research interviews, we will describe perspectives of natural resource professionals who work with Indigenous communities. They identify what these communities believe are driving natural resource challenges, possible solutions, and share their perspective on knowledge co-production (whether it is happening or driving their work). Three main themes include climate change adaptation, tribal capacity, and wildlife management issues. We will also review survey data on small-scale forest management, including several family forest owner surveys to explore emerging topics like interest in conservation programs, the link between forest ownership and wellbeing, knowledge and awareness of threats, and awareness and uptake of agroforestry practices. Weaving together these many data sources, we will describe what opportunities may exist for outreach and engagement of this important forest ownership category and discuss how this region may be similar or different from other U.S. regions and the global of small-scale, community, and indigenous forestry communities.

Initial growth of forest species in an experimental plot for Forest Landscape Restoration

The Scientific Committee - Potpourri session
Claudia Guadalupe Salcedo Rivas[1]
Maria Laura Quevedo Fernandez[1], Lila Mabel Gamarra Ruiz Diaz[1], Lidia Florencia Perez de Molas[1], Alexander Abdel Fleitas Saucedo[1], Haroldo Nicolas Silva Imas[2]
[1] Universidad Nacional de Asunción
[2] Itaipu Binacional, Paraguay

Abstract: Forest Landscape Restoration is a process that facilitates the recovery of a forest environment that has been partially or completely degraded, damaged, or destroyed (FAO 2017). The success of Restoration projects largely depends on the initial establishment of forest species. That is why this study intended to evaluate the initial growth, at 15 months, of tree species in Forest Landscape Restoration plots. The study area corresponds to an experimental plot of Itaipu Binacional, located in the district of Hernandarias, Alto Paraná department, Paraguay.

An experimental plot of 5.9 hectares was established using a completely randomized block design with 5 replications and 8 treatments. Each experimental unit has a total area of 1,800 m2. A total of 30 species were planted, including both cover and biodiversity species for the conservation strip, and native and exotic species for the exploitation strip.

The species that showed the higher growth in diameter at breast height and height were clones of *Eucalyptus urophylla x E. camaldulensis* and *Eucalyptus urophylla x E. grandis*, and among the native species, *Mimosa bimucronata* (DC.) *Kuntze var. bimucronata* stood out. In terms of canopy area, in addition to *Eucalyptus urophylla x E. camaldulensis* and *Mimosa bimucronata* (DC.*) Kuntze var. bimucronata*, *Solanum granulosum-leprosum Dunal was noteworthy*.

In both analyzed variables, the exotic species (*Eucalyptus sp.)* and two of the native species exhibited the highest values due to their great adaptability to these conditions and environments.

Initial performance evaluation of two hybrid eucalyptus clones in the Experimental Plot for Forest Landscape Restoration, Alto Paraná, Paraguay.

[1] Universidad Nacional de Asuncion
[2] Itaipu Binacional, Paraguay

Abstract: The association in the early stage of Forest Restoration with native species and economically valuable fast-growing species such as Eucalyptus spp. can reduce the initial costs associated with what, in addition to generating economic returns during the early years of the process. That is why this study intended to understand the initial performance of 2 hybrids of Eucalyptus spp. In a forest landscape restoration trial located in the Alto Paraná Department, Paraguay, on a property owned by Itaipu Binacional. The trial consists of two treatments and 5 randomly distributed blocks, where both treatments have a strip of exploited species and a strip of conservation species. The difference between both treatments lies solely in the exploited species strip, where treatment 1 (T1) consists of the association of Eucalyptus urophylla x E. grandis for timber purposes, with a spacing of 3x3 m, and treatment 2 (T2) consists of the association between Eucalyptus urophylla x E. camaldulensis for energy purposes, with a spacing of 3x2 m. In T1, pruning up to 9 m is planned, as well as two thinning operations and final harvesting at 10 years, whereas in T2, harvesting is planned at 5 years after plantation. The plantation was established in May 2021, and the dendrometric variables, diameter at breast height (DBH), total height, and crown coverage, were recorded at 12 months. The results showed an average DBH of 627 mm for T1 and 74.56 mm for T2. As for the average height variable, T1 yielded 417.3 cm, while T2 yielded 496.4 cm. In contrast, the average crown area variable resulted in 3.28 m2 for T1 and 4.63 m2 for T2, respectively. These data reflect significant initial performance of T2 with the aim of obtaining an important economic return.

Integrating Deforestation Risk for Fairness REDD+ Benefit Sharing in Indonesia: A Case Study of Jurisdictional-based REDD+ Program in Jambi Province

The Scientific Committee - Potpourri session

Riko Wahyudi[1, 2]
Christian Silangen[1], Muis Fajar[1]
[1] Research Centre for Climate Change – University of Indonesia (RCCC-UI)
[2] Indonesia Expert Association for Climate Change and Forestry (APIK Indonesia)

Abstract: In order to distribute REDD+ benefits effectively, efficiently and fairly to beneficiaries in subnational jurisdiction, two distribution criteria proposed i.e.: historical emissions (tCO_{2e}) and forest cover (ha). Forest cover is proposed to accommodate beneficiaries who have protected forests in their area which has relatively smaller historical emissions as a result of protecting and maintaining the forest for years compared to beneficiaries whose areas are not preserved, deforested and degraded but are implementing REDD+. Interestingly, a simulation result of the jurisdictional-based REDD+ benefit sharing in Jambi province for 2018 using the two criteria, indicate an imbalance in the benefit allocation, where the forest areas managed at national level (national parks, nature reserves, etc.) received greater benefits than others, mainly Forest Management Units (FMUs) under subnational government's control. This is due to the fact that the national park areas cover over one third of the jurisdiction, an imbalance which will be a source of dispute from the subnational perspective. This paper explores the possibility of integrating deforestation risk as one of the main criteria to determine REDD+ benefit sharing along with the existing indicators. Using a deliberation, the appropriate local determinants for deforestation risk determined to be included in the construction of the risk criterion. Ultimately, the paper delivers a set of recommendations of what are the best criteria for the calculation of REDD+ benefit sharing. Although this paper takes the case study of Jambi province, paper also explores the feasibility of such results to be applied in other regions in Indonesia

INVESTIGATION OF PUBLIC PERCEPTIONS AND PREFERENCES REGARDING RECREATIONAL FORESTS: exploratory study in the Ukrainian Carpathians

The Scientific Committee - Potpourri session
Oksana Pelyukh
Taras Parpan[1], Lyudmyla Zahvoyska[2]
[1] Ukrainian Research Institute of Mountain Forestry named after P.S. Pasternak
[2] University of Valladolid

Abstract: For the post-war recovery of Ukraine, including restoration of its natural capital, it is important to understand public preferences and expectations concerning forest ecosystem services. Although today a significant part of the forests in the Ukrainian Carpathians is of artificial origin, we cannot say that they were designed and managed with a clear vision of arising challenges and intention to maximize multiple benefits generated by forest ecosystems. Growing local demand for recreation in the Carpathian Mountains gives rise to new challenges related to the need for formation of recreationally attractive forests. In recent decades in Europe, many studies have been conducted on public perception of recreational forests, and preferences concerning their attributes. However, studies conducted recently in Ukraine, considered forests as a generalized concept, without attention to forests' attributes. In this exploratory study we investigated public perceptions and preferences, both stated and revealed, regarding attributes of recreational forests and recreational objects in the Ukrainian Carpathians. People's willingness to travel to enjoy a forest with appropriate attributes and their revealed behavior were analyzed, with a focus on species mixture, age structure, presence of deadwood, distance, location distance etc. Set of techniques, like non-parametric statistics, choice experiment method and travel cost method were applied to provide an insight into the research question. Integration of the revealed perceptions and preferences regarding recreational forests and objects into innovative forest decision-making enables synergy of benefits like an increasing attractiveness of recreational forests and forest landscapes, improvement of forest resistance to climate change, satisfy a local demand on wood biomass and strengthen fire resistance of recreational forests.

Is climate change exacerbating national park---community conflict: A case study of Qilian Mountain National Park, China

The Scientific Committee - Potpourri session

Shuning Zhu[1]
Weiye Wang[1], Jinlong Liu[1]
[1] School of Agricultural Economics and Rural Development, Renmin University of China,

Abstract: Access restrictions for natural resource use of local people induced by the establishment of national parks, often result in conflicts, thus jeopardizing conservation goals. Meanwhile, communities have also been severely challenged by climate change since the 21st century, and whether this exacerbates local animosity towards the national park. By taking a community resilience perspective, this paper furnishes a renewed look at how climate changes affect the tendency of conflict. For this purpose, this study conducts an in-depth qualitative study based on semi-structured interviews with local communities in Qilian Mountain National Park. It will be ascertained that the conflict between the national park and locals tends to exacerbate under the threat of climate change, and community resilience capacity mediates the relationship. Communities of interest have higher community resilience compared to communities of geography. Communities of geography inability to adopt adaptation strategies to help them adapt to the adverse effects of climate change, leads to stiffer conflicts with the national park directorate. It also discusses measures to strengthen the resilience of communities to adapt to changing socio-economic conditions. The study highlights the importance of community resilience in achieving a harmonious balance between nature conservation and the well-being of local communities.

LOCAL COMMUNITY PERCEPTION ON THE ECOTOURISM POTENTIALITIES OF THE DELTA MONO BIOSPHERE RESERVE IN SOUTHERN BENIN

The Scientific Committee - Potpourri session
Sêlomè Grâce Vicentia Desdémone DADELE[1]
[1] Laboratory of Applied Ecology, University of Abomey-Calavi

Abstract: Ecotourism contributes to conserving natural resources and promoting natural and cultural resources stewardship. However, without the strong support and involvement of local people, it is not easy to achieve the stated goals. This study aimed to understand the local people's perception of the ecotourism potentialities of the Delta Mono Biosphere in order to inform policymakers. We conducted a semi-structured interview of 120 respondents from *Lokossa, Houéyogbé* and *Athiémé* districts surrounding Delta Mono Biosphere Reserve. We also did 104 km of transect survey to assess the diversity of the wildlife in the reserve. Our findings confirmed the presence of 08 mammalian species, 32 species of birds and 3 species of reptiles which were also recognized as a potential for ecotourism by the local population. This Biosphere Reserve provided several ecosystem services and the most cited by the respondents were provision (27,32%), support (25,85%) and cultural (23,41%) ecosystem services. Among the cultural ecosystem services, it highlighted many sacred forests and other traditional activities (fishing and small game hunting) valuable in ecotourism. The respondents call for support from the government to organize community-based ecotourism. The main threat to the conservation of these resources is the low motivation of the local communities who don't perceive all potential positive impacts of the Biosphere, if well managed. Detailed understanding and consideration of socioeconomic and demographic characteristics can contribute to effective outreach and planning processes, potentially resulting in the higher promotion of ecotourism.

Keywords: wetlands, ecosystem services, biodiversity, ecotourism potential, Benin

Mapping the Distribution of the Eurasian Hoopoe Upupa epops and the Pine Processionary Moth in Lebanon based on a Citizen Science Approach

The Scientific Committee - Potpourri session

Leila Rossa Mouawad[1]
Salim Kattar[1], Dany El Obeid[1], Jad Rizkallah[1], Samara El Haddad[2], Karma Bou Azza[2]
[1] Lebanese University - Faculty of Agronomy
[2] Lebanon Reforestation Initiative

Abstract: The Pine Processionary Moth (PPM) has long been attacking Mediterranean forests. In its defense strategy, Lebanon was focused mainly on pesticides, more recently on biocontrol, leaving natural predators as an understudied field. Add to that an inherited lack of forest inventory, biological diversity assessment and a broad gap when it comes to avifauna and its link in the natural control of forest pests.

For the first time ever in Lebanon, this study aims at understanding the status of the Eurasian hoopoe, all while assessing the damage caused by the PPM, in an attempt to explain the relationship between the two species and their relation to other factors. Based on Citizen Science (CS), the data of the two species covering the years 2017 to 2022 resulted from various sources: a Google Form shared nationally among individuals, groups, NGOs, pages, ministries and more; Passive data collected from Facebook groups and individual posts; Personal communication with key people; and eBird.

After filtering the data, distribution maps were developed on ArcMap, and an attempt was done on Statistica software using an Analysis of Variance (ANOVA) test to correlate the PPM and the Eurasian hoopoe. However, due to many inconveniences and disparities in the results, no statistically valid correlation between the two studied species was found at this stage. As a result, research guidelines with the required experimental procedures to reveal the underlying correlation between the two studied species were offered.

Additionally, based on a “Responsible Hunting Areas” map developed by a local NGO, the varying damage from the PPM between Cazas was linked to Important Bird Areas (IBAs), highlighting the importance of multiple birds, including the Eurasian hoopoe, as natural predators of this pest.

This paper was concluded with a conservation roadmap and based on its findings, a set of recommendations for each stakeholder was proposed.

Having depicted completely understudied species in Lebanon, this paper serves as a stepping stone in the field of biodiversity conservation, as it sets the path for future researchers willing to work on the same urgent topic, in a context of Climate Change and increased pest outbreaks.

Marine climate regulation mechanisms also drive terrestrial moth populations

The Scientific Committee - Potpourri session
Julia J.J. Fält-Nardmann[1]
Heta E.J. Rousi[2], Betty Marjamäki[1], Ilmari Juutilainen[3], Tommi Andersson[1], Juhani Itämies[3], Jari Hänninen[2], Pekka Niemelä[4]
[1] Kevo Subarctic Research Institute, University of Turku, 20014 Utsjoki, Finland
[2] Archipelago Research Institute (Seili), University of Turku, FI-21660, Nauvo, Finland
[3] University of Oulu, 90014 Oulu, Finland
[4] Institute of Dentistry, University of Turku, Lemminkäisenkatu 2, 20520 Turku, Finland

Abstract: Time series data analyses were used to compare trends and changes in the biomasses of Subarctic moth (1971–2017) and northern Baltic Sea zooplankton (1966–2019) as well as to analyse how both groups were affected by climate variables.

There were no significant changes in total moth biomasses unless the outbreaking species *Epirrita autumnata*, with slightly increasing biomass, was included into the analysis. Biomasses of species flying every year, overwintering as eggs, feeding on both herbaceous and woody plants and generalists feeding on three or more plants increased significantly. In contrast, biomasses of species overwintering as larvae, feeding on something else than living plants, feeding on sprout or root, feeding on just herbaceous plants and specialists feeding on one plant only, remarkably decreased. Regarding zooplankton, the biomasses of all zooplankton groups decreased. Decreases of marine and brackish water species were the most obvious.

The driving role of NAO and observed regime shifts in the Baltic and North Seas were studied regarding both invertebrate groups. In addition, regarding moths, the role of growing season temperature sums and precipitation were studied. Mostly the spring (March–May) NAO index, which correlated positively with temperature, best explained biomass changes and trends in moths. The spring NAO negatively affected species which flew every year, which overwintered as larvae and species which used more than three nutrition plants. Species eating herbaceous plants had a bigger biomass during the first regime in 1972–1975 but concerning other groups regime shifts were not important for moths. Additionally, temperature sum until 15th of June had a significant negative effect on moths which overwintered as larvae.

Winter (December–March) NAO index was relevant for zooplankton. It was a significant factor for cladocerans, whereas observed regime shifts (1976 and 1990) best explained marine (1976 and 1990) and brackish (1976) copepod biomasses. Additionally, the effect of ice-covered period on zooplankton was investigated and it best explained biomass changes in freshwater copepods.

Our results indicate significant effects of climate change on moths and zooplankton, but the climatic regulation mechanisms affect these invertebrate groups differently, for instance due to phenological and ecosystem related differences.

Migration, Traditional Ecological Knowledge, and Biodiversity Conservation in Sacred Forests: A Case Study of Igbo Olodumare, Nigeria

The Scientific Committee - Potpourri session

Samuel Adeyanju[1]
Jonathan C. Onyekwelu[2]
[1] Faculty of Forestry, University of British Columbia, Vancouver, Canada.
[2] Department of Forestry and Wood Technology, The Federal University of Technology, Akure, Nigeria.

Abstract: Sacred forests are globally recognized as a form of community-based conservation for their role in protecting biodiversity within and outside the global protected area network. However, the existence of sacred forests in many cultures and societies were not primarily for conservation purpose but rather for cultural and religious purposes. In many cases, the traditional ecological knowledge (TEK) which is integral to the existence of sacred forests continues to face significant threats. In this paper, we draw from primary data collected from survey questionnaires, focus groups and participant observations in Igbo Olodumare sacred forest in the Southwest region of Nigeria. We examine threats facing the sacred forest to determine how such threats could impact the long-term conservation of biodiversity in the forest. We found that there are two main threats to the long-term biodiversity conservation in Olodumare sacred forest: (1) the increased presence of migrant farmers who are unfamiliar with TEK, and (2) the knowledge vacuum resulting from the migration of local elders who are custodian of TEK to cities. When compared with other sacred forests in southwest Nigeria with fewer immigration, we found that the biodiversity conservation status of sacred forests is heavily dependent on threat levels and degradation. Our findings highlight the adverse impact of migration (from rural-urban and vice versa) on sacred forest conservation and offer suggestions to strengthen traditional ecological knowledge through engaging multiple stakeholders within and beyond the forest community.

Modelling tree height-diameter and biomass growth relationship of planted Melia volkensii (Gurke.) stand in drylands of Kenya

The Scientific Committee - Potpourri session
James Ndufa[1]
Hisaya Miyashita[2], Nellie Oduor[3], Samuel Auka[4]
[1] Kenya Forestry Research Institute (KEFRI), P.O. Box 20412 – 00200, Nairobi, Kenya

[3] National Forest Products Research Programme, P.O. Box 64636 – 00620, Nairobi, Kenya
[4] Drylands Eco-region Forestry Research Programme, P.O. Box 892 - 90200, Kitui, Kenya

Abstract: *Melia volkensii* tree growing in drylands of Kenya have a potential of reversing environmental degradation and at the same time improved farmer's livelihoods through sale of high quality timber. Melia planted on-farms support smallholder farmer's livelihoods and play an important role in global carbon cycle because of it short rotation. However, reducing emissions of greenhouse gases from deforestation and forest degradation (REDD) require stringent carbon measuring, reporting and verifying methods which is lacking especially for indigenous species. This study aims to evaluated the distribution of above- and below-ground-biomass and carbon socks of *Melia,* an important indigenous species that is being promoted for reforestations of degraded lands by developing robust allometric equation for estimating biomass and carbon using easy to measure growth parameter like diameter at breast height (DBH) and height . Five to ten trees were sampled and there height, DBH and aboveground biomass destructively harvested from trees of ages 5, 7.9 and 11 in Kibwezi site and 10, 12, 14 and 25 in Tiva site. Roots from sampled trees were subsequently excavated and weighed for estimation of root biomass. At Tiva site, 14 years Melia tree had at attained a height of 10.0m, a DBH of 20.0cm, and accumulated total biomass of 252 kg DM kg/tree and 125 kg carbon/tree which is equivalent to 157 tons DM/ha and 78.68 tons carbon/ha respectively at tree density of 625 tree/ha. At Kibwezi site, 11 year old Melia had at attained a height of 8.6m, a DBH of 23.4cm and accumulated total biomass of 274 kg DM kg/tree and 136.8 kg carbon/tree which is equivalent to 171 tons DM/ha and 86 tons carbon/ha respectively. Belowground to aboveground ratio was 0.21. Diameter at breast height alone provided reliable prediction of belowground biomass (R^2=0.97), aboveground biomass (R^2=93) and total biomass (R^2=0.94). This study recommends diameter at breast height as the basis for estimating biomass in drylands landscapes for estimating carbon sequestration potential of Melia planted on farms. Reforestation degraded farmlands with Melia can contribute climate change mitigation and REDD++ initiative

Monitoring of Forest Phenology (1982 - 2023) in the Western Ghats, India: Integrating Landsat and PhenoCam Data

The Scientific Committee - Potpourri session

KARUN JOSE[1]
Rajiv Kumar Chaturvedi[1]
[1] Birla Institute Of Technology And Science, GOA

Abstract: Monitoring forest phenology is crucial for understanding climate change as it provides insights into the timing and duration of key biological events, such as leaf emergence and flowering. These events are sensitive to climate variations and can help assess the impacts of changing environmental conditions on ecosystems. The Western Ghats in India holds immense importance due to its exceptional biodiversity, encompassing nine different forest types that support numerous endemic species. Each forest type possesses a distinct set of species and ecological processes. In the context of climate change, comprehending the impact of climate on forest phenology in this highly biodiverse hotspot becomes imperative. This study aims to investigate the changes in forest phenology over the past four decades (1982-2023) in various forest ecosystems of the Western Ghats, using Landsat data. The obtained results will be validated by incorporating available ground and PhenoCam data. Furthermore, this study will explore the drivers that regulate phenological dates across different forest types, shedding light on the factors influencing the timing of crucial biological events in response to climate and environmental conditions. By examining the phenological changes in diverse forest types within the Western Ghats, we can evaluate their resilience and vulnerability to climate change. Ultimately, this research will contribute to a comprehensive understanding of forest phenology in the Western Ghats and its correlation with climate change. The findings will aid in assessing ecosystem responses to climate variability and provide valuable insights for devising conservation and management strategies for preserving the region's unique biodiversity.

Morphological Taxonomy and Distribution of Dodder (Cuscuta species) in Kenya

The Scientific Committee - Potpourri session

Magrate Kaigoingi[1], Jane Njuguna[1], Linus Mwangi[1], Stepehn Omondi[1], Priscilla Kimani[1], Jane Njehu[1], Angela Muthama[1], Charles Magare[1], Asenath Adienge[1], Beryn Otieno[1], Rashide Moile[1], Olivia Nyaundi[1], Rufo Jillo[1]
[1] Kenya Forestry Research Institute (KEFRI), P.O. Box 20412-00200, Nairobi- Kenya

Abstract: Dodders are parasitic plants that attack other plants. In Kenya, reports on Dodder have identified *Cuscuta reflexa, Cuscuta campestris,* and *Cuscuta kilimanjari* however, other observations and reports of other Dodder species infestations indicated that several species may be widespread in the county. The weed poses a threat to this region's ecosystem and biodiversity with adverse environmental impacts. Currently, the identity of the species causing havoc in the Kenyan ecosystems is not known. Data on accurate information on the extent of parasite spread and damage caused by dodders on plants as well as the magnitude of their socio-economic impacts is also lacking. A national survey was carried out to identify sites with Dodder infestations using transects to taxonomically identify species in Kenya, their distribution and infestation. Dodder samples were collected from the infested areas and characterized morphologically. Host weeds was also determined. Known road transects were used in the collection of samples at a distance of 1km apart. Identification was done by examining the morphological features such as colour and floral characteristics and compared with known keys. Western and Rift Valley were the most affected areas while Eastern and Coastal areas had moderate infestations. Six species of Dodder were identified and their occurrence documented. The species identified were: *Cuscuta kilimanjari* (85.4%)*, Cuscuta suaveolens* (5.4%), *Cuscuta campestris* (4.3%) *Cuscuta planiflora* (3.7%) *Cuscuta epilinum* (0.5%) and *Cuscuta australis* (0.5%). *Cuscuta kilimanjari* was the most widely distributed species and had a wide host range. It was the dominant species in the Eastern Kenya region. *Cuscuta suaveolens* and *Cuscuta australis* were only found in Central Kenya region. *Cuscuta planiflora* was found in both Central and Nyanza. *Cuscuta campestris* was found in both the Central and Rift Valley regions. *Cuscuta epilum* was only found in Rift Valley on *Bougainvillea gabra.* The major species attacked by *Cuscuta sp.* are *Thevetia peruviana* followed by *Lantana camara* and *Senna siamea*. The *Cuscuta spp* were found to affect different plant species including high agricultural crops and trees. The findings of the study have expanded the distribution and host range of Dodders in Kenya.

Keywords: *Cuscuta spp, Taxonomy, Morphology, Distribution, Kenya*

Natural regeneration of Pinus sylvestris and Betula spp. onto carbon-rich soils drives net ecosystem carbon losses

The Scientific Committee - Potpourri session

Naomi C Housego[1, 2, 3]
Thomas C Parker[1], Lorna E Street[2], Elena I Vanguelova[3], Ruth J Mitchell[1]
[1] Ecological Sciences, The James Hutton Institute, UK
[2] School of GeoSciences, University of Edinburgh, UK
[3] Forest Research, UK

Abstract: Forest restoration is proposed to address the joint biodiversity and climate crises. However, tree establishment onto carbon-rich podzolic soils can drive soil carbon losses, via ground preparation such as mounding or ploughing. These soil carbon losses can exceed tree biomass carbon gains at the timescale relevant to 2050 net zero targets. Thus, reforestation via natural regeneration has been proposed as a solution, as soil carbon losses via ground preparation would be avoided.

However, we hypothesise that soil carbon losses via tree-soil interactions following natural regeneration onto carbon-rich soils could still drive net ecosystem carbon losses at timescales relevant to net zero. Thus, to quantify soil carbon losses in the absence of ground preparation, we investigated the ecosystem carbon stock changes that follow natural regeneration.

In the Cairngorms, Scotland, we identified sites of 25-30-year-old *Pinus sylvestris* and *Betula* natural regeneration onto *Calluna vulgaris*-dominated moorland with podzolic soils. We measured tree, vegetation, and soil carbon stocks at intervals along an eight metre transect from single naturally regenerated trees into uncolonised moorland.

Soil carbon stocks were lower in the rooting zone of the trees, compared to eight metres away in open moorland. Overall, total soil carbon stocks decreased 2.7 t C/ha per metre from the tree. On average, 0.5 t C/ha of soil carbon was gained in the upper layers of the soil, where litterfall occurred, with each metre from the tree, although this varied between tree species due to different litterfall masses and chemistries. Yet, on average, 3.2 t C/ha of soil carbon was lost in the lower layers of the soil, where tree rooting occurred, per metre from the tree, and this was consistent between the tree species. This suggests the role of tree-soil interactions in driving soil carbon losses. At the ecosystem scale, soil carbon losses exceeded tree carbon gains, resulting in net ecosystem carbon losses following natural regeneration onto carbon-rich soils.

Thus, when evaluating the contribution of naturally regenerated forests to climate change mitigation, soil type and potential soil carbon losses should be considered relative to tree carbon gains, especially at the timescale relevant to 2050 net zero targets.

Notes on the Pollination Dynamics of Smooth Narra (Pterocarpus indicus Willd. forma indicus) in Laguna, Philippines

The Scientific Committee - Potpourri session
Mario Angelo Mundin[1]
Dianne Joy D. Aguilon[2]
[1] Material Science Division - Physics and Mechanics Section, Forest Products Research and Development Institute, Department of Science and Technology, Los Baños, 4031, Laguna, Philippines
[2] Department of Forest Biological Sciences, College of Forestry and Natural Resources, University of the Philippines Los Baños, 4031, Laguna, Philippines

Abstract: Smooth Narra (*Pterocarpus indicus* Willd. forma *indicus*) is an important indigenous tree found in the Philippines. The pollination dynamics of smooth narra were studied from March to April of 2017 during its peak flowering at the College of Forestry and Natural Resources Campus of the University of the Philippines Los Banos. Its pollination syndrome, floral developmental stage, and associated floral visitors and possible pollinators were elucidated under field conditions. The floral development of smooth narra was described. A total of 13 taxa of floral visitors were recorded. Bees such as *Xylocopa*, *Tetragonula,* and *Apis* were observed foraging on the inflorescence. *Tetragonula* has the highest Index of Visitation Rate (IVR) of 412.09 while the weevil Curculionidae yields the lowest IVR of 0.04. Smooth narra has some notable floral visitations and potential insect-mediated pollination may occur. However, more studies are needed to better understand the role of insects as pollinators for *Pterocarpus indicus* and to explore the potential implications for its reproductive success and genetic diversity.

OCCURENCE OF ARMILLARIA RHIZOMORPHS IN PEAT SOILS

The Scientific Committee - Potpourri session
Lauma Silbauma[1]
Darta Klavina[1], Tuula Piri[2], Katrīna Smeltere[1], Kaspars Polmanis[1], Andis Lazdiņš[1], Jurģis Jansons[1], Tālis Gaitnieks[1]
[1] Latvian State Forest Research Institute Silava, Rigas 111, Salaspils LV 2169, Latvia
[2] Natural Resources Institute Finland LUKE, Latokartanonkaari 9, 00790 Helsinki, Finland

Abstract: *Heterobasidion* and *Armillaria* spp. are the most important root-rot-causing pathogens of conifers. *Armillaria* species primary spread by rhizomorphs and occasionally can cause severe economical losses in spruce stands. High incidence of Heterobasidion root rot has been observed in some spruce stands on peat soils in Latvia whereas the prevalence of *Armillaria* sp. in peat soils is largely unknown. The aim of the current study was to evaluate occurrence of *Armillaria* rhizomorphs in six Norway spruce stands on peat soils infected with *Heterobasidion*.

Armillaria rhizomorphs were found in 60 out of 90 soil samples. The total length of rhizomorphs per sample (volume – 2355 cm^3) ranged from 5.2 to 763.9 cm (49.6 cm on average). *Armillaria cepestipes* was detected in 85% of samples, and *Armillaria borealis* in35%. The total length of *Armillaria* rhizomorphs per square meter of soil at a 3 cm depth was on average 6.2 m. Obtained data indicates that peat favours development of *Armillaria* rhizomorphs.

Organic carbon storage, soil respiration and nutrient elements under Prosopis trees

The Scientific Committee - Potpourri session
Tahereh Alizadeh[1]
Hashem Habashi[2], Mohammad Matinizadeh[1], Seyed Moosa Sadeghi[1], **Mehrdad Zarafshar**[3]
[1] Research Institute of Forests and Rangelands, Agricultural Research, Education and Extension Organization (AREEO), Tehran, Iran
[2] Gorgan University of Agricultural Sciences and Natural Resources, Gorgan, Iran.
[3] Department of forestry and wood technology Linnaeus University.

Abstract: Background and objectives: In arid and semi-arid ecosystems, the relationship between tree species and
habitat is fragile due to environmental stresses. The role of native trees in carbon storage and change in
soil biological properties is important. (Prosopis cineraria (L.) Druce) is one of the most important native
species in the Sahara-Sindhi area, which has a good ability to establishment. The non-native species of
(Prosopis juliflora (SW) DC) is widely planted with fast growth. Trees in these areas can have a range of
different effects on the soil of under canopy.
Materials and methods: To measure basic and induce respiration, OC, N and P, 24 soil samples were collected from 0-30 cm depth randomly from under and outside canopy of both species. To calculate SOC with the cylinder in a 1×1 m 2 plot, sampling was done of soil to obtain the BD and OC. For measuring SOC in litter and grass cover, were collected and their weight was recorded. Finally, 120 samples were taken in south of Iran, Assaluyeh.
Results: The results of analysis of fragmented plots showed that the effect of species as the main factor
on basic and induce respiration was significant and it was in Prosopis cineraria 2.73
and 22.47 mgCo 2 in day and hour and in Prosopis juliflora 0.9 and 15.57 mgCo 2 in day and hour, respectively was more in Prosopis cineraria. The interaction effect of species in the sampling location on
available P was significant and its value was 23.68 ppm under canopy. The effect of sampling location was significant for all variables studied and under canopy was more.
Conclusion: Due to the positive effect of native species on soil respiration is very vital and negative effect of non-native species on soil respiration can reduce microbial activity. It is recommended to use
native species for natural forests and avoid entry of non-native species into.

Participatory Forest Management shortfalls! A review of Twenty Years of process implementation in Kenya

The Scientific Committee - Potpourri session
Musingo Tito E. Mbuvi[1]
Leila Ndalilo[1], Paul Matiku[2], Paul Gacheru[2]
[1] Kenya Forestry Research Institute (KEFRI)
[2] Nature Kenya

Abstract: Participatory Forest Management (PFM) was introduced in Kenya as a result of local and national pressure by communities and civil society organizations to reduce forest destruction. This was to be a departure from the government-centered approach to community based approach premised on the benefits witnessed in Nepal and India. Despite, the successful piloting of the approach there were concerns that it had not transferred adequate powers to communities nor contributed fairly and equitably to improved community livelihoods. A was undertaken through household's case study approach in Arabuko Sokoke, Kakamega, Kereita and Gathiuru forests through household surveys, expert discussions, Focus group discussion and key informant interview to determine if the challenges were policy, institutional, human or practice based. Results of the study indicated that PFM has fairly contributed to conservation and livelihood improvement. The process had introduced diverse livelihood sources for households and an opportunity for community participation in forest management and decision making, led to the formation of community organizations and multi-stakeholder forest management teams. The organizations have become fund raisers, forest managers and nexus for rural development. It was clear that livelihood improvement is not being adequately achieved in high biodiversity indigenous forests. This calls for innovative alternative community livelihood improvement activities. Moreover, although the community indicated that they have done their best to conserve the forest, the government has not provided adequate support to conservation. Moreover, CFAs are faced with governance challenges such as poor leadership, lack of accountability and transparency, non-adherence to their constitutions requirements and lack of established physical offices which have hindered the effective performance of CFAs. The study recommends continuous PFM awareness and training which should be phased and target all stakeholders and their categories of officials. Adequate resources should be allocated for PFM implementation process to ensure fair, just and equitable benefit sharing mechanism. There is need to provide incentives for community participation in PFM. In order for PFM to be institutionalization, improve livelihoods and create wealth and ensure good governance, PFM by-laws/subsidiary legislation to facilitate PFM implementation at station level and to support national uniformity will have to be enacted.

Patterns of Species and Functional Diversity along Environmental Gradients of Yayu Coffee Forest Biosphere Reserve Zonation, Southwest Ethiopia

The Scientific Committee - Potpourri session

Ferede Abuye Jeldu[1]
Motuma Tolera[1], Teshale Woldeamanuel[1]
[1] Hawassa University, Wondo Genet College of Forestry and NRs, Wondo Genet, Ethiopia

Abstract: In current ecological research, there is an urgent need to have trait based functional information at local as well as at global scales for effective forest landscape restoration. In this study functional diversity of Yayu Coffee Forest Biosphere Reserve (YCFBR) Southwest Ethiopia was quantified to enhance knowledge of these dynamic mechanisms using trait based diversity. Data was collected from 90 proportionally distributed plots along disturbance levels from core, buffer and transitional zones of YCFBR. For functional trait diversity estimation, traits relevant to plant-life strategy, competition ability and response to disturbances and climate change were selected. Multiple regression model was performed to test the response of species diversity and functional diversity along disturbance and environmental gradients. Also, mixed effects model was used to test the effects of environmental variables on functional diversity using R software. The results revealed that, a total of 83 plant species from 67 genera and 42 families were identified in the YCFBR. Functional diversity showed a linear decreasing pattern with increase of disturbance intensity and environmental factors in the YCFBR. From this, anthropogenic disturbances and environmental variables were the most important factors influencing the species diversity and functional diversity of YCFBR, which may affects ecosystem processes. This findings can be used in decision-making by policy makers for conservation and restoration of biosphere reserve. Further studies should be conducted to predict the relationships of species diversity with forest ecosystem services for climate change mitigation and the effects of climate change on forest biosphere reserve of Southwest Ethiopia.

Keywords: Biosphere reserve; Functional diversity; Southwest Ethiopia; Yayu coffee forest biosphere reserve; zonation.

Perspectives, Impacts, and Management of Stakeholder Groups on Forest Conflicts: A Case Study of Taitung Anshuo Region in Taiwan

The Scientific Committee - Potpourri session

Yi-Jie Rung[1]
Tai-Hsuan Yu[1], Ming-Yuan Huang[1], Kun-Cheng Chang[1]
[1] Department of Forestry and Natural Resources, National Chiayi University, Taiwan

Abstract: From 1945 to 1975, the Taiwan government implemented a policy of leasing forest land to the public for reforestation in order to restore forests that had been previously deforested or abandoned. However, since 1990, due to environmental, economic, and legal factors, most leaseholders have adopted a passive management approach. In recent years, there have been some leased land in the Anshuo area of Taitung, administered by the National Property Administration, planning for logging activities. It has raised concerns among environmental groups due to the presence of endangered species such as *Pasania chiaratuangensis* and *Pasania shinsuensis* listed in the Taiwan Red Book of Vascular Plants. This study aims to examine the attitudes of leaseholders towards conflicts between forest management and ecological conservation, and to explore the feasibility of implementing the payments for environmental services (PES) approach through the design of a "Fagaceae Conservation Fund" (FCF).

This study employed in-depth interviews with a total of 17 stakeholders. The findings revealed that inadequate communication was the main cause of forest conflicts in the Anshuo area. Whether there is a forest management plan and the intensity of logging were identified as significant factors contributing to conflicts. Distrust among environment protection groups, leaseholders, and government agencies also played an important role.

Regarding the feasibility of the FCF, the study indicated that when the fund's operation is entrusted solely to leaseholders, the feasibility decreases. Instead, it is suggested to develop a cooperative model between leaseholders and universities. While leaseholders provide the forest land management rights, the practical management is implemented by external entities, such as forestry companies or schools. This managing model was believed to be more acceptable to leaseholders. However, respondents from environmental protection groups expressed concerns about potential ecological damage resulting from the collection of fruits of Fagaceae. The study suggests that in order to address these concerns, face-to-face communication between individuals holding different positions should be facilitated, allowing for a more direct understanding of each other's perspectives.

Phenological mapping of understory invasive species residing in forest realm using machine learning algorithms

The Scientific Committee - Potpourri session
Kariya Ishita Bhaveshkumar[1]
Rajani Kant Verma[1], Laxmi Kant Sharma[1]
[1] Department of Environmental Science, Remote sensing and GIS lab, Central University of Rajasthan, Bandarsindri-305817, [India]

Abstract: Forests, crucial sources of living are being threatened by invasive plant species since past decade. Growth phase of these invasive species have affected the biodiversity, effectively replacing the rich and endemic species in forest realm. In past few years it has been noticed that invasion can become uncontrollable if necessary measures are not incorporated. Therefore, mapping and monitoring invasive plant species in forest realm is becoming a topic of such a prime importance. To map understory invasive plant species from forests has always been a task. In this paper, phenology plays vital role to study temporal curve for different vegetation indices affecting in growth and senescence period. Phenology has prime importance in separability analysis of inter and intra species discrimination. Multispectral images from Sentinel-2 dataset is used for forest and invasive species discrimination which is easily available and accessible around the globe. Mostly high spatial resolution dataset is used to map invasive plant species but this technique can be proved effective for above stated problem with multispectral images. Further, machine learning algorithms were incorporated to understand the most effective algorithm in pixel-based classification. In broad category, regression tree-based algorithms (CART and SVM), decision tree-based algorithms (RF and GTB) and probabilistic algorithm (GMM) were implemented to understand the best technique for above mentioned problem. Decision tree-based classifiers were most effective ones where accuracy of RF and GTB were 92.33% and 93.99% respectively. Results obtained so far shows that machine learning algorithms are still most effective for pixel based classification. Thus, this study has shown a technical procedure to follow to segregate invasive plant species from forest area.

Plantations of native tree species in Africa: a synthesis of tree survival and growth across plantation methods in the Guineo-Congolian region

The Scientific Committee - Potpourri session
Crispin Ilunga-Mulala[1]
Jean-Louis Doucet[1], Achille Biwolé[2], Nils Bourland[3], Gauthier Ligot[1]
[1] Forest Is Life, TERRA Teaching and Research Centre, Gembloux Agro-Bio Tech, University of Liège, Passage des Déportés 2, 5030 Gembloux, Belgium
[2] Laboratory of Forest Resources and Wood Valorisation, Advanced Teacher's Training College for Technical Education, University of Douala, P.O. Box. 1872, Douala, Cameroon
[3] Service of Wood Biology, Royal Museum for Central Africa, 13 Leuvensesteenweg, 3080 Tervuren, Belgium

Abstract: In the Guineo-Congolian region, forest plantations of native tree species were established and tested with different silvicultural itineraries and objectives in several countries. The results of these tests remained scattered, hampering our ability to identify the key drivers of plantation performance.

We then conducted a systematic literature review to gather, in a single dataset, records of planted tree survival and growth for the different planted tree species. From 37 studies, we compiled records of tree age, survival, mean height and diameter of 70 native tree species in 394 plantations across 8 countries of the Guineo-Congolian region. We modelled tree survival, height and diameter increments using linear mixed-effects models.

We found that the mean annual survival rate was 89.0 ± 15.2% in plantations whose mean age was 11.8 ± 14.7 years. The survival rate significantly varied with plantation methods, forest type, composition and differences in annual rainfall at plantation sites. Mean height growth was 90.9 ± 57.1 cm $year^{-1}$ and was higher for pioneer species (102.1 ± 63.2 cm $year^{-1}$) and in evergreen forests (126.1 ± 63.5 cm $year^{-1}$). Variation in height increment was significantly related to plantation age, forest type, species guild and leaf phenology. Plantation methods did not explain the differences in height increments. Stem diameter increment was 12.4 ± 7.5 mm $year^{-1}$ and slightly higher for pioneer species (13.2 ± 8.4 mm $year^{-1}$). This increment depended on plantation method and was the highest after clear-cutting (15.5 ± 6.8 mm $year^{-1}$). On average, the evergreen species showed a higher diameter increment (14.8 ± 7.6 mm $year^{-1}$) than the semi-deciduous species. We found high between-site variability for height increment and survival rate, but to a lesser extent for diameter increment.

These results helped identify the factors driving plantation performance and could guide foresters in choosing the best silvicultural itineraries for tree species.

POLICY AND LEGAL FRAMEWORK FOR FOREST MANAGEMENT IN ECUADOR: A MULTISECTORAL APPROACH TO STRENGTHEN GOVERNANCE

The Scientific Committee - Potpourri session

Jessica Estefania Coronel Carvajal[1]
Byron Maza[2], Rosa Mecha López[1], Fernando González Botija[1]
[1] Instituto de Ciencias Ambientales, Universidad Complutense de Madrid, Madrid, España
[2] Facultad de Ciencias de la Tierra y Agua, Universidad Regional Amazónica Ikiam, Tena, Ecuador

Abstract: Ecuador is a megadiverse country and its forests cover 51% of its territory. Despite the consolidation of legal instruments for land management and planning in the past decade, the annual net deforestation rate in 2016 went from 61,112 ha (-0.48%) to 87,535 ha (-0.76%) in 2020. The main drivers of deforestation were land use change for animal husbandry and agricultural activities, infrastructure development, and extractive activities (e.g., oil and mining). This situation is aggravated by conflicts among the different sectors as the contribution of forests to the national economy is underestimated compared to other productive sectors that generate higher income such as oil or agriculture, but that don´t have long-term sustainability goals and fail to achieve national objectives to reduce deforestation. The study analyzed the fragmentation of conflicting policy and regulatory frameworks in land management from 2010 to 2023 through a multi-sectoral implementation approach that facilitates forest management and contributes to reducing deforestation and strengthening governance. We used a qualitative content approach through the selection of sectoral policies and legal frameworks related to forest management and interviews with key stakeholders. Legal and policy instruments were assessed focusing mainly on national and decentralized public institutions including aspects related to land management, impacts between productive sectors and environmental policies. The results show gaps and ambiguity in the regulations that generate problems of implementation and effectiveness in the territorial planning of forests and their long-term management. Policy instruments should be constituted by the different institutions and decentralized governments with a multisectoral approach to regulate and recognize the importance of forest management and planning. Finally, policy and regulatory alternatives for land use management are presented, as well as proposals for legal reform to facilitate forest management.

KEWORDS: Forest patrimony, forests, territorial planning, management, governance.

POTENTIAL OF HYPHOLOMA SPP. TO IMPROVE EFFICACY OF PHLEBIOPSIS GIGANTEA AGAINST HETEROBASIDION ROOT ROT

The Scientific Committee - Potpourri session

Dārta Kļaviņa[1]
Guglielmo Lione[2], Kristīne Kenigsvalde[1], Lauma Silbauma[1], Martina Pellicciaro[2], Keitlīna Krastiņa[1], Lība Rudzīte[1], Tālis Gaitnieks[1], Paolo Gonthier[2]
[1] Latvian State Forest Research Institute Silava, Rigas 111, Salaspils LV 2169, Latvia
[2] Department of Agricultural, Forest and Food Sciences (DISAFA), University of Torino, Largo Paolo Braccini 2, 10095 Grugliasco, Italy

Abstract: Heterobasidion root rot caused by the fungal pathogen *Heterobasidion* spp. is responsible for significant damage in conifer stands. The spread of the pathogen can be limited by using chemical and biological control agents. The commercial biological preparation Rotstop® containing a single strain of the fungus *Phlebiopsis gigantea* is widely used to treat conifer stumps in Latvia and other countries of Central and Northern Europe. It is important to consider the use of other fungi in the biological preparations to reduce the potential negative impact of using a single *P. gigantea* isolate on the biodiversity of stump colonizing fungi in the long-term.

The antagonism of *P. gigantea* and *Hypholoma* spp. against *Heterobasidion* spp. has been demonstrated in various experiments. However, no studies have been conducted to assess and compare the efficacy of individual isolates and mixed suspensions of these fungi in limiting the spread of *Heterobasidion* spp. in wood of *Pinus sylvestris* and *Picea abies*.

The results of the experiments show that *Hypholoma* spp. isolates in mixed suspensions with *P. gigantea* favour the development of *P. gigantea* mycelium in *Pinus sylvestris* wood. The origin and wood surface colonization rate of *P. gigantea* isolate have a significant effect on the efficacy of mixed suspension against *Heterobasidion* spp. Wood treatment with *Hypholoma* spp. isolates had no negative effects on the natural *P. gigantea* establishment and spread.

Keywords: *Heterobasidion*, *Hypholoma*, *Phlebiopsis gigantea*, biological control, root rot.

Preliminary risk assessment of invasive forest pest: Climatic suitability for established non-native insects in Korea

The Scientific Committee - Potpourri session
Min-Jung Kim[1]
Yonghwan Park[1], Youngwoo Nam[1]
[1] Forest Entomology and Pathology Division, National Insititute of Forest Science

Abstract: The increase in international trade and climate change have provided an opportunity for numerous non-native insects to be introduced and eatablished in non-native regions around the world. These non-native insects are currently considered as invasive forest pests, so it is important to prevent new introduction of these non-native insects that is likely to eatablish and cause damage. This study aims to evaluate whether climate suitability can serve as a predictive indicator for potential invasive pests. Geographic information of presence points for 74 non-native insect species, already established or reported in Korea, were obtained from the GBIF database. Climatic suitability of each species was estimated using bioclimatic variables provided by WorldClim. The presence data and randomly generated pseudo-absence data were used to georeferenced the bioclimatic variables to build climatic niche models. The climate suitability for each species was predicted by Classification Tree Analysis (CTA), Boosted Regression Tree (BRT), and Random Forest (RF) algorithms, which were subsequently integrated into an ensemble model. The final models for each species showed high predictive performance. Notably, the ten species known as major forest insect pests in Korea exhibited distinctly higher climatic suitability compared to the remaining species. Therefore, to estimate of climatic suitability of non-native insects can be used to evaluate the invasiveness of the insects that may become future invasive forest pests. In addtion, such information can be used to prepare a list of non-native insect species that can establish and become pests when introducing Korea.

Regeneration of forest ecosystems in heavily contaminated and disturbed habitat conditions - a case study of afforested post-sulfur mine sites

The Scientific Committee - Potpourri session

Justyna Likus-Cieślik[1]
Marcin Pietrzykowski[1]
[1] University of Agriculture in Krakow, Faculty of Forestry, Department of Ecological Engineering and Forest Hydrology, Al. 29-listopada 46, 31-425 Kraków, Poland

Abstract: Referring to the discussion at the European Union forum on biodiversity and ecosystem restoration at climate change, the threat of drought, and extreme weather events, it seems important to consider different scenarios for ecosystem regeneration in disturbed site conditions.

Quite well example for studying the reaction of forest ecosystems and their resistance to extreme conditions are reclaimed and afforested post-industrial areas. The area of the former sulfur mine is characterized by high sulfur and acidity concentration, therefore plants exist under environmental stress. A comprehensive study of soil properties, plant reactions to excessive sulfur concentration, and surface water chemistry in the restored forest ecosystem of a former sulfur mine (southern Poland, 50°32′N; 21°47′E) was made.

Sulfur contamination of topsoil (0-20 cm), the spatial distribution of contamination, surface water chemistry, growth reaction, vitality, and mineral supply of Common birch (*Betula pendula* Roth.) and Scots pine (*Pinus sylvestris* L.), as well as the chemical composition of this and wood small-reed (*Calamagrostis epigejos* L.) were investigated on an area of over 200 ha of an afforested ecosystem after borehole sulfur mining.

It was found that hot-spots with high sulfur concentrations in soil reaching even 45,000 mg kg $^{-1}$, pH below 2.0 were still reported, however, it occupied hardly 2% of the researched area. Surface waters were characterized by an excessive concentration of sulfate ions (average 935.13 mg$\cdot$L^{-1}) and calcium ions (up to 434 mg$\cdot$L^{-1}), which was connected with the sulfur mining process and sludge lime used in neutralization. Wood small-reed was found to adapt well to the conditions of elevated sulfur concentration. Observations of plant reactions and changes, e.g. chemistry, taking place in small/local ecosystems are very important to learn about plant reactions to severe stress and apply knowledge in the context of ongoing environmental and climate changes.

Representation of peatlands in G4M-X model

The Scientific Committee - Potpourri session
Andre (Mahdi) Nakhavali[1]
Andrey Lessa Derci Augustynczik[1], Petr Havlík[1]
[1] International Institute for Applied Systems Analysis (IIASA), Laxenburg, Austria

Abstract: Despite constituting a mere 3% of the Earth's terrestrial surface, peatlands represent uniquely carbon (C) rich ecosystems that contribute significantly to global soil C stocks. Their remarkable ability to sequester C underlines their integral role in the global C cycle and necessitates accurate representation in Integrated Assessment Models (IAMs) and land use models (LUMs) to leverage their contribution to climate mitigation pathways.

Nevertheless, existing LUMs often lack peatland representation or simplify the complex nature of peatlands by assigning them a fixed grid cell fraction associated with predefined soil attributes. Such a methodology overlooks the fact that soils exhibit a spectrum from mineral to organic types, with the thickness of the organic layer over the mineral soil varying considerably, substantially affecting the total peatland emissions. Moreover, peatland soils are dynamic entities where the thickness of the organic layer and its properties change over time.

The limited scope of the prevailing LUMs fails to satisfactorily capture the wide range of soil types and inherent dynamics characteristic of peatlands. As such, it is imperative to improve the representation of peatland soils in these models, to more accurately simulate these crucial ecosystems. This improvement will facilitate a deeper understanding of their influence on climate dynamics and contribute towards a more comprehensive representation of the global C cycle.

In this study, we introduced modifications to the original soil C dynamics of the RothC model as implemented in the G4M-X model. These changes provide a more realistic representation of organic C and its dynamics within the modified soil layers enhancing the representation of soil organic depth and enabling its representation in the land use model GLOBIOM. We subsequently evaluated these novel developments against data from 216 sites where peatland C measurements were available. The results indicated that the model effectively reproduces the accurate distribution of the soil organic layer at the observed depths. This advancement signifies a substantial step towards understanding the role of peatlands in the global terrestrial C cycle and mitigation efforts.

Role of Forestry in Circular Green Economy

The Scientific Committee - Potpourri session
Rishika Sharma[1]
Varun Grover[1]
[1] Indian Institute of Forest Management

Abstract: Science had already accepted Climate Change as one of the major global issues which humanity is facing. Since 1990 world's forest area has shrunk by 178 million ha. Highest rate of net forest losses is recorded in Africa, and South America, but on the brighter side, during the last decade forest area increased in Asia, Oceania and Europe. On the whole total forest carbon stock is decreasing with declining forest area. (GFRA 2020)

In recent years, the concept of circular green economy (CGE) has been emerging as an important intervention that can provide several solutions to climate change through the adoption and changes of various strategies of manufacturing, production systems and consumption patterns.

Economies are being based on the end of waste, reducing environmental damage through smart designing, alternative materials which are less resource consuming, materials use and comprehensive regenerating systems with a closed loop of entire production cycle/system for re-use of basic materials. CGE is based on SDG 12, Sustainable consumption and production. EU Green Deal is a real example towards strengthening steps in this direction.

CGE offers a strong strategy that has the higher-level potential to generate more revenue if applied systematically at the country level as well as the global level to achieve climate change and sustainable development targets. It will strengthen interlinkages between private sectors and government policies and promote the adoption of modern science and data-based concepts in national policies.

The paper sought to explore the following areas of circular economy in the forestry sector
1) Explore the number of viable options/models/designs based on existing literature and case studies to achieve CEG in the production process for various industrial value chains such as Design/models for renewable materials, waste management, functionality, recyclability, circularity, circular business models, and design for long-life use of products by reuse, repair, and refurbishment.
2) Ways to achieve the different components of CGE under various sections of the sectoral and national policies directly related to Indian private as well as government sectors by emphasising the role of the circular green economy (CGE) to achieve sustainable development of forest/ToF sector.

Soil Organic Carbon and Nitrogen Storage Under Different Vegetation Types and Reclamation Treatment on Carboniferous Rocks on Coal Mine Heaps

The Scientific Committee - Potpourri session
Amisalu Milkias Misebo[1]
Bartłomiej Woś[1], Edyta Sierka[2], Marcin Pietrzykowski[1]
[1] University of Agriculture in Krakow
[2] University of Silesia in Katowice

Abstract: Abstract

In this paper, we present the relationship between vegetation type (woodland, forbland, and grassland) and reclamation technique (with topsoil vs. without topsoil and cultivation vs. succession) on soil organic carbon (SOC) and total nitrogen (TN) in developing soils on carboniferous rocks on coal mine heaps. Soil samples were collected from the litter layer (Oi+Oe horizons) and the A horizons (0–10 cm). The results indicate that SOC and TN were significantly affected by vegetation type and reclamation method. Woodland exhibited higher SOC and TN in the Oi+Oe horizons than the other vegetation types. Reclamation with topsoil and cultivation resulted in the highest SOC_{stock} and TN_{stock} values in the A horizons (0–10 cm) under woodland and forbland compared to succession on bare carboniferous rock without topsoil with the same vegetation. In grassland, there was no significant difference in SOC_{stock} under topsoil application and cultivation; however, significantly higher TN_{stock} was observed in areas with 0–10 cm of reclaimed topsoil. Based on the results, topsoil reclamation is recommended to improve SOC accumulation if the mining site is restored using woodland. Conversely, grassland accumulates the same amount of SOC with or without topsoil reclamation. Considering the difficulty of obtaining topsoil, we suggest that grasses are optimal for SOC accumulation at mining sites, followed by forbs.

Keywords: reclamation, topsoil, succession, coal mine, soil organic carbon

Spatial Modelling for Assessment of Sub-tropical Forest Health in World's Oldest Hills Range (Aravalli) India under Changing Climatic Conditions

The Scientific Committee - Potpourri session
Laxmi Kant Sharma[1]
Alok Raj[1]
[1] Central University of Rajasthan

Abstract: In India's semi-arid climatic zone, the Aravalli hills range is an ecotone between the Thar Desert and the Gangetic plain, covering about 10% of the forest cover of Western India. Notably, the upper range of the hills has a high population density; this range has encountered substantial areal transformation in the last five decades. However, we believe that the enhancement of green cover within this range has occurred primarily due to discontinuous degradation within the entire range, without geographical alteration. We use MODIS products to compare and contrast spatiotemporal ecological dynamics between different sub-ranges (upper, middle, and lower) of Aravalli between 2000 and 2021. Specifically, we adopt seven eco-biophysical parameters that include EVI, LAI, PTC, PNTV, ET, NPP, and LST. Also using stationed based rainfall, average temperature, T_{min} and T_{max} as well relative humidity datasets of study period. Pixel-based seasonal time-series trend evaluation for MODIS imagery composite within the GEE platform, using the Ordinary Least Square (OLS) regression method identified that forest enhancement is experienced in some parts of different ranges. We also observed some human-induced factors and natural stressors that could possibly be responsible for forest health dynamics. The results will provide valuable insights into the vulnerability and resilience of these forests to climate change and help inform future conservation and management strategies. Thus, we suggest sustainable planning and policy changes for people who are under anthropocentric stress; this we believe would help management practices.

Spatio-temporal variation in deep soil water use patterns of overstorey and understorey layers in subtropical plantations predicts community assembly

Abstract: Deep soil water utilization allows plants to cope with drought stress. Identifying patterns of deep soil water utilization in forest ecosystems has important implications for understanding adaptations to changes in the terrestrial hydrologic cycle and resistance of forests to future expected anomalous droughts and heat waves. However, little is known about the roles of the understorey layers in driving spatio-temporal variations of deep soil water in forests and how the patterns of deep soil water use among life-forms contribute to community assembly processes. We assessed the spatio-temporal patterns and determinants of deep water utilization of tree, shrub and herb layers in subtropical coniferous plantations and investigated associations between deep water use parameters and dominance and richness of understorey vegetation. We found that the understorey layer had a higher reliance on deep soil water in the dry season, a larger seasonal plasticity of deep soil water uptake, but lower spatial variability in deep soil water utilization than the tree layer. We showed that greater reliance of the tree layer on deep soil water was associated with decreased shrub layer diversity, whereas greater reliance of the shrub layer on deep water was associated with increased herb layer diversity. Our results highlight the roles of understorey layers in driving the temporal dynamics of deep soil water in forests and improve our understanding of how deep soil water use patterns among life-forms shape community assembly in forests. Because higher deep water reliance of the tree layer was associated with decreased shrub layer diversity, we hypothesize that regions with modest droughts that reduce the shallow soil water pools may increase the deep soil water utilization of trees thereby decreasing shrub diversity.

Abstract:

The carbon balance of a continuous cover forest in relation to clear-cutting forestry

The Scientific Committee - Potpourri session
Achim Grelle[1]
Johan Bergh[1]
[1] Linnaeus University

Abstract: Today more than 80% of the Swedish forest is managed by clearcutting (CF), with C losses during the clearcut phase. After harvest, it takes 15% of the rotation period before the regrowing forest turns into a C sink on annual basis again. Another 15% pass before the C losses of the clearcut phase are compensated by consecutive C uptake, i.e., before the forest is "C neutral" and becomes a C sink again in the perspective of a rotation period. Consequently, the mean annual C uptake during several rotation periods is ca. 65% of the maximum annual C uptake, i.e., the periodic annual C uptake at the forest's most productive age.

In continuous cover (CCF) forests, on the other hand, no clearcut phase ever leads to C losses. Instead, the C uptake is assumed to be more or less in steady state, with variations caused by periodic selective harvests. Regeneration is mostly natural, with less silvicultural options than in CF. The climate benefits of CCF compared with CF are determined by the mean annual C uptake in relation to the amounts of harvested biomass.

In a pioneering project, we are studying the C balance of a CCF forest in southern Sweden by continuous measurements of ecosystem CO_2 fluxes by the Eddy-covariance technique. The well-documented forest has been managed without clear-cutting for generations, and 10% of the stems are harvested selectively on a decadal basis. During the 4-years project period, one such selective harvest is carried out. First results indicate a large potential C uptake by CCF.

The measured annual C budgets are compared with mean annual C uptake in CF forests, determined by chronosequences. In addition, the maximum annual C uptake of a CF forest in the same geographical region is determined. This provides a solid ground to determine the C sequestration potential of CCF in relation to CF.

Analyzes of soil C and soil respiration in both forest types are used to study C allocation and components of the C balance. Even aspects of biodiversity and C stored in harvested products are considered in the study.

The case of the conservation of the elephant corridors in the Western Ghats in Tamil Nadu, India

The Scientific Committee - Potpourri session

Archana S K[1]
[1] School of Planning and Architecture, Department of Landscape Architecture, Bhopal, Madhya Pradesh, India

Abstract: Increasing population, along with the supporting agriculture and infrastructural developments and the rapidly increasing tourism sector have resulted in the fragmentation of the forest habitats in the Western Ghats, especially in the Nilgiris Biosphere Reserve situated in the state of Tamil Nadu in India. This paper specifically focusses on the Singara - Bokkapuram elephant corridor, which falls under the Mudumalai Wildlife Sanctuary, which lies in a crucial location in the Western Ghats connecting the state of Tamil Nadu with Karnataka and Kerala, enabling the movement of wild elephants.

This region, being a tourism-based economy, has been rapidly implementing various infrastructure projects to support the increasing tourist influx. Providing connectivity to the various tourist centers through roads and rails has resulted in the fragmentation of these landscapes imposing a threat on the elephant corridors. Besides, many revenue villages around this corridor depend on them for their resources including cattle grazing, fuel wood collection and collecting other non-timber forest products as well. Such disturbances have resulted in the habitat degradation and have become a major threat these corridors. As a result of all these human interventions, the continuity in such corridors is disturbed and an increase in the cases of human-elephant conflict could be observed.

This paper highlights the risks of these forests not adapting to these conflicts, as the expecations in terms of the role of these forests for different stakeholders is highly divergent. Hence, the conservation of these corridors would require a comprehensive understanding of the social, cultural, ecological and economic factors involved.

The study emphasizes the need for a collaborative and participatory approach to forest management that involves all the stakeholders, including the local communities, government agencies, NGOs, and private sector actors. The paper recommends implementing conservation agreements, sustainable forest management practices ensuring ecological, social and economic sustainability, promoting agroforestry practices, and sustainable tourist activities to ensure the long-term conservation of the Singara - Bokkapuram corridor and other vital forest habitats.

The Comparison of Smallholders' Economic Profitability in the Management of State Forests and Private Forests, Java Island, Indonesia

The Scientific Committee - Potpourri session

Lina Dwi Lestari[1]
Budiadi Budiadi[2], Wiyono Wiyono[3], Moch Sofiyulloh[2], Suyanto Suyanto[4], Kazuhiro Harada[1]
[1] Graduate School of Bioagricultural Sciences, Nagoya University
[2] Faculty of Forestry, Gadjah Mada University
[3] Vocational School, Gadjah Mada University
[4] World Agroforestry

Abstract: Java Island is the most populous island in Indonesia, where population pressure and poverty among the people living around the forest pose challenges to forest management. The state forests are managed using the *tumpangsari* system (*taungya*), in which smallholders have no opportunity to cultivate the land after the annual cropping period ends. While privately-owned forests have disintegrated land management with scattered areas. To compare the economic profitability, the state forest in Ngawi, East Java, and the private forest in Paliyan, Yogyakarta, were selected as areas of interest. In this research, private forests were divided into: 1) *tegalan* (trees along border) and 2) *alas* (woodlots). Focus group discussions with three forest farmer groups for each location were done using the Land-Use Profitability Assessment (LUPA) framework by World Agroforestry (ICRAF). The economic values gained by farmers from the state forests were the lowest, with a net present value (NPV) of 490.51 USD ha^{-1} and an equal annual equivalent (EAE) of 119.98 USD. The gross income was only profitable in years 1-3, then decreased by 54% and 45% in years 4 and 5. In private forests, the *tegalan* had the highest NPV and EAE, 3079.66 USD ha^{-1} and 250.93 USD, respectively, while the alas had an NPV of 2658.04 USD ha^{-1} and an EAE of 216.57 USD. Regarding the workforce in the state forest, *tegalan* and *alas* were; 79, 74, and 12 laborers per year, respectively. The state forests with a *tumpangsari* system have the lowest economic benefits but the highest labor absorption. On the other hand, in the private forests, the *tegalan* has the highest NPV and EAE and has high manpower, while the *alas* is only oriented towards long-term savings. Farming in state forests is seemingly the least profitable compared to private forests. Hence, permanent intercropping using shade-tolerant species after the annual cropping period can be introduced to elevate the income of smallholders in state forests.

The Concept of the Human-Forest Relationship (HFR) – Definition and Potentials for Forest Conflicts Mitigation

Abstract: Human attitudes and practices play a major role in forest conflicts. This abstract introduces the concept of human-forest relationship (HFR) and its potential for understanding, mitigating, and resolving forest conflicts.

Individuals, as societal actors, maintain and change the ways forests are perceived, valorized and managed. The HFR concept's potential lies in its ability to identify and describe the processes by which people's forest-related meanings, such as beliefs, emotions, and values, as well as practices are formed. These meanings and practices are a result of people's personal experiences, life and family histories, cultural and societal backgrounds, and the forest that surrounds them.

The HFR is the conceptual approach identifying and describing the roles that forests play in people's daily lives and identities. The concept enables analyzing people's relationships with forests, that is individual meanings and practices attached to forests. It also highlights the reciprocal relation between meanings and practices.

The HFR concept depicts, firstly, what different benefits and functions of forests are valued by whom and, secondly, what decisions and forest management regimes are accepted or opposed and why. Besides past and present forest-related meanings and practices, HFR also possesses the future dimension. Conflicts arise when one's vision or expectation of the current or future state of forests and their affordances are threatened.

In conflict dynamics, the various HFRs – forest related meanings and practices – affect the emergence and escalation of conflict. The HFR concept aims to clarify various drivers and causes for forest conflicts. Knowledge and understanding of the different human-forest relationships offer options for mitigation and resolving of these conflicts.

The effect of afforestation on soil respiration and methane flux at cutaway peatlands

The Scientific Committee - Potpourri session
Liisa Jokelainen[1]
[1] Liisa Jokelainen, University of Helsinki

Abstract: In Finland, afforestation has been the main after-use for cutaway peatlands, but only a few studies have been conducted on the climate impacts of afforestation. Here, we studied the effect of afforestation on soil carbon dioxide (CO_2) and methane (CH_4) fluxes, litterfall and vegetation C stocks at cutaway peatlands.

The study was conducted at five cutaway peatlands in Central Finland in 2021–2023. CO_2 and CH_4 fluxes were measured with closed chambers from 14 sample plots, along with measurements of water table level (WT) soil temperatures, above ground litterfall, and tree stand C stocks. CO_2 efflux was measured from vegetated and unvegetated points to separate total (Rtot) and heterotrophic (Rhet) respiration. Forest stand age varied from 0-57 years and peat layer thickness from 10 to over 100 cm.

The mean fluxes of Rtot and Rhet varied between 0.15 and 0.59 g m^{-2} h^{-1} and 0.15 and 0.35 g m^{-2} h^{-1}, respectively (2021-2022 data). Soil temperature and forest stand age correlated positively and peat layer thickness negatively with soil respiration. WT did not have significant effect on soil respiration.

The mean CH_4 fluxes from the vegetated points varied between -51.3 and 129.8 µg m^{-2} h^{-1} (2021-2022 data). Forest stand age and peat layer thickness correlated with CH4 flux, whereas WT did not. Non-afforested sample plots acted as methane sources and the sample plots with the more mature forest acted as methane sinks.

Based on this study, afforestation increases soil respiration and decreases methane emissions. However, the suitability of afforestation as an after-use method based on greenhouse gas emissions cannot be concluded based only on these results. Ecosystem level results with litterfall and changes in vegetation C stocks will be amended to the results, to estimate the climate impact of afforestation.

The form of a tree: Strigolactone-deficient tree mutant reveals connection between higher order branching and decreased auxin gradient along main stem

The Scientific Committee - Potpourri session
Kaisa Nieminen[1, 2]
[1] Natural Resources Institute Finland (Luke), Finland
[2] University of Helsinki, Finland

Abstract: Due to their long-life span, trees and bushes develop an increasing order of branches in a perennial manner. In contrast to a tall tree, with a clearly defined main stem and branching order, a bush is shorter with a less apparent main stem and branching pattern. To address the developmental basis of these two forms, we studied several naturally occurring architectural variants in birch (*Betula* sp.). Using a forward genetics approach, we identified a bushy *kanttarelli* variant with a loss-of-function mutation in the *BpMAX1* gene required for strigolactone (SL) biosynthesis. While *kanttarelli* is shorter than a wild-type (WT) birch, it still had the same number of primary branches, whereas the number of secondary branches is increased, contributing to the bush-like phenotype. To confirm that the identified mutation was behind the phenotype, we phenocopied the *kanttarelli* mutation in transgenic *BpMAX1::RNAi*birch lines. SL profiling confirmed that both *kanttarelli* and transgenic lines produced very limited SL amounts. Interestingly, the auxin (IAA) distribution along the main stem was different between the WT and a *BpMAX1::RNAi* line. In the WT, the auxin concentration was forming a gradient, being higher in the uppermost internodes and decreasing towards the base of the stem, whereas in the transgenic line this gradient was not observed. Through modelling, we showed that the different IAA distribution pattern may result from the difference in the number of higher order branches and the plant height. Future studies will define whether the IAA gradient itself affects any aspects of plant architecture.

The Integration of Remote Sensing and Field Surveys to Detect Ecologically Damaged Areas for Restoration

The Scientific Committee - Potpourri session

Kyungil Lee[1]
Seong Woo Jeon[2], Hyun Chan Sung[2]
[1] Seoul National University of Science and Technology
[2] Korea University

Abstract: Ecological damage refers to the reduction in the value of the environment due to human activities and natural disasters such as climate change and biological disease. The area where ecological damage mainly occurs is the forest and restoration and management of damage is more important than other ecosystems. If a damaged forest is left unattended, secondary damage such as landslides is highly likely, so it should be restored prior to other ecosystems. The intensity of forest damage is worsening worldwide, and the importance of forest restoration projects at the national level is increasing. However, it is difficult to proceed forest restoration owing to lack of data on location and features of damaged forestry or vegetation species. In the absence of data on damaged forest, policy decision such as restoration prioritization and planning become difficult. In this study, ecologically damaged areas including forest for restoration in South Korea were detected using remote sensing and field surveys. For the analysis, national standardized vector datasets and Google Earth images were used; and field surveys were conducted from 2018 to early 2020. Our results showed that 62% of the ecological damage that occurred in South Korea existed in forest ecosystems; the damaged areas were mostly smaller than 50,000 m2 and most of the causes and types of damage due to human activities such as development were soil erosion related. In addition, the use and role of remote sensing to establish a database of the current status of the illegally damaged area distribution and legally appropriate ecological restoration plan at the national level could be suggested .

The Lauraceae evolution and the regulation of terpenoids biosynthesis

The Scientific Committee - Potpourri session
Yangdong Wang[1, 2]
Yicun Chen[2], Ming Gao[2], Yunxiao Zhao[2]
[1] Chinese Academy of Forestry
[2] Research Institute of Subtropical Forestry, Chinese Academy of Forestry

Abstract: Plants are capable of synthesizing a vast array of natural small molecule compounds with different structures and functions, including alkaloids, steroids, tannins, flavonoids, and terpenoids, making them excellent 'chemists'. The Lauraceae family, in particular, is abundant in monoterpene compounds such as Linalool, camphor, eucalyptol, borneol, and citral. This family of plants is widely used for its high-value essence and spices, and is known as the 'king of spices'. China is the largest producer and exporter of Lauraceae essential oil raw materials, accounting for approximately 70% of the international market. We present here a chromosome-level assembly of the Litsea cubeba genome, along with low-coverage genomic and transcriptomic data for many other Lauraceae. Phylogenomic analyses show phylogenetic discordance at the position of Magnoliids, suggesting incomplete lineage sorting during the divergence of monocots, eudicots, and Magnoliids. An ancient whole-genome duplication (WGD) event occurred just before the divergence of Laurales and Magnoliales; subsequently, independent WGDs occurred almost simultaneously in the three Lauralean lineages. Comparative genomic analysis revealed that the monoterpene synthase gene family expanded significantly in the Lauraceae during WGD events, providing a genetic basis for the synthesis of its abundant monoterpene compounds. Furthermore, the functional verification of monoterpene synthases in Lauraceae are conducted, which are responsible for the production of specific volatile compounds. We identify TPS18, 22, 25, 42 could synthesis citral, linalool, α-pinene and other major monoterpenes form GPP. The functional differentiation of mono-TPSs, which are key genes for monoterpene skeleton synthesis, determines the diversity of monoterpene compounds. Additionally, this study identifies a Lauraceae-specific citral biosynthesis gene cluster, which includes MYB44 as a regulator and two ADHs as the modified enzyme. This cluster exhibits divergency in Lauraceae. The findings of this study provide insights into the evolution of the Lauraceae and the genetic basis for specific scent evolution.

The Role of Community-Based Resource Management Structures in Forest Landscape Restoration

The Scientific Committee - Potpourri session
Mike Boachie[1]
Shalom Addo-Danso[2], Joana Ameyaw[1]
[1] Department of Silviculture and Forest Management, Kwame Nkrumah University of Science and Technology
[2] Forestry Research Institute of Ghana, Council for Scientific and Industrial Research

Abstract: Forest Landscape Restoration (FLR) plays a crucial role in averting deforestation, conserving biodiversity, mitigating climate change, and promoting sustainable development by reviving degraded forest ecosystems. As part of Ghana's emission reduction efforts, specific areas have been designated as Hotspot Intervention Areas (HIA) where local structures have been established to promote interventions including FLR. These structures were established to ensure community involvement in decision-making processes related to forest restoration. Such local community involvement in FLR have become important because they create a win-win situation for the environment and the local communities. The success of such FLR efforts however depend on the extent of community acceptance and engagement. The study therefore assessed the extent of representation and information flow within the Community-Based Resource Management (CBRM) structures, local people's perspectives on the CBRM structures and how such perspectives affect forest landscape restoration. These structures were established to ensure community involvement in decision-making processes related to forest restoration. Data were collected through semi-structured interviews and focus group discussions with sixty-two respondents. including members of the Hotspot Management Board, Sub-HIA Executive Committees, Community Resource Management Areas (CREMA), Community Resource Management Committees (CRMCs), and community members in the Juabeso-Bia landscape. Key informants from state institutions and Civil Society Organizations (CSOs) were also interviewed. The study established a multi-dimensional information flow within the CBRM structures, emphasizing the importance of communication across the different levels of governance. Additionally, the study shows the need for gender representation throughout the governance structure. Community members' perceptions of the CBRM structures had evolved from viewing them solely as information dissemination platforms to recognizing CBRM structures as participatory governance mechanisms where their voices are heard in forest landscape restoration. This shift in perception was attributed to the pivotal role of civil society organizations who alongside the forest landscape restoration, provided support to strengthen the community-based resource management structures through sensitization workshops and capacity building programs. The study exemplifies how community members who consider themselves marginalized due to socio-political differences, could sabotage forest landscape restoration activities.

The scale-dependent effect of forest characteristics on grouse occupancy varies the role of the green infrastructure for habitat maintenance

The Scientific Committee - Potpourri session

[4] Natural Resources Institute Finland (Luke), Oulu, Finland

Abstract: Maintaining forest habitats for several species requires an integrated planning of the green infrastructure (GI) comprising networks of protected areas with matrix-level management. However, the capacity of the GI to supply habitat may vary at different spatial scales, depending on how its management affects forest characteristics related to the ecological niche of the species. The purpose of our work was to evaluate the impact that the GI has on forest characteristics and how these affect forest grouse occupancy at multiple spatial scales.

To evaluate how grouse occupancy is affected by forest structure, we fitted Generalized Additive Mixed Models (GAMMs) linking the stand-level species presence/absence in the Finnish forests with forest variables related to composition and structure. To evaluate the impact of the GI, on top of the GAMMs we tested how conservation areas and matrix management affected grouse occupancy. The GAMMs were developed separately at each of three spatial scales (local=stand scale, home range=1 km, wildlife triangle =5 km). Occupancy for four forest grouse species (hazel grouse, black grouse, capercaillie, and willow grouse) was modeled using nationwide wildlife triangle census data and stand-level forest variables provided by the Finnish Forestry Centers.

We found that some forest characteristics were invariantly important in predicting occupancy at each scale for all the grouse species. For example, diversity in tree volumes increased grouse occupancy especially at stand and 1-km scales, while mean tree age decreased grouse occupancy mostly at 1-km and 5-km scales. On the other hand, other predictors affected occupancy at different scales in a species-specific way. Protected areas increased grouse occupancy at the regional scale, while matrix management at the stand scale.

In conclusion, our research proves that modeling occupancy with forest variables at different spatial scales can better inform forest managers about the species' potential use of the landscape. The evidence that different elements of the GI affect differently grouse occupancy at different spatial scales calls for a multiscale approach to conservation and management. This finding suggests that management should be applied at the relevant scale to affect forest characteristics improving species occupancy.

The wood anatomical structure between two dated marks reveals periodicity of secondary growth of rainforest species

Abstract: In the tropics, specifically in equatorial dense rainforests, xylogenesis is influenced by minimal climatic seasonality, and many tropical trees do not exhibit clear growth rings. This makes it challenging to conduct retrospective analyses and predict future tree performance. This research examines the presence, distinctness, and periodicity of growth rings in dominant tree species in two semi-deciduous rainforests that differ in precipitation patterns. We investigated eighteen tree species common to both forests. Using the cambial marking technique, we verified the presence and periodicity of growth-ring boundaries in the wood produced between marking and collection through microscopic and macroscopic observation. The study found that all eighteen species can form visible growth rings at both sites. However, the periodicity of ring formation varied significantly within and between species, and within sites. Trees from the site with a well-defined dry season were more likely to form periodic growth rings compared to those from the site with less pronounced rainfall seasonality. The distinctness of the formed rings, however, did not depend on the site. Periodic growth-ring formation was more likely in fast-growing trees.

Towards territorial forest-based bioeconomies through value webs from native palms in Colombia

The Scientific Committee - Potpourri session
Ricardo Vargas Carpintero[1]
Lina Mayorga Duarte[1], Tatiana Rojas[2], Felipe Garcia Cardona[3]
[1] Dept. Biobased Resources in the Bioeconomy, Institute of Crop Sciences, University of Hohenheim
[2] Dept. Social and Institutional Change in Agricultural Development, Hans-Ruthenberg-Institute for Tropical Agricultural Sciences, University of Hohenheim
[3] Center for Biodiversity Economics and Finance, Alexander von Humboldt Biological Resources Research Institute

Abstract: Colombia is a highly bio- and ethno-diverse country. Its territory contains 314 types of ecosystems that provide habitat to about 76000 species of flora and fauna. Ethnic diversity is represented by 87 indigenous groups and afro-colombians (14% of Colombia's population), who have collective ownership rights of 34% of the national territory, mainly in forest areas. These forest ecosystems cover around 60 million hectares — 52% of total national area — and are highly threatened by deforestation. The dynamics between the on-going societal transition in the post-conflict phase, the imperative of biodiversity conservation and the need of providing fair livelihood options for inhabitants of rural areas indicate a complex social-ecological context. With this background, bioeconomy has emerged as a development pathway fostered by the Green Growth Strategy (2018) and the Bioeconomy Mission (2021), acknowledging the need of a territorial approach and seeing natural wealth as a key upgrading factor. From the about 26000 of identified plant species in Colombia, more than 6000 are used by humans. Most of them have been so far neglected and their sustainable use could be promoted by regulatory frameworks recently implemented, such as the Decree 690 of 2021, which enable the conditions for using Wild Flora and Non-Timber Forest Products (NTFPs). Among plant resources for NTFPs in Colombia, palms (Aracaceae) native to Colombia represent one of the largest plant families, with more than 250 species. Palms are used for multiple purposes mainly by forest-based communities and they are part of the cultural identity across the national territory. Taking palms as case study, we discuss the potential of NTFPs for Colombia's bioeconomy with the imperative of balancing forest conservation and socio-economic development. This requires considering the associated social-ecological relations and the key ecological role of palms in forests. Accordingly, we explore possible pathways for native palms as a source of NTFPs in 'territorial forest-based bioeconomies' in Colombia, integrating their biological, ecological, sociocultural and socioeconomic value in value web systems. We discuss the role of community-based approaches to NTFPs, possible governance strategies and the role of traditional and scientific knowledge towards developing forest-based value webs in Colombian territories.

Trade-off, synergies, and quantification of ecosystems services in Patagonia headstreams: The effect of land use changes.

The Scientific Committee - Potpourri session
Paulo Moreno Meynard[1]
Brian Reid[1], Anna Astorga[1]
[1] Centro de Investigación en Ecosistemas de la Patagonia (CIEP), Coyhaique, Chile

Abstract: Watersheds integrate vegetation, soils, geology, hydrology, and climate, and the watershed concept is fundamental in the management and conservation of the earth's critical zone. Small watersheds where streams of 0-2 order are formed might be assumed as ideally representative and sensitive to the two major drivers of terrestrial landscapes: changes in land use/soils and variability in climate forcing (including climate change). We evaluated small watersheds as potential ecosystem units based on a network of small headwater basins and their streams (2-5 km2; 0-1 order) in western Chilean Patagonia: 12 basins in four groups along a strong climatic gradient (precipitation 700-2000 mm/yr), each group consisting of three land use grades (intact, moderate and high level of intervention). We monitored over 7 years of flows, sediments, and chemistry on the streams and forestry plots on the watershed to quantify several ecosystem functions such as fiber products, water yield, carbon sequestration, soil conservation, and species richness as biodiversity proxy. Through the use of Bayesian networks, we were able to identify variations in ecosystem services, highlighting the effects of land use changes and climate gradients. Furthermore, we observed a range of trade-offs and synergies between these services.

Transcriptome and morpho-physiological analyses reveal factors regulating cone bud differentiation in Qinghai spruce (Picea crassifolia Kom.)

Abstract: Coniferous species are mostly monoecious. Their usage in forest plantations is largely limited by the low and unstable yields of seed cones. Gibberellins (GAs) and ethylene are central gender regulators in flowering, although knowledge about their metabolism is limited in conifers. Here, we explore gender determination regulators, especially GA and ethylene metabolism genes, in Qinghai spruce (*Picea crassifolia* Kom.) by transcriptome analysis of female, male and vegetative buds during bud formation and development. Year-round observations were performed to determine the window of bud differentiation. Samples of buds before and after differentiation were collected for RNA sequencing, which showed that the bud gender determination process occurred before the morphological differentiation of female, male and vegetative buds. Sixteen homologs of GA metabolism genes were identified in the transcriptome. Concentrations of GA_1, GA_3, GA_9 and GA_{15} were identified and quantified using ultra-high-performance liquid chromatography high-resolution mass spectrometry (UPLC-HRMS). Furthermore, phylogenetic analysis was performed on 9 putative ACC synthesis (ACS) genes identified in the transcriptomes, and quantitative real-time PCR was conducted to examine gene expression. Our study provides information on GA and ethylene metabolism genes in female, male and vegetative buds during bud differentiation. Overall, fine-tuned regulation of GA metabolism contributes to both the reproductive transition and gender differentiation in this species, whereas ethylene might affect male cone bud formation. The current findings could further our knowledge about the regulatory mechanisms underlying the gender differentiation of cone buds.

Undoing colonial legacies and reversing the trajectory of indigenous tree and forest management in Kenya

The Scientific Committee - Potpourri session
Benedict Odhiambo[1]
Rosa Goodman[2]
[1] GISSAFOP AFRICA
[2] Swedish University of Agricultural Sciences

Abstract: This study points to the decline of indigenous forests and shortage of hardwood timber in Kenya as a systemic problem that has evolved over decades of colonial legacy and undervaluation of the potential of indigenous forests. In pre-colonial times, indigenous forests were managed by indigenous communities. They had their own rules and management systems that guaranteed sustainable use. During the colonial period—after very little research and scanty evidence—indigenous species were declared not suitable for industrial round wood supply. Forestry shifted focus to intensive management of exotic plantations and has remained so post-colonial era—as has the perception that indigenous species cannot be productive.

However, hardwood timber from natural forests was and still is prized for a multitude of commercial and subsistence uses. After rapid deforestation in the early 1980s, commercial use of indigenous species was banned in 1986. This slowed forest loss, but indigenous forests have continued to dwindle in area and quality. Furthermore, there are no policies that promote growth and utilization of indigenous trees; and without any chance for economic gains from planting and maintaining them, communities and farmers do not do so on their own. Though likely well-intentioned and necessary at the time, we believe that the ban on utilization of indigenous species in Kenya is now working against the conservation of natural forests and needs to be updated.

We present our study reviewing the history of Kenya forest policies and identify policy gaps. Through interviews with key government agencies, forest policy experts, private practitioners, wood merchants and agroforestry farming communities, we identify barriers, opportunities and interest in the restoration, management and utilization of indigenous tree species.

This is extremely timely, as large-scale tree-based restoration and climate projects are being funded and implemented in Kenya and around the world. Communities need to be able to benefit from their forests in order to maintain and scale such efforts and achieve the desired benefits for biodiversity, climate, ecosystems and sustainable development. Change in forest policies to promote indigenous species will help Kenya create the enabling conditions necessary to attract international funding for such multi-win initiatives.

Unlocking Opportunities: Bioeconomy-Based Tourism as an Emerging Trend

The Scientific Committee - Potpourri session

Radek Rinn[1]
Markéta Kalábová[1], Vilém Jarský[1]
[1] Czech University of Life Sciences Prague, Faculty of Forestry and Wood Sciences, Czechia

Abstract: Forestry-related tourism is gaining increasing recognition not only in Western societies. People are becoming more aware of the multifaceted importance of forests, not just for ecological value but also for the recreational opportunities and their positive impact on physical and mental well-being. The tourism sector, in general, has witnessed significant growth and has emerged as one of the fastest-growing industries. However, the outbreak of the Covid-19 pandemic has brought about unprecedented disruptions and declines in tourism activities and trends. Paradoxically, the pandemic has also intensified the demand for travel and experiences connected to nature and forests.

In light of the prevailing trends that support the bioeconomy concept, the current period presents a remarkable opportunity to reshape the entire tourism sector in alignment with the principles of the bioeconomy. Nevertheless, it poses a challenge to determine the feasibility and suitable conditions for integrating tourism within the bioeconomy concept.

To explore this issue, research was conducted across selected European Union countries, aiming to represent various geographical regions. The analysis encompassed a total of 12 states and the European Union as a whole, with variations observed in terms of their approach to the bioeconomy and the adoption of their own bioeconomy strategies. Based on the extent of emphasis on tourism in the examined documents, the states were categorized into three groups. Despite the variations, it is evident that tourism is acknowledged within the bioeconomy strategies of the countries.

Bioeconomy-based tourism has emerged as a novel concept that aligns with the principles of the bioeconomy approach. The primary focus lies in promoting sustainable tourism practices that effectively integrate economic and environmental considerations. This involves optimizing the utilization of natural resources, minimizing wastage, and fostering economic growth through responsible tourism management.

In conclusion, there is a growing recognition of the significance of forests and nature-related experiences in tourism. The current global circumstances present both challenges and opportunities for integrating tourism within the bioeconomy concept. By embracing sustainable practices, tourism can contribute to the effective utilization of natural resources while supporting economic growth, thereby creating a model that aligns with the principles of the bioeconomy.

Use and Management of Bauhinia thonningii by smallholder farmers in different agro-ecological zones of Northern Ethiopia

The Scientific Committee - Potpourri session

Abstract: *Bauhinia thonningii* is one of the indigenous leguminous tree species that fix nitrogen and contributes to several medicinal and nutritional values in Africa. The aim of this study was to assess the effect of indigenous knowledge on the use, management, attitude and practices on the conservation of *B. thonningii*. Totally six sub-districts were selected purposely based on the abundance of B. thonningii availability and farmers' utilization practices in the M2 and SM3 of Tselemti district, north western Tigray, Ethiopia. Structured interviews using Open Data Kit, semi-structured interviews with key informants, FGD, field observation, and secondary data sources were used to collect data for the study. Descriptive statistics and compare means by using one-sample t-test were employed to present the quantitative and qualitative variables obtained from the survey. The consumption of fruits (89% and 89%) and seeds (89% and 86%) by livestock were significantly higher than leaves (75% and 78%) in M2 and SM3. The abundance of *B. thonningii* has decreased according to 78% and 67% of respondents in the Warm moist lowlands (M2) and Tepid sub-moist mid highlands (SM3) agroecologies, respectively. The species is used for fodder by most farmers (97.8%) mainly to fill the fodder deficits during times of fodder shortage. Leaves, twigs and pods of *B. thonningii* were reported as edible parts of the plant by cattle, sheep and goats. Fresh leaves and seeds were common forms of feeding by 41% of the respondents in M2 and 47% in SM3 agroecology. The main threats are animal forage, followed by harvesting for fuel wood and charcoal production. The fodder from the species was more preferred by cattle, goats, sheep and camel in both agroecologies. Agricultural crops were cultivated by 67% in M2 and 31% in SM3 of respondents near the plant because of high soil fertility. The plant has a high use value in the study areas evidenced by multiple uses. Therefore, value addition to maximize benefits and enhance conservation, public awareness and community based management activities need to be encouraged. Attention should also be geared towards research and development on various aspects of the plant.

Using the 3PG model to project forest dynamics under different scenarios. An application to the Portuguese production forest using NFI data as input

The Scientific Committee - Potpourri session

Susana Barreiro[1], Marta Baptista-Coelho[1], Catarina Jorge[1], Jean Magalhães[1], Jorge Nunes[1], Joana A Paulo[1], Paula Soares[1]
[1] Centro de Estudos Florestais, Instituto Superior de Agronomia, Universidade de Lisboa

Abstract: The use of process-based models to produce growth and yield predictions is gaining relevance over traditional empirical models. Such models, integrating the main physical, biogeochemical and physiological processes involved in forest growth and development, give a mechanistic description of the interactions between the living plants and their environment and are able to assess the energy balance and the cycling of water, carbon and nutrients within a given ecosystem. This presentation analyses the use of the 3PG model, a simple process-based stand model requiring few parameter values and readily available data as input, to project NFI data. The 3PG model has been parameterized for growth simulation of eucalyptus, maritime pine and cork oak, the 3 most important forest species in Portugal that together occupy 71% of the total forest area. The 3PG model has been implemented in the standsSIM regional simulator and used using a GIS data base with a pixel size compatible with the NFI grids (500x500 m for the phot plots and 2x2 km for the field plots), including a large set of environmental information, including environmental variables and climate scenarios. The simulations based on the present climate were compared with similar simulations based on the existing empirical odels (GLOBULUS, PINASTER and SUBER, respectively for eucalyptus, maritime pine and cork oak) as a bench mark. Different scenarios of forest policy, forest management and climate were prepared and the 3PG model under the standsSIM simulator used to compare a series of sustainability indicators among the different scenarios.

Utilization of small softwood logs harvested in Western United States forest restoration programs in structural mass timber panels

The Scientific Committee - Potpourri session
Lech Muszynski[1]
Mariapaola Riggio[1], SIna Jahedi[1], Sujit Bhandari[1], Seung hyun Hong[1], Sukhyun Joo[1]
[1] Oregon State University

Abstract: Every year, restoration programs in Western United States generate large amounts of low-value small logs of underutilized softwood species. USDA is seeking value-added markets for the material in order to offset high costs of the restoration programs. It is expected that one of such markets may be the engineered wood sector, particularly structural mass timber products such as CLT and glulam. However, visual grades of lumber produced from small logs do not meet benchmark design properties published in US National Design Specifications (NDS) for respective species due to high content of juvenile practically barring them from structural applications. Similarly, it has been uncertain how the fire resistance and char rates of the lumber with substantial juvenile wood content compared to NDS fire performance guidelines. The long-term goal of research conducted at the Oregon State University is to address the barriers. The specific objective of current research is to determine standard NDS design characteristics for lumber processed from small diameter logs harvested in forest restoration programs and develop technologies that would allow utilization of thin and narrow lumber in mass timber products. The presentation will include the conceptual framework of the project, its history, progress and updated outcomes.

Value Chain on Industrial Agroforestry: A Smart Agroforestry Model to Achieve Circular Bioeconomy – Learnings from Tamil Nadu, India

The Scientific Committee - Potpourri session
Parthiban K.T.[1]
Sekar I[1], Umesh Kanna[1], Rajendran P[1], Kumar P[1], Devanand P.S.[1]
[1] Forest College and Research Institute, Tamil Nadu Agricultural University, Mettupalayam

Abstract: India in general and the state of Tamil Nadu in particular has witnessed accelerated wood demand which has been estimated to over 70 million MT to meet the raw material requirement of wood-based industries. Forests played a vital role in meeting the industrial raw material requirement; however, with an enactment of Forest Conservation Act (1980), coupled with policy directions through National Forest (2008) and Agroforestry (2014) Policies have stopped the availability of wood from the forest and guided the industries to source the raw material through agro and farm forestry. However, the agroforestry promotion has witnessed wide range of challenges and constraints from the entire Production to Consumption System (PCS). Hence, a value chain on Industrial Agroforestry was conceived and implemented from 2008 till now which resolved the barriers through technological, organizational and marketing interventions. The development and deployment of High Yielding Short Rotation (HYSR) clones, Smart Silviculture and Multifunctional Agroforestry have augmented the productivity levels from 10 m^3 /ha/ annum to the levels of over 30 m^3 /ha/ annum. The introduction of value addition technology has translated agroforestry residues into value-added products thereby addresses the issues of reuse and recycling process and facilitate in augmenting circular bioeconomy. The establishment of Consortium of Industrial Agroforestry has linked all stakeholders involved in the entire PCS system. The introduction of contract farming models ensured buyback and price support system. Above all, the conceptualization and implementation of Agroforestry Incubator extended bioeconomic development through new business enterprises. In a holistic development, the current value chain system act as a smart agroforestry model and created self-reliance in raw material security (80,000 ha in a span of over 10 years), social development (300 man days of employment/ ha), economic development (BCR over 3:1) and environmental amelioration (3.5 mil. ton of Carbon) thereby extent a greater scope of replication across the world.

Vegetation Management Effects on Soil Nutrient Bioavalilability in Contrasting Site Conditions in the Pacific Northwest

The Scientific Committee - Potpourri session
Carlos Gonzalez-Benecke[1]
Emily Von Blon[1]
[1] Oregon State University, Dept. of Forest Engineering, Resources, and Management, United States

Abstract: Forest vegetation management (VM) is an integral part of reforestation planning by temporarily reducing the abundance of competing vegetation and allowing seedlings greater access to resources, particularly water, which is critical for seedling growth and survival during the annual summer drought in the Pacific Northwest of the United States (PNW). However, this reduction in abundance of early-seral vegetation may be affecting plant root turnover, soil microorganism abundance and dynamics, and soil nutrient bioavailability, which may impact the capacity of soils to support the projected increase in forest production. Plant Root Simulator (PRS) probes are an effective surrogate for bio-mimicking nutrient absorption by plant roots; they are ion exchange resin membranes held in plastic supports that can be inserted into the soil to measure ion supply *in situ*. To understand the effects of VM on soil nutrient bioavailability, PRS probes were installed in two sites with contrasting environmental conditions in coastal and inland Oregon state. Each site was planted with Douglas-fir seedlings and contains treatment plots with three replicates of eight combinations of VM regimes. Four PRS probe pairs were installed in all no-action control plots and all of the most intensive treatment plots, which includes a pre-planting herbicide application and a post-planting spring release herbicide application during the first and second growing seasons. The PRS probes remained in the soil from April to July of 2022, one year after the last herbicide application at the coastal site and three years after the last herbicide application at the inland site. At the two study sites tested, VM had no effect in reducing soil nutrient availability. However, there was a marginal trend of reducing potassium at both sites. At the coastal site, VM increased the availability of copper and zinc, and had a marginal trend of increasing calcium, sulfur, and most micronutrients. Our results therefore suggest that VM tends to either have little to effect on soil nutrient bioavailability, or may temporarily increase the availability of some macro and micronutrients.

Visualizing forest management and climate scenarios as basis for communication of forest adaptation needs to practitioners and the society

[2] Forest Owner Association Styria

Abstract: In the last decade, the direct consequences of climate change for Austria's and Europe's forests have become visible to a frightening extent. Large-scale forest damage caused by bark beetles, more frequent wet snow events, storms and forest fires resulted into new challenges for the forestry sector and dependent wood value chains that were previously unthinkable. With the risks of climate change and the uncertain economic outlook, the motivation of forest owners to participate in forest management is decreasing. This is particularly true for the high number of forest owners that manage small areas of less than 200 ha. In addition, the group of absent forest owners living in urban areas is increasing. Yet, active forest management is urgently needed in order to initiate forest conversion and to adapt forests to future climate conditions.

Forest change and the urgently required management activities including for example the establishment of mixed forests, intensified thinning regimes or assisted migration are difficult to communicate to forest owners and the society as long as no immediate climate change effects are being experienced. Moreover, also the possible economic consequences of forest conversion are difficult to explain. Therefore, forest owners, especially thus with small forest areas, often hesitate to initiate the highly needed adaptation measures.

Here, we introduce a present study, where interactive 3D visualizations were created to communicate the effects of different forest management alternatives and climate scenarios for forest development and the resulting landscape structure. The 3D visualizations are based upon simulations of forest growth and management with the climate sensitive forest growth simulator CALDIS. The simulations provide outputs for a wide range of forest ecosystem services and functions. The project area is the province of Styria in Austria and the data basis for the simulations is the Austrian Forest Inventory and the dynamic site classification of Styria. These visualizations should help to communicate the changes in the forest and which adaptions are necessary. The communication of the model outputs and 3D visualizations are accompanied by various regional events and a wide range of stakeholders from forest management and owner associations.

Vulnerability of the Dry Tropical Forests in Nicaragua's Central American Dry Corridor: Insights from El Tigre-Asososca over a 1200-Year Period

The Scientific Committee - Potpourri session
William Harvey[1, 2]
Irene Torreggiani[2], Lina Cabrera Sáenz[3], Alexander Geurds[2]
[1] Oxford Systematic Reviews, 266 Banbury Road, Oxford,OX2 7DL, UK
[2] School of Archaeology, University of Oxford, 36 BeaumontStreet, Oxford OX1 2PG, UK
[3] Ocean Engineering and Marine Science Department, Florida Institute of Technology, 150 W University Blvd, Melbourne, FL.

Abstract: The Central American Dry Corridor is a region characterized by hydro-climatic variability and dominated by Dry Tropical Forests (DTF). These forests have been highly sensitive to climate variations, such as the Medieval Climate Anomaly and Little Ice Age, as well as pre-Columbian and post-Columbian anthropogenic development. This study examines the vulnerability of DTF ecosystems surrounding El Tigre-Asososca, Nicaragua, over a ~1200-year period. By utilizing proxy analyses of fossil pollen, macroscopic charcoal, and *Sporormiella*, the study reconstructs past vegetation dynamics, burning activities, and herbivorous animal abundance.

Through the integration of multiple proxies, this research provides insights into the historical responses of DTF to climatic fluctuations and anthropogenic disturbances in the El Tigre-Asososca region of Pacific Nicaragua. The findings have important implications for future land management and conservation strategies by identifying the key drivers of change in DTF ecosystems. Considering the impacts of climate variations and anthropogenic activities, the study offers a valuable understanding into the resilience and potential adaptation strategies that can be employed to protect DTF in the face of ongoing climate change and human development in this region.

Wood modification with nano-silica fortified polyvinyl acetate: Enhancing dimensional stability and hardness

The Scientific Committee - Potpourri session
Priya Nagraik[1]
S. R. Shukla[1]
[1] Institute of Wood Science and Technology, Bengaluru, India

Abstract: Wood modification with polymeric resins fortified with nanoparticles is a promising technique to enhance the performance of wood. In this study, nano-wood composites (NWC) were prepared from Poplar wood (*Populus deltoides*) using polyvinyl acetate (PVAc) fortified with different concentrations of nano-silica (1, 3 and 5%) following vacuum and pressure method in a closed chamber. The real time tangential swelling and surface hardness (indentation) of the impregnated wood samples were measured using linear voltage displacement transducers (LVDTs) based customized swell-o-meter and Universal timber testing machine (UTM) respectively. The dispersion stability of nano-silica fortified PVAc, microstructures and distribution of nanoparticles and PVAc in the impregnated wood were observed using dynamic light scattering (DLS) technique, scanning electron microscopy and energy dispersive X-ray spectroscopy (SEM-EDX) respectively. Stable dispersions of nano-silica were achieved with polyvinyl acetate having zeta potential of -35 mV. The results showed that addition of nano-silica significantly improved the dimensional stability and surface hardness of the impregnated wood samples. The total tangential swelling was found to be reduced by 35% for the Poplar wood impregnated with PVAc fortified with 5% nano-silica compared to untreated samples. The end and side hardness values were increased by 27% and 33% with PVAc fortified with 5% nano-silica compared to untreated samples. The microstructural analysis revealed that nano-silica particles were uniformly distributed inside the wood microstructures, filled the voids and deposited on the cell wall, resulting in reduced water absorption thereby leading to the improved dimensional stability and enhanced surface hardness of the nano-wood composites. The findings also confirmed that nano-silica can be used to improve the performance of low-quality woods for their possible utilisation in certain value-added applications.

Woody debris volume and nutrient retention following conventional pulpwood and wood pellet feedstock harvests in the southeastern US

The Scientific Committee - Potpourri session
Hannah Bays[1]
Chad Bolding[1], Joseph Conrad[1], Alicia Peduzzi[2], Holly Munro[2], Scott Barrett[3]
[1] University of Georgia, Harley Langdale Center for Forest Business, USA
[2] University of Georgia, Warnell School of Forestry and Natural Resources, USA
[3] Virginia Tech, Forest Resource and Environmental Conservation, USA

Abstract: Wood pellets have emerged as an important feedstock for bioenergy fuel production and demand is expected to increase as renewable energy production expands globally. Planted pine (Pinus spp.) stands in the southeastern United States (US) are the major producer of raw material for manufacturing wood pellets, which are predominately being exported to Europe to meet renewable energy goals. Increased utilization of wood pellet feedstock is often sourced from in-woods chips or roundwood, using either pulpwood-sized roundwood or logging residues from harvesting chip-n-saw or sawtimber products, and may be sourced from first thinnings or clearcuts. Harvesting to produce wood for pellet plants may result in more intensive harvesting and less residual debris retained post-harvest. Concerns associated with increased debris removal include changes in post-harvest site characteristics that may affect future growth and the depletion of available organic matter and nutrients over time. This study evaluated 90 recent (<1-yr) operational harvests in the southeastern US to determine residue and nutrient retention and spatial distribution of debris across the sites. Sites were separated by harvest type (e.g., clearcuts, thinnings), and harvest method (e.g., roundwood for pulpwood markets, roundwood for pellet markets, and in-woods chipping for pellet markets). Residual woody material was measured using the planar intersect method and characterized by operation harvest feature (landings, harvest areas, skid trails). Heat maps were used to display the distribution of material and areas of significant reduction. Samples collected for nutrient analysis were categorized by size and decay class. This study is one of the first field-based experiments designed to evaluate the distribution and retention of residual material across wood pellet operations. It is important to delineate the differences in post-harvest site characteristics between conventional and wood pellet operations to develop more efficient resource utilization and to help guide sustainable growth of the bioenergy sector.

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Ancient forest plant species as indicators of post-agricultural forest regeneration in the Carpathians

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Zofia Jabs-Sobocińska[1, 2]
Andrzej N. Affek[2], Jan Marek Matuszkiewicz[1]
[1] Faculty of Geography and Regional Studies, University of Warsaw, Krakowskie Przedmieście 30, 00-927 Warsaw, Poland
[2] Institute of Geography and Spatial Organization, Polish Academy of Sciences, Twarda 51/55, 00-818 Warsaw, Poland

Abstract: In the Polish Eastern Carpathians thousands of hectares of agricultural land were abandoned following the displacement of Ukrainian-speaking population in the 1940s, which resulted in widespread reforestation. Therefore, today, large areas of 60-70 years old post-agricultural forests span across the region, interspersed with well-preserved ancient beech forests. In light of the global goal of increasing forest cover**,** investigating forests that developed recently and are mature enough to compare their understory species composition with ancient forests is crucial for the research on regeneration and biodiversity of both existing and future secondary forests.

Our objective was first to map forests developed after 1940s as a result of afforestation or natural succession on abandoned agricultural land in the Polish Eastern Carpathians, and then to assess their regeneration rate based on understory species composition and its comparison with ancient forests. We also aimed to identify environmental variables that affect forest regeneration in mountainous areas. To map post-agricultural forests in the study area we used archival remote sensing data: German Flown Aerial Photography from 1944, Corona satellite images from 1969 and Sentinel-2 satellite images from 2020. Then, on randomly selected 294 forest plots we took phytosociological relevés, hemispherical photographs, and collected soil samples. Based on the analysis of relevés, we compiled a list of ancient forest plant species which was later used to quantify the Forest Maturity Index and the regeneration rate of post-agricultural forests. We also parametrized multiple regression models to find environmental factors that best explain forest regeneration.

We showed that there are 53,800 ha of 60-70 years old post-agricultural forests in the study area, constituting 27.6% of all forests. The results of field investigation revealed 15 understory species (out of 215) meeting the criteria of ancient forest species and 9 species with significantly higher cover and frequency in post-agricultural forests. Our preliminary modeling results demonstrated that regeneration rate decreases with elevation and increases with slope steepness. We currently test our hypothesis that the rate of regeneration decreases with distance from ancient forest.

Close-to-nature forest management in sub-humid Mediterranean mixed forests: description and evaluation of the silvicultural treatments

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Eduardo Collado[1, 2]
Jaime Coello[1], Mario Beltrán[1], Lluís Coll[2, 3], Míriam Piqué[1, 2]
[1] Forest Science and Technology Centre of Catalonia (CTFC), Ctra de Sant Llorenç de Morunys, km 2, 25280 Solsona, Lleida, Spain.
[2] Joint Research Unit CTFC – AGROTECNIO - CERCA, Av. Alcalde Rovira Roure 191, E-25198 Lleida, Spain.
[3] Department of Agricultural and Forest Sciences and Engineering (DCEFA), University of Lleida, Lleida, Spain.

Abstract: There is a growing need for adaptive forest management strategies that promote forest diversity and complexity and forest resistance and resilience to climate change impacts, while maintaining the system's ecological and economical sustainability. In this sense, silvicultural treatments based on close-to-nature principles were applied in ca. 200 ha of sub-humid Mediterranean mixed forests in Catalonia (N-E Spain). The main goal was to promote trees with the highest economic or ecological value by applying low-intensity selective thinning, while maintaining a mixed and multi-stratified stand structure. In this study, we describe and evaluate the short-term effects of the silvicultural prescriptions conducted in 39 mixed stands of conifers and broad-leaved tree species (e.g., holm and common oak, chestnut, pine, cherry, ash and maple trees). We relied on: (i) 70 permanent sample plots for the evaluation of different indicators (dasometric, understory, biodiversity, vulnerability to fire, etc.); (ii) 9 paired-plots (i.e., 9 managed plots, 9 control plots) for the quantification of the inter-annual tree growth at individual tree level; and (iii) 4 paired-plots for monitoring the intra-annual tree growth with dendrometers and hourly soil water content with FDR sensors. The effect of the treatments on tree growth and soil moisture was investigated by Spearman correlation analyses and mixed-effects models. We observed how a reduction in competition generally showed positive effects on the radial growth of different future crop trees and species and soil water content, despite the treatments were of low intensity. This single-tree selection system, that protects the forest microclimate, had also succeeded in maintaining the stand heterogeneity and diversity by reducing the competition and vulnerability to fires, laying the foundations for the future forest capitalization.

Close-to-nature silviculture worn out? From preserving the status quo to suiting climate change

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Daniel Scherrer[1]
Barbara Moser[1], Thomas Wohlgemuth[1]
[1] Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Switzerland

Abstract: The widely accepted assumption that untouched natural forests are inherently stable and resilient is being challenged by the rapid environmental changes of the 21st century. Close-to-nature silviculture (CNS) seeks to mimic natural forest dynamics by promoting native species suited to specific sites and facilitating natural regeneration. However, the suitability of tree species in the face of shifting environmental conditions raises concerns about maintaining future forest resilience. Empirical observations and model predictions reveal increasing stress on forests, particularly on water-limited soils, leading to recurring episodes of mortality. The slow response of forests to climate change can be attributed to the long lifespan and generation times of trees, as well as asymmetric competition within dense forest stands. Our research underscores the profound influence of disturbance severity and frequency on forest dynamics and highlights the potential for adapting tree species composition accordingly. Large-scale disturbances such as forest fires or windstorms reset the succession process, initiating the development of a novel forest starting from pioneer species. This process can unfold over several decades or centuries, with outcomes heavily dependent on concurrent environmental conditions. Conversely, small-scale disturbances, such as the death of individual trees, prompt the direct ingrowth of surrounding tree species, regardless of prevailing climatic conditions. Forest regeneration in small gaps, driven solely by seed availability or advance regeneration, tends to be subject to the long-term dominance of shade-tolerant climax species such as European Beech. Light-demanding and drought-tolerant "future" species such as oaks, lime, and maples struggle to establish themselves in shaded environments. In Switzerland, CNS practices promote traditional species composition, allowing for limited inclusion of either foreign provenances of native tree species or non-native tree species. While close-to-nature silviculture aims to facilitate natural processes and incremental adaptation, this management approach impedes rapid changes in tree species and hinders forest adaptation to the escalating pace of summer droughts, particularly in Central Europe. In light of increasing hot-droughts during the summer season, we propose an evaluation of a more adaptive CNS approach, which combines natural regeneration of native species with opportunistic tree species, ranging from pioneers to drought-resistant species, with the support of assisted plantations.

Close-to-nature silviculture: a long-standing approach in Romanian forests

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Valeriu-Norocel Nicolescu[1]
[1] Transylvania University of Brasov, Faculty of Silviculture and Forest Engineering, Brasov, Romania

Abstract: Close-to-nature silviculture, a multifunctional forest management with the target to obtain healthy and stable forests that produce wood (as well as non-wood forest products) with a minimum human intervention, has been traditionally applied in Romanian forests, dominated (68 percent by volume) by broadleaved tree species such as European beech *Fagus sylvatica* (37 percent) and oaks (especially sessile oak *Quercus petraea*, pedunculate oak *Q. robur*, Turkey oak *Q. cerris*, Hungarian oak *Q. frainetto*) (12 per cent). It has included some milestones such as:
- establishment of forests by using silvicultural systems (e.g., single-tree and group selection system, irregular shelterwood system, group shelterwood system) providing the natural regeneration under shelter of main forest species (broadleaves such as European beech, sessile oak, pedunculate oak, Turkey oak, Hungarian oak, as well as conifers like Norway spruce *Picea abies* and silver fir *Abies alba*), mostly in multi-species stands. The structure of such stands is multi-aged/irregular and provides a permanent soil cover;
- small-scale use of clearcutting (only in even-aged and pure Norway spruce, Scots pine (*Pinus sylvestris*) and European larch (*Larix decidua*) stands), the size of cutting area being reduced gradually from maximum 30 hectares in 1953 to maximum 3 hectares nowadays;
- application of low intensity thinning (up to 16 percent by volume), directed to favour the trees showing a good prospect for the future;
- predominant use of native tree species, mostly in mixed stands, and very limited use of non-native tree species (e.g., Douglas-fir *Pseudotsuga menziesii*, northern red oak *Quercus rubra*, black walnut *Juglans nigra*), especially for the enrichment/as supplement of natural stands to add economic revenue.

Obviously, close-to-nature silviculture, even providing many advantages for forest stability, biodiversity, recreation, aesthetics, soil protection, water management, has quite important disadvantages:
- difficult application of uneven-aged forest systems such as single-tree selection system, based on a 10-year cycle of forest inventory and requiring a high density of skidding trails and forest roads as well as skilled staff;
- high level of logging damages to residual stand, soil and young natural regeneration;
- last but not least, a quite strong resistance of field foresters towards a more complicated-to-apply forest management system.

Development of species-specific biomass equations for saltbush (Atriplex nummularia) in the Mediterranean region

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

ERIC CUDJOE[1]
R. Ruiz-Peinado[2], Shamim Ahmed[3], Felipe Bravo[1]
[1] SMART Ecosystems Research Group, Department of Plant Production and Forest Resources, University Institute of Research in Sustainable Forest Management (iuFOR), Associated R+D+I Unit of CSIC, Higher Technical School of Agricultural Engineering of Palencia, University of Valladolid, Avda. de Madrid
[2] Department of Forest Dynamics and Management, Institute of Forest Science (ICIFOR-INIA), CSIC, Ctra. A Coruña, km 7.5, 28040, Madrid, Spain
[3] Chair for Forest Growth and Yield Science, Department of Life Science Systems, TUM School of Life Sciences, Technical University of Munich, Hans-Carl-von-Carlowitz- Platz 2, 85354 Freising, Germany

Abstract: Accurate estimation of the aboveground biomass of shrubs is crucial for the effective conservation and management of Mediterranean ecosystems, particularly under the pressures of climate change and resource scarcity. Generalized biomass equations may not provide an accurate representation of biomass for specific plant species. This pioneering study introduces the first species-specific biomass equations for saltbush (*Atriplex nummularia*) in arid and semi-arid regions where shrubs play a key role in the ecosystem's biomass structure. In this study, we employed a destructive sampling technique on 243 saltbush individuals, focusing on shrubs aged 3, 5, and 7 years. Linear mixed-effects modeling was used for statistical analysis, with shrub height (H, m), basal diameter (D, cm), crown area (Ca, m^2), and age (years) as predictor variables. We found that the most accurate prediction models differed based on the biomass type. For aboveground biomass, D^2H and age were the most effective predictors. Similarly, D^2H and age were the best variables for predicting wood biomass. In contrast, D^2 alone provided the most accurate prediction of leaf biomass. The results suggest that accurately estimating aboveground and wood biomass requires plant size and age metrics, whereas leaf biomass is significantly influenced by basal diameter, demonstrating that distinct factors influence different biomass components. This study emphasizes the need for a management plan that ensures the sustainable and efficient use of natural resources, such as saltbush, over time. While progress has been made in developing biomass equations for saltbush, further research is required to refine and validate these models, considering site-specific conditions and potential climate change effects to improve biomass quantification accuracy.

Effect of aspect and altitudinal gradient on vegetation pattern and carbon storage potential in the western Himalaya

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Chaman Lal Thakur[1]
Sonam Rajput[1], D R Bhardwaj[1], Dhirender Kumar[1]
[1] Dr YS Parmar University of Horticulture and Forestry, Nauni, Solan, Himachal Pradesh

Abstract: The Himalayan Forests are one of the fragile ecosystems that has experienced anthropogenic disruptions, leading to a decline in biodiversity and diminished biomass and carbon stock. Therefore, the study was carried out in the western Himalaya forest of Kandaghat, Solan Forest Division of Himachal Pradesh, India, The study area was divided into three altitudinal ranges, Viz., lower altitude (<1800 m), middle altitude (1800-2100m), and higher altitude (>2100 m), and four aspects (northern, southern, western, and eastern). The objective of the research was to provide a description and analysis of the impact of changes in the arrangement and composition of vegetation across different elevations and aspects. A comprehensive inventory of the flora revealed the presence of 45 distinct plant species, categorised into 13 tree species, 22 shrub species, and 13 herbaceous species, all of which were classified into 33 distinct families. The study further revealed that the tree density was highest (280.49 N ha^{-1}) at the middle altitudinal range on the northern aspect, while the lowest density (119.09 N ha^{-1}) was observed at a higher altitudinal range (>2100m) on the southern aspect. The highest density of shrubs (16,202 N ha^{-1}) and herbs (1,23,574 N ha^{-1}) was observed at a lower altitude on the southern aspect. Furthermore, it was observed that the herbaceous layer exhibited a higher degree of vegetation diversity compared to the shrub layer. This can be attributed to the relatively lower development of the canopy, which allows for ample sunlight to penetrate the ground and facilitate lush growth. The study observed a positive correlation between altitude and solar radiation across all aspects. The study found that the highest tree biomass (161.42 t ha^{-1}), carbon stock (80.71 t C ha^{-1}), and vegetation carbon density (83.47 t C ha^{-1}) were observed on the northern aspect at the middle altitudinal range while shrub biomass (2.56 t ha^{-1}) was highest at lower altitudinal range and herb biomass (3.21 t ha^{-1}) was at middle altitudinal range. Hence, it is imperative to accord significant consideration to altitude and aspect in order to effectively manage biodiversity and alleviate the impact of climate change.

Effect of water and potassium supply on the development and growth of teak plantations in the context of climate change

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Kossi Novinyo SEGLA[1]
Tom-Ihèou Prénam TANTOKO[1], Kossi ADJONOU[1], Adzo Dzifa KOKUTSE[1], Kouami KOKOU[1]
[1] Laboratoire de Recherche Forestière, Faculté des Sciences, Université de Lomé, BP 1515, Lomé, Togo

Abstract: In Togo, teak (*Tectona grandis* L. f.) is the most important plantation species exploited by the government and local communities to meet the demand for timber and other wood products. Due to the lack of genetic enrichment, current plantations exhibit low productivity. Actions have been initiated to improve the genetic material and adapt it to the current production systems in Togo. In this context, the Forest Research Laboratory of the University of Lomé has established a forest station in Zogbépimé since 2015, where new imported teak genotypes such as Taliwas, Luasong, Perlis, and Indian teak are being tested. This study aims to analyze the effect of irrigation and water exclusion in situ on the growth of teak genotypes (Taliwas, Luasong, Perlis) and the effect of potassium supply on the growth of Indian teak trees.

To achieve this, experimental plots were subjected to water supply through irrigation and potassium application during the dry season. Dendrometric characteristics were measured before the treatments in 2020 and subsequently recorded after 12 and 24 months. The results indicate that irrigation and potassium application have a positive effect on the height and diameter growth of teak trees. Between 2021 and 2022, the height increment rates for the control plots ranged from 12.23% ± 6.56 to 19.44% ± 6.42, while for the irrigated plots, it ranged from 14.37% ± 7.43 to 24.20% ± 13.39. The diameter at breast height (DBH) increment rates after 24 months varied from 6.79% ± 5.04 to 22.10% ± 5.97 for the control plots and from 9.24% ± 6.07 to 24.80% ± 10.95 for the irrigated plots. In terms of the plots subjected to potassium application, the height increment rates between 2021 and 2022 were 15.07% ± 8.09 and 10.50% ± 7.36 for the treated and control plots, respectively, and the diameter increment rates were 10% ± 6.94 for the control plots and 12.99% ± 6 for the treated plots.

The results of the three teak provenances introduced in Togo and subjected to irrigation suggest that these provenances could adapt to climate variability. Potassium application significantly improved stand productivity.

Establishment of Colombian Pine (Retrophyllum rospigliosii) Plantations for Ecological Restoration and Carbon Sequestration

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Jorge Andres Ramirez Correa[1]
Adriana María Marín Vélez[2]
[1] Universidad del Cauca
[2] Departamento de Planeación Forestal, Smurfit Kappa Colombia.

Abstract: The Colombian pine (*Retrophyllum rospigliosii*) is a native and endangered coniferous species of the Podocarpaceae family that is of great ecological and economic importance in the Andean region of Colombia as source of timber or non-timber forest products. However, due to a lack of knowledge about its silviculture and management, large-scale propagation of the species in degraded areas has not been possible. This study evaluates various aspects of propagation, silviculture, biomass, and carbon sequestration based on the largest and monitored *R. rospigliosii* plantations established for restoration purposes in Colombia. *R. rospigliosii*restoration plantations were established between 1998 and 1999 in the departments of Antioquia and Cauca and were monitored by Smurfit Kappa-Carton de Colombia and the National Federation of Coffee Growers of Colombia. The evaluation of seed germination was carried out at the University of Cauca (Popayán). The study found that pre-germination treatments, including mechanical scarification plus the application of cytokinin, gibberellic acid, and indole-butyric acid, increased germination percent up to 85% compared to 33% in the control treatment. Early forest fertilization with medium to high levels of nitrogen and phosphorus, without potassium, significantly increased species growth, reaching a volume increase of almost 25% in the long-term compared to control plots. Established *R. rospigliosii* plantations reached relatively low dimensions after 20 years, with an average diameter of 22 cm, height of 18.1 m, and volume of 159.4 m^3 ha^{-1}. The low growth values found were strongly related to the topography of the area (86%, $p<0.05$), since the species is very site-selective, preferring convex and west-facing sites. The allometric equations adjusted to determine biomass and carbon in the plantation showed coefficients of determination greater than 90%, indicating a biomass accumulation of 125 tons ha^{-1} after 20 years, corresponding to a carbon sequestration of 54 ton C ha^{-1} or 194 ton CO2e ha^{-1}. These results summarize the main findings of one of the few long-term monitored experiments using native species for restoration and highlight the potential of *R. rospigliosii* plantations for carbon sequestration and climate change mitigation.

Evaluating tree biomass in continuous-cover Norway spruce stands

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Otto Saikkonen[1]
Markus Holopainen[1], Juha Hyyppä[2], Jiri Pyörälä[1], Sauli Valkonen[3]
[1] University of Helsinki
[2] National Land Survey of Finland
[3] Natural Resources Institute Finland

Abstract: In Nordic countries even-aged forest management has been the dominant silvicultural practice. Reassessment of the forest management practices is needed because of biodiversity loss and climate change. Ecosystem-based forest management systems have been proposed as alternatives, or complementary practices to the intensive, even-aged forestry. Continuous-cover forestry is suggested to be one of the most promising practices of the ecosystem-based forest management toolbox. The research of continuous-cover forests has been lacking especially from the point-of-view of tree characteristics and wood properties.

Tree biomass models are an efficient way to examine carbon pools and to understand growth and yield of the forest. In our study we evaluate and compare stem biomass of continuous-cover and even-aged forest Norway spruce (*Picea Abies* (L.) H. Karst.) stands. We approach the stem biomass modelling with terrestrial laser scanning (TLS) data and x-ray diffraction measurements to estimate stem density profile of the tree stems. We assess one of the most used biomass models in Finland (Repola 2007). As the model is based on even-aged forests, here we examine the need to re-parametrize the model for continuous-cover forests. Our data from both continuous-cover and even-aged forests allows us to compare tree biomass at tree level and scale it up to stand level.

Our preliminary results show that stem taper between continuous-cover and even-aged forests is not statistically different. We hypothesise that although the stem form was similar the biomass might differ between the two management practices as biomass calculations adds stem density to the model. Previous studies have shown that slow juvenile growth of Norway spruces in understories affects wood density by reducing the lower-density juvenile wood in continuous-cover treatment trees. These results call importance of studies examining how the wood density affect the tree stem biomass and what is the effect of the forest practices to tree biomass.

Evaluating 'close to nature silviculture' for mitigating carbon emissions in the Balsam Fir-White Birch forests in Quebec under climate change

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Sanjoy Roy[1, 2, 3]
[1] Sanjoy Roy, Département des sciences du bois et de la forêt, Université Laval, Canada
[2] Evelyne Thiffault, Département des sciences du bois et de la forêt, Université Laval, Canada
[3] Frédérik Doyon, Institut des Sciences de la Forêt tempérée, Université du Québec en Outaouais, Canada

Abstract: The oversimplification of forest structure because of the use of clear-cut harvesting practices over the past decades in Quebec has raised concerns for future forest resilience and carbon dynamics under climate change. Continuous cover silviculture is being explored to improve carbon dynamics (i) by increasing forest resilience under climate change and future disturbances and (ii) by favouring conifer seedling regeneration over thermophilous broadleaf seedlings. This study aims to compare stand carbon and regeneration dynamics between conventional regular structure and irregular continuous-cover practices for both short-and-long terms in the balsam fir-white birch bioclimatic domain of Quebec. We will use the spatially explicit process-based model 'HETEOFOR' to do this. We will then use CBM-CFS3 and its Forest Harvested Wood Products module to track the carbon dynamics from the ecosystem to the harvested wood products. In the short term, we expect that the regeneration of thermophilous broadleaf species will be proportional to the intensity of the partial cuts used in irregular continuous-cover practices. However, with multiple successional rotations and assuming the overstory gap occupancy from remaining trees, it will ultimately favor balsam fir seedlings in the long term. Carbon sequestration (in terms of CO_2-equivalent) is expected to increase in the long term in irregular continuous cover practices over regular clear-cut practices. The carbon storage in wood products is also expected to be higher in continuous cover silviculture because of the advantage of tree selection and considering the wood substitution effect. We further hypothesize that the forest will remain a net carbon sink under continuous cover practices. In contrast, under clear-cut practices, the forest is expected to act as a carbon source for a period starting after each harvest rotation because the microbial decomposition rate of carbon should be much higher compared to the subsequent carbon sequestration rate from trees.

Future of European forests under climate change and close to nature forestry assessed with high resolution resource model

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Gert-Jan Nabuurs[1, 2]
Sara Filipek[1], Silke Jacobs[1], Bas Lerink[1], Ajdin Starcevic[1], Mariana Hassegawa[3], Pieter Johannes Verkerk[3], Johanna Klapper[3], Yasmin Maximo[3], janne Jarvikyla[3], marco Patacca[1, 2], nicola Bozzolan[2, 4], louis Konig[1, 2, 5], geerten hengeveld[1], igor staritsky[1], mart-jan schelhaas[1]

[5] ETH Zurich

Abstract: European forest are rapidly changing: pressures from climate change and disturbances are increasing, as well as demands for goods and services. Analysing these future trends and where they possibly clash is very important. We gathered detailed NFI plot data and its individual tree measurements, now comprising >300,000 NFI plots and >4 million remeasured trees, thanks to 17 NFIs. For the demand side, we compiled the European Forest Industry Database (EUFID), which encompasses the location and capacity of 6,000 forest industry facilities, categorized into three value-chains: sawmills, pulp and paper, and bioenergy.

We developed the EFISCEN-space model, which now has spatially explicit distribution of timber resources at national forest inventory plot level, including details about the species and diameter composition. We fitted climate dependent tree growth functions, mortality functions and ingrowth functions, as well as litterfall rates and soil carbon models. High resolution (1x1 km) projections of the future carbon balance European forests, soils and harvested wood products under adaptive forest management will be presented, addressing new Regulations from the EU (nature restoration law). Forward looking regimes in which tree species dynamically shift and where forest management takes into account restoration needs and a closer to nature forest management are incorporated. In this way we can analyse and show from regional to EU level, results concerning biodiversity (indicators like dead wood and structure) to a full system carbon balance and level of fulfilling wood demand by assortment. Also the role of industry and how it can adapt to sudden disturbances and availability of wood is analysed.

Growing Grass, Cattle, and Pine Trees All at the Same Space in East Texas, USA

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

I-Kuai Hung[1]
Hans Williams[1], Jason Grogan[1], David Kulhavy[1], Daniel Unger[1], Yanli Zhang[1]
[1] Stephen F. Austin State University

Abstract: East Texas of the United States of America is known for its pine plantations for timber production. Meanwhile, raising cattle or growing grass for livestock is also an important component on the landscape and for the economy. While timberland is beneficial to the environment in terms of soil and water conservation as well as wildlife habitat, it requires substantially initial investment and generates revenue infrequently. On the other hand, pastureland for livestock or forage production yields annual income, but at the cost of soil erosion and water quality degradation. To balance to two, which seem to be conflicting with each other, a practice known as silvopasture is a win-win alternative. It is an agroforestry practice that combines the production of timber and livestock forage on the same land. By diversifying the products and income, the use of land becomes more sustainable while generating revenue and protecting the environment at the same time. Starting 2019, part of the Walter C. Todd Agricultural Research Center of Stephen F. Austin State University near Nacogdoches, Texas was established for silvopasture. Different silvopasture treatments were applied that included converting pasture to silvopasture by planting native grass and pine seedling, converting forest to silvopasture by removing pine trees to create corridors for cattle, and keeping existing pine plantation unthinned as control. This project was partially funded by Natural Resources Conservation Service of US Department of Agriculture the through its Conservation Innovation Grant managed by the Arthur Temple College of Forestry and Agriculture. The site has served as a Silvopasture and Native Grass demonstration area that welcomed more than 120 potential silvopasture producers with on-site tours. A virtual tour of the silvopasture practice was also launched in November 2021. The landscape change over time of this silvopasture site has been monitored through drone surveys. Landowners who may not have farms large enough to dedicate separate areas for timber production and forage production are likely to be most benefited by silvopasture practices.

Implementation of climate-smart practices with bamboo for adaptation and generation of resilience to face climate change in the Amazon Region

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Pablo Jacome[1]
Pablo Izquierdo[1], Raphael Paucar[1], Carlos Falconi[1], Samuel Morales[1]
[1] International Bamboo and Rattan Organisation -INBAR

Abstract: The Amazon Region, the world's largest humid tropical forest, is renowned for its cultural and biological diversity. With an area of 6.7 million km² shared by eight countries, it supports over 10% of Earth's known species and provides vital ecosystem services to local communities. However, uncontrolled expansion of agriculture, livestock production, mining, and unsustainable practices threaten the region's unique biology and cultures.
Bamboo, utilized in the Americas for thousands of years, presents a sustainable solution for climate change adaptation. The Amazon regions of Colombia, Ecuador, and Peru boast a rich diversity of native bamboos, with 28 reported species. Bamboo can be found in natural forests, plantations, and intermixed with local vegetation. Its cultivation empowers rural populations to develop smart strategies in the face of changing climate patterns.

This study focuses on implementing climate-smart practices with bamboo in the Amazon. In collaboration with 41 communities and associations across Colombia, Ecuador, and Peru, covering 283 hectares, climate-smart practices have been identified and implemented since 2021. These practices include using bamboo for riverbank protection, restoring degraded areas from livestock activities, employing live barriers for slope stabilization, creating wildlife corridors, integrating bamboo into agroforestry and silvopastoral systems, and utilizing bamboo for low-carbon infrastructure.

The adoption of these practices contributes significantly to adaptation and mitigation efforts in the Amazonia region. By harnessing the potential of bamboo, local populations and landowners enhance their resilience to climate change impacts. Moreover, the use of native bamboo species emphasizes the importance of conserving local biodiversity and promoting sustainable practices.

This study demonstrates the viability and effectiveness of bamboo-based climate-smart agriculture in the Amazon Region. The outcomes of this study provide valuable insights for policymakers, land managers, and stakeholders involved in climate change adaptation and sustainable development. By embracing bamboo as a versatile and resilient resource, the Amazon Region can safeguard its unique ecosystems, cultures, and livelihoods in the face of climate challenges.

Keywords: Amazon Region, climate change adaptation, climate-smart practices, bamboo, resilience, sustainable development.

IMPORTANCE OF NATIVE SPECIES FOR ENRICHMENT PLANTING TOWARD CLOSE TO NATURE SILVICULTURE IN TROPICAL RAINFOREST IN INDONESIA

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Widiyatno Widiyatno[1]

[1] Laboratory of Silviculture and Agroforestry, Faculty of Forestry, Universitas Gadjah Mada, INDONESIA

Abstract: Tropical rainforest is one of the most species-rich in the terrestrial ecosystem in terms of species richness and endemics that support 18.7% of the world's plant biodiversity. One of the dominant native species in tropical rainforests in Indonesia is the dipterocarps species However, forest degradation has a direct effect to be loss of plant biodiversity, especially increasing the status of dipterocarps become the risk of extinction. One of the methods to rehabilitate secondary tropical rainforest is enrichment strip planting using native species. The native species could be used for enrich and productivity of tropical rain forest what were *Shorea leprosula*, S.platyclados, S.johorensis, S.parvifolia and S.macrophyllal The mean annual diameter increment of those species was 1.7 cm/year (more than 300% of natural regeneration of dipterocarps in tropical rain forest). Enrichment planting with native species offers several advantages, including the conservation of both the species themselves and their genetic diversity, while also adapting to the local environment for mitigation climate change. Furthermore, the practice of enrichment planting holds the potential to increase the standing stock of secondary tropical rainforests and contribute to the conservation of dipterocarp species.

Influence of Tree Attributes on silver fir (Abies alba Mill.) transitioning to higher defoliation classes determined by logistic regression

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Anamarija Jazbec[1]
Damir Ugarković[1], Mladen Ognjenović[2], Mislav Vedriš[1]
[1] University of Zagreb Faculty of Forestry and Wood Technology, Zagreb, Croatia
[2] Njuškalo Ltd, Department of BI, Analytics and Research, Zagreb, Croatia

Abstract: Crown defoliation is one of several non-specific indicators of tree vitality and depends on numerous abiotic and biotic factors. In Croatia, the selective management of silver fir (*Abies alba Mill.*) forests may involve pure or mixed stands, which can be affected by various disturbances resulting in unbalanced tree attributes. The aim of this study was to estimate the probability of trees transitioning from one defoliation class to the next, examine the influence of stand structure on that process by comparing two sites with contrasting stand structure, and to analyse the changes in tree defoliation and survival over a 17-year period. In order to estimate the probability that trees are in higher than lower defoliation class, we used logistic regression with binary response, using defoliation classes: healthy 1(<25%), damaged 2(25-60%), severely damaged 3(>60%) as the dependent variable, and DBH (used as a measure of physiological maturity), crown length and crown canopy class as independent variables. Since crown position is categorical (dominant, codominant, intermediate, suppressed) we used dummy variables where the dominant category was taken as the baseline.

We evaluated models for each phase comparison of the dependent variable: level of defoliation class 2 vs. 1 and 3 vs. 2 for trees in 1990. After that, we used the Stuart-Maxwell test to determine whether the distribution of defoliation in 1990 and 2007 differed significantly for the same trees. In order to estimate the probability that trees that were defoliation level 1 or 2 in the year 1990 changed to a higher defoliation level over time, we used logistic regression.

The results showed that Site A had the highest tree mortality due to a disturbed selection structure with a higher ratio of old trees with large DBH. Additionally, DBH was found to be a significant predictor of the probability of trees being higher defoliation class, with a linear trend of increasing probability with increasing DBH. Crown position and height were also found to be significant predictors of defoliation class. When implementing silvicultural treatments, DBH, crown position, and crown properties should be considered, and appropriate forestry measures should be implemented in a timely manner

Landscape forestry in the tropics: moderating between close-to-nature and close-to-people-paradigms?

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

SVEN GÜNTER[1]

[1] Thünen Institute of Forestry, Hamburg, Germany

Abstract: Demographic trends, global economic development and climate change are putting tropical ecosystems and societies under extreme pressure with open questions about consequences for biodiversity conservation and human welfare. For a long time, identifying best management practices from close-to-nature silviculture was frequently considered as guideline for forest management. However, even the tried-and-tested principles of stand-based management or species-site match, are being shaken to its foundations by the rapid changes in the natural environment and society. New challenges require new principles. In this talk I will identify and critically discuss existing paradigms of management and tropical silviculture from first a close-to-nature and secondly a close-to-people perspective. Can landscape approaches moderate between these antagonistic poles under the light of global change? This includes questions of how to address spatial and temporal scales at the human-environment interface and how to reconcile forest user needs and practices with societal goals in a changing world. As part of the LaForeT-project (www.la-foret.org) a total of 500 forest inventories and 4000 interviews with households and focus groups of rural communities were carried out in 36 landscapes in Ecuador, Zambia and the Philippines. Based on different case studies from this project potentials and limitations of the landscape forestry concept will be discussed with respective implications for silviculture and forest landscape restoration. In addition, it is discussed whether the panarchy theory can provide an accompanying theoretical framework for both adaptive management and landscape approaches that combine human and natural dimensions.

Large-scale mistletoe inventory on Scots pine in Central Poland

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Roman Wójcik[1]
Wojciech Kędziora[1]
[1] Warsaw University of Life Sciences, Institute of Forest Sciences, POLAND

Abstract: Mistletoe (*Viscum album* L.) is a semi-parasitic plant and in moderate abundance, it does not pose a lethal threat to a tree. However, recent droughts have made a heavy impact on forests and mistletoe in recent years began to appear on a larger scale in places where it has never been a threat before. The main purpose of this research was to perform a large-scale inventory of the mistletoe in the Kozienice Forest District (Central Poland) for assessing the number of mistletoe on individual trees and in the stands as well as to test a new inventory method adapted to Polish conditions. It is based on random sample plots, each consisting of 15 trees, on which the impact of mistletoe is assessed. On every sample plot the mistletoe occurrence, location in the crown, estimate of the percentage within the crown and the number of mistletoe on a tree are assessed. In addition, for further analysis, information on the stand (forest habitat type, site index) as well as measured trees (age, diameter, Kraft class, crown length, loss of assimilation apparatus, crown type) levels is recorded. For the current analyses, we used 400 sample plots, on which 6000 trees were assessed. Results show that 31% of trees are infected by mistletoe. Over 35% of the infected trees were damaged heavily by more than 6 specimens per single tree.

Lorenze Curve and Gini Index to evaluate the Diametric Distribution in Permanent Plots

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Celio Gregório de Vasconcelos Jossefa[1]
Cláudio Gumane Francisco Juizo[1], Arnaldo Ernesto Uetela[1], Valente André Fenias Moiane[1]
[1] Instituto Superior Politécnico de Manica

Abstract: As part of the process of installing permanent plots carried out by the National Network of Permanent Sampling Plots, plots were installed in Mozambique in Gorongosa National Park and Chimanimani National Park. Therefore, the present work aimed to evaluate the dimetric distribution of tree species in 3 permanent plots using the Lorenz curve and the Gini index. The study was carried out in permanent square plots of 1 ha installed in the Chimanimani National Park (AS01) and Gorongosa National Park (SZ02 and SZ03). To facilitate measurement, the plot was divided into 50 sub-plots of size 20 m x 10 m, where trees with DBH ≥ 10 cm were measured. In the North-South direction, 5 of these sub-plots were systematically selected for the measurement of trees/shrubs with diameters between 5 cm ≥ DBH < 10 cm. For the construction of the Lorenz Curve, the observable values in the data set were ordered in ascending order, and based on the accumulated relative frequency of individuals and diameter. The Gini Index was estimated using the Gini Index Equation. The results showed that in the survey of the tree population, with DBH ≥ 10 cm, there was a higher concentration of individuals in the smallest diameter class. When the diametric interval is increased, the number of trees becomes reduced. Thus, the diametric distribution of the population is continuous and decreasing, concentrating the largest number of trees.ha-¹ in the smallest diameter classes and, therefore, the smallest number of trees.ha-¹ in the largest diametric intervals. Thus, the ecological stability of the population with DBH ≥ 10 is verified. In the three permanent plots, a degree of inequality in the distribution of individuals in certain diametric classes was observed. The Gini Index values were 0.13 for the ASO1 plot, 0.23 for the SZ02 plot and 0.18 for the SZ03 plot. These values represent a smaller diametric inequality of the individuals observed within the three plots.

Modelling future forest dynamics in Switzerland to support the bioeconomy transition in the construction sector

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Achille Mauri[1]
Maximiliano Costa[1], Eugénie Paul-Limoges[2], Frank Krumm[2], Verena Griess[1], Andreas Rigling[1, 2], Harald Bugmann[1]
[1] Institute of Terrestrial Ecosystems ITES, Swiss Federal Istitute of Technology, ETH Zürich, Universitätstrasse 16 Zurich, Switzerland
[2] Forest Dynamics, Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Zürcherstrasse Birmensdorf, Switzerland

Abstract: Switzerland has an ambitious goal to drastically reduce CO_2 emissions by 2050. In particular, the construction sector has immense potential by substituting carbon-intense material (e.g. concrete and steel) with biomaterials such as wood. However, to investigate the availability of domestic wood to sustain this transition, an assessment of future forest biomass availability as well as tree species composition is needed.

As part of the multidisciplinary project, MainWood, which is aimed at leveraging the transition to a construction bioeconomy across the wood supply chain in Switzerland, we simulate future forest development under anticipated climate scenarios (moderate and strong change) and for various stakeholders' informed management strategies. In addition, we evaluate forest exposure to risks such as fire, windthrow and pest outbreaks.

We select case study regions representing the most important production regions of Switzerland. To assess tree species' climate suitability and growth dynamics, we employ a dynamic process-based model at stand scale (ForClim), which we generalized at the landscape level. The model is initialized using a representative stand type approach, where forest stands are populated with locally adapted individual tree datasets using a novel statistical method based on the fourth Swiss National Forest Inventory.

Our simulations are based on state-of-the-art climate scenarios and different types of forest management scenarios: a "Business-As-Usual" scenario (Swiss close-to-nature and multi-purpose forestry) and alternative stakeholder-informed scenarios, including segregated management approaches (e.g., short-rotation and plantation systems) to meet expected future demand in wood production. We also evaluate how alternative forest management scenarios affect biodiversity, which will require a balance between wood extraction and dead wood remaining in the forest.

We found an increase in forest productivity expected at higher elevations, which however might not benefit the bioeconomy transition due to the difficult and costly harvesting operations in mountainous regions. At lower elevations, forest productivity will decrease, however, in a scenario of assisted migration the strong shift towards a higher proportion of deciduous tree species might counter-balance this loss. This will require the development of new technologies capable of implementing cost-effective construction processes that use new timber engineering products based on a mix of softwood and hardwood species.

Next Generation Forestry - Case Studies from Ghana & the Philippines

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Camille Rebelo[1]
Samantha Wilde[1]
[1] EcoPlanet Bamboo

Abstract: Over the past decade EcoPlanet Bamboo pioneered “close to nature silviculture” in Nicaragua, through an innovative framework restoring some of the most marginal and degraded ex forested lands utilizing a long term strategy with native timber bamboo. The term plantation raises an image of neat rows of monoculture trees, yet the 3,500 hectare successful restoration farms in Nicaragua could not look more different.

EcoPlanet is now expanding this framework through PPP’s with the Government of Ghana and the Philippines on close-to-nature forestry spanning 20,000 hectares of degraded lands. These marginal lands are undergoing restoration into productive ecosystems, proving that next generation forestry is possible, and providing a platform for such integrated restoration forests to become the norm rather than the exception.

Carbon finance allows for a move away from a pure focus on IRR – what has traditionally driven the monoculture plantation forestry industry into its current practices. Select species of sympodial clumping bamboo, with a priority given to native species, are manually interplanted with the aim of protecting and enhancing whatever biodiversity remains. This is complemented by the additional planting of key native tree species at different stages of the restoration pathway.

The result is that just 47% of these 20,000 hectares represnts bamboo while 53% represents biodiversity – a significant increase from the typical 20-30% conservation areas of certified timber plantations. Furthermore, this bamboo is fully integrated amongst remnant forest patches and standing trees, creating a biodiverse forested ecosystem at a landscape scale vs the traditional split between productive and conservation forests.

As a grass ,bamboo benefits from selective annual thinning of individual poles from each bamboo clump, while not affecting either carbon gains, or the permanent canopy cover it provides. This allows a unique scenario of a forest providing vast volumes of deforestation-free biomass without any impact on its long term ecosystem functions and promoting, vs removing biodiversity.

This framework results in a functioning forested ecosystem that moves the paradigm away from monoculture timber plantations and towards one where productive forest species, biodiversity and people can exist in harmony.

Regenerative forestry actions aiming to make Finnish forests increasingly vibrant and diverse

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Tiina Laine[1]
Timo Lehesvirta[1], Silja Pitkänen-Arte[1], Vesa Junnikkala[1], Juho Rantala[1]
[1] Metsä Group, P.O. Box 10, FI-02020 METSÄ, Finland

Abstract: Metsä Group launched in March 2023 regenerative forestry principles aiming to enhance the state of nature by 2030. Metsä Group is a Finnish forest industry group focusing its operations in Finland providing wood supply and forest services to owner-members of its parent company Metsäliitto Cooperative. Regenerative forestry disconnects the economic growth and biodiversity loss including numerous measures that enhance biodiversity and the resilience of forests as the climate changes.

Regenerative forestry is based on the industrial use of native tree species. The goal is to diversify tree species composition and thus halt biodiversity loss. In forests with a diverse range of species and age classes, competition between species prevents the success of species cause forest damages. As the lack of decaying wood continues to be the most common single cause for the endangerment of forest species, regenerative forestry accelerates the creation of decaying wood. To secure the living conditions of species that inhabit ecologically valuable habitats, special attention is paid for biodiversity hot spots such as herb-rich forests, esker forest habitats and fire habitats. Also, water protection is being developed on peatlands.

Metsä Group Plus, a new forest management model, is one of the key practical measures for achieving targets of regenerative forestry. Under Metsä Group Plus model, more retention trees and high biodiversity stumps are left per hectare of forest during felling than certification systems require. Also the burning of retention trees will be increased and the highest level requirements of buffer zones around waterbodies is implemented. Other actions include sparing sparsely occurring broadleaved trees in wood supply in Finland. Metsä Group also helps to target FSC protection to the most valuable sites for nature through the Habitat Site Service.

The goal is to enhance make Finnish forests increasingly vibrant and diverse by 2030 as part of the strategy of regenerative forestry. The effects of regenerative forestry are measured using the best available information based on science-based data. Metsä Group's forest services are being developed in versatile manner. We are seeking new wide ranging cooperation to enhance biodiversity and to develop measurement of our actions.

Results of forest management for fire prevention on trees' vitality under extreme drought events

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Alma Piermattei[1, 2]
Davide Ascoli[1], Alan Crivellaro[2], Roberta Berretti[1], Alessia Bono[1], Matteo Garbarino[1], Raffaella Marzano[1], Fabio Meloni[1], Donato Morresi[1], Luca Musio[1], Francesca Secchi[1], Davide Vecchio[1], Renzo Motta[1]

[2] "Stefan cel Mare" University of Suceava, Faculty of Forestry, Forest Biometrics Laboratory, Romania

Abstract: The mitigation of wildfire impacts in mountain dry conifer forests relies on variable retention harvesting along fuel breaks and understory fuel management, including prescribed burning. However, the current increase in drought events can negatively impact the vitality and survival of the retained trees suddenly exposed to an open forest structure. Indeed, in the last two years extreme drought is affecting Scots pine forests in the southwestern European Alps with an increase of yellowing needles in the top branches already before the start of the growing season. Here we quantify the effects of drought on trees' vitality (tree growth rate, yellow needles percentage, and wood hydraulics) in areas managed for fire prevention with controlled areas using an interdisciplinary approach based on dendrochronology, remote sensing, and wood anatomical analysis. Our preliminary results show that tree vitality is lower in treated areas when compared to controls. Therefore, we must adjust the intensity of thinning to maintain trade-offs between fire hazard mitigation and preserving tree vitality under drought conditions. This study is performed under the project Agritech.

Silvicultural Management for Enhancing Natural Regeneration of climate-vulnerable Abies nephrolepis in Mt. Hwa-ack, Korea

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Go Eun Park[1]
Jong Bin Jung[1], Kiwoong Lee[1], Seongchul Jung[1], Wonil Choi[1]
[1] Division of Forest Ecology, National Institute of Forest Science

Abstract: This study aims to identify appropriate silvicultural management practices considering the impact of climate change on subalpine evergreen conifer forests to enhance natural regeneration. The practical research site was established in Mt. Hwa-ack in Korea where *Abies nephrolepis* is distributed. *A. nephrolepis* is one of the representative climate-vulnerable species in Korea and is suffering problems with massive dead caused by heat waves and limited natural regeneration (lack of seedlings and ingrowth limitation). Considering species composition, stand structure, and micro-climate conditions (solar radiation, temperature, and relative humidity in the air and temperature and water contents in the soil) in eighteen plots (10m x 10m/plot), the experimental design was conducted. Thinning operations were implemented in November 2022 to control solar radiation conditions on the forest floor. In March 2023, the average seedling mortality in thinned plots (4.6 %) was lower compared to the control plots (7.4 %) with statistical significance ($p<0.05$). While solar radiation is essential for seedling growth, it can also be a limiting factor affecting soil moisture content and contributing to heat waves. Therefore, mid-term monitoring is necessary to assess the effectiveness of the treatment. To evaluate the efficacy of the silvicultural management approach, we're planning to monitor changes in seedling emergence, mortality, growth, and microclimate conditions. The practical outcomes of this research are expected to contribute to the in-situ conservation of vulnerable subalpine conifer forests in Korea.

Silvopastures for ensuring fodder and environmental security in semi arid regions

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Kamini Gautam[1]
R V Kumar[1], Sunil Kumar[1], Amit Kumar Singh[1], Avijit Ghosh[1], A K Roy[1]
[1] ICAR-Indian Grassland and Fodder Research Institute, Jhansi-284003, Uttar Pradesh, India

Abstract: Approximately 80% people living in the semi arid zones are dependent on livestock for their livelihood security. However, livestock sector in these regions are facing severe scarcity of quality fodder impacting the livestock productivity negatively in the zone. Thus, ensuring quality fodder supply in the region is very crucial to support local livelihood. Erratic rain fall, continuous drought spells coupled with the poor soil productivity make it difficult to spare agricultural lands in the region for fodder cultivation. Further, there is need to enhance vegetation cover in the region to create carbon dioxide sinks for environmental security as these regions are very sensitive to climate change. Under such scenario, silvopasture systems are sustainable land use option that can be easily established under degraded lands/alternate lands to ensure round the year fodder security and sequester huge amount of carbon dioxide in its biomass. Thus, silvopasture systems established at ICAR-IGFRI, Jhansi, India, consisting of three tree species viz. *Acacia nilotica*, *Ficus infectoria* and *Morus alba* and shrub *Leuceana leucocephala* in combination with two grass species (*Megathyrsus maximus* & *Chrysopogon fulvus*) and a fodder legume *Stylosanthes seabrana* were studied to unravel fodder production and carbon sequestration potential of silvopastures under semi arid conditions. *Megathyrsus maximus* produced higher green fodder biomass (33.07 Mg/ha) followed by *Chrysopogon fulvus* (22.54 Mg/ha) and *Stylosanthes seabrana* (4.62 Mg/ha) with different tree/shrub combinations of silvopastoral systems. Crown lopping (30%) of tree species and pollarding of shrub species produced maximum edible green biomass in *F. infectoria* (5.72 Mg/ha) followed by *L. leucocephala* (5.01 Mg/ha), *A. nilotica* (3.93 t/ha) and *M. alba* (2.87 Mg/ha). At the age of 12 years, total biomass carbon stock (above & below ground) of silvopasture system ranged from 8.56 to 27.74 Mg C/ha with maximum under *A. nilotica* + *C. fulvus* (27.74 Mg C/ha) combination. Thus, establishment of silvopasture systems with suitable tree grass/legume combination in semiarid zone are viable option to ensure fodder as well as environmental security.

Technical and financial evaluation of enrichment planting in logging gaps with two high-value timber species in the eastern Amazon

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Rodrigo Pinto[1]
Gustavo Schwartz[2], Edson Vidal[1]
[1] University of Sao Paulo
[2] Embrapa Eastern Amazon

Abstract: Enrichment planting in logging gaps is an important silvicultural treatment to promote long-term timber production in tropical forests. Technical and financial information on enrichment planting with wood species of high commercial value in logging gaps is still poor in the literature, which creates uncertainty for decision makers about the method's effectiveness. To contribute to the discussion, this work aimed to technically and financially evaluate enrichment planting with *Swietenia macrophylla* and *Handroanthus serratifolius* in logging gaps of a managed forest in order to serve as a model to recover and increase production of these species in future cutting cycles. An experiment on enrichment planting was established in 46 logging gaps in 2009 with measurements of planted individuals in 2011, 2014, and 2017. A cost-benefit analysis using net present value (NPV) and a sensitivity analysis was carried out on different interest rates (10%, 11% and 12%) from 2023 for the production of roundwood and sawnwood. Eight years after planting, individuals of *Swietenia* and *Handroanthus* presented a diameter at breast height of 7.88 ± 1.41 cm and 5.20 ± 1.00 cm, and a Periodic Annual Increment (PAI) of 0.98 ± 0.38 cm year^{-1} and 0.65 ± 0.22 cm year^{-1}, respectively. At the last measurement, *Swietenia* and *Handroanthus* individuals presented survival percentage of 51% and 24% and mortality rate of 8% and 16% year^{-1}, respectively. NPV was negative for *Swietenia* and *Handroanthus* for both roundwood and sawnwood harvestedat 60 and 90 years. By increasing the PAI by 10% and 20%, the same result is obtained. Despite these results, we believe that the development of credit lines to encourage the planting of high-value species, combined with the generation of carbon credits, can promote the production and conservation of *Swietenia* and *Handronthus* in managed areas and ensure the maintenance of these species extremely threatened in their natural environments.

The Carbon sink potential of arbor forests in China from 2020 to 2100: comparison of different forest management scenarios

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Haikui Li[1]
Jianghuan Qin[1], Pengju Liu[1]
[1] Institute of Forest Resource Information Techniques, Chinese Academy of Forestry, Beijing 100091, China

Abstract: Forests store a large part of carbon and have high carbon sequestration potential, contributing to mitigating climate change. Here, we used three growth models which fit biological characteristics of trees and four National Forest Resources Survey to assess the carbon sink potential of Chinese existing and afforestation forests from 2020 to 2100 under the assumption of afforestation and different forest management scenarios. The results showed that Richard, Hossfeld and Korf provided a good fit for 26 kinds of vegetation biomass with forest age in natural and planted forests. The carbon stock model parameters have been verified with plot survey data. We compare observed data and predicted and find that carbon stocks of Chinese existing arbor forests would be 18.17 Pg in 2100 which has 7.61 Pg in 2020. The carbon sink potential of natural forest (0.129 Pg C/year–0.045 Pg C/year) is much greater than that of planted forests (0.105 Pg C/year–0.018 Pg C/year). Plantation management measures such as tree species replacement can increase carbon sinks in about 20 years. Tree species management for afforestation using tree species with strong carbon sink capacity in existing plantations can significantly increase carbon stocks. Natural forests such as broad-leaved forests, oak, and coniferous and broad-leaved mixed forests in Northeast and Southwest China are contributors to carbon stocks. Artificial forests such as Chinese fir forest, poplar forest and coniferous and broad-leaved mixed forest in central and southern China provide a strong guarantee for forest carbon sequestration due to their rapid growth rate. Overall, our findings will provide valuable guidelines to policymakers for designing strategies of the carbon neutrality target of 2060 with the implementation of effective management strategies for existing forests and expansion of afforestation.

The challenge to regenerate oaks in close-to-nature forestry in Central Europe

S1.1 Close-to-nature silviculture for global change adaptation and mitigation
Tobias Modrow[1]
Christian Kuehne[2], Martin Kohler[1], Ulrich Kohnle[3], **Juergen Bauhus**[1]
[1] University of Freiburg, Chair of Silviculture, Germany
[2] Division of Forestry and Forest Resources, Norwegian Institute of Bioeconomy Research, Norway
[3] Department of Forest Growth, Forest Research Institute Baden-Württemberg, Germany

Abstract: The establishment of tree regeneration without creating large canopy openings is challenging in close-to-nature forest management (CTNFM) for light-demanding species, for example of the genus *Quercus*. In central Europe, seedlings of *Q. petraea* or *Q. robur* can be quickly overgrown by other, more shade-tolerant tree species if light availability is low. To assess how *Q. petraea* can be successfully regenerated in accordance with CTNFM principles, several studies were conducted.

In an initial literature review, we identified light availability, presence of competing vegetation, oak seedling density, deer browsing, and tending practices as most important factors for success or failure of regeneration. In subsequent studies, we analysed the light environment in 57 shelterwood systems and 51 canopy gaps across Germany, and assessed growth of oak seedlings in relation to light availability and competing vegetation in selected gaps. At all levels of light availability, height growth of oak seedlings was inferior to that of competing tree species such as *Fagus sylvatica* or *Carpinus betulus*. At the same time, early establishment of blackberry had negative effects on oak density and thus regeneration success. The spatial heterogeneity of radiation increased significantly in gaps up to 0.6 ha in size, while it was comparatively low in shelterwoods regardless of stand density. Based on our results, oak regeneration should be initially established at light conditions of 20-30% of radiation in the open, which provides for sufficient height growth in oak seedlings while reducing establishment of blackberry. Once saplings can no longer be overgrown by ground vegetation, radiation should be increased to above 50% to increase the capacity of oak to compete in height growth with companion tree species. This phased establishment can be achieved with shelterwoods in which canopy cover is gradually reduced to regenerate oak dominated stands. For mixed-species stands with groups of oaks, gaps of about 20-30 m diameter are recommended to initiate regeneration. With increasing light requirements of seedlings, gaps need to be expanded to achieve > 50% light in the open. Even with optimal light conditions in the different establishment phases, intensive tending is necessary to promote oak seedlings and saplings.

Thinning in a resprouting forest for climate change adaptation

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Katinka Ruthrof[1]
Gavan McGrath[1], Richard Van Dongen[1], Willa Veber[2], Sophie Brennan[2], Joseph Fontaine[2]
[1] Department of Biodiversity, Conservation and Attractions, Western Australia, Australia
[2] Murdoch University, Western Australia, Australia

Abstract: A warming and drying climate in many regions has, and increasingly will, put forest ecosystems under stress and are a challenge for forest management. Concurrently, past management, such as timber harvesting in resprouting forests, have altered stand structure to create dense regrowth, with implications for forest resilience, streamflow, and riparian habitat under projected climatic conditions. One of the main intervention techniques to adjust stand structure is via thinning, which removes stems, and may increase soil moisture, and protect riparian zones and other habitats. Understanding how thinning can help mitigate vulnerability to warming and drying is challenging because it requires consideration of processes that occur on temporal scales from seconds to decades and spatial scales from cells to continents. To overcome this challenge, we integrated multi-scale and multidisciplinary data, including remote sensing, UAV-based LiDAR and multispectral data, ecological stand level data, molecular tools, and social research and outreach. These will help us examine a range of metrics including forest cover, stress, structure, flora, fauna, fungi, fire severity, hydrology, geophysics, fuel loads, compaction, herbicide residues, soil microbiome, carbon, and community perspectives. Results thus far suggest thinned catchments and their riparian zones lose less cover during drought/heatwave events, thinning leads to higher soil compaction on snig tracks and elevated 1hr fuels and coarse woody debris in the short term, depending on the type of thinning operation. An open and transparent quantification of responses to forest thinning is critical for understanding ecological benefits and tradeoffs for each type of thinning method, and for community acceptance of this form of proactive forest management intervention.

Transition from clear-cut based to closer-to-nature forestry clashes with short-term climate goals in Nordic countries

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Holger Metzler[1]
Samuli Launiainen[2], Giulia Vico[3], Oskar Franklin[4]
[1] Department of Forest Ecology and Management, Swedish University of Agricultural Sciences
[2] Natural Resources Institute Finland (Luke)
[3] Department of Crop Production Ecology, Swedish University of Agricultural Sciences
[4] International Institute for Applied Systems Analysis (IIASA)

Abstract: Boreal forests comprise approximately 45% of the global stock of growing timber. The currently dominant forest management model in northern Europe focuses on growing even-aged, homogeneous stands of a few hectares with a clear-cutting cycle of 80-120 years. This clear-cut based forestry (business as usual, BAU), with its main focus on production, has led to degradation of other important ecosystem services, such as climate regulation, non-timber forest products, recreation, water regulation and purification, maintenance of soil productivity, biodiversity, and air-quality regulation.

Being one of the largest biomes on the planet, boreal forests have enormous potential to mitigate climate change by taking up and holding back carbon from the atmosphere. In order to assess their potential to mitigate climate change, it is mandatory not to look exclusively at the amount of carbon but also for how long this carbon is retained from the atmosphere. This retention time is crucial to compare the avoided radiative damage to the atmosphere of different management strategies.

We developed a novel mass-balanced and process-based compartmental boreal forest management model potentially comprising trees of different ages and species that follows the carbon path from its photosynthetical fixation until its return to the atmosphere by autotrophic or heterotrophic respiration or by wood-product burning. This model allows to assess potential climate change mitigation in terms of avoided radiative damage.

Continuous-cover forestry (as one way of closer-to-nature forestry, CNF) is superior to BAU for most parts of a rotation time of 80 years in terms of climate change mitigation potential. However, during a phase of transitioning from BAU to an established continuous-cover forestry, the climate change mitigation potential decreases. Moreover, this decrease fortifies if starting the transition phase is delayed.

Consequently, a transition from BAU to CNF as envisioned by the EU Forest Strategy 2030 clashes with short-term climate goals of carbon neutrality in Nordic countries (Finland: by 2035, Sweden: by 2045). However, the earlier the transition process starts, the smaller will be its long-term radiative damage to the atmosphere relative to the current business as usual.

Transitioning towards continuous cover forestry: How to sample for precise estimates of sustainability indicators.

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Mathias Leiter[1]
Hubert Hasenauer[1]
[1] Institute of Silviculture, University of Natural Resources and Life Sciences, Vienna, Peter-Jordan-Str. 82, A-1190 Vienna, Austria

Abstract: The even-aged forests stand in Central Europe are threatened by climate change and increasing forest disturbances. To address this issue, forest stands are being transformed into more resistant and resilient mixed continuous cover forests, through changes in forest management. This creates a new challenge that is often ignored: The transition towards more structurally diverse stands implies a reevaluation of the size of forest management units and forest sampling designs. With data from established continuous cover forests, even-aged forests, and forests in transition from even-aged to continuous cover management, that use Fixed Area Plots Sampling and/or Angle Count Sampling with different radii and basal area factors, we cover the majority of European forest management systems and their respective sampling designs. We analysed different forest enterprises and evaluated their forest management systems and forest inventory systems. By doing so, we derived the sampling precision of sustainability indicators in the respective management system, such as increment and changes in stem number per DBH class for continuous cover management. Additionally, using the single-tree growth simulator MOSES, we simulated the transition of even-aged forests to continuous cover forests and analysed the needed changes in the sampling design. Our research yielded hands-on guides for forest managers. These guidelines highlight the essential changes in the size of management units and sampling designs, necessary to reach a certain precision of sustainability indicators in transitioning and continuous cover stands.

WHAT ARE THE IMPACTS OF PARTIAL CUTS ON BOREAL ABOVEGROUND CARBON STOCKS?

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Martín Alcalá Pajares[1, 2]
Miguel Montoro Girona[1, 2, 3], Annie DesRochers[1, 2, 4]
[1] Groupe de Recherche en Écologie de la MRC Abitbi (GREMA).

[3] Grupo de Análisis y Planificación del Medio Natural, Universidad de Huelva, Huelva, Spain.
[4] Centre d'étude de la forêt, Université du Québec à Montréal, Montréal, Quebec, Canada.

Abstract: The boreal biome holds one-third of the world's carbon stock, with two-thirds of its forest being managed. Awareness of the environmental impacts of clear cuts has grown along with interest in exploring more sustainable management practices. As a result, partial cuts have emerged as a promising alternative to clear cuts. Yet, the sustainability of partial cuts from the carbon sequestration point of view is not completely understood. Moreover, the sustainability of partial cuts is questioned due to high post-harvest mortality rates caused by windthrow, and the impact of this natural disturbance on aboveground carbon stock remains unclear. This research aims to evaluate the effect of partial cuts and post-harvest windthrow mortality on mid-term aboveground carbon stocking. We selected 24 jack pine stands in Eastern Canada creating a harvest intensity gradient with control (0%), commercial thinning (30-35%), and shelterwood cut (40-50%) stands. Eight stands were selected for each harvest intensity and one 600 m² plot was installed in each stand. A total of 1056 tree cores (36 cores per plot) were extracted and analyzed using a dendrochronological approach. Harvest was performed 8 to 14 years before the study. Tree carbon stock was calculated using allometric equations. Our analyses revealed that carbon stock was reduced by 26% in commercial thinning and 41% in shelterwood cut treatments compared to control stands. Control stands showed a 0.6% reduction in carbon stocking due to windthrow whereas this proportion reached 2% for commercial thinning and 5% in the case of shelterwood cut. These results suggest that partial cuts reduce the aboveground carbon stocks, and that this reduction increases with increasing harvest intensity. These findings offer crucial insights to better understand the impacts of partial cuts and post-harvest windthrow mortality on boreal carbon balance to guarantee the sustainability of these treatments when implemented in the boreal forest.

Keywords: allometric equations, boreal forest, carbon sequestration, dendrochronology, silviculture, windthrow.

Where is our forest management heading towards? Analysis of the long-term effects of a forest management practices in the Community Forestry of Nepal

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

[3] Institute of Forestry, Dean Office, Kathmandu
[4] United Nations Development Programme, Nepal

Abstract: In Nepal, forest management is protection oriented with the main priority in increasing and maintaining the growing stock volume of the forests. This approach has increased the forest cover successfully, but the timber quantity and quality remain unexplored. Based on longitudinal forest inventory data of permanent sample plots over five time periods, this contribution analysis the change of the forest condition over the last two decades (2005, 2010, 2013, 2016 and 2022) for a Community Forest in the Terai region, focusing on basal increment, in-growth and regeneration. The Community Forest has been largely used for subsistence purpose, where trees basal 13.4 in 2005 to 23.1 m^2 per ha in 2022, however the increment has mostly in large size trees. The number of small size tree (less than 10 cm DBH) per ha decreased in all inventory period whereas elderly tree increased marginally. Furthermore, the condition of the regeneration is poor and even declining. This is primarily due to the practice of grass collection and haphazard harvesting of small the size trees during grass cutting. As establishment new tree is very limited, and diameter classes are dominated by large tree, stand structure does not of reassemble with inverse J shape curve, Hence, forest sustainability remain in questions. This is due to adoption of selective felling where priority is removing trees without considering their species characteristics. There is a need to shift the current forest management approach of the forests, in order to maintain an inverse J shape curve, support a continuous regeneration in the long run and increase the forest structure of the forests.

Why do the portfolios of forest management systems vary so much across Europe?

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Per Angelstam[1, 2]
Michael Manton[3]
[1] Inland Norway of Applied Sciences
[2] Swedish University of Agricultural Sciences
[3] Vytautus Magnus University

Abstract: Background: To cope with desires for "more of everything" from forest landscapes, and with built-in conflicts among different benefits, actors and stakeholders, one option is to apply different portfolios of forest management systems in different social-ecological contexts. Within the European continent, there is large variation in both the range of desired benefits, and application of different forest management systems.

Aim: The aim of this study is to test the hypothesis that the relative proportions of continuous cover and even-aged forest management systems applied among European regions can be explained by the complex net effect of physical, ecological and social system drivers.

Methods: We apply a comparative approach involving 24 countries. For each country, we collected data about physical variables (e.g., terrain and climate), ecological variables (e.g., life history traits of tree species), and social system variables (e.g., land ownership and types of value chains). We then carried out multivariate analyses to explore patterns in the application of different forest management systems across Europe.

Results: The variables exhibiting most variation were continuous cover forestry, terrain steepness and jobs per forest area. The multivariate analysis explained 74% of the variation in the dataset, with PCA1 (52%) positively related to deciduous tree species and negatively to conifers, and PCA2 (22%) positively related to shade-intolerant, and negatively to shade-tolerant and forest jobs. There were three main clusters of countries, which we summarise as Nordic-Baltic, Central European, and Mediterranean.

Conclusions: Using physical, ecological and social system indicators, the current variation in forest management systems on the European continent could be explained. However, because neither continuous cover nor even-aged forest management systems aiming at maximum sustained yield wood production have capacity to maintain biodiversity and strengthen resilience in the context of climate change, additional forest management systems need to be applied. This includes the emulation of natural forest and cultural woodland dynamics by applying new "closer-to-nature" forest management systems, which need to be complemented with spatial planning that segregates the delivery of different forest ecosystem service benefits.

“Planting conifers and reserving broadleaved tree species” --the “close-to-nature” silviculture in Northeast China

S1.1 Close-to-nature silviculture for global change adaptation and mitigation

Hailong Shen[1]
[1] School of Forestry, Northeast Forestry University, Harbin 150040, China

Abstract: The dynamic management approach of “planting conifers and reserving broadleaved tree species” (PCRB) in Northeast China’s temperate forest region was developed for restoring and/or reestablishing near zonal climax, the mixed forest of Korean pine and broadleaved tree species in humid temperate areas in East Asia, from the secondary forest which was derived from the primary forest of it. It is a typical “close-to-nature” silviculture that is combined the two contrasting trends in contemporary silviculture of ecologically-based practices and natural regeneration and technologically-based practices and plantation forestry, because of many of the secondary forest has become the mixed forest by artificially planted Korean pine and naturally regenerated broadleaved leaved tree species. Through or promoting the growth of Korean pine trees and broadleaved trees harmoniously, microspace of individual trees of Korean pine was quantitatively regulated according to Opening Degrees and the morphological development of Korean pine trees was elucidated by long time positioning investigation, and the following results give a sound support for our opinion: (1) the ratio of lower 2 wheel lateral branch base diameter to diameter at breast height (BBD/DBH) could be the indicator of under canopy Korean pine tree light environment, the smaller the better; (2) the response patterns of height, diameter, crown width and individual tree volume of different age-class Korean pine trees to each OP were different, OP=2.0 was significantly better than other two OPs for 30-year-old and 15-year-old Korean pine populations but no certain pattern for that of 9-year-old Korean pine population, especially, the individual volume of Korean pine trees in OP=2.0 were 197% and 113% higher than that of OP=1.0 and 1.5 respectively for 30-year-old population and 212% and 343% for 15-year-old population but no evident changes for 9-year-old population; ten year data of height, diameter and individual volume showed the same patterns; (3) 28.2% Korean trees in OP=2.0 for 30-year-old population has reached to the upper tree canopy height but only 4.1% and 1.1% for other two OPs. Conclusion: The practice of PCRB support that it is true of our recognition of “close-to nature” silviculture.

Abstract: An increase in ozone (O_3) is currently placing plant ecosystems under stress and may adversely affect the nutrient use of plants. Plants may modify leaf turnover rates and nutrient distribution at the organ level to respond to O_3 damage. We explored leaf turnover rate and allocation of primary (C, N, P, K) and secondary macronutrients (Ca, S, Mg) under several O_3 treatments (ambient concentration, AA, with a daily hourly average of 35 ppb; 1.5 x AA; 2.0 x AA) and fertilization levels (N: 0 and 80 kg N ha^{-1} y^{-1}; P: 0 and 80 kg N ha^{-1} y^{-1}) in an O_3 sensitive poplar clone (Oxford: *P. maximowiczii Henry* × *P. berolinensis Dippel*) in a Free-Air Controlled Exposure (FACE) experiment. The results indicate that both fertilization and O_3 had a significant influence on the nutrient content. Specifically, fertilization and O_3 increased foliar C and N contents (+5.8% and +34.2%, respectively) and root Ca and Mg contents (+46.3% and +70.2%, respectively). The leaf turnover rate was faster due to increased O_3 exposure. However, the PCA analysis showed that O_3 fumigation overall affected the allocation of primary and secondary elements. Plants usually try to increase the concentration of certain elements in their cell walls and other components to mitigate the damage caused by high levels of ozone. Consequently, the different displays of element allocation, such as nitrogen (N), in plant leaves in reaction to elevated O_3 levels can have significant ecological implications.

Anthropogenic disturbances and the emergence of native diseases

S1.2 Forest health under climate change and air pollution

Abstract: Human-induced global changes are significantly altering natural forest ecosystems. Specifically, stressed tree species near the limits of their native ranges and those growing on marginal sites display various signs of poor health. This talk will focus on complex tree diseases (declines) caused by native pathogens and the key environmental drivers contributing to this phenomenon. These systems are frequently complex, with multiple drivers at work. Through four case studies conducted on different continents, we explored the underlying environmental drivers, both direct and indirect, responsible for these decline syndromes. While climate and weather events are commonly associated with forest decline, we discovered that disturbances caused by forest management or changes in land use also play a significant role globally. Changes in land use have directly benefited pathogens such as root rots in the Pyrenees (Spain) or indirectly by making the environment more conducive for canker and foliar diseases in Australia and USA. Shifting our focus towards understanding land-use changes could enhance our comprehension of ongoing decline issues. The coming century will likely witness an unprecedented increase in forest pathogen epidemics, necessitating a proactive rather than reactive approach. Diseases caused by native pathogens with complex aetiologies will become more prevalent, and effectively recognizing, characterizing, and managing these epidemics is challenging because the pathogens are often already widespread, making eradication unfeasible. We must adopt a comprehensive "whole ecosystem" perspective to address these challenges, highlighting the various factors and interconnections involved in forest declines. This approach enables us to tailor management strategies to each unique scenario. The proposed framework outlines six vital questions that need answering to untangle the direct and indirect environmental drivers behind tree declines.

Birch is a model system for acclimation and adaptation of northern forest ecosystems to rapidly changing environment

S1.2 Forest health under climate change and air pollution

Elina Oksanen[1]
[1] Department of Environmental and Biological Sciences, University of Eastern Finland, POB 80101 Joensuu, Finland

Abstract: Northern forest ecosystems are exposed to rapid environmental change, i.e., climate warming, extended growing seasons, increasing greenhouse gases, and changes in precipitation and water availability, accompanied by increasing pressure of herbivores and pathogens. *Betula* species are important deciduous trees species in the boreal zone, with extensive distribution across Eurasia. Silver birch (*Betula pendula* Roth) is an excellent model system for the adaptation and acclimation of northern trees to climate change due to recent advances in genomics, high genetic variation, and intensive studies with different abiotic and biotic stress factors. The aim of this presentation is to show the current understanding about the responses and acclimation mechanisms of birch species to changing environment in Scandinavia, based on our long-term common garden experiments across Finland and Europe and numerous open-field studies e.g. with elevated temperature, humidity, ozone and CO_2, complemented with novel spectral imaging research approaches. Our studies have shown that warming climate and increasing CO_2 is expected to increase the growth and biomass of birch, but the risk of herbivore damage will increase with negative impact on carbon sink strength. Deleterious impacts of high humidity, soil drought and increasing ozone conditions have been clearly demonstrated. In most studies, major shifts in metabolism as well as in carbon and nutrient balance have been documents, which may have further ecological impacts. However, high plasticity and genotypic variation predict excellent acclimation capacity of birches in a rapidly changing environment and a rich genetic pool for sustainable forestry. We have been able to demonstrate, for example, successful growth and performance of Italian genotypes in Finland and a special adaptation of northern genotypes to continuous summer-time sunlight conditions, i.e. “polar day syndrome”. In addition, birch species have a positive impact on biodiversity especially in mixed tree stands and reforestation areas and therefore deserve more attention in Scandinavian and European tree breeding programmes and silvicultural strategies. More research needed for multiple-stress interactions (e.g. increasing CO_2 x water stress), belowground processes and *B. pubescens,* which is better adapted to northern/subarctic and wet conditions as compared to *B. pendula.*

Can epigenetics help us understand climate-adapted phenotypes?

S1.2 Forest health under climate change and air pollution

Lily Peck[1]
Victoria L. Sork[1, 2]
[1] University of California, Los Angeles, Department of Ecology and Evolutionary Biology, USA
[2] University of California, Los Angeles, Institute of the Environment and Sustainability, USA

Abstract: Forests and climate are inherently linked, with the earliest documented assertion as far back as the 15th century. Today, our rapidly warming climate threatens the health of forest ecosystems and all the benefits they provide. Plant development is well documented to change in response to a wide range of environmental conditions, including severe examples such as drought stress. These plastic responses can shape phenotypes through underlying genetic variation and/or epigenetic variation (where DNA is modified without changing its sequence). DNA methylation is one such epigenetic mechanism that may be able to 'switch off' gene expression or suppress transposable element insertions by binding to a specific DNA sequence. Resolving the connections of DNA methylation with gene expression, phenotypic plasticity, and fitness in trees will clarify the extent to which epigenetics shapes tree response. This talk investigates DNA methylation and gene expression associated with drought-response phenotypes in a California endemic oak, *Quercus lobata* Née, an emerging model tree system, to provide practical tools for tree conservation. We report an experiment that uses whole genomes, transcriptomes, and methylomes from six families of half-sib progeny to measure response to drought stress. Specifically, we test the hypothesis that DNA methylation affects gene expression and ecophysiological phenotypes differentially between control and water-stress treatments. Early data show that drought stress results in extensive remodelling of tree methylomes, and it is not just important whether DNA methylation has occurred, but *where* and *how much.* We find methylated regions at the start- and stop-sites around genes, and, for some loci, it appears to be strongly and inversely correlated with gene expression. However, we also find a genetic basis for gene expression and ecophysiological response. We discuss the extent to which DNA methylation relative to genetic factors shapes oak response to climate change. In closing, we point out that many forest habitats are currently being restored and replanted with little knowledge of how individual trees will respond to a rapidly warming climate. Thus, a better understanding of the genetic and epigenetic causes of climate-adapted phenotypic response will help develop management strategies to preserve the oak ecosystem health.

Can Norway spruce be vaccinated against fungal infection and insect attack?

S1.2 Forest health under climate change and air pollution

Abstract: Norway Spruce, *Picea abies*, is a long-lived, coniferous tree that faces many types of biotic stress over its lifetime. Therefore, it has evolved multiple layers of defense to protect itself from pathogenic and insect attacks. This defense system can be enhanced by applying external stimuli such as the natural plant hormone, methyl Jasmonate (MeJA). MeJA can both directly induce and prime tree defenses for future attacks as a cost-effective defense strategy. Studies in 48-year-old and 2-year-old Norway spruce trees show that spraying bark with MeJA resulted in fewer successful bark beetle attacks and reduce the lesion length from blue-stain fungus. This enhance protection may last weeks to years. Investigation of the mechanisms of MeJA-induced resistance (MeJA-IR) showed that MeJA directly induces the formation of traumatic resin ducts. However, accumulation of metabolites, such as terpenes and catechin, and expression of pathogenesis-related (PR) genes show a primed response. Additionally, MeJA alters the expression of epigenetic regulators, especially those associated with RNA-directed DNA methylation, suggesting epigenetic mechanisms are involved in the priming of defense in Norway spruce. We are currently investigating where epigenetic changes occur, how long MeJA-IR persist and how MeJA-IR effects spruce symbioses in order to make MeJA usage more practical in forest management.

Cedrus deodara tree-ring PDSI reconstruction identified monsoon failure in northern Pakistan in the mid-17th century

Abstract: As climatic chnages continues, the frequency and intensity of drought are being excerbated by increased temperatures. In norther Pakistan, knowledge of drought variability that extend beyond the instrumental period (ca. befor 1965) is scarce. Here, use tree-ring data from *Cedrus deodara* to provide a 487-yr warm season (Mar-Apr) drought reconstruction back to 1530 AD. The results showed that pluvial conditions were observed during the period occures 1678-1684, 1919-1936, 1947-1951, 1986-1998 and 2003-2010, while the driest periods occured 1544-1560, 1611-1624, 1737-1746, 1661-1666, 1773-1816, 1870-1886 and 1910-1913. The 17th century contained the highest number of extreme drought events (n=17), while the 19th century contained the heighest number of pluvials (n=6); no single wet years was captured after the 1690-1790 AD events. The influence of the Pacific Decadal Oscillation(PDO) and Indian Ocean Heat Content (IOHC) were statistically weak (r=,P<). This might have been the reason for the complete failure of the monsoon, whereas the drought events were more pronounced in the region. The results suggest that the influence of the PDO and IOHC strengthed the monsoon over the Dir mountains and weakened the monsoon over the Chitral Mountains, ehich had drought the 17th century, however the realistic simulationof the monsoon weakening pattern at the regional scale is still a challenge for climate models. New paleoproxy records will allow us to understand future analyses of climate uncertainties, which are highly concerning subjects in regards to current climate change.

Chemical priming of defence in forest health: oak- powdery mildew interaction

S1.2 Forest health under climate change and air pollution

Rosa Sanchez-Lucas[1]
Jack Bosanquet[1], Victoria Pastor[2], Estrella Luna[1]
[1] Birmingham Institute of Forest Research, School of Biosciences, University of Birmingham, Birmingham B15 2TT, United Kingdom
[2] Metabolic Integration and Cell Signalling Group, University Jaume I, 12071 Castellon, Spain

Abstract: Plants are continually exposed to multiple stresses, currently more frequent in a climate change scenario. However, plants have developed highly sophisticated strategies to face these threats. One strategy is the priming, a sensitisation of plant defence mechanisms. Many chemicals can trigger priming but it is not well studied in oak. This work aims to determine whether oak seedlings can express chemical-induced priming and its potential trade-off in growth. Oak seedlings were treated with salicylic acid (SA), jasmonic acid (JA) and β-aminobutyric acid (BABA) 7 days before infection with *Erysiphe alphitoides*, causal agent of oak powdery mildew (PM), to which seedlings show extremely high vulnerability. Growth presented greater differences after PM infection, generally, BABA-treated plants were smaller. SA and BABA treatments result in enhanced resistance to PM and JA in enhanced susceptibility. Resistance by SA and BABA was exclusively based on priming of SA-dependent gene expression and callose deposition, respectively. To investigate the mechanisms behind specific SA and BABA priming, untargeted metabolome and transcriptome analyses were performed. Green leaves were collected at 0, 1 and 2 days post infection. Metabolites were subjected to LC-MS/MS. Spectra were filtered using XCMS R script and MarVis was employed to putatively identify metabolites and pathways. A total of 272 for SA and 313 for BABA differentially accumulated masses were observed. Pathway enrichment analysis determined that BABA priming is mostly dependent on alkaloids biosynthesis, whereas SA failed to identify any specific pathways. Transcriptome data was analysed using the *Quercus robur* genome as reference (www.oakgenome.fr) with Python (HTSeq) and R scripts (DESeq2). DEG profiling showed similar patterns with some of the metabolite enriched pathways observed. Summarising, we have identified molecular markers of priming in oak seedlings. Our results, in terms of enhanced resistance to PM and early/late responses depending on the chemical applied, provide valuable information to fight pathogens in oak seedlings. Currently, we are testing the effect of putative identified metabolites responsible for priming by BABA and SA. Our results will provide valuable information to fight PM disease in oak seedlings, as it is considered a bottleneck for woodland regeneration.

Climate change impacts on Norway spruce in Eastern Europe: Early warning signals of forest decline

S1.2 Forest health under climate change and air pollution

[4] Center for Mountain Economy (CE–MONT), Vatra Dornei, Romania

Abstract: Climate change is affecting forest ecosystems globally, in particular through warming as well as increases in the frequency and intensity of extreme events. Norway spruce (*Picea abies* (L.) Karst.) is one of the most important coniferous tree species in Europe. In recent extremely dry years in Central Europe, spruce suffered and large dieback has been observed. In Eastern Europe, no decline in spruce has been reported so far, but the anticipated changes in climate pose the question how the future of these forests may look like.

To assess the current state of spruce forests in Eastern Europe, we established a tree-ring network consisting of 157 Norway spruce chronologies of different age distributed along elevational transects in the Eastern Carpathians, Romania. We evaluated early warning signals of climate-change induced stress, i.e. (1) growth decline, (2) increased sensitivity of tree growth (assessed over the statistics first-order autocorrelation and standard deviation), and (3) increased growth synchrony. Furthermore, we used resilience indices to quantify the resistance of trees to extreme climatic events as well as their capacity to recover.

A pronounced growth decline was observed over the last two decades, which was strongest in younger stands and at lower elevations. At high elevations, Norway spruce was found to recover slower after drought events. Overall, our findings highlight an increased vulnerability of spruce in Eastern Europe. With ongoing climate change, high mortality and forest dieback may be expected also in this part of Europe.

Does global warming affect the emergence of new and native forest pathogens?

S1.2 Forest health under climate change and air pollution

Alberto Santini[1]
Alessandra Gionni[1], Nicola Luchi[1]
[1] National Research Council, Institute for Sustainable Plant Protection. Via Madonna del Piano, 10 50019 Sesto fiorentino, Italy

Abstract: Climate change has widespread impacts on ecosystems, which are subject to severe disturbances and become more vulnerable to many biotic and abiotic stressors. Warmer temperatures have been associated with an increased risk of disease development in plants. In addition, increasing temperatures make available new areas to be colonized and make possible pathogens' survival.

In northern latitudes, an increase in temperature (and water from snow and ice melt) should improve plant growth, but may, at the same time, make them more prone to disease. Indeed, under conditions of optimal resource availability, plants tend to allocate energy to growth-related processes rather than differentiation-related processes, which include secondary metabolic events with a general role in defense against pests and pathogens. In addition, milder and wetter climates may be an advantage for some pathogens.

Stresses associated with perturbations induced by global change may predispose plants in natural systems to infection. Conversely, plant pathogens may take advantage of these extreme events. As with other organisms, different pathogens react differently to climate change, meaning that while secondary pathogens are theoretically advantaged by plant stressors, primary pathogens may be frustrated by them.

Here we considered several examples of both introduced and native forest pathogens, analyzed their reaction to changing climatic conditions, and formulated some hypotheses to explain differential results, basing on both host and pathogen ecophysiology.

Effects of timing of budburst on Norway spruce susceptibility to the bark beetle Ips typographus and its fungal symbiont Grosmannia europhioides

S1.2 Forest health under climate change and air pollution

[5] Department of Natural Science, Design and Sustainable Development, Mid Sweden University S-851 70 Sundsvall, Sweden

Abstract: We studied the relationships between defense reactions to a bark beetle-associated bluestain fungus and susceptibility of Norway spruce to bark beetle attacks, to generate understanding of the influence abiotic factors has on the defense capacity in trees in the Swedish Norway spruce breeding program. In Sweden, the drought in 2018 weakened spruce trees and caused a bark beetle outbreak, which is still ongoing. The ongoing climate change is likely to increase the risk for this type of large-scale outbreaks, motivating the need to gain a better understanding of the variation in host defense capacity.

To estimate the potential of spruce's defenses, we have inoculated spruces with bluestain fungus (*Grosmannia europhioides*) and measured the tree's defense reaction at defined intervals in a spruce clone trial in central Sweden during the summer of 2022. We have also studied attacks by the spruce bark beetle (*Ips typographus*) using attack boxes to assess: (1) the necrotic lesions in comparison to the inoculation of the bluestain fungus; (2) the relationship between the defense ability of spruce clones and the ability to produce traumatic resin ducts, and (3) the defense potential of late-budburst of spruce clones vs. earlier-budburst clones.

Early-budburst clones produced significantly smaller necrotic lesions in the phloem following fungal inoculation compared to late-budburst clones. Early-budburst clones also showed a lower proportion of bark beetle attacks in the attack boxes compared to late-budburst clones (31% vs 41%).

In southern and central Sweden, late-budburst spruce clones are recommended (by "plantval"; the web-based tool developed by Skogforsk) in areas with a high risk of late spring frost. As late-budburst clones are more susceptible to attacks by both bark beetles and bluestain fungus than earlier-budburst clones, the earlier budburst clones should be used on sites with a low risk of late spring frost.

Enhancing the assessment of ozone visible foliar injury (O3_VFI): A tool for identifying O3_VFI and its dynamic interaction with stomatal regulation

S1.2 Forest health under climate change and air pollution

Barbara Baesso Moura[1, 2]

[3] Department of Agriculture, Food, Environment and Forestry (DAGRI), University of Florence, Piazzale delle Cascine, 18, 50144, Firenze, Italy

Abstract: Ozone (O_3) is a secondary tropospheric pollutant that exhibits high toxicity to various plant species. Exposure to ambient O_3, and the particular ability of species to absorb gases through the stomatal conductance process, promotes the entry of these pollutants into the leaves. Visible foliar injury (O_3_VFI) can occur in sensitive plant species depending on the duration and level of O_3 to which plants are exposed. In angiosperms, O_3_VFI is indicated by dot-like or confluent whitish to dark-brown stippling associated with interveinal discoloration in the form of bleaching, bronzing, or reddening patterns. These symptoms form gradients of increasing severity basipetal, and their development is prevented by shading. Although O_3_VFI follows a particular development pattern, these symptoms exhibit distinct characteristics among species. The identification of O_3_VFI in various diffuse forest sites throughout Europe must be performed by trained individuals who can identify and quantify such symptoms across a range of species. In this study, we propose a new field assessment tool for O_3_VFI recognition based on the systematic evaluation of color composition based on a large set of pictures taken during five years of field assessment in forest sites in Italy. The color composition related to O_3_VFI in different species was achieved with appropriate software (Photoshop) able to select colors perceptible to the human eye. A color palette was created, which can be highly useful for observers involved in the field identification of O_3_VFI. Furthermore, for the Oxford (*Populus maximowiczii* Henry × *Populus berolinensis* Dippel), a comprehensive evaluation was conducted, correlating the predominant colors distributed in symptomatic leaves with the gas exchange capacity of the species. This analysis confirmed that the degree of damage development is associated with a progressive loss of stomatal movement regulation capacity, known as stomatal sluggishness. This study contributes to the assessment and dissemination of high-quality O3_VFI images, which will be valuable to several observers responsible for monitoring O_3_VFI and for theunderstanding the effects of O_3 on plants' physiological parameters.

Evaluating post-fire recovery of six 2017 summer fires in Sicily with Sentinel-2 time series analysis

S1.2 Forest health under climate change and air pollution

Chiara Zabeo[1]
Olakunle Joshua Ogunyemi[1], Anna Barbati
[1] Università degli Studi della Tuscia, Department for Innovation in Biological, Agro-food and Forest systems (DIBAF), Italy

Abstract: Forest fires are a common disturbance in the Mediterranean Basin, and plant communities native to the area have developed adaptation mechanisms to it. However, the current climate change scenarios with increasing fire regime may pose a challenge for these species. In this study, six fires that occurred in the Region Sicily during summer of 2017 were considered. Sentinel-2 imagery was collected every two months on the areas up to December 2022. The differenced Normalized Burn Ratio (dNBR) index was calculated to define the burn severity in the areas into three levels; then, the Normalized Burn Ratio (NBR) was used to monitor the post-fire vegetation recovery at patch level of the main four forest categories in the burned area, which are *Eucalyptus* spp. reforestation, Mediterranean conifers reforestation, Mediterranean maquis and *Q. ilex* forest. The TIMESAT software has been used to extract seasonal vegetation growth cycle parameters from the time series. A Random Forest model was set up to understand which variables among spectral, climatic and topographic ones had the most impact on the post-fire recovery, or degradation, of the patches. Results showed that the Mediterranean maquis, regardless of severity level, is the forest type that showed the fastest and most evident recovery, followed by the *Q. ilex* forest, then the *Eucalyptus* spp. reforestation and Mediterranean conifers; these latter two categories are also the ones that reported the highest number of patches showing degradation signs up to December 2022. As for the Random Forest model results, pre-fire conditions and fire severity in the patch were the most significant explanatory variables regardless of forest type and recovery level, followed by climatic and eventually topographic ones, apart from the *Q. ilex* forest, for which aspect was the most relevant variable analyzed. The results confirmed that the Mediterranean maquis is the most resilient category among the four considered, but attention should be paid as an increasing fire regime, coupled with climate anomalies such as lack of precipitation and higher temperatures, can generate a homogeneous fire-prone shrubland which can cause landscape degradation.

Exploring non-linearity in Norway Spruce dendroclimatic models in Carpathians

S1.2 Forest health under climate change and air pollution

Abstract: Decrypting and understanding tree growth response to climate is still a central challenge in tree ring science. Various statistical methods were applied, from linear correlation to machine learning techniques, from frequentist to bayesian approaches or process-based models. The study aimed to evaluate the relationship between tree ring index and seasonal climate parameters (temperature, precipitation and SPEI) using machine learning techniques (Random Forest Analysis - RFA). The dataset consists of a large tree-ring network of 157 Norway spruce chronologies (3012 trees), from managed stands, covering different age classes and distributed along an altitudinal gradient in Eastern Carpathians (Romania). Daily climate data from E-OBS grid data downscale to a high-resolution grid (1 km2) (Moreno and Hasenauer (2016) were aggregated on a seasonal time scale. Raw tree ring widths were detrended using a 30-year cubic spline with a 50% frequency cut-off. To explore the non-linearity of the relationship between tree ring index (TRWI) and seasonal climate, we perform the random forest analysis (RFA) as a multivariate non-parametric regression method. The Increased Mean Square Error (%IMSE) was used as a robust measure of the variable importance. Non-linearity in tree growth response to climate was evaluated using partial dependence plots of RFA. Based on Random Forest analysis, the most important climate variables on Norway spruce radial growth were the drought intensity from the previous autumn and summer. The winter temperature had high relative importance as well (RFA). The differences in growth-climate responses within the altitudinal classes were highlighted. Partial dependence plots from RFA indicate a non-linear relationship between spruce growth and previous autumn temperature as well as the SPEI and the previous summer SPEI. Our preliminary results show that the relationship between Norway Spruce radial growth and climate, in the Eastern Carpathians, is complex and requires future investigations.

Forest health under climate change and its mitigation in Africa

S1.2 Forest health under climate change and air pollution

Alice Muchugi[1]
Woubit Dawit Bedane[1]
[1] International Livestock Research Institute (ILRI), Addis Ababa, Ethiopia

Abstract: Over the past decades forest coverage is reducing at annual rate of ca. 3.9 million ha in Africa due to population pressure for settlement and agricultural expansion. Moreover, the ongoing climate changes has impacted the forest sector through longer growing seasons, expansion of insect species ranges, and increased frequency of wildfires. The increase in temperature and rainfall provides a warm and humid environment necessary for rapid multiplication of pests. There is an increasing challenge in Sub-Saharan due to climate change impacts on the pest survival, development, reproduction and spread as well as altering host defenses and susceptibility. The desert locust infestation in Eastern Africa is the most recent example of how climate change can lead to unprecedented damage on crops, grass, shrubs, and trees. In 2019, desert locust has destroyed 70,000 hectares of farmland in Somalia and Ethiopia. This has substantially affected the livelihoods of stallholder farmers and agriculture ecosystem. To alleviate the problem, cross-border surveillance and research collaboration are needed as well as authorities need to produce risk map to guide interventions to effectively control pests' outbreak. The forest ecosystem also plays an important role in maintaining biodiversity, enhancing climate resilience, and providing ecosystem services. Research has shown that increasing tree species richness/diversity of the forest ecosystem can improve tree resistance to insect pest damage. In this review paper, the present knowledge on the impacts of climate change on forests and forest pests and action taken to mitigate the impact in Africa is reviewed and summarized.

Hyperspectral and conventional colour imaging approaches in high-throughput phenotyping of drought responses of Populus tremula

S1.2 Forest health under climate change and air pollution

[3] National Plant Phenotyping Infrastructure, P.O.Box 27 (Latokartanonkaari 7) 00014, University of Helsinki, Finland.

Abstract: The application of imaging techniques in forest tree phenotyping allows for non-invasive, high-throughput monitoring of stress-related phenotypic traits, early stress detection, and the selection of tolerant genotypes. This study presents a methodological approach for incorporating a portable, low-cost hyperspectral imaging (HSI) system to the pipeline of an automated high-throughput phenotyping facility for drought stress and recovery monitoring. We acquired hyperspectral and conventional colour (RGB) images of 33 *Populus tremula* genotypes exposed to a four-week drought and a two-week recovery period. Hyperspectral images were analysed with K-means clustering and RGB images with a 25-hue colour segmentation. Classifications based on these two non-invasive imaging techniques were used for early detection and detailed characterization of the drought responses and the progress of recovery. The advantages of HSI compared to RGB imaging were evaluated alongside the benefits of integrating data from two imaging modalities. We found differing responses to drought stress in the *Populus tremula* genotypes studied. The effects of drought stress on *Populus tremula* induced physiological and biochemical changes detected in the growth, photosynthesis and foliar spectral reflectance before it was visible to human eyes, indicating that early-stage markers for assessing plant condition could be developed. Complementary phenotyping approaches can improve the detailed characterisation of phenotypic traits associated with a drought stress response.

IMPACTS OF ENHANCED CO2 ON OAK DEFENCES AGAINST POWDERY MILDEW

S1.2 Forest health under climate change and air pollution

Mark Raw[1]
Rosa Sanchez-Lucas[1], Emma Platt[1], Victoria Pastor[2], **Estrella Luna**[1]
[1] Birmingham Institute of Forest Research, School of Biosciences, University of Birmingham, Birmingham B15 2TT, United Kingdom
[2] Metabolic Integration and Cell Signalling Group, University Jaume I, 12071 Castellon, Spain

Abstract: Rising levels of atmospheric Carbon Dioxide (CO_2), have been demonstrated as harmful for environment and human health. Different strategies are in place to mitigate it such as reducing deforestation and increasing forested areas. In the UK, planting strategies include oak species as autochthonous tree species in european forest. However, young oak are highly susceptible to *Erysiphe alphitoides*, the causal agent of oak powdery mildew (PM), which is considered a limiting factor in oak woodland regeneration. Previous work in our group has shown that elevated CO_2 (eCO_2) causes seedlings to become more susceptible to the PM infection, which could have devastating future impacts. However, mature oaks are able to tolerate annual PM infection. We aim to understand how eCO_2 impacts mature oaks and seedlings comparing both experimental systems. For this, monthly leaf samples from mature oak canopy levels were collected from May-September. In parallel, leaves from naturally regenerated seedlings were collected after summer. Leaf-metabolites were subjected to LC-ESI-QTOF-MS/MS. Spectra were filtered using the XCMS R script and MarVis was employed to putatively identify metabolites and pathways. Mature trees showed low differentially expressed metabolites amounts within the same month, however changes occurred gradually over the months also demonstrating highly different patterns of expression between the months where the PM is present from those without, being May and September the extreme profiles corresponding to disease pressure. Comparisons between mature oak trees and an earlier experiment on oak seedlings were performed. Seedling profiles showed unique expression patterns but many of these compound groups are shared between young and mature trees. Putative identified metabolites are majorly related to secondary metabolism, phenylpropanoids and terpenoids, indicating eCO_2 impacts in defence mechanisms.

Mapping Vegetative Stress in Mangroves under the Influence of Climate Change: PRISMA Data Analysis and Insights

S1.2 Forest health under climate change and air pollution

NASLA NAJEEB[1]
Rajiv Kumar Chaturvedi[1]
[1] Birla Institute Of Technology And Science, Goa campus

Abstract: Mangroves are vital ecosystems found in coastal areas worldwide, providing ecological, economic, and social benefits such as coastal protection, biodiversity support, habitat provision, carbon sequestration, water quality maintenance, fisheries support, livelihoods, tourism, recreation, and climate resilience for coastal communities. In Goa, Western Ghats, mangroves play a significant role, inhabiting various coastal locations, including estuaries, creeks, and backwaters. However, like in other regions, mangroves in Goa face threats such as habitat degradation, pollution, urbanization, and unsustainable fishing practices. Conservation efforts are crucial to safeguard these valuable ecosystems, ensuring their ecological functions and benefits to the environment and local communities. This study focuses on identifying and mapping vegetative stress in the mangroves of Goa using time-series hyperspectral PRISMA data and field observations. Different narrow-banded vegetation indices (VIs) affected by vegetation stress will be tested and calculated based on Separability (S) and Coefficient of discrimination (R^2) statistical tests to determine effective vegetation stress indices. The analysis prioritizes stress indices with the highest S and R^2 values for weighted and combined pixels. The resulting weighted combination index will be used to detect and map vegetation stress in mangroves. The findings will be validated by analysing spectral data from healthy and stressed plants in real-world conditions, comparing them to the vegetation stress assessment generated by ENVI software's agriculture stress tool (AST). Furthermore, the study will investigate the factors and drivers contributing to vegetation stress in mangroves in recent years, shedding light on underlying causes such as habitat degradation, pollution, urbanization, or unsustainable fishing practices affecting mangrove health in the Goa region. The developed weighted combination index will be utilized to detect and map vegetation stress, providing spatial information on areas of high stress within the studied mangrove ecosystems. By evaluating the calculated VIs, the study aims to determine the most effective indices for assessing the health and condition of mangroves in the Goa region.

Modeling and Mapping Habitat Suitability of Highland Bamboo under Climate Change in Ethiopia

S1.2 Forest health under climate change and air pollution

Dagnew Yebeyen[1]

[2] School of Earth Science, Addis Ababa University, Addis Ababa
[3] Department of Remote Sensing, Ethiopia Space Science and Geospatial Institute, Addis Ababa

Abstract: Highland bamboo (*Oldeania alpina* formerly *Arundinaria alpina* or *Yushania alpina*) is a species of significant conservation value in Afromontane ecosystems across Africa. It also plays a significant role in the livelihoods of local communities. However, global climate change is anticipated to alter its ecological niche, leading to range shifts and possible habitat contractions. This study aimed to identify potentially suitable habitats for highland bamboo in Ethiopia, determine the resilience of the species under climate change, and establish the environmental factors affecting its habitat. Species distribution modeling (SDM) was implemented in the SDM R package using 231 georeferenced presence records together with climate, topographic, and soil data. To assess climate change risks to the species, predictive models were developed assuming climate scenarios for 2061–2080 under two shared socio-economic pathways (SSPs), namely, SSP2-45 and SSP5-85. The results indicated that highland bamboo mainly grows in high elevation areas with altitudes of 2100–3100 m asl with mean annual temperatures of 11.5–19.3 ºC, annual precipitation of 873–1962 mm, precipitation of the driest quarter of 36–147 mm, soil pH of 5.6, and soil CEC of 30.7 cmolc/kg. The current potentially suitable habitat for this species in Ethiopia was estimated at 61,831.58 km^2, with the majority of habitats being in the southern and southwestern parts of the country. Our models predicted that the suitable habitat will shrink by 13.4% under the SSP5-85 scenario, while potential new suitable areas for this species were identified under the SSP2-45 scenario. Future vulnerable areas were mostly found in central Ethiopia. Based on the predictions, we conclude that most of the suitable habitats for highland bamboo will remain suitable between the years 2061 and 2080.

Optimizing tree density for creating resilient forests with climate change

S1.2 Forest health under climate change and air pollution

Frank Sterck[1]
Steven de Goede[2], Eva Meijers[1], Marleen Vos[1], Jorad de Vries[1], Ciska Veen[2]
[1] wageningen university
[2] netherlands institute of ecology

Abstract: International agreements aim at creating forests that are productive, resilient to climate change, and that store carbon to mitigate global warming. These aims are challenged by increased tree mortality rates and decreased tree growth rates in response to increased incidence of drought. The challenge remains to develop forest management systems that increases productivity, resilience and carbon storage of trees and soils under climate change, but the scientific base and management guidelines for this are not yet operational.

Our aim is to quantify the effects of drought and management-controlled tree density on forest productivity, forest resilience, and carbon storage in trees and soils. We hypothesize that such targets can be achieved via controlling stand density using low levels of tree harvest intensity.

We use a multi-site, forest experiment covering 15 plots of >1ha (5 for beech, Scots pine, and Douglas fir, respectively), with 4 stand density treatments (control, 20% trees removed, 80% trees removed and clear-cut) in each plot. We quantified nutrient-, water- and carbon stocks and fluxes by measurements on: nutrient deposition, weathering, leaching and tree removal; water and carbon dynamics in trees and soils using automized sensors systems; responses of the biological soil community (mycorrhizae composition and abundance) and their role in decomposition and carbon storage in soils.

We show how low harvest intensity levels 1) mitigate negative effects of reduced nutrient deposition and increased leaching on forest nutrient budget, 2) favour mycorrhizal communities and their role to soil carbon storage, 3) reduce tree dehydration during dry, hot periods, (4) and improve tree growth and regeneration. These trends are consistent across species, but quantitatively these responses differed across species. We also present a mechanistic 3D forest models that is tested and calibrated and forest experimental data, and aims to integrating, understanding and projecting long-term management implications for forest dynamics under climate change.

Our results imply that a selection forest system with regular low intensity harvest, but without end harvest, creates the most productive, resilient forests for different tree species on poor soils. Model validation for different tree species, soils and climates will be required for application across continental scale.

Ozone as a threat for Northemispheric forests

S1.2 Forest health under climate change and air pollution

ALESSANDRA DE MARCO[1]

[3] CEAM

Abstract: Surface ozone (O3) is a threat to forests by decreasing photosynthesis and, consequently, influencing the strength of land carbon sink and the forest productivity. However, due to the lack of continuous surface O3 measurements, observational-based assessments of O3 impacts on forests are largely missing at hemispheric to global scales. Currently, some metrics are used for regulatory purposes by governments or national agencies to protect forests against the negative impacts of ozone: in particular**,** exposure-based metrics, i.e. AOT40, and a new standard POD1, based on ozone uptake by the forests. We analyse here the different air quality standards set or proposed to protect forests from O3 and to evaluate their spatial and temporal consistency while assessing their effectiveness in protecting northern-hemisphere forests. On the basis of the standards, we calculated the expected biomass losses, by the use of appropriated dose-response functions. Then, we compare the results with the information obtained from a complex land surface model (ORCHIDEE). We show how the proposed concentration-based air quality standards substantially overestimate the extension of potential vulnerable regions, predicting that 46% and 61% of the Northern Hemisphere (NH) forested area are at risk of O3 pollution. Conversely, the new proposed standard (POD1) identifies lower extension of vulnerability regions (39.6%). A comparison between expected biomass losses obtained with different standard and ORCHIDEE results were performed. We found in general very low levels of correlation between biomass losses and GPP or biomass losses calculated by ORCHIDEE, but the correlation is dependent by forest type.

OZONE RISK ASSESSMENT IN THE MEDITERRANEAN REGION: PARAMETIZING SOIL MOISTURE LIMITATIONS ON STOMATAL UPTAKE

S1.2 Forest health under climate change and air pollution

[5] Dept. Space, Earth & Environ., Chalmers University of Technology, Gothenburg, Sweden

Abstract: Ozone (O_3) can produce several harmful effects, including defoliation of tree crowns, growth decrease or leaf damage that are more related with the stomatal uptake by plants than with the concentration in ambient air. In the Mediterranean region of Europe, where high O_3 concentrations are frequently recorded, soil moisture act as one of the main limiting factors for O_3 stomatal uptake. In agreement with this, O_3 risk assessment methodologies developed in the framework of the UNECE Air Convention are currently based on the phytotoxic O_3 dose (POD_y). Our objective is to parameterize the stomatal response functions to soil moisture to improve the estimation of POD_y under water-limited conditions, particularly in the Mediterranean region. The EMEP MSC-W Chemical Transport Model is using a general soil moisture index (SMI) parameterization to simulate the impact of soil moisture on POD_y. Measured soil moisture at different sites in Italy and Spain and pre-dawn leaf water potential and gas exchange data from scientific literature and field datasets have been used to develop SMI and soil water potential functions for Mediterranean forest and semi-natural vegetation species.
Comparison of modeled and observed SMI shows that it is a suitable index to reflect seasonal and inter-annual variability in soil moisture, but tends to overestimate soil moisture in dry seasons and sites. In consequence, modelled SMI and the standard parameterization resulted in overestimation of POD_y up to 9% and 38% for Holm oak and annual pastures, respectively, compared with calculations using observed soil moisture and species-specific parametrizations at a field site in Spain. Greater variations in POD_y estimation are found when varying the soil moisture monitoring depth. The soil water potential seems to be more suitable for POD_y calculations at the local scale.

Pest risk survey of Cupressus lusitanica in Rift Valley Ecoregion of Kenya

S1.2 Forest health under climate change and air pollution

Angela Muthama[1]
[1] Kenya Forestry Research Institute

Abstract: Cupressaceae species are a major plantation species in Kenya that were introduced in the early 1900s by British foresters to address timber and wood products shortage in the British protectorate. Among the first species introduced were *Cupressus macrocarpa, Widdringtonia whytei* and *Cupressus torulosa*. The three species have since been abandoned due to pest and disease attack. *Cupressus lusitanica* replaced *C. macrocarpa* which was badly affected by *Monochaetia unicornis* canker which was first reported in the country in 1952. The present study was conducted to identify causes of die-back and death on *C. lusitanica* in the Rift Valley region of Kenya. Fifty six (56) stands of cypress ranging between 3 to 10 hectares (ha) in size were surveyed and disease incidence and severity scored in the dry and wet seasons. The plantations surveyed were also checked for symptoms of insect pest attack. Samples of twigs and seeds of affected trees were collected in sterile khaki packs and preserved in cooler boxes for analysis in the laboratory. No insect pests were recorded in all stands surveyed but disease severity ranged from category 1 (healthy) to 5 (dead). Fungal isolation was carried out using moist chambering and agar methods on 2% malt extract agar (MEA). *Botryosphaeria sp*. 45%, *Pestalotia sp*. 33%, and *Fusarium sp*. 10% were the most commonly isolated fungal species. The identified fungal species were then tested for pathogenicity and developed similar symptoms as those recorded in the field. The fungal species *Botryosphaeria sp.* and *Pestalotia sp*. were re-isolated from the inoculated tree branches. Molecular identification of the fungal species to species level is ongoing. The study identifies a major threat to large scale planting of cypress in the country necessitating selection of resistant varieties of *C. lusitanica* for futuure plantation establishment for timber. Changes in climate have created a major risk of susceptibility to pests and diseases from tree species that were previously thought to be resistant. Continuous monitoring for disease and insect pests attack will identify high risk areas in a timely manner for proactive management and control of tree damage and mortality in plantation forestry.

PESTS AND DISEASES AFFECTING MANGROVE FORESTS: A CASE STUDY OF LAMU AND KILIFI COUNTIES, KENYA

S1.2 Forest health under climate change and air pollution

Jane Njuguna[1]
Simon Nyahe[1], Stanley Nadir[1], Gladys Rutto[1], Angela Muthama[1], Emmanuel Karisa[1]
[1] Kenya Forestry Research Institute (KEFRI), Nairobi, 20412 - 00200, Kenya.

Abstract: Mangroves render numerous socio-economic ecosystem services including poles; timber, fruits, medicine, and breeding zones for aquatic creatures. The role of blue forests in climate change mitigation cannot be underrated as they sequester more carbon compared to terrestrial species and help control erosion and ocean winds. Globally, mangroves health is threatened by both biotic and abiotic factors reducing forest cover hence need for this study. From literature, several pathogens including *Ceriospora rhizophorae, Colletotrichum sp., Pestalotiopsis sp., Polystigma sonneratiae Botrosphaeria ribis* have been reported to attack mangroves with little to no data for Kenya. A pest and disease survey was carried out in Lamu and Kilifi mangrove ecosystems to identify pests and diseases affecting mangroves. The study focused on identification, species specificity, occurrences and severity of infestation and infection. Sediment from affected mangroves sites were also analyzed. The surveyed areas were dominated by *S. alba*, *C. tagal*, *R. mucronata*, *A. marina, B. gymnorhiza*, *L. racemosa*, and *X . moluccensis* in mixed or pure stands. From results; *S. alba* was highly infested by the metabellid larvae moth (*Salagena obsolescens*) and wood boring beetle (*Bottegia rubra)* resulting in massive dieback with severity reaching 90% of sampled population. Snail infestation was more prevalent in *A. marina* and *R. mucronata* and very severe (80%) in dry season. Barnacles, bagworms, and lichen infestation were pronounced in *R. mucronata* and *C. tagal* especially the young sapling and planted seedlings resulting. Incidences of *A. marina* infested by crabs was reported. Sediment quality tests showed high levels of nutrients like phosphorus, nitrogen and heavy metals resulting from soil erosion. In conclusion, most pests and diseases were reported in *R. mucronata*, *A. marina* and *S. alba* and therefore more research on epidemiology to avail critical information on their impacts and management as this is a major emerging problem threatening benefits from blue economy and conservation efforts.

Key words: Mangroves, Pests, Diseases, Management, Kenya

Poor host choice in Leptocyte species could be harnessed for protection of Susceptible Eucalyptus plantations

S1.2 Forest health under climate change and air pollution

Beryn Otieno[1, 2]
Martin Steinbauer[1]
[1] Department of Ecology, Environment and Evolution, La Trobe University, Melbourne, Victoria 3086, Australia
[2] Forest Health Department, Kenya Forestry Research Institute, Kenya

Abstract: The productivity of Eucalyptus species outside Australia is threatened by invasive insects such as the thelytokous parthenogenetic galling wasp *Leptocybe invasa* Fisher & LaSalle (Hymenoptera: Eulophidae). Different species and genotypes of eucalypt have shown variability in galling, apparently providing opportunities for selection and improvement of seedlings available to growers. We hypothesized that females will only select, for oviposition, hosts plants that will best support larval survival according to female preference-larval performance hypothesis. The objective of the study was to quantify variability in preference of the wasp and host plant resistance *E. camaldulensis* (29 genotypes representing 7 subspecies).

We investigated host acceptance for oviposition by female wasps in response to young leaves of 29 genotypes (grown under nursery and field conditions) representative of all seven subspecies of Eucalyptus camaldulensis Dehnh. We also carried out studies on wasp galling incidences and intensities in common garden arboreta comprising all the 29 genotypes and planted in different agro-ecological zones suitable for *E. camaldulensis*. These genotypes were planted in Western and Eastern Kenya and allowed to suffer natural infestation in field conditions.

Females of *Leptocybe invasa* showed no apparent discrimination to any of *E. camaldulensis* genotypes and laid eggs on all of them despite variability in their chemical and physical characteristics that were studied. Larval survival however occurred variably in different genotypes with subspecies *simulata* supporting no gall development while subspecies *minima* supported the highest. This indicates that not all genotype accepted for oviposition by female wasps were good host plants to support larval survival.

These results find application in management of the insect in its invaded regions as several *E. camaldulensis* species can be planted together to reduce damage on the susceptible genotypes. Studies should be carried out in other non- galled *Eucalyptus* species to investigate whether they are readily accepted for oviposition.

Key Words: *Leptocybe invasa*, *Eucalyptus camaldulensis*, genotypes, variability, host preference, host resistance.

Productivity of Chir pine (Pinus roxburghii Sargent.) based silvipasture forest ecosystems in relation to fire incidence in north-western Himalaya

S1.2 Forest health under climate change and air pollution

Jyoti Chaudhary[1]
D.R. Bhardwaj[1]
[1] Dr YS Parmar University of Horticulture and Forestry, Nauni, Solan, Himachal, India

Abstract: Forests play a crucial role in upholding the livelihoods of local people, environmental conservation and ecological stability. Forest fires have emerged as a prominent natural calamity and pose a significant danger to forest ecosystems worldwide, resulting in substantial biodiversity loss and environmental pollution. The primary factor responsible for the occurrence of forest fires in the western Himalayas is the substantial buildup of Chir pine (*Pinus roxburghii*) needles, which possess high combustibility and consequently contribute to the repeated incidents of fires. Consequently, it is imperative to establish appropriate management protocols to achieve optimal productivity and prevent damage to the pine forest ecosystem caused by wildfires. The present study aimed to evaluate the impact of forest fires on the floristic composition, biomass and carbon density, and soil physico-chemical characteristics across different altitudinal ranges (900-1200 m and 1200-1500 m above mean sea level) in four distinct forest fire zones (high, medium, low and non-fire zones. The findings of the study revealed that the non-fire zone had the highest recorded tree density at both altitudes, while the medium-fire zone had the highest density of shrubs. The tree and shrub species' regeneration pattern in fire zones exhibited the greatest success in the high-fire zone, whereas the medium-fire zone recorded the highest grass productivity (2.23 Mg ha^{-1}). The non-fire zone exhibited the highest tree carbon density (84.29 Mg C ha^{-1}) conversely the high-fire zone displayed the highest under-story carbon (2.35 Mg C ha^{-1}). The non-fire zone exhibited the highest recorded density of ecosystem carbon, reaching a maximum of 142.67 Mg C ha^{-1}. There is a notable variation in soil properties in relation to changes in altitude with medium and low-fire zone found to exhibit higher values of soil parameters. The non-fire zone exhibited the highest carbon management index value, reaching a maximum of 223.95. Overall, the study concludes that it is imperative to implement measures aimed at effectively managing fire in order to preserve biodiversity, reduce carbon dioxide emissions, and regulate the provisioning services of chir pine-dominated forest stands located in the north-western Himalayas.

Suitability of Vangueria infausta (Burch) subsp. rotundata (Robyns) and Berchemia discolor (Klotzsch) Hemsl for Dryland Agroforestry in Kenya

S1.2 Forest health under climate change and air pollution

Susan W. Karani[1]
Jane W. Njuguna[1]
[1] Kenya Forestry Research Institute (KEFRI), Nairobi, 20412 - 00200, Kenya

Abstract: Agroforestry systems in the drylands have been promoted as a means of increasing socio-economic and landscape productivity in Kenya. However, experiences show that frequent droughts, fungal and insect attacks continue to limit the productivity and development of these systems in East Africa. This is has been shown by the gradual deaths of many exotic tree species used. Therefore, attempts are being made to screen indigenous tree species for use in the drylands. The aim of this study was to assess the suitability of two tree indigenous tree species; *Vangueria rotundata* and *Berchemia discolor* as alternatives for dryland agroforestry in Kenya. The survey assessed the incidence and severity of canker and dieback disease and isolated fungi affecting *V. rotundata* and *B. discolor* in Tiva and Ikanga sites in Kitui County, and Mukange in Makueni County. Fungi were isolated from infected leaves, branches, and twigs of the two tree species using standard isolation techniques on malt extract agar and identified using both conventional and molecular methods. The CTAB method was used to extract the DNA from the fungal isolates followed by PCR amplification and sequencing of the ITS gene region. The resulting sequences were subjected to a nucleotide BLAST search, and the fungi identified by comparing the sequences with closely related sequences in the NCBI database. Fifteen fungal species belonging to seven fungal families *Botryosphaeriaceae, Sporocadaceae*, *Nectriaceae*, *Trichosphaeriaceae*, *Pleosporaceae*, *Diaporthaceae,* and *Glomerellaceae* were identified. Fungi from the *Botryosphaeriaceae* family were the most dominant. A pathogenicity test conducted using *Alanphillipsia aloeigena*, *Lasiodiplodia lignicola*, and *Dothiorella sp*., *f*ungal species from the *Botryosphaeriaceae* family on *V. rotundata, B. discolor,* and selected native agroforestry tree species viz. *Croton megalocarpus* Hutch and *Tamarindus indica* Lam. and *Olea europeae* L. showed that they were the cause of the canker and dieback symptoms. However, pathogenicity was lowest on *B. discolor f*ollowed by *V. rotundata.* The study concluded that these two species were tolerant to the canker and dieback pathogens and therefore are potential candidates for dryland agroforestry in Eastern Kenya drylands.

Thermal buffering of retention forestry in a changing climate: Status, drivers and future ecological applications

S1.2 Forest health under climate change and air pollution

Shengmin Zhang[1]
Jörgen Sjögren[2], Mari Jönsson[1]
[1] SLU Swedish Species Information Centre, Swedish University of Agricultural Sciences, SE-750 07 Uppsala, Sweden
[2] Department of Wildlife, Fish and Environmental Studies, Swedish University of Agricultural Sciences, Skogsmarksgränd, SE-901 83 Umeå, Sweden

Abstract: Retention forestry is increasingly adopted as an alternative to clearcutting practices and involves retaining structural and compositional complexity (e.g., living and dead trees) from preharvest to postharvest. Past studies have examined the role of retention forestry in supporting various ecosystem functions and biodiversity, whilst its microclimate buffering capacity has been largely neglected. We investigated the microclimates and the underlying mechanisms of retention forests relative to clearcuts and old forests in a boreal forest landscape in central Sweden. We found that both air temperature and vapour pressure deficit (VPD) differed significantly between the forest types. Old forests consistently exhibited the highest macroclimate buffering capacity, followed by retention forests, while clearcuts displayed the lowest capacity. Basal area and canopy cover were identified as the key determinants influencing air temperature and VPD across the forest types. These microclimate differences were further attributed to differences in tree species diversity, standing and lying dead trees. Maintaining diverse tree species indirectly lowered the stand's maximum temperature via its positive effect on the canopy cover, while large volumes of lying dead trees tended to raise the maximum temperature by negatively impacting basal area and canopy cover. In addition, standing dead trees directly lowered the maximum temperature within forest stands. Finally, edge effects were observed in the retention forests, with south-facing edges experiencing significantly higher maximum temperature and VPD compared to north-facing edges and forest interiors, while reducing the lying dead stems in the south-facing edges can mitigate this edge effect. Our findings support the positive influence of retention practices on a stand's microclimate buffering, achieved through preserving diverse tree species, standing dead stems, and implementing measures to prevent wind-induced tree mortality, particularly in south-facing edges. Forest managers and policy makers can utilize these results to minimize the climate-change impacts on below-canopy biodiversity and ecosystem functioning.

Traits underlying differences in resistance between non-induced and induced Norway spruce emblings and seedlings

Abstract: There are various methods to enhance plant resistance and minimize pest damage. In conifers, treatment with methyl jasmonate (MeJA), a stress-signaling plant hormone associated with defence responses, has been found to increase resistance to the pine weevil *Hylobius abietis*, a major forest regeneration pest in Europe. Similarly, studies on Norway spruce (*Picea abies*) plants propagated through somatic embryogenesis (SE), a clonal multiplication process, have also shown increased resistance to the pine weevil when compared to conventional spruce seedlings. In a recent field and lab study examining the combined effects of SE and MeJA, we found that SE-propagated plants (emblings hereafter) treated with MeJA exhibited much greater resistance than plants in each of the separate treatments (SE or MeJA). Remarkably, MeJA-treated emblings experienced an 86% and 48% reduction in damage in the field and lab respectively, and a 98% decrease in mortality in the field, when compared to untreated seedlings. However, the specific mechanisms or traits underlying this response are not known.

Using induced (MeJA and/or mechanical damage) and non-induced 2-year-old Norway spruce, we investigated differences between emblings and seedlings in (1) resin duct number, size and density, and (2) bark terpene chemistry.

Preliminary results indicate that emblings and seedlings indeed exhibit differences, both in resin duct formation as well as terpene chemistry. However, emblings appear to have similar numbers of constitutive resin ducts and a lower number of traumatic resin ducts relative to seedlings. Moreover, emblings tend to have lower concentrations of some terpene compounds relative to seedlings. Further analyses are in progress to uncover other potential differences in resin duct morphology, and pinpoint specific compounds that differ between non-induced and induced emblings and seedlings.

Using satellite imagery to investigate regime shifts in a degraded Miombo woodland in Zambia

S1.2 Forest health under climate change and air pollution

Lori Giagnacovo[1]
Paulo Negri Bernardino[1], Bart Muys[1], Sybryn Maes[1]
[1] Division of Forest, Nature & Landscape, KU Leuven, Belgium

Abstract: The extensive Miombo woodlands in Zambia and neighbouring countries are threatened by exploitation and climate change, despite their importance for millions of people's livelihoods in southern Africa. Severe droughts make fire disturbances more intense and frequent, which aggravates the ongoing woodland degradation. This can lead to a transition towards an alternative stable state when a critical fire disturbance threshold is reached, i.e. a regime shift. Evidence shows that regime shifts can be anticipated by detecting early-warning signals such as critical slowing down (CSD) in the recovery rates of the vegetation to disturbances such as fires. This study provides empirical evidence for a regime shift that occurred in a highly degraded Miombo woodland site in Zambia, i.e. Katanino Forest Reserve. Based on a combination of field data characterizing the vegetation structure and remote sensing NDVI time series, we demonstrate that a major abrupt shift in vegetation greenness occurred in the study area around 2015 after a prolonged period of intense forest degradation. Further, we show that the regime shift was preceded by CSD in vegetation greenness, quantified here as autocorrelation at-lag-1 trends in NDVI time series. Finally, we identify fire frequency as an ecological driver of the detected regime shift across the study area. Our study is one of the first to combine field with remote sensing data to examine CSD over an entire study area. This type of analysis can provide an important method for restoration practitioners to monitor pending regime shifts and identify ecological drivers of such shifts. Practitioners could use this type of information to adapt their planned restoration interventions to the distance to a pending or a past regime shift, which can ultimately improve restoration program outcomes.

Water availability determines heat stress impacts in temperate broadleaved tree species

S1.2 Forest health under climate change and air pollution

Jana Zeppan[1]
Lisa Hülsmann[2], Nadine Rühr[1]
[1] KIT Karlsruhe Institute of Technology, Institute of Meteorology and Climate Research – Atmospheric Environmental Research (IMK-IFU), Germany
[2] University of Bayreuth, Ecosystem Analysis and Simulation, Germany

Abstract: Heat waves and co-occurring droughts are increasing in frequency and magnitude globally. Thus far, our understanding of how common temperate broadleaved trees respond to summer heat and particularly combined heat and drought is limited. Yet broadleaved tree species might become more important for future forest composition in a changing climate. This study explores how three temperate broadleaved tree species *Acer platanoides*, *Quercus robur* and *Fagus sylvatica* respond to increasing temperature under restricted or ample water availability. Using single-tree-chambers, we investigated how leaf temperature, tree carbon and water relations as well as leaf senescence were affected by a step-wise air temperature increase from 25°C to a maximum of 45°C in a well-watered control or drought treatment.

In all species, transpiration increased along air temperature resulting in leaf cooling under well-watered conditions, while leaf temperatures exceeded air temperatures in the drought treatment. With increasing temperatures net assimilation declined while overall root and shoot respiration were maintained. In the drought treatment, respiration already exceeded assimilation at 25°C for *A. platanoides* and *Q. robur*, whereas the control treatments of all species were able to keep a positive net carbon uptake even beyond 40°C air temperature. The negative impact of drought was also visible in higher leaf senescence compared to the control treatment, except for *Q. robur* which did not show signs of leaf damage.

In summary, our findings highlight the critical importance of water availability during heat stress to mitigate high tissue temperatures and sustain a positive net carbon uptake.

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Adapting choice of species and seed origin to enhance and preserve European forest carbon sink

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Debojyoti Chakraborty[1]
Silvio Schueler[1]
[1] Austrian Research Centre for Forests (BFW)

Abstract: The role of European forests as carbon sinks is increasingly endangered by climate change-induced droughts and disturbance events. On the policy level, European Union has an ambitious plan to increase the terrestrial carbon sink and achieve net zero emissions by 2050. Adaptive management strategies such as choice of species and planting materials are therefore crucial for maintaining forest carbon sinks and increasing forest resilience. Assisted migration (AM) of forest tree species and populations was suggested to avoid maladaptation and to maintain forest growth under future climate. We identified AM schemes for seven major European tree species based on 587 range-wide provenance trials, evaluating more than 3000 provenances. Using models that account for environmental and genetic factors of phenotypic trait variations, we estimated the annual aboveground carbon sink (CS) of 40-year-old trees under current and projected future climate by adapting species composition and seed sources.

To increase forest resilience under climate change, coniferous trees might need to be replaced by deciduous trees in large parts of their distribution, with significant consequences for ecosystem services and biodiversity. If local seed provenances are employed, this change will result in a decrease of the current CS of 44 $Tgyr^{-1}$ by 32-43% until 2061-80. However, if seed provenances adapted to the future climate are utilized, current CS can be maintained or even increased to 46-55 $Tgyr^{-1}$. Transnational AM can boost both resilience and the CS of European forests

Assessing soil carbon and nitrogen cycles three years after a large wildfire in Scots pine forest

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

[8] Federal Institute for Geosciences and Natural Resources, Germany

Abstract: In 2018, Sweden faced one of the most extreme wildfire seasons in modern history, highly impacting parts of the boreal forest ecosystem. Carbon (C) and nitrogen (N) plays a crucial role in the functioning and productivity of boreal forests. During a wildfire, the soil nutrients and organisms may be lost because of the reduction in the soil organic layer, impeding the fitness of the surviving or regenerating vegetation. With projected alterations in boreal forest fire regimes due to climate warming, there is a urgent need to identify sustainable post-fire management strategies.

We investigated the impact of wildfire and post-fire forest management in the C and N cycles in a Scots pine forest in central Sweden. In the summer of 2021, three years after the wildfire, we measured soil respiration and gross N mineralization, nitrification and NO_3^- and NH_4^+ consumption rates, using the ^{15}N-pool dilution technique by injecting ^{15}N labels in the soil *in situ*. We anticipated that the forest floor in high fire severity stands, where a significant portion of the soil organic layer is consumed, experience the most pronounced adverse impact compared to low fire severity and unburnt soil. In low fire severity soils, where the soil organic layer remains, fire may reduce the soil C to N ratio. This encourages gross N mineralization as N is in excess and therefore we expected enhanced gross N mineralization rate in low fire severity soil as compared to high and unburnt soil. Further, we expected that soil organisms stand a better chance of re-establishing soil processes in an unlogged forest compared to a salvage-logged forest, in low fire severity stands where the trees survived the fire. In this contribution we will present the outcomes of our measurements and discuss their implications for how post-wildfire severity following salvage logging impact the soil C and N cycles. The reduced production of plant available inorganic nitrogen, combined with the loss of the soil organic layer, could have significant long-term implications for the sustainability of boreal forests. Therefore, our objective is to provide informative insights that can facilitate the development of sustainable forest management practices.

Assessment and monitoring of carbon stocks at two degraded and semi-degraded wild pear stands in the Zagros forests, Iran

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Sayed Kazem Bordbar[1, 2]

[4] Paris-Saclay Université

Abstract: Zagros forests are among the natural ecosystems of Iran, which, due to their vast extent, play an important role in the carbon cycle, therefore, determining the carbon stock and monitoring its changes can play an important role in management planning. This research was conducted in two sample plots (100 × 100 meters) located in Fars Province, Iran. In order to estimate the above-ground carbon stock, the quantitative characteristics of all the trees in the sample plots were counted. Also, in each sample plot, five soil samples were taken regularly from a depth of 0-30 cm and the content of carbon, nitrogen, phosphorus, moisture, microbial respiration, apparent specific gravity, and percentage of soil gravel were measured along 4 years. First of all, our data indicated that human and livestock grazing extensively have shifted tree community from Pyrus stand to Crataegus stand. The above-ground biomass of trees in the semi-degraded and degraded plots was calculated as 8.21 and 15.85 tons per hectare, respectively. Also, the amount of carbon stored on the ground in degraded and semi-dagraded plots was 8.26 and 4.22 tons per hectare, respectively. The comparison of soil carbon stock between the sample plots of semi-degraded and the degraded showed that the average soil organic carbon stock in the semi-degraded plot is 164.2 and in the degraded plot is 75.2 tons per hectare. Our finding exposed that forest degradation extensively impact on forest ecosystem services. In this regard, plant diversity and soil carbon stock profoundly has been declined by the forest degradation actions.

Availability of soil nitrogen determines CO2 fertilization effect on urban forestry species-Physio-biochemical response of Neolamarckia cadamba

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Manish Singh[1, 2]
[1] Manish Singh
[2] Dr Hukum Singh

Abstract: Climate change is not a say of tomorrow but today's reality and to meet carbon neutrality targets of Sustainable development goals through forestry systems, the study of urban forestry species is important to mitigate climate change. Enhanced CO_2 and nutrient-deficient soils are major stress that hamper the biochemical traits of urban forestry species, including climate adaption and potential. This study suggests whether nutrient availability (nitrogen) improves CO_2 fertilization effects and biochemical response of urban forestry tree species (*Neolamarckia cadamba*). The plants were grown in nitrogen regimes (Low - N_{200} Kg N ha^{-1}, medium - N_{300} Kg N ha^{-1}, and high - N_{500} Kg N ha^{-1}) within enhanced CO_2 concentration (800±20 µmol mol^{-1}). Elevated CO_2 levels were found to increase plant biomass and alter plant nitrogen metabolism, leading to changes in the production of secondary metabolites, antioxidants, physiological and biochemical responses. The foliar transpiration, protein content, chlorophyll, gross primary productivity (GPP), night plant respiration (NPR), net primary productivity (NPP), net ecosystem exchange (NEE) were enhanced by 39%, 43%, 36%, 17%, 65%, 99%, 96% respectively under high nitrogen availability in CO_2 fertilization conditions whereas declined malondialdehyde content by 36% under high nitrogen availability and CO_2-enriched environment compared to counterparts. We reported that biochemical traits were significantly improved under enhanced CO_2 concentration and applied nitrogen compared to ambient CO_2 concentration and low soil nitrogen availability. It was reported in my study that how nitrogen interventions improve the gross primary productivity, net ecosystem exchange and water use efficiency of the *Neolamarckia cadamba* that is crucial and important for deciding the mitigation potential of the species We inferred that nutrient (nitrogen) management practices would improve the benefits of rising atmospheric CO_2 concentration, which enhances physio-biochemical response (CO_2 fertilization effect) of urban forestry species. To meet carbon neutrality targets of Sustainable development goals through forestry systems, Kadam can act as wonder agroforestry species as its carbon exchange mechanisms increase with nitrogen interventions.

Can fertilization of forest accelerate adaption to a warmer climate?

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Karolina Pehrson[1]
Anna Jensen[1]
[1] Linnaeus University, Forestry and Wood Technology, Sweden

Abstract: Today's changing climate with rising temperatures and differences in precipitation is forcing the forest to adapt faster than a normal evolutionary process. A common suggestion to forest owners is changing the composition of species in the forest. This method is relative complicated and time consuming. Instead, we want to test an alternative method that would be easier to imply – this fertilization. We hypothesize that fertilization can improve the individual trees' capacity to acclimate their photosynthetic apparatus to changing temperatures.

In this project we compare two forest areas, one in southern parts of Sweden and the other in northern parts, giving us two populations with relative different climate and conditions. Within these areas we have both fertilized and unfertilized trees of several species. Fertilization is often thought of as a tool mainly for increasing forests' productivity. However, we believe nitrogen could also contribute to an acclimation to a warmer climate through physiological adaptations within the tree. If possible, we will also include habitats that vary in access for water, this would include a possible effect of abiotic stress and the efficiency of taking up fertilizers combined with access to water. In all we are hoping to get a greater understanding of nitrogen's role in the acclimation of the photosynthesis apparatus.

If our hypothesis is supported by the data, this would be an important mechanism through which fertilization can improve forests' ability to bind CO_2. This in turn could have wide-ranging consequences for society's ability to use forests as a carbon sink.

Carbon Budget Modelling to Predict Carbon Stocks in Temperate Forests: a case study over Canadian forests

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Brigitte Leblon[1]
Jason Heffner[2], James Steenberg[3]
[1] Faculty of Natural Resources Management, Lakehead University, Canada
[2] Faculty of Environment and Natural Resources, Albert-Ludwigs University of Freiburg, Germany
[3] Forestry Division, Nova Scotia Department of Natural Resources and Renewables, Canada

Abstract: In response to the global climate crisis, several provinces in Canada are testing the Carbon Budget Model of the Canadian Forest Sector (CBM-CFS3) and associated methodologies to assess the carbon dynamics of their forestry sector. The CBM-CFS3 bases simulations on a range of studies and national forest inventory plots to predict carbon dynamics using merchantable volume yield curves. The provinces maintain permanent forest sample plots (PSPs), that allow the development of empirical province-specific carbon models with allometric equations. This study compares forest carbon stocks predicted with the empirical and CBM-CFS3 models in the case of various forest types in Nova Scotia. The empirical models were stratified into five forest types and predicted the carbon for seven carbon pools as a function of the plot age. Predictions with the empirical and CBM-CFS3 models were assessed against observed PSP data at the plot level and compared against each other at the stand and landscape levels. At the plot level, the empirical models predicted carbon closer to the observed data than the CBM-CFS3 model, with the extent of over- or under-estimation depending on the carbon pool and forest type. At the stand scale, the CBM-CFS3 model predicted forest carbon to be within 3.1%–17.6% of the empirical model on average. Differences in predictions between the CBM-CFS3 and empirical models decreased to within 2.4% of the empirical models at the landscape level. Thus, the implications of using one method over the other decrease as the prediction scale increases from stand to landscape level, and the implications fluctuate as a function of the forest type and age.

Carbon density, Nutrient storage and Microbial characteristics of forest ecosystems in mid hill conditions of north-western Himalayan

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

L.C. Langlentombi[1]
D.R. Bhardwaj[2]
[1] ICAR Complex for NEH Region, Manipur centre, Lamphelpat Imphal, Manipur, India
[2] Dr YS Parmar University of Horticulture and Forestry, Nauni, Solan, Himachal, India

Abstract: Environmental degradation and climate change are significant problems of the 21st century to be addressed for the survival of the human race. Forests are one of the most important solutions to addressing the effects of climate change as approximately 2.6 billion tonnes of carbon dioxide, one-third of the CO_2 released from burning fossil fuels, is absorbed by forests every year. The present study evaluated the potential of 16 forest ecosystems for their carbon storage, nutrient status and soil microbial properties in the mid-hills of north-western Himalaya. The results revealed that maximum vegetation and ecosystem carbon density was recorded in Lower Western Himalayan Ban-Oak Forest with values of 228.26 Mg C ha^{-1} and 382.07 Mg C ha^{-1}, respectively. Shiwalik chir pine forest had the highest nitrogen concentration (13226.33 kg ha^{-1}). Lower Western Himalayan Ban-Oak had the highest phosphorus concentration (2989.19 kg ha^{-1}). The highest potassium concentration (5335.87 kg ha^{-1}) was found in the Leucaena leucocephala plantation. Lower Western Himalayan Ban-Oak had the highest calcium content (37499 kg ha^{-1}). Soil organic carbon (2.35%), available nitrogen (519.44 kg ha^{-1}), available potassium (575.01 kg ha^{-1}) and exchangeable calcium were highest in the northern dry mixed deciduous forest (1683.82 mg kg^{-1}). Whereas Lower Western Himalayan Ban-Oak had the most increased available phosphorus (23.31 kg ha^{-1}) and CEC (17.38 mg kg^{-1}) and Natural grasslands had the highest exchangeable magnesium (934.68 mg kg^{-1}). The highest bulk density (1.49 g cm^{-3}) and soil pH (7.17) was found in Natural grasslands. The maximum soil EC (0.22 dsm^{-1}) was recorded under Dry bamboo brakes. Lower Western Himalayan Ban-Oak showed a significantly faster rate of surface litter decomposition in comparison with other forest ecosystems. Northern dry mixed deciduous forest had the highest soil microbial activity (0.26 CO_2 evolution g^{-1} soil), microbial biomass (1094.49 µg g^{-1} soil) and bacterial count (195.21 x105 cfc g^{-1} soil). This study concluded that the Lower Western Himalayan Ban-Oak Forest has greater potential for carbon storage and nutrient replenishment rate and needs to be conserved and promoted for arresting environmental degradation and climate change.

Carbon fluxes of a natural Mediterranean Aleppo pine ecosystem using eddy covariance and soil respiration measurements

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Nikos Markos[1]
Giorgos Xanthopoulos[2], Kalliopi Radolgou[2], Christoforos Pappas[3], Gavriil Spyroglou[1], Mariangela Fotelli[1]

[3] Department of Civil Engineering, University of Patras, Rio, 26504, Patra, Greece

Abstract: The accurate estimation of ecosystem carbon and water fluxes is critical for the assessment of the biogeochemical cycles at the local, regional, and global scale and for understanding their response to the ongoing climate change. The eddy covariance technique is a useful tool for providing high-frequency and long-term measurements of ecosystem level carbon, water, and energy fluxes. However, while temperate and boreal forests are quite well-studied, less information is available for arid and semi-arid areas, such as those at eastern Mediterranean basin. Aleppo pine (*Pinus halepensis* L.) is widely spread in the Mediterranean region and Greece represents the eastern European limit of the species' natural distribution. Aleppo pine is well-adapted to the xerothermic conditions of the region, however, to date there is limited knowledge on the land – atmosphere interactions of natural Aleppo pine forests.

In this study, a monitoring site has been established in a natural, coastal Aleppo pine forest in Chalkidiki, Greece, which belongs to the national and European Long-Term Ecological Research network (LTER) and is protected by NATURA 2000. The site is equipped with an eddy flux tower and a full meteorological station that performs continuous eddy covariance and meteorological observations (air and soil temperature, precipitation, vapour pressure deficit, solar radiation, soil moisture and temperature). Moreover, soil respiration continuous measurements are performed with a close-path soil CO_2 analyzer. Finally, seasonal phenological dynamics are quantified with vegetation indices from satellite remote sensing.

The aims of this study, which is carried out within the ECOCARBON project, are to (1) present the annual pattern of ecosystem primary productivity and evapotranspiration at the study site, (2) assess the main environmental drivers and their contribution to carbon and water fluxes and (3) assess the most representative vegetation indices for the ecosystem's fluxes and phenological phases.

Carbon sequestration potential of eight economically important tree species in Northeast China under climate change

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

[2] University of Alberta, Department of Renewable Resources
[3] Chinese Academy of Forestry, Research Institute of Forestry Policy and Information
[4] University of Freiburg, Chair of Forest Growth and Dendroecology

Abstract: The carbon sequestration potential of forest ecosystems is expected to play a crucial role in mitigating global warming, depending on how climate change will affect tree growth under various local environmental conditions. Here, we investigated the climatic limiting factors for forest tree growth and future carbon sequestration potential for eight economically important forest tree species in Zhongtiao Mountains of Shanxi Province in China. Specifically, we test if moisture limitations compromise annual radial increments (ARI) and a carbon sequestration index (IC), based on tree-rings and wood density. A bootstrapped response function analysis of historical detrended ARIs, reveals statistically significant moisture limitations in two or more summer months for half of the species investigated. Using a custom heat:moisture index based on these seasonal growth limitations, we predict IC under multi-model CMIP6 climate change projections for the region. Under moderate future climate scenarios for the period 2041-2070, the carbon sequestration potential for most species is likely to increase significantly. This is because under current climate only some species experience moisture limitations, and a projected increase in seasonal precipitation mitigates these growth limitations. We conclude that model projections are favorable for carbon sequestration and future commercial forestry potential in the Zhongtiao Mountain forestry region.

Carbon stock estimation in halophytic wooded savannas of Uruguay: an ecosystem approach.

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Andrés Baietto[1]
Andrés Hirigoyen[2], Carolina Toranza[1], Franco Schinato[1], Maximiliano González[3], Rafael Navarro Cerrillo[4]

[2] National Research Program of Forest Production, National Agriculture Research Institute, INIA, Tacuarembó, Uruguay.
[3] Soil and Water Department, Faculty of Agronomy, University of the Republic, Montevideo, Uruguay.
[4] University of Cordoba, Department of Forestry Engineering, Laboratory of Silviculture, Dendrochronology and Climate Change, Campus de Rabanales, Crta. IV, km 396, Córdoba, Spain.

Abstract: Savannas constitute a combination of tree and shrub patches with an herbaceous understory. This biome contributes significantly to the soil organic carbon (SOC) and above-ground biomass (AGB) carbon (C) stock globally. In Uruguay, subtropical wooded savannas cover 100,000 ha approximately, of which 28% is restricted to sodic soils. However, there are few studies about the contribution of each ecosystem component to the C stock and the development of site-specific allometric equations. In this sense, the objectives of this study were: *(i)* fit allometric equations for the AGB of the most frequent tree species and *(ii)* quantify the contribution of each component (soil, trees, shrubs, and herbaceous plants) to the ecosystem C stock. The study area corresponded to 5 ha of subtropical halophytic wooded savannas on typic natraqualfs from the protected area "Esteros y Algarrobales del Río Uruguay". Five plots (20 x 20 m) were randomly installed, measuring the basal diameter (BD), diameter at breast height (DBH), and total height (H) of each tree. At each plot, a soil sampling was performed to estimate the SOC stock up to the B_{tn} horizon (57 cm depth). Then, a semi-destructive biomass estimation was carried out, considering 30 individuals of *Neltuma affinis* and 23 of *Vachellia caven*, the most frequent tree species. For shrubs and herbaceous plants, a destructive sampling was applied, arranging 15 (2 x 2 m) and 30 (0.2 x 0.4 m) sub-plots randomly inside the main plots for each component, respectively. For *Neltuma affinis* the fitted equation was: AGB (kg tree^{-1}) = exp [− 1.282 + 0.402 × BD − 0.006 × BD^2]; R^2*-adj* = 0.97; *RMSE* = 9.92. For *Vachellia caven* the adjusted model was: AGB (kg tree^{-1}) = BD^2 × [0 .041 + 0.002 × BD × H]; R^2*-adj* = 0.98; *RMSE* = 5.31. The ecosystem C stock reached 116.71 ± 11.07 Mg ha^{-1}, of which 90.7% was contained in the soil, 8.3% in the trees, 0.8% in the herbaceous plants, and 0.2% in the shrubs. These results highlight the value of subtropical halophytic wooded savannas as C sinks and their importance in the mitigation of global warming under a climate change scenario.

Carbon stocks and fluxes of a natural Mediterranean Aleppo pine ecosystem

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Giorgos Xanthopoulos[1]
Kalliopi Radoglou[1], Gavriil Spyroglou[2], Christoforos Pappas[3], **Mariangela Fotelli**[2]
[1] Department of Forestry and Management of Environment and Natural Resources, Democritus University of Thrace, N. Orestiada, Greece

[3] Department of Civil Engineering, University of Patras, Rio, 26504, Patra, Greece

Abstract: Climate change challenges forest ecosystems worldwide with increasing cases of forest degradation and loss of biodiversity. While the atmospheric CO_2 increases, forests play a crucial role in mitigating climate change by acting as carbon sinks, absorbing and storing carbon dioxide as biomass. Mediterranean forests are particularly vulnerable to climate change, setting, thus, as high priority to understand and quantify the carbon stocks and fluxes in such ecosystems. This study is carried out within the project ECOCARBON, at a natural, near-coastal Aleppo pine ecosystem in Chalkidiki, Greece which is part of the national and European Long-Term Ecological Research network (LTER) as well as the NATURA 2000 network of protected areas. Our goal is to estimate the carbon stocks (above-, and below-ground biomass of both the tree overstorey and the shrub understorey, forest floor, deadwood, soil organic carbon) and fluxes (litterfall and fine root production and turnover) of the ecosystem during one year. Moreover, the carbon dioxide equivalents sequestered by the studied ecosystem will be calculated in order to determine its contribution to the carbon footprint of the region. In the study area, 15 sampling plots of 0.1 ha area each have been established, taking into account their spatial distribution, as well as tree and understorey density, for the estimation of all carbon stocks and fluxes. The mean diameter at breast height of the Aleppo pine stands in this region is 34.70 cm, and the tree age ranges from 30 to 110 years. Currently, information on the carbon sequestration of natural ecosystems, particularly taking into account the carbon storage in the understorey shrub layer, is scarce in Greece. Here we present the methodology and the estimates of carbon stocks and fluxes in all forest components and we discuss the effect of driving mechanisms, such as seasonal climatic variability, tree age and stand density on the ecosystem's carbon sequestration potential.

Changes in soil organic carbon following afforestation of former cropland: two repeated samplings of oak and Norway spruce chronosequences

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Ming Yu[1]
Carsten W. Müller[1], Benedicte Monica Bennike Lütken[1], Lars Vesterdal[1]
[1] Department of Geosciences and Natural Resource Management, University of Copenhagen, Denmark

Abstract: Afforestation of former cropland has the potential to sequester atmospheric CO_2, but the contribution of soils and the specific effects of tree species and time since afforestation on soil organic carbon (SOC) dynamics remains uncertain. Consequently, long-term experimental platforms and continuous monitoring of SOC dynamics are needed to explore the specific sink strength of soils after afforestation. The chronosequence approach has been widely used for the assessment of temporal changes in new forest ecosystems after land-use change by the space-for-time substitution, but a combination with repeated sampling provides the potential to make up for the shortcomings of the chronosequence approach, which may be restricted by confounding site-related factors.

During more than two decades, a unique combined chronosequence and resampling study of oak and Norway spruce stands have been conducted in former cropland in Denmark with the aim of estimating the effects of afforestation on soil C sequestration. The results from previous studies indicated that afforestation of former cropland within the temperate region may induce soil C loss during the first decades followed by a recovery phase of yet unknown duration.

The previous studies studied only bulk SOC but the sequestration mechanisms require studies of the specific pools of SOC, as characterized by e.g. physical fractionation, and the origin and chemistry of the soil organic matter (SOM). Hence, fractionation of the bulk soil to characterize particulate- and mineral-associated organic matter and tracing the plant- and microbial-derived SOM by biomarkers is now introduced to understand the plant–soil-microbial interaction behind SOC dynamics following afforestation. Based on the third sampling and comparison of three chronosequence trajectories, this presentation will address (1) the changes in SOC stocks and the rate of C sequestration after >50 years of afforestation, (2) the difference in SOC stocks and C sequestration rate between two tree species in forest floors and mineral soil, (3) the mechanisms and stability of SOC to discuss the long-term SOC dynamics affected by afforestation.

Changes in the forest carbon dynamics of the North American deciduous forest can be expected in the future with the arrival of Asian jumping worms

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Obed Asamoah[1]
[1] Université du Québec en Outaouais/ Isfort - Institut des Sciences de la Forêt tempérée (ISFORT)

Abstract: The invasion of Asian jumping worms (Amynthas spp.) in the deciduous forests of Northeastern North America has raised concerns regarding the potential alterations in forest carbon dynamics. This study aims to assess the future impact of Asian jumping worms on forest carbon dynamics. Through a comprehensive review of existing literature, I synthesised available information concerning the effects of Asian jumping worms on litter decomposition, soil respiration, nutrient cycling, and vegetation dynamics, which collectively influence the forest carbon dynamics of the Northeastern North American forest. The review adhered to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines to extract studies and data that directly and indirectly reported the effects of Asian jumping worms on forest carbon dynamics in the deciduous forests of Northeastern North America. The findings of our study indicate that Asian jumping worms can expedite litter decomposition, leading to increased nutrient mineralisation and alterations in physical soil properties. Consequently, this may result in elevated soil respiration rates and a reduction in the potential for carbon sequestration within the forest ecosystem. Furthermore, changes in vegetation composition and nutrient availability, attributable to the activity of Asian jumping worms, may impact aboveground carbon stocks. However, the precise level, consequence, and direction of these effects require further clarification, as they are likely to vary depending on worm density, infestation duration, and environmental conditions. To gain a comprehensive understanding of the specific impacts of Asian jumping worms on forest carbon dynamics, future studies should emphasise long-term monitoring to evaluate the spread of these worms and their adaptive mechanisms in response to the environment. It is crucial to comprehend the potential changes in forest carbon dynamics associated with the invasion of Asian jumping worms in order to develop effective management strategies. The integrity and functionality of Northeastern North American deciduous forests are of utmost importance in the face of this invasive species.

Changing quantity and sources of plant litter inputs for 5 years alters CO2 efflux and carbon stocks in the organic layer but not in the mineral soil

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Fidèle Bognounou[1], **David Paré**[1]
[1] Natural Resources Canada, Canadian Forest Service, Québec, QC, Canada

Abstract: Despite critical roles played by soil organic matter (SOM) including C sequestration, nutrient provision and moisture retention, SOM dynamics in forests are poorly understood. A litter manipulation experiment was established in 2016 in a white pine (*Pinus strobus*) plantation near Québec City, Canada, to monitor the long-term impact of changing quantity and sources of plant litter inputs on soil C. Treatments include double litter (DL), no litter (NL), no roots (NR), no input (NI) and control (CO), consistent with the standard treatments of the Detrital Input and Removal Treatments (DIRT) network, as well as specific treatments consisting in double wood (DW), wood ash (WA) and nitrogen fertilizer (NF) addition.

Continuous monitoring of soil CO2 efflux revealed higher C losses for the double input treatments (DL, DW) and WA, whereas lower ones were observed for all exclusion treatments (NL, NR and NI), relative to the control. While no significant changes were found in mineral soil C after 5 years of litter manipulation, important C stock changes were observed in the organic layer with lowest values for all litter exclusion treatments. Results on soil water, eDNA, soil physical fractions and stable isotopes are also presented and discussed.

These results show that despite dramatic changes in C fluxes, in and out of the soil system, changes in mineral soil C are difficult to observe and highlight that the processes responsible for accumulation and (de)stabilisation of C are slow, especially in these forests of the hemiboreal zone. Collectively, results from this study and from other sites of the DIRT network reveal that alteration of forest productivity and associated litter inputs due to climate change, forest management, or other disturbances will not likely result in soil carbon stabilization or destabilization in the short term.

Chemical composition and stability of soil organic matter density fractions under forest type change

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: Changes in the temperate forest species composition are expected under global change. At the same time, forest soil carbon sequestration is studied as a potential tool of climate change mitigation. Thus, we need to know how the expected change in species composition will affect soil carbon storage. It has already been shown that coniferous litter is of lower quality and higher stability and is preferentially stored in more vulnerable organic horizons. However, we lack information on the effect of forest type on the stability of soil organic carbon in mineral horizons. Here, we focus on the chemical composition and stability of the density fractions of soil organic matter in the mineral horizon under deciduous and coniferous forests. We expect contrasting qualities in light fractions under the two types of forest, but not in mineral-associated organic matter that is highly microbially transformed.

Climate change, megafires and the fate of Australia's Eucalyptus forests

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Chris Weston[1]
Liubov Volkova[1]
[1] School of Agriculture, Food and Ecosystem Sciences, The University of Melbourne, Creswick 3363, Victoria, Australia

Abstract: Multiple fires of more than 1 M hectare have burned through the forests of south-eastern Australia over the last 4 decades, impacting over 12 M ha of *Eucalyptus* forest. Within these forests the obligate-seeder eucalypts usually regenerate from seed following high intensity fire that kills the seed-bearing trees, while resprouter eucalypts regenerate to varying degrees from the existing stems depending on the intensity of fire. In fire-killed forests seeds released from the canopy usually regenerate profusely with high seedling densities followed by competition-induced thinning and mortality. Over the last 160 years, large bushfires in obligate seeder type forests have usually started in January or February at the height of the summer. With warming climate fires are trending to start earlier in summer, prior to the full maturation of seeds, potentially impacting regeneration success. The more frequent weather extremes seem to be reducing fire intervals to less than 20 to 40 years – and this may limit the seed source for recovery of obligate seeder forests following future fires, and the structure of forests may be altered through fire-induced increases in mortality. This presentation discusses the potential for climate change to increase fire, stimulate forest mortality, alter forest structure and reduce the carbon carrying capacity of *Eucalyptus* forests. The results of field studies of the recovery trajectory of these forests over the last 4 decades are drawn on to explore active forest management actions, including thinning, planned burning and invasive weed control, to increase forest resilience to climate change and the risk of severe fires in the future, and to either build, maintain or limit declines in forest carbon stock.

Context matters: window of opportunity for forest managers to optimize soil carbon stability

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

[4] University of Copenhagen

Abstract: Despite the general agreement that maximizing carbon storage and its persistence in forest soils are top priorities in the context of climate change mitigation, our knowledge on how to steer soil organic carbon through forest management remains limited. For some soils, tree species selection based on litter quality has been shown a powerful measure to boost SOC stocks and stability, whereas on other locations similar efforts result in insignificant or even opposite effects. A better understanding of which mechanisms underpin such context-dependency is needed in order to focus and prioritize management efforts for carbon sequestration. In many temperate forests, soil pH is low and acid buffering mechanisms play a key role in belowground ecosystem functioning. These non-linear mechanisms result in threshold behavior in soil pH, which considerably mediates tree species effects on carbon cycling. The threshold between the exchange buffer and the aluminum buffer around a pH-H2O of 4.5 is of particular relevance for temperate forests. When a shift between these buffer domains occurs, it triggers changes in multiple compartments in the soil, ultimately altering the way carbon is incorporated and transformed. Moreover, the impact of such a shift can be amplified by feedback loops between tree species, soil biota and edaphic conditions. Hence, taking into account context-dependencies related to soil acidity will allow developing more efficient, context-explicit management strategies to optimize SOC stocks and their stability.

Correlation between soil variables in the Humid Forest of the Eastern Region, Paraguay.

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Alejandra Mendoza Rober[1]
Lila Mabel Gamarra Ruiz Diaz[1], Lidia Florencia Perez de Molas[1], Maria Laura Quevedo Fernández[1]
[1] Universidad Nacional de Asunción

Abstract: The physical and chemical properties of the soil are related to the water and nutrient quality and availability for plants, allowing for proper root development and ensuring optimal growth. The aim of this research was to determine if there is a correlation between the soil chemical parameter: organic material, and the physical parameters: sand, clay, silt, as well as organic carbon in the humid forest stratum of the Eastern region (BHRO) in Paraguay. The data were collected in 2015 as part of the national forest inventory. Twenty plots were sampled, and soil samples were collected using a 100 cc cylinder at the following depths: A (0-5 cm), B (25-30 cm), and C (45-50 cm). Soil sample analysis was conducted at the Laboratory of "Compañía Tecnológica de Comercio y Servicios Agropecuarios" TECSA S.A. Pearson correlation analysis was performed between the soil variables and principal component analysis (PCA) for all sampled plots at the three depths (A, B, C). The depth with the highest correlation in the analysis (>30%) was chosen (HENDERSON, 2003). Depth A showed the highest correlation, therefore the other depths were excluded. A weak positive correlation was observed between silt and clay and organic matter in the BHRO, indicating that the presence of these soil variables does not contribute to the increase or decrease of the sampled organic matter. The variables that showed a strong negative correlation were sand and clay, indicating their contrasting physical or chemical characteristics. Organic carbon showed a strong positive correlation with organic matter, indicating that the presence of one contributes to the presence of the other. Understanding the physical and chemical properties of the soil and their interrelationships could positively influence the selection and implementation of any forest activity that may affect its productivity.

Diminishing legacy effects from forest fertilization on stand structure, vegetation community, and soil function.

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: Fertilization with N is a cost-effective way of increasing forest biomass yield and increasing timber harvest profitability, while the impacts on the ecosystem are usually assumed to disappear within 10 years of application. To clarify if legacy effects are longer-lasting, we analysed 21 Pinus *sylvesteris* and *Picea abies* stands. The stands, 25 years old at the time of this study, were fertilized with 150 kg N ha^{-1} once or twice during the previous stand rotation, or unfertilized. We preformed follow-up measurements on soil N mineralisation and N availability, forest growth, ground vegetation community composition, soil and vegetation C/N ratios and soil C stocks, many of which were shown to be responsive to legacy N fertilization earlier in stand development. Our results show that all the significant effects present in the previous measurement period (over a decade ago), were weaker or completely absent in the current study (i.e. 25 years after initiation of the new stand). These results indicate that legacy effects of fertilization during the previous stand rotation diminished through time, indicating an eventual convergence of stand properties between fertilized and unfertilized stands. Given that convergence does not appear to occur until c. 25 years into the subsequent stand rotation and c. 40 years following N fertilization, it suggests that care should be taken to mitigate unwanted, long-term effects when utilizing N addition to promote tree growth in boreal forest.

Disentangling the effects of tree species communities on litter decomposition in forests of the northern hemisphere, using standardized litter

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: Litter decomposition is a key ecosystem function in forests. Through its impact on carbon, nutrient and water cycles it regulates nutrient availability and the carbon budget in forests. The major factors influencing decomposition are well documented on regional and global scales, but this is less so at the local scale. Under similar conditions of macroclimate, topography and soil, litter decomposition under forests is expected to depend mainly on tree species composition, this through the direct effects of litter quality and indirect effects of the tree canopy. The tree canopy shapes the local decomposition environment by the accumulation of organic matter and the regulation of the local microclimate.

The scope of this project is to disentangle these direct and indirect effect on litter decomposition at a local scale. Therefore, a unique experimental setup was conducted in the geographical arboretum of Tervuren, Belgium. Here, patches of tree species from temperate and boreal regions were planted in a common garden. By selecting similar (initial) site condition and stands that are at least 40 years old, we assume that the trees had sufficient time to "shape" their environment. This research can therefore focus specifically on tree species composition and their direct and indirect impacts.

We analyzed the decomposition rates for two types of standardized litter substitutes: green tea (high quality litter) and rooibos tea (low-quality litter). We incubated 1440 teabags at two depths for a 3-month period under all 120 selected stands. At the same time, we characterized the local stand composition, decomposition environment and corresponding litterfall. We hypothesized that the decomposition of low-quality rooibos would mainly be driven by tree identity (matrix quality) while high-quality green tea would mainly be influenced by stand structure (microclimate). First results suggest that different (interacting) mechanisms are controlling the decomposition rates of the corresponding litter quality (high/low) and placement (forest floor/upper soil).

Through highlighting these specific tree species effects on decomposition, we can increase our knowledge on mixing tree species with different traits and origins, and their potential carbon storage in forest soils.

Disentangling the impact of nitrogen availability on forest soil organic matter dynamics – Modelling the interplay of microbial and plant responses

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: Nitrogen (N) enrichment (e.g., via N deposition) is a major global change factor that strongly influences forest soils. Recent meta-analyses have shown that N addition positively impacts total soil organic carbon (SOC) stock, scaling positively with increasing dose and duration. Past experiments also showed that excess N directly affects microbial activity and SOC decomposition more strongly than plant litter production. This contradicts the assumptions on the role of N in most soil biogeochemistry models.

Furthermore, the composition of SOC depends on N availability, as N does not act on bulk SOC uniformly. Rather, excess N tends to suppress the decomposition of recalcitrant SOC pools such as lignin-rich materials and protein-rich, low C:N organic matter, whereas it speeds up the decomposition of labile organic matter, owing to changing enzyme activities, microbial biomass, and community composition. However, a coherent mechanism to explain this divergent response of different C pools to N is still lacking and needs to be incorporated into soil models.

We investigated the complex effects of N availability on both SOC quantity and quality (e.g., particulate organic carbon and mineral-associated organic carbon) using a novel model derived from the CENTURY soil submodel combined with the ForClim forest gap model. We amended CENTURY with new process equations representing hypothesized enzymatic, microbial and plant responses under varying N availability (relative to C availability) based on the literature. Multiple model variants are set up to reflect different combinations of these processes and are validated by comparing to data collected across a wide environmental gradient in Switzerland and beyond. Our modelling reveals the relative importance and relevance of these processes across different forest sites, thereby allowing us to distil a coherent mechanistic account of N influences on forest SOC dynamics. Lastly, we also test the legacy effect of N in a scenario where N deposition rises first and then declines (similar to what happens in reality, e.g., in Europe), revealing hysteresis via positive feedback from N retention, i.e., higher N availability leads to more SOM stored that can in turn release more N via mineralization.

Drought reduces rhizosphere soil carbon inputs and shifts soil microbial communities in a pine forest

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: Severe droughts impact soil organic carbon (SOC) cycling. Yet, there is limited understanding of drought effects on rhizosphere C, which contribute to new SOC formation while fueling soil microbial communities and thus SOC mineralization. Here, we quantified rhizosphere C inputs and losses in a long-term irrigation experiment in a dry Scots pine forest using ^{13}C-enriched soil ingrowth bags. Fungal and bacterial communities inside the ingrowth bags and in adjacent soils were analyzed by Illumina MiSeq sequencing.

After two years, new SOC formation was 5 times greater in root-accessible vs. root-exclusion bags. In the first year, the new SOC formation was stimulated by water addition as compared to natural drought, both in root-accessible (+25%) and root-exclusion bags (+50%). In contrast, old C losses increased in root-accessible bags under irrigation (+88%), resulting in an overall limited effect on the SOC balance within bags. After two years, the irrigation showed a limited effect on new SOC both in root-accessible and root-exclusion bags. The lacking irrigation effect on new SOC may be partly related to greater respiratory losses of new soil C (i.e. +55% old C losses under irrigation), suggesting increased rhizosphere C inputs under irrigation, which were rapidly mineralized. In support, root ingrowth in root-accessible bags increased by 70% under irrigation. The increased supply of belowground C and increased C turnover in the rhizosphere under irrigation was paralleled by shifts in fungal and bacterial communities in ingrowth bags as well as in adjacent soils. Accordingly, the presence of roots was a main driver of fungal and bacterial community structures in the ingrowth bags.

Overall, our results in this long-term irrigation experiment imply that naturally dry conditions slow SOC cycling, suppressing both rhizosphere C inputs and losses. The reduced supply of belowground C leads to cascading effects on soil microbial community composition under drought.

Dynamics of carbon storage in a tropical Eucalyptus plantation over multiple rotations

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: Eucalyptus is the most widely planted forest genus worldwide. In Brazil, Eucalyptus plantations rank among the world's most productive forests and cover more than 7.5 Mha. Improving our understanding of the dynamics of carbon storage in these anthropized ecosystems and how management practices, especially clear-cutting, affect it is important for future land sink projections. Here, we present an unprecedented 14-years series of continuous CO_2 fluxes (net ecosystem productivity, NEP) from Eddy-covariance measurements conducted in a commercial Eucalyptus plantation in Southern Brazil (the EUCFLUX project). The measurement period encompasses 3 rotations (including a full rotation of 9 years). Clear-cutting were followed by planting after a delay of 1.5 month after the first harvest and 5 months after the second harvest. NEP data were compared to the stem biomass exported at harvest to estimate the long-term C storage of the plantation (i.e., the net ecosystem carbon balance, NECB).

We show that NEP reached a maximum value of ~2 MgC/ha/month, totaling ~86 MgC/ha in a 9-year rotation. Clear-cuttings turned the plantation into a net carbon source for 7 and 12 months after the first and second harvest, corresponding to the emission of ~8 and ~11 MgC/ha, respectively. The payback period (the amount of time before the plantation recaptures as much CO_2 as was emitted after harvest) was 19 and 30 months, respectively. When using the time of planting as reference, the data was remarkably similar between rotations: the plantation turned into a net C sink 5.5 months after planting and emitted ~5MgC/ha during this period. Ten months after planting, the plantation already sequestered as much C as was emitted in the first months of the rotation. However, we found that NECB was close to zero. This suggests that despite having very high NEP, below-ground and litter C storage is low in this plantation and that the trunk export at harvest is a C flux of comparable importance as the NEP integrated between two consecutive harvests. Therefore, our results suggest that C storage in the soil stabilizes after successive rotations in highly productive commercial Eucalyptus plantations.

Effect of coastal reforestation on soil chemical characteristics of grey mangrove forests

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: The effect of reforestation on mangrove forests is poorly understood. The purpose of this study is to assess how some soil chemical properties of mangrove forests are affected by reforestation. For this purpose, a large unvegetated vacant gap (2000 m^2) was selected for reforestation. In January 2018, 10 soil samples were randomly collected for laboratory analysis using tubes with 0.5 m in diameter and 30 cm in length. After the initial soil sampling, 125 grey mangrove seedlings were planted in the gap. In January 2022, 10 soil samples were collected from the same positions for chemical analysis. Besides of soil microbial carbon (C_{mic}) and electrical conductivity (EC), the concentration of zinc (Zn), sodium (Na^+), magnesium (Mg^{2+}), Phosphors (P), and organic carbon (OC) were measured for all soil samples and then statistically analyzed using t-student (t-paired). The results indicated that the concentration of Mg^{2+} (16.62%), P (15.38%), OC (45%) and microbial biomass carbon (47.53%) were significantly increased in the 5-year reforested gap relative to the bare gap ($P<0.05$). The electrical conductivity (-19%) and Na^+ (-18.5%) were lower in planted gap than those of bare soil ($p<0.05$). The changes are likely the result of the grey mangroves influence on tidal induction and the input of litter. Hence, mangrove planting the coastal area, not only improve the soil nutrients of the habitats but also decline the soil salinity. Our study highlights the importance of rehabilitation of Mangrove forest stands by direct seedling plantations.

Effect of elevated air humidity and soil moisture on water flux and foliar nutrient content in silver birch: the Free Air Humidity Manipulation study

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Priit Kupper[1]
Gristin Rohula-Okunev[1], Katrin Rosenvald[1], Arvo Tullus[1], Arne Sellin[1]

Abstract: Air humidity can influence ecosystem functioning and its components in several ways, inducing primarily changes in the intensity of evapotranspiration. Changes in evapotranspiration affect the balance of water and minerals in trees and, consequently, the growth rate. A Free Air Humidity Manipulation (FAHM) experimental facility (https://sisu.ut.ee/fahm1/main?lang=en) was established in South-East Estonia to investigate the impact of elevated air humidity and soil moisture on trees and forest ecosystem functioning. The measurements of the current study were conducted at the FAHM experimental site in the droughty summer of 2018. We aimed to elucidate the effect of elevated air humidity and soil moisture on water flux and nutrient uptake (NPK) in silver birch trees from the 22nd of May to the 22nd of September. The average long-term increase in air relative humidity is 5-6% in humidification (H) treatment compared to control (C) conditions during mist fumigation (applied from 9:00 to 19:00 h from May to September) in the FAHM experiment. The natural precipitation was 186 mm during the study period (36% below long-term average). In soil irrigation treatment (I), the experimental plots were additionally watered once a week, whereas the total amount of added water equalled to 140 mm of precipitation. Our results demonstrated significant differences among treatments in tree sap flux density (F) and foliar nutrient concentrations. The timing of autumnal leaf abscission varied between treatments depending on F and foliar [N]. The delayed leaf abscission was positively related to tree diameter increment of the following year (2019). Our findings suggest that trees of H treatment behaved differently from those of I and C treatments and confirm the distinct effects of elevated air humidity and soil moisture on trees' functioning.

Effect of land use change on soil phosphorus: how does deforestation, time since crop establishment, and agricultural management affect P lability?

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: Soil phosphorus is an essential nutrient for plant growth and ecosystem functioning. Various factors can influence the availability and distribution of the different P forms. This study aimed to investigate the effects of land use, time since deforestation, and agricultural management on soil P forms using a sequential Tiessen and Moir fractionation approach. We compared cultivated soils that have experienced deforestation for three periods (25, 34, and 72 years) and the neighboring undisturbed forest soils, located in Central Macedonia Region, northern Greece. Two different agricultural management practices were examined: conventional tillage with irrigation for cotton-wheat rotation with alternating crops every two years, and reduced tillage without irrigation for wheat cultivation. The Tiessen and Moir sequential phosphorus fractionation method was used to differentiate soil phosphorus fractions based on their lability. Results revealed a significant 90% increase in total P content following deforestation and cultivation, as determined by the sequential procedure. Labile P forms exhibited a substantial 140% increase, moderately labile forms increased by 110%, and residual forms increased by 60%. Differences in soil P forms were observed between wheat fields and cotton-wheat rotation fields, highlighting the influence of land management practices on P dynamics. Furthermore, the time since deforestation played a pivotal role in shaping soil P distribution with previously deforested sites showing lower moderately labile organic P content and a higher proportion of labile organic P and moderately labile inorganic forms. This underscores the importance of considering the legacy effects of land-use change on soil P availability. In conclusion, this study demonstrates that land use, time since deforestation, and agricultural management practices significantly impact soil P forms. A comprehensive understanding of soil P fraction dynamics is essential for effective land management and sustainable agricultural practices. The findings contribute to existing knowledge on soil P cycling and offer valuable insights for land managers and policymakers to develop strategies for enhancing soil health and nutrient management in diverse land use scenarios.

EFFECT OF LAND USE CHANGE ON SOIL QUALITY AT SELECTED DEGRADED LAND AND FOREST PLANTATION IN MALAYSIA

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

[4] Department of Land Management, Faculty of Agriculture, UPM, Selangor, Malaysia

Abstract: Forest land conversion is a significant issue driven by population growth and economic development in any developing and developed countries. Converting forests into other uses like agriculture or urbanization can have adverse effects on soil properties. Forests are complex ecosystems that have evolved over thousands of years, and their removal can cause changes in soil physical, chemical, and biological characteristics. Deforestation often involves removing the forest canopy, leading to increased soil erosion and loss of organic matter. This loss affects soil fertility and its ability to support plant growth. Tree removal also alters soil moisture levels, impacting soil structure and nutrient availability. The study aims to assess the impact of land use change on soil quality in Kuala Kubu Bharu, Selangor, Malaysia. The study was conducted on an open forest area, a natural forest owned by a private company, and an active agricultural area with a forest plantation. Soil samples were collected at three different locations, using a soil auger at depths of 20-30 cm. The samples were air-dried for 24 hours and sieved to remove small pebbles. We used the pipette method to determine soil texture (sand, silt, and clay) and CHNS analysis and Atomic Absorption Spectrophotometer (AAS) to analyze soil chemical properties (pH, cation exchange capacity, total carbon, total nitrogen, and exchangeable bases such as Ca, Mg, K, and Na). We are expected to develop sustainable land-use practices and mitigating the negative impacts of land-use change on soil health. The results of the study will provide insights into the effects of different land uses on soil health and guide efforts to mitigate these changes.

Effects of biochar and microbial soil amendments on post-mined soil: implications for shortleaf pine (Pinus echinata) restoration

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Casey Iwamoto[1]

[1] Mississippi State University, Department of Forestry
[2] University of Wisconsin-Madison, Department of Soil Science

Abstract: Coal strip mining has left degraded soils throughout the southeastern United States. These soils tend to have low pH, high bulk density, impacted hydrologic processes, and an accumulation of heavy metals that limit revegetation and reforestation efforts. Shortleaf pine (*Pinus echinata*) has a natural ability to grow on post-mined sites and has the largest native range in the southeastern United States, making it an ideal species for restoration efforts. However, limited empirical field trials have been conducted on the success of soil amendments on both soil health and tree productivity. A field trial was established on a reclaimed mining site in 2021. The shortleaf pine was planted in a completely randomized block design with 10x10-foot spacing with two treatments: biochar and microbial inoculation in four replicates. Soil bulk density, pH, heavy metal content, electrical conductivity, carbon content, and nitrogen content were measured every three months. Shortleaf pine survival and growth through height and ground line diameter measurements were also taken at planting and at the end of each growing season.

After two years, overall survival is 71.07 ± 6.59 % with the lowest survival in the microbial treatment at 59.26 ± 10.92% and the highest survival in the biochar treatment at 77.08 ± 3.08%. Soil amendments were found to have significantly (p<0.05) impacted height change. Tree height growth was the largest in the biochar treatment at 35.51 ± 2.89 cm and lowest in the microbial treatment at 10.41 ± 3.02 cm. Although not significantly impacted by soil treatment, mean carbon content increased in the mixture treatment of both biochar and microbial soil amendments by 2% while all other treatments decreased.

Year 3 analysis is pending. Future results are expected to show a more productive environment than the original reclaimed mining site for shortleaf pine. This study will create evidence for the use of biochar and microbial soil amendments in restoration on post-mined sites.

Effects of clearcut forestry on soil respiration and aboveground litterfall in mature boreal spruce forests of south-eastern Norway

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Rieke Lo Madsen[1]
Johan Asplund[1], Line Nybakken[1], Rebecca Biong[1], Håvard Kauserud[2], O. Janne Kjønaas[3]

[3] Norwegian Institute of Bioeconomy Research, Division of Forest and Forest Resources, Norway

Abstract: Forests constitute the largest terrestrial carbon (C) stock in Norway, and forest ecosystems at these latitudes are important for global C dynamics particularly due to their large belowground C stocks. Clearcut harvesting is generally thought to reduce soil C stocks; however, knowledge on long-term effects is limited since most of the data come from studies done within 15 years of harvest. Furthermore, we lack understanding of the underlying C-flux components, especially in clearcut forests that have reached maturity.

In a paired plot design at 12 locations in south-eastern Norway, we compare mature clearcut Norway spruce forests with nearby forests that have never been subject to clearcutting. We have collected two full years of aboveground tree litterfall, with monthly collections during the snow free period of 2022. In addition, we have measured in situ soil respiration using LI-COR Smart Chamber (8200-01S) and carbon dioxide (CO_2) analyser (LI-870). Soil respiration measurements were performed monthly during the snow free period from September 2021 to November 2022. Following the last respiration measurements, we collected soil samples from inside the chamber collars to perform chemical analysis (C and nitrogen). We report both soil CO_2-efflux per area and per gram C. In addition, we use microclimatic variables and stand parameters to help explain variability in soil respiration.

Investigating the major soil C input and output in the two types of forests, we aim to disclose potential long-term differences in C cycling caused by forest management. Utilizing a unique study design with mature Norway spruce stands we contribute new data about soil C processes from the late stage of a typical rotation period in stands subjected to clearcut harvesting and in near natural stands in south-eastern Norway.

Effects of intensive Acacia mearnsii cultivation on soil acidity and soil fertility indicators

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

[3] Hawassa University Wondo Genet College of Forestry

Abstract: The Fagita Lekoma district in northwest Ethiopia has undergone a significant land-use change over the last two decades. Around 50% of the cropland has been converted from annual crop agriculture to short rotation agroforestry using *Acacia mearnsii*, a tree speciecs native to Australia, over a period of 20 years. The land use change is primarily driven by the market demand for charcoal. The *Acacia* cultivation leads to significant biomass removal from the field when it is harvested every 4 to 6 years. This study aims to analyze the effects of intensive *Acacia mearnsii* cultivation on soil acidity and available nutrient status, considering different rotation frequencies of the cultivation. A total of 144 soil samples were collected between April and May 2022 from plantation stands of different stand age and rotation cycles. The data was analyzed using a two-way Analysis of Variance (ANOVA), followed by a post hoc test to identify significant differences between the *Acacia* plantation rotation cycles. Soil acidity (both pH and exchangeable acidity) was higher with increasing number of rotation cycles; however, the results were not statistically significant. No statistically signficant difference was observed among the different cycles of plantation rotation for available soil N (1M KCl extractable NH_4^+ and NO_3^-). Active carbon got higher with stand age across all rotation cycles but was lower with an increased frequency of plantation. There was a statistically significant difference between the first and second rotation cycles, while no statistically significant difference was observed for plantations under the third rotation cycle. No notable difference in phosphatase enzyme activity was observed among the different rotation cycles. The percentages of total organic carbon and nitrogen decreased as the rotation cycle increased. A statistically significant difference was observed between the first and third rotation cycles for both soil properties. Despite the fact that the tree benefits the soil through it's nitrogen-fixing abilities, the export of other soil nutrients raises concern, as acidity seems to increase with cultivation frequency. Our results contradicts earlier observations that claim that the *Acacia* plantations are neutralizing soil acidity.

Effects of structural complexity in temperate forests on decomposition processes

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Johanna Asch[1]
Marcell Peters[1], Michael Scherer-Lorenzen[2]
[1] Department of Animal Ecology and Tropical Biology, Biocenter, University of Würzburg, Am Hubland, 79074 Würzburg, Germany
[2] Department of Geobotany, Faculty of Biology, University of Freiburg, Schänzlestraße 1, 79104 Freiburg, Germany

Abstract: Temperate production forests have experienced a homogenization of forest structure under established management regimes, leading to a reduction of possible different ecological niches and a change in local microclimatic conditions, and subsequently a loss of ecosystem functions and biodiversity. Management approaches such as the Enhancement of Structural Beta Complexity (ESBC) aim at reintroducing heterogeneity in production forests by emulating natural disturbances and succession through silvicultural manipulations.
By breaking down organic matter and making it available for other organisms, decomposition processes are an integral part of nutrient and carbon cycling, but are often not in the focus of scientific studies, especially the decomposition of animal derived necromass such as carcasses. Controlled by factors such as microclimate, decomposer abundance and substrate quality, all of which are directly influenced by forest stand structure, decomposition processes are likely strongly affected by homogenisation. As part of the BETA-FOR research unit this study aims at disentangling the relationship between homogenization and decomposition in temperate production forests with a focus on decomposition rates and decomposer diversity.
BETA-FOR has introduced nine different ESBC treatments at eleven forests sites in production forests in Germany, each site comprised of nine ESBC-patches and nine control-patches. On each patch, decomposition rates of different necromass such as animal dung, rat carcasses and leaf litter were determined by exposing the materials to patch conditions for specific lengths of time. Pitfall traps baited with animal necromass (dung and carcasses) were installed directly afterwards to investigate decomposer diversity. Field experiments were started in summer 2022 and are still on going.
Preliminary results show a greater variance of decomposition rates of rat carcasses and animal dung, as well as an overall faster decomposition of rat carcasses on ESBC-sites. Analysis of seasonal variation and decomposer diversity are still in progress. However, first results indicate stronger differences in decomposition efficiency and thus nutrient turnover in addition to higher beta-diversity of decomposers, when forest sites are more structurally heterogeneous. ESCB-management could therefore be a useful strategy to improve nutrient cycling in production forests and increase decomposer diversity across spatial scales.

Elevated nitrate leaching risks under pure Douglas fir stands can be lowered by mixing with European beech

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Klara Mrak[1]
Estela Covre Foltran[1], Norbert Lamersdorf[1]
[1] Soil Science of Temperate Ecosystems, University of Göttingen

Abstract: Forest management aims for productive and stable forests that continuously provide ecosystem goods and services, including balancing nutrient fluxes (nitrogen). Increasing heat and frequent droughts in temperate European forests make the introduction of non-native Douglas fir (*Pseudotsuga menziesii*) an increasingly relevant climate change adaptation strategy, particularly as an admixture to native tree species, such as European beech (*Fagus sylvatica*).

Douglas fir can alter biogeochemical processes in forest soils, potentially leading to an excess of nitrogen in the ecosystem, but the biotic and abiotic controls of this effect need further examination (species interactions, soil type). Here we studied nitrate leaching on plots of two contrasting regions (southern loamy and northern sandy site) planted with either pure Douglas fir, pure Norway spruce (*Picea abies*), pure European beech or a mixture of beech with either of the conifers. We used P80 suction lysimeters at 5 and 60 cm soil depth and collected soil solution over two continuous years to estimate nitrate leaching risks.

We found highest concentrations of nitrate in soil solution in lower soil layers under Douglas fir, which corroborates the findings of some studies conducted in pure stands. In Douglas fir-beech mixed stands, however, we found significantly reduced and sustained nitrate concentrations in soil solution, implying a mixture effect. Furthermore, soil texture played a key role in controlling nitrate leaching under Douglas fir as indicated by increased leaching on sites with finer soil texture. We discuss the results considering throughfall, litter, soil and microbial characteristics.

We conclude that Douglas fir stands pose a relatively higher leaching risk than Norway Spruce and a considerably higher risks compared to beech stands. However, the low susceptibility to leaching of beech stands seems to be a strong effect trait in mixtures, diminishing the high leaching potential Douglas fir induces on some sites. Low leaching potential is key to sustain adequate nutrition in temperate forests and reduces pollution of groundwater. Our findings strongly urge forestry experts to carefully assess site conditions and foster mixtures with European beech when planting Douglas fir.

Evaluation of carbon sequestration capacity of Forest Ecosystem based on the InVEST model

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Zou Wentao[1]
Zhang Chao[1]
[1] Research Institute of Forestry Policy and Information, Chinese Academy of Forestry

Abstract: InVEST model has been widely used in all aspects of forest ecosystem service assessment for its advances in driving data collection, quantitative and spatial description of results simulations *et al*. However, during the application of this model, how to calibrate the model locally and how to eliminate the problem of low applicability to areas presenting weak land cover change caused by the simplification of the model is the key points to estimate the ecosystem services accurately. In this study, Kaihua county, the headwaters of Qian Tang river in Zhejiang, East China, was chosen as an example to analyze the changes of carbon stocks from 2000 to 2020. Results showed that forest is the dominant land cover in Kaihua accounting for 77.16%~81.64% at the year 2000, 2010 and 2020, variations of forest carbon stocks showed an insignificant trends only 4.16% and 3.95 from 2000 to 2010, and 2010 to 2020, individually. There are two reasons for this, one is that the changes of land covers were weak during the 20-year study period. The other one is that the carbon sequestrations caused by annual growth of different forest types including woodlands, shrubs, and sparse woodlands etc, were ignored during the process of carbon storage calculation in the InVEST model. Therefore, annual carbon sequestration increments were introduced to revise the results of the InVEST model, and the modified carbon storage increments reached 13.80% and 10.57%, respectively. Additionally, not all the age groups of forest have the same carbon sequestrate rates, the young and middle-aged forests have the largest increments while capacity of carbon sequestration among the near-mature and matured age groups declined significantly. Therefore, further research should quantify the impacts of changes in the proportions of young forests, middle-aged forests, near-mature forests, and matured forests ranged from 27.89, 39.62, 17.40, 15.09 in the year 2004 to 40.82, 36.66, 2.87, 9.65 in the year 2017, to improve the scientificity and accuracy of carbon sequestration modeling of forest ecosystems.

Evaluation of the impact of establishing electrical transmission lines on carbon stocks in upland forests

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Ariane Belleau[1]
Evelyne Thiffault[1], David Paré[2]
[1] Laval University, Department of Wood and Forest Sciences, Canada
[2] Natural Resources Canada, Laurientian Forestry Centre, Canada

Abstract: Quebec could become a major player in greenhouse gas reduction through its capacity to export hydroelectricity to neighboring jurisdictions to contribute to their decarbonization efforts. In 2020, Quebec's energetic potential was estimated at 32 TWh based on Hydro-Quebec's surplus. This will undoubtedly lead to an expansion of the hydroelectric transmission network within Quebec's territory. It should be noted that the transmission line network for hydroelectricity in Quebec covers approximately 170,000 hectares, with the majority located in forested areas. However, although we currently know the impacts of the construction and maintenance of transmission lines on biodiversity, we are unaware of the actual carbon footprint of these lines on forested areas. Calculations in Canada's official greenhouse gas inventory are currently imprecise regarding land-use change, which are used for that type of linear disturbance.

The goal of this research project was to quantify the carbon stocks alongside the transmission lines across different forest ecosystems of Quebec and to evaluate their distribution and variability through various bioclimatic zones. The different carbon stocks that were measured include living biomass (aboveground and belowground), dead organic matter (deadwood and litter), and soils (soil organic matter) at different depths. The analysis of stocks were mainly conducted along two gradients of variability: i) the local ecological gradient created by the corridors of the transmission lines themselves and ii) the bioclimatic gradient of the hydroelectric network. In each of the study zones, sampling was conducted in the corridor, in the forests on the periphery of the corridor for a possible edge effect, and in the deeper undisturbed forests as control.

We observed that total carbon stocks were influenced by position in the transect, but not by bioclimatic zones. Corridor plots had significantly lower total carbon stocks than the other plots by the absence of grown forests. Furthermore, no significant difference was found in aboveground carbon stocks between edge plots and control plots, suggesting no significant edge effect by implementing corridors. Altogether, the accuracy of hydroelectricity's life cycle will be improved by these results and could potentially influence future policies concerning its exportation.

Explicit inclusion of forest canopy microclimate temperature buffering in a process-based model

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

[4] Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Birmensdorf, Switzerland
[5] Berchtesgaden National Park, Berchtesgaden, Germany

Abstract: Forest canopy buffering of macroclimate temperatures is well documented, but how local effects of microclimatic buffering scale up to long-term, broad-scale forest and disturbance dynamics remains unresolved. Forest management and processes such as carbon and nutrient cycling occur at landscape scales, making forest landscape simulation models important tools for projecting change. Yet, to date microclimate has not been explicitly considered in these models. We address these research gaps by explicitly modeling microclimatic temperature buffering as a function of topography, forest structure and composition, and seasonal phenology in the individual-based forest landscape and disturbance model iLand. We specifically ask, *How does simulated temperature buffering capacity vary in a topographically complex mountain landscape?* We compiled previously published data from over 300 plots widely distributed throughout temperate European forests and fit multiple linear regressions predicting monthly minimum and maximum buffering capacity (microclimate [at 1 m height] minus macroclimate, or free-air, temperature). In a forested mountain landscape (Berchtesgaden National Park, Germany), we simulated forest change, dynamic bark beetle disturbances, and microclimatic buffering at 10 m spatial resolution for 20 years under recent historical climate (2000-2020). Average annual daily maximum temperature buffer (TMaxBuffer) was -0.6°C and varied between summer (-1.1°C) and winter (-0.1°C). Forest types differed in temperature buffering capacity. Some forests (beech, spruce, mixed conifer-broadleaved) tended to cool maximum and warm minimum spring and summer temperatures, whereas others (larch-pine, dwarf mountain pine) showed the opposite trend. Bark beetle outbreaks reduced summer microclimatic buffering capacity by 70% (-1.6°C pre-outbreak to -0.5°C post-outbreak summer TMaxBuffer). With explicit inclusion of microclimate temperature, iLand can be used to explore how forest canopy buffering affects key processes such as decomposition, bark beetle dynamics, and tree regeneration over space and time. Understanding if and how microclimate temperature affects forest processes and scales up to landscape change is critical as climate warms and disturbances increase.

Factors driving changes in plant and microbial communities between coniferous and broadleaf deciduous boreal forests

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Juanita Carolina Rodríguez Rodríguez[1]

[2] Université du Québec à Montréal, Department of Biological Sciences, Canada

Abstract: Changes in tree-canopy dominance can alter ecosystem functioning and habitat conditions for plant and microbial understory communities. Natural and anthropogenic disturbances have produced changes in tree-canopy dominance from coniferous to broadleaf deciduous forests, generating shifts in litter inputs and understory community composition. With a 5-year *in situ* experiment in eastern Canada, we analyzed the factors driving changes in understory plant and microbial communities and the resistance to shifts between forest types, using adjacent stands with similar topoedaphic conditions dominated by black spruce (*Picea mariana* (Miller) Britton, Sterns & Poggenburgh) and trembling aspen (*Populus tremuloides Michx.*) forests. We first analyzed how shifts in litter deposition affected plant understory community composition. Then, understory communities were physically exchanged between forest types, to determine their resistance under a new tree-canopy dominance through time, as well as the resilience of the forest understory after the transplantation. Finally, after 5 years of cumulative treatments of litter addition and understory transplantations, we used high throughput sequencing to identify changes in soil bacterial and fungal communities among treatments and forest types and to compare their community composition to the phyllosphere communities from leaves of both tree types. Results indicate that the diverse understory vegetation of aspen forests were resistant through time both after changes in litter deposition and in the new habitat of black spruce-dominated forest. In contrast, spruce understory (*e.g.* mosses and ericaceous plants) was negatively affected by broadleaf litter addition and transplants into aspen stands were invaded by aspen understory community species over time. Soil bacterial and fungal community composition was driven by a legacy effect of each forest as they were not affected by aboveground changes in plant understory composition or litter inputs, being different from the tree phyllosphere. Our study highlights the resistance and resilience of aspen forests and its role in plant and microbial diversity, in contrast to black spruce forests. Understory vegetation plays a crucial role in the resilience and preservation of ecosystem services in boreal ecosystems, particularly in the face of increasing changes in tree-canopy dominance in the boreal biome.

Foliar nutrient status of main European forest tree species and its association with forest growth

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

[2] UC Louvain
[3] University of Natural Resources and Life Sciences (BOKU)
[4] Natural Resources Institute Finland (Luke)

Abstract: Nutrients in forest ecosystems have a significant impact on tree growth and vitality. As the capacity of forests to sequester carbon increases with nutrient availability, it is essential to consider tree nutrient status when simulating future forest carbon uptake.

In this analysis, we make use of more than three decades of foliage data as part of the ICP Forests European monitoring network to analyze the nutritional foliar status of main European forest tree species. Temporal trends of foliar phosphorous (P) concentrations exhibited significant decline in main forest tree species. Over the investigated spatial domain of around 300 European monitoring plots, the percent change of foliar P concentration was in the range of – 6.1% to – 2.9% for beech, oak, pine, and spruce over 10 years relative to the year 2012, which could result in a weakening of carbon sequestration capacity in Europe if trees become increasingly P deficient. Trends of foliar nitrogen to phosphorous (N/P) ratios were significantly positive by tendency on multiple forest monitoring plots for oak and pine. This change in N/P balance suggests an increasing degeneration of P nutrition relative to N nutrition with potential adverse progression of tree canopy defoliation and discoloration.

In a follow-up analysis, we investigate the impact of meteorological parameters such as vapor pressure deficit and precipitation on ICP Forests growth data in intensive European monitoring plots of high and low nutritional status in order to examine the nutritional effect on climate-dependent tree growth rates and advance the link of carbon and nutrient cycles.

Forest Degradation in the Anthropocene: What and how much are we losing?

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Gerardo Vergara-Asenjo[1]
Julian Sabattini[2], Johanne Pelletier[3], Bastienne Schlegel[1]
[1] Instituto Forestal (INFOR), Valdivia, Chile
[2] Universidad Nacional de Entre Ríos, CONICET, Argentina
[3] CGIAR Standing Panel on Impact Assessment, USA

Abstract: Forest degradation is a global human-induced phenomenon posing a major threat to ecosystem services, biodiversity and human well-being, being also a precursor to further forest loss. Although there is a large and growing source of literature documenting the environmental impacts of forest degradation, there are no comprehensive analyses of the impacts of degradation on forests. To address this knowledge gap, we conducted a systematic review of scholarly databases related to forest degradation and related terms for the period 1990-2022. This presentation outlines the concepts, causes, methods, and impacts of forest degradation at global and regional scales, under a conceptual model, contributing to understand their final effects on attributes, functioning or resilience. To this end we approach two main questions: What is being affected? At what level or intensity? Our results contribute to determine the scope of human influence on forests and allow better and more informed decisions in local and regional contexts for conservation and management efforts, also orientating future research in the area.

Forest soil carbon cycle in a drier climate – linking experiments, monitoring and natural gradient studies

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: Dry extremes are increasing in frequency. Impacts of drought on soils and their biota range from immediate reductions of metabolic activities, acclimation of physiological processes to species shifts. Longer-term responses encompassing changes in soil organic matter (SOM) depend on carbon allocation from plants into soils and on the resilience of forest ecosystems to drought, which include the recovery from drought and the adaptation of plant and soil communities. Here, we present results from experimental manipulations of water regimes in forests at daily to multi-annual time scales as well as from natural precipitation gradients reflecting longer-term trajectories.

At daily to monthly time scales, we show in whole tree ^{13}C-pulse labelling experiments in a young beech forest and a mature pine forest, that drought suppresses the coupling of above- and belowground communities. Less new tree assimilates are allocated to the soil and their microbial communities (here measured as ^{13}C-PLFA). However, upon rewetting trees allocate greater amounts of assimilates belowground, probably to regain rhizosphere functions.

In a 20-year long irrigation experiment in a drought prone pine forest, water addition strongly increased soil C inputs by litterfall but also C outputs by soil respiration by a factor of two to three. Irrigation promoted bacteria and fungi with more copiotrophic life-style strategies being typical for a high C availability. We relate these shifts in microbial communities not only directly to the altered water regime but rather to a belowground "system change". Long-term irrigation induced a vertical redistribution of SOM from the organic layer into the mineral soil, which in turn affects SOM composition and microbial communities. The likely mechanisms for the SOM changes include a greater rhizodeposition as well as an increased incorporation of litter into the mineral soil through soil fauna reflected by a many-fold increase in the abundance and activity of soil fauna (e.g. earthworms) in irrigated soils. These findings indicate that reoccurring summer droughts reduce C inputs and storage in the mineral soil in this pine forest. This pattern is congruent with larger scale patterns across Swiss forest soils, showing declining soil C stocks with decreasing annual precipitation.

Greenhouse gases flux from forest cover loss between 1984 and 2022 and livestock grazing in tropical dry forests: a simulated analysis

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Nereoh Leley[1, 2]
David Langat[1], Abdalla Kisiwa[1], Geoffry Maina[2], John Otuoma[1], James Ndufa[1], Joseph Ruhiu[3], Christine Koskey[1]
[1] Kenya Forestry Research Institute, P.O Box 20412 -Nairobi, Kenya
[2] Egerton University, Faculty of Environment and Resources Development, Njoro Campus, P.O. Box 536, Egerton, Kenya
[3] US forest Service, Kenya Country Office

Abstract: The Agriculture, Forestry and Other Land Use (AFOLU) sector accounts for about 23% of global greenhouse gas (GHG) emissions mainly carbon dioxide (CO_2), nitrous oxide (N_2O) and methane (CH_4). At the same time, well managed ecosystems in the sector contribute to climate change mitigation with the potential of absorbing about one third of the global anthropogenic CO_2 emissions. This study simulated the net GHG fluxes in a business-as-usual (BAU) scenario from forest degradation through illegal logging and intensive livestock grazing; and potential GHG offset options targeting community-driven restoration and livestock population management. Remote sensing was applied to compute forest cover change between 1984 and 2022 to indicate degradation level in Chepalungu Forest (5,004 ha), a tropical dry forest in Kenya. Reference carbon stocks were estimated from a similar non-degraded forest through inventory, while livestock population was determined using direct count approach. Tier 2 data were used to estimate GHG flux using EX-Ante Carbon-balance Tool. In about four decades, the forest area declined circa 87%. The existing livestock population in the forest composed of cattle, goats and donkeys was estimated at 27,005 under low productivity management. Under BAU scenario, emissions from forest degradation and grazing were estimated at 43,026 TCO_2eyr^{-1} (17,125 and 25,901 TCO_2eyr^{-1}, respectively). Restoration and sustainable management of 2,110 ha of degraded forest land and proportional livestock reduction by 280% to achieve the required carrying capacity led to an emission reduction of 64%, thus creating a net sink of 27,548 TCO_2e annually. Forest restoration had the highest flux share (40%) as potential net sink of CO_2 through biomass build up, while livestock management reduced net enteric CH_4 and N_2O emissions from manure by 55 and 5% respectively. These findings suggest that avoiding forest degradation and maintaining appropriate stocking rates in natural systems has a high potential to mitigate against climate change. Further, countermeasures that balance community needs and emission reductions, such as agroforestry, silvo-pasture and a shift to low methane emitting livestock may also significantly reduce emission levels.

How does the exclosure affect the chemical and biological properties of soil in oak forests?

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Maryam Teimouri[1]
Mehrdad Zarafshar[1], Tahereh Alizadeh[1]
[1] Research Institute of Forests and Rangelands, Agricultural Research, Education and Extension Organization (AREEO), Tehran, Iran

Abstract: Human activities and the entry of livestock make destroying the forest as well as soil destruction
the basis of the life of terrestrial ecosystems. In this study, the effect of exclosure on some chemical and biological properties of soil was investigated in two Iranian oak habitats, Chari (exclosure) and Mavraz (without exclosure) habitats in Chaharmahal va Bakhtiari province. Soil samples were collected from a depth of 0-10 cm and chemical characteristics (pH, electrical conductivity, percentage of moisture, carbon and organic matter, total nitrogen, available phosphorus) and biological characteristics (microbial biomass carbon, soil respiration, substrate induced respiration, nitrification potential) were measured during two years. The Results showed that the effect of the site (exclosure) on available phosphorus, total nitrogen, substrate-induced respiration, the effect of time on carbon and organic matter, soil respiration and nitrification potential, and the effect of their interaction on electrical conductivity, organic carbon, organic matter, soil respiration, and nitrification potential was significant. The result indicated that the amount of available phosphorus in Chari (exclosure) due to higher vegetation cover and species diversity. The increase in total nitrogen in Mavraz habitat can be explained by the entry of livestock waste. There is a positive relationship between biological activity and organic carbon. In conclusion, habitat exclosure affects the biological and chemical properties of soil and has positive effects on soil fertility in the long term and consequently oak trees health.

How extreme weather events affect the dynamics of the coarse wood debris in a Secondary Atlantic Forest Fragment?

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Mariany Filipini de Freitas[1]
Carlos Moreira Miquelino Eleto Torres[1], **Maria Paula Miranda Xavier Rufino**[1], Klisman Oliveira[1], Valéria de Fatima Silva[1], Paulo Henrique Villanova[1], Laércio Antonio Gonçalves Jacovine[1]
[1] Departamento de Engenharia Florestal, Universidade Federal de Viçosa, Brazil

Abstract: Extreme events, such as strong winds and storms, have a great influence on forest dynamics. The occurrence of extreme weather events has been increasing in the world, due to the worsening of climate changes. Such events cause tree mortality, which leads to an increase in necromass and alteration in the forest carbon stock. However, there are a few studies in the Atlantic Forest, even with the relevance of understanding the effects of extreme events on this biome. Our goal was to quantify the volume, necromass and carbon stock of the coarse wood debris (CWD) before and after the occurrence of a strong storm and to evaluate the impacts of the event on the forest components. The study area is a secondary forest fragment, with an area of 17 hectares, located in Viçosa, Minas Gerais, Brazil. The storm occurred in October 2019 and lasted about 5 hours, with wind gusts reaching 82.4 km/h and accumulated precipitation of 112.4 mm, with 67 mm recorded in the first hour. Coarse wood debris, such as branches, stumps and fallen trees on the ground and with a diameter ≥ 5 cm, were inventoried in 10 plots of 1000 m² (20 x 50 m), a few days before and shortly after the occurrence from the storm. Carbon content values were obtained using a dry combustion elemental analyser. The volume, necromass and carbon stock of the CWD before the storm was 31.57 m^3 ha^{-1}, 16.05 Mg ha^{-1} and 7.93 MgC ha^{-1}, respectively. After the storm, volume, necromass and carbon stock reached a total of 38.72 m^3 ha^{-1}, 20.12 Mg ha^{-1} and 9.94 MgC ha^{-1}, respectively. The carbon stock after the storm increased by about 2.01 MgC ha^{-1}, with the greatest impact being in CWD with lesser degree of decomposition. It is concluded that storms can influence the carbon dynamics of a forest, being interesting to study its effects within the Atlantic Forest as well as for several forests in the world.

How fast does forest carbon recover after fires – a perspective from south-eastern Australian temperate forests

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Luba Volkova[1]
Chris Weston[1]
[1] The University of Melbourne, Faculty of Science

Abstract: The Black summer 2020 wildfires burnt through about 7 Mha of mainly temperate Eucalyptus forests in south-east Australia, releasing an equivalent of Australia's total net annual emissions.

Study sites in SE Australia that had been assessed for all aboveground C pools in 2016, were burnt in high intensity prescribed burns in 2018, and high to moderate severity wildfires 2020. Carbon recovery was assessed in 2023, three years following moderate to high severity wildfires and five years after high intensity prescribed burns.

Within 6 months after wildfire tree mortality accounted for about 20 MgC/ha (or 10%) of carbon transfer from live to dead trees with a further similar amount 3-5 years after fires. Carbon loss from live trees burnt in high severity wildfires was 40 Mg C/ha (or 20%) with further loss of 5 MgC/ha after 3 years. In contrast, carbon loss from moderate severity wildfires and high intensity prescribed burns was only a half of that with a sign of recovery 3-5 years after. Compared with 2016 only 50% pre-fire live trees remained alive in 2023, with almost no recruitment of new Eucalyptus trees but profuse regeneration of Acacias.

Fires consumed about 50% of carbon stored in dead standing trees with no significant changes observed in CWD because of the recruitment of new CWD following fires. While all litter on the forest floor was burnt in fires, rapid recovery of litter due to litterfall from scorched and killed trees resulted in full recovery of litter soon after fires, and a doubling of litter loads 3-5 years after fires. Findings of this study question the assumption of exponential fuel recovery currently used in carbon assessment and fire modelling in Australia.

Our findings also indicate that as fire severity increases, carbon loss increases and recovery time is longer, suggesting that increase in fire occurrences and severity associated with climate change will reduce carbon carrying capacity for these temperate forests. Implication for the regional carbon balance will be discussed in this talk.

Identifying mycorrhizal decomposer fungi and their relationship to forestry in Sweden

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Erica Packard[1]
Karina Clemmensen[2], Anders Dahlberg[2], Leticia Pérez-Izquierdo[3], Johan Stendahl[1], Marie Spohn[1], Björn Lindahl[1]
[1] Swedish University of Agricultural Sciences, Department of Soil and Environment, Sweden
[2] Swedish University of Agricultural Sciences, Department of Forest Mycology and Plant Pathology, Sweden
[3] Scientific Campus of the University of the Basque Country, Basque Centre for Climate Change (BC3), Spain

Abstract: Mycorrhizal fungi form essential symbiotic relationships with the roots of plants, where the fungal partner grows into the soil, accessing nutrients and transferring some to their plant host in exchange for photosynthates. Some ectomycorrhizal fungi – here termed as mycorrhizal decomposers – possess genes coding for potent oxidative enzymes, such as manganese dependent peroxidases. Previous research suggests that certain fungi with these enzymes may reduce carbon stocks and potentially contribute to forest productivity by cycling organic nitrogen. Yet, current rotation forestry decreases ectomycorrhizal fungal diversity and may interfere with the pivotal activities of mycorrhizal decomposers. We explored which mycorrhizal fungi belong to this unique group in Swedish forest soils, and how they are related to forest disturbances, such as tree harvesting. Potential Mn-peroxidase activity and fungal community data were collected with high spatial resolution from six pine and six spruce forests in central Sweden, encompassing both young (15-20 years) and old (> 80 years) stands. We evaluated potential drivers of Mn-peroxidase activity, including soil fertility (based on carbon to nitrogen ratio and soil pH) and fungal community composition. We found little spatial auto-correlation in potential Mn-peroxidase activity even within 10 cm, indicating that hot-spots of enzyme activity are highly localised. Within site variation in enzyme activity was better explained by variation in the fungal community than by soil fertility. Some ectomycorrhizal groups with genetic potential to produce Mn-peroxidases, such as *Cortinarius semisanguineus* s.l, *Hysterangium* spp., *Gautieria monticola, Russula* spp., and *Lactarius* spp. were were significantly co-localised with hot-spots of Mn-peroxidase activity. Based on the Swedish Forest Soil Inventory data these fungi, which were identified as potentially important mycorrhizal decomposers, vary in their sensitivity to tree harvest. Notably, *C. semisanguineus* is present even in relatively recently cut forests (< 60 years old), while *Cortinarius aurae* s.l*,* is predominantly present in forests that have never experienced cutting. The finding suggests that some mycorrhizal decomposers are better adapted to fast recolonization after clear-cutting.

Immediate and carry-over effects of late-spring frost and drought on forest gross primary productivity capacity in the Northern Hemisphere

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Liang Chen[1]

Abstract: Forests are increasingly exposed to extreme global warming-induced climatic events. However, the immediate and carry-over effects of extreme events on forests are still poorly understood. Gross primary productivity (GPP) capacity is regarded as a good proxy of the ecosystem's functional stability, reflecting its physiological response to its surroundings. Using eddy covariance data from 34 forest sites in the Northern Hemisphere, we analyzed the immediate and carry-over effects of late-spring frost (LSF) and growing season drought on needle-leaf and broadleaf forests. Path analysis was applied to reveal the plausible reasons behind the varied responses of forests to extreme events. The results show that LSF had clear immediate effects on the GPP capacity of both needle-leaf and broadleaf forests. However, GPP capacity in needle-leaf forests was more sensitive to drought than in broadleaf forests. There was no interaction between LSF and drought in either needle-leaf or broadleaf forests. Drought effects were still visible when LSF and drought coexisted in needle-leaf forests. Path analysis further showed that the response of GPP capacity to drought differed between needle-leaf and broadleaf forests, mainly due to the difference in the sensitivity of canopy conductance. Moreover, LSF had a more severe and long-lasting carry-over effect on forests than drought. These results enrich our understanding of the mechanisms of forest response to extreme events across forest types.

Impact of bamboo on nutrient cycling and soil carbon stocks in highlands of Kenya

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Riziki Mwadalu[1]
James Ndufa[1], Mohamed Elema[1], Mary Gathara[1]
[1] Kenya Forestry Research Institute

Abstract: Bamboo is among the fastest growing woody plant in the world with proven potential for soil erosion control, climate change mitigation and adaptation. Kenya has a total bamboo growing area of 133,273 hectares, concentrated in mountain ranges and forests. In Kenya, bamboo is gazetted as the 16th cash crop with potential for contributing towards economic development. Recently, bamboo growing has received massive attention from the Government and private investors. As bamboo plantations increase, there is need to quantify other ecosystem services accrued to the species such as nutrient cycling and carbon storage. Nutrient cycling and soil carbon stocks (CS) are vital factors in soil health which significantly affects ecosystem functioning. However, there is inadequate information on impact of different bamboo species on soil nutrients dynamics and soil carbon stocks. As such, data was collected from cropland (control) and 12-year-old bamboo plantations of *Dendrocalamus brandisii, Bambusa tulda, Dendrocalamus membranaceous, Bambusa vulgaris* and *Dendrocalamus asper* at Muguga, Kenya*.* Soil samples were collected from depths of 0-20 cm. Leaf litter quantities and litter quality were determined for the different bamboo species. The results showed significant differences in CS across land-use systems ($p<0.04$) with *Dendrocalamus brandisii* having the highest CS of 70.46 t C/ha while the cropland had the lowest CS of 41.48 t C/ha; a difference of 69.9%. In terms of soil nutrients, significant differences were only observed for nitrogen and phosphorus ($p<0.04$ and $p<0.01$, respectively) with *Dendrocalamus asper* recording the highest phosphorus concentration (29.6 ppm) while the control had the lowest concentration (4.53 ppm). Nitrogen concentration was significantly higher in the farmland ($p<0.05$) due to constant application of nitrogen fertilizer while soils under *Bambusa tulda* had 106% higher extractable potassium than the farmland. *Dendrocalamus brandisii* recorded the highest leaf litter of 2.25 t/ha. In terms of litter quality, *Dendrocalamus brandisii* had the lowest C/N ratio of 28.7 while *Dendrocalamus membranaceous* had the highest C/N ratio of 49.8. This study shows that bamboo plantations have the potential of mitigating climate change through soil carbon storage and enhancing nutrient cycling which is crucial for optimal ecosystem functioning.

Impact of forest management on forest carbon accumulation.

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Krzysztof Korzeniewski[1]
Damian Czubak[1]
[1] Department of Geomatics Forest Research Institute, Sękocin Stary, 3 Braci Leśnej Street, 05-090 Raszyn, Poland

Abstract: In the age of climate change, increasing greenhouse gas emissions and EU regulations, Poland, as a member of the European Union, is obliged to take the necessary measures to become an environmentally friendly country. This results in pressure for new environmentally friendly solutions. We has taken steps to use forestry practises developed so far (between 2017 and now) to increase carbon accumulation. Data was collected from approximately 6,662 hectares where management practises such as natural regeneration, the introduction of understory stands or the introduction of fast-growing species such as Douglas fir were implemented. The Carbon Budget Model of the Canadian Forest Sector (CBM-CFS3) was used for modelling. The outcome of the work is to estimate the impact of different management measures on carbon sequestration and/or retention and to select the best management practises in terms of carbon sequestration. Previous work and experience indicate that the greatest impact on carbon sequestration comes from the introduction of understory stands, natural regeneration and reduced tillage interventions when establishing new forest areas. The scientific studies conducted (e.g., carbon content in the soil, growth rate of trees in the stand, or carbon content in individual components of the forest ecosystem), combined with their verification in forestry practice, enabled the development of forest management practices that maximize the amount of carbon sequestered or stored.

Impact of soil compaction by forestry machinery on tree radial increments

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Daniel Tomčík[1]

[2] Czech University of Life Sciences Prague, Faculty of Forestry and Wood Sciences, Czech Republic

Abstract: Forestry machinery is a necessity for active forest stand management. The increasing weight of machines used in forests substantially affects soil conditions as their passage causes soil compaction, and changes in physical, chemical, and biological properties of soils. The changes in soil characteristics subsequently influence tree growth and productivity. The aim of the work was to quantify the impact of soil compaction on the radial growth of trees. The empirical material was obtained from tree cores sampled from 57 trees growing at a permanent research plot located at the University Forestry Enterprise of the Technical University in Zvolen, Slovakia. We evaluated the intensity of soil compaction after the passage of a forestry skidder LKT 81 ITL in 2020 with a digital penetrometer (Eijkelkamp Penetrologger 0615SA) and the density of passages. The results showed that one year after the skidder passages, the radial increment was significantly reduced by 28%. A significant reduction in radial tree increment was also confirmed when comparing the mean radial increment derived from the three years before and three years after the soil compaction. Soil compaction with the skidder within a radius of 3 m around a tree had the greatest negative effect on the radial increment. The findings confirmed that the passage of forestry machinery has a substantial negative effect on the productivity of trees occurring in the vicinity of passages. Hence, minimising the impact of heavy machinery on forest ecosystems by following operational rules with regard to weather conditions, spatial and temporal planning of forestry operations, and development novel technologies with reduced negative impacts on forest soils is highly recommended to ensure long-term ecosystem sustainability.

Influence of trees age, heights, social classes, silvicultural management and tissue types on the growth rates and chemical elements content

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Cyriac Mvolo[1]
Ahmed Koubaa[2], James D. Stewart[1], Venceslas Goudiaby[3], Emmanuel A. Boakye[3], Christopher Helmeste[1]

[3] Département des Sciences Biologiques, Université du Québec à Montréal

Abstract: White spruce has always represented a significant part of biomass feedstock used by the Canadian wood industries. The end-use of a species requires a certain wood quality attribute (WQA), known to be influenced by climate and forest management. Unfortunately, there still have many uncertainties. For example, the accuracy and precision with which carbon (C) amounts have been accounted for in forests have been questioned. As countries seek to comply with agreements to reduce global warming and industries seek to maximize bioenergy potential, this matter has increased international concern. White spruce (*Picea glauca* (Moench) Voss) stand density management trials (thinning and spacing) in the Petawawa Research Forest, Ontario, Canada, were sampled to evaluate carbon, nitrogen and other chemicals concentration variation within trees and plots of differing stand density. Many parameters, including trees' age, sampling heights, social classes, silvicultural management and woody tissue types were tested on nine wood quality attributes (ring width, ring density, tracheid length, tracheid diameter, latewood proportion, intra-ring density variation, ring area, earlywood width, and latewood width) and eight wood chemical attributes (freeze-dried carbon, freeze-dried nitrogen, freeze-dried hydrogen, oven-dried carbon, oven-dried nitrogen, oven-dried hydrogen, volatile mass fraction and volatile carbon). Tests were performed in both the juvenile wood area and the mature wood area. Growth rates was found to be influenced by both thinning and spacing, but the impact of silvicultural management on WQA was limited. The variations in the juvenile wood and the mature differed with WQA. The variations in WQA associated with sampling heights were stronger than those associated with spacing. The spacing intensities impacted wood chemical attributes, with C content being higher in wider square spacings, while the reverse was true for N and H, which exhibited higher content in smaller square spacings. The results also suggested that when it comes to the content of chemical elements, bark and knots should be treated as separate fuel types, whereas other woody tissues can be aggregated. Finally, the results suggested that oven-dried carbon should continue to be used within the bioenergy industry, while freeze-dried carbon must become the preferred standard for carbon accounting protocols.

Insights from a chronosequence study: conifer-to-broadleaf forest conversion drives nitrate leaching in winter

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

[4] Faculty of Forestry and Wood Science, CZU, Prague, Czechia

Abstract: From the 18th century onwards, extensive deforestation of native broadleaved species and subsequent reforestation with coniferous species took place in various regions of Europe. However, in recent decades, there has been a growing interest in converting these coniferous forests back, driven by the need for climate adaptation, enhancing biodiversity, and improving water quality. While coniferous plantations contribute to the economy through timber production, they often lead to increased levels of soil nitrate leaching, particularly after prolonged exposure to high levels of NH_3 and NO_x deposition. In contrast, broadleaved forests in the same location typically show lower level of nitrate leaching. However, the impact of such conversions on sites previously occupied by coniferous plantations on soil solution chemistry remains largely unknown.

In this study, we examined a chronosequence of 26 plots representing the process of converting coniferous to broadleaf forests in Thetford Forest, United Kingdom. During July-August 2021, we observed an increased rate of in situ net soil nitrification in the top 10-30 cm of soil in plots that were converted 5-8 years ago. Additionally, plots converted 10-13 years ago showed an accumulation of total nitrogen (N) in deep soils (30-90 cm). We found a negative correlation between nitrification rate and soil carbon (C) and N stocks, as well as pH. Conversely, we observed a positive correlation between nitrification and the thickness of the organic layer. Soil solution and throughfall samples were collected and chemically analysed monthly from August 2021 to July 2022. Peak nitrate leaching values occurred in February, and the order of decreasing values was as follows: stands converted 10-13 years ago > stands converted 5-8 years ago > mature coniferous stands > mature broadleaved stands.

Since there was no significant relationship between total annual nitrate leaching and nitrification or soil C and N stocks, we propose that changes in nitrate leaching fluxes were primarily driven by alterations in water fluxes. The association between nitrate leaching, leaching of base cations, soil acidification, and aluminium toxicity suggests that elevated levels of nitrate leaching prior to the growing season may have implications for the health and growth of broadleaf forests on converted coniferous sites.

Invasive pest effects on tree demographics and equilibrium carbon storage capacity across the northeastern US

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

[2] USDA Forest Service
[3] Purdue University, Department of Forestry and Natural Resources
[4] Virginia Tech University, Department of Forest Resources and Environmental Conservation

Abstract: Nonnative pests and diseases have dramatic negative effects on forests that are particularly acute in northeastern North America where the density of invasive forest pests and pathogens is highest. The short and medium-term consequences of these invasions on host trees are well established. However, the ways in which the introduction of these organisms influences long-term structure, composition, and biomass storage capacity of affected forests are considerably less well understood. We used Forest Inventory and Analysis data from the USDA Forest Service to examine temporal trends and/or newly established equilibria in demographic properties of forests impacted by dominant forest pests introduced into northeastern North America over the past 140 years. Analyses to date have shown that tree demographic shifts in response to beech bark disease (BBD) significantly reduce carbon storage capacity of impacted eastern hardwood forests, while for green and white ash, forest recovery (albeit with a dramatically reduced ash component) is more likely in the wake of the Emerald ash borer. More specifically, beech baseline relative morality is twice as high in forests with the longest duration of BBD and beech small-stem abundance is ten times higher than in forests without BBD. This suggests that BBD has caused a shift in the forests' demographic equilibrium from normal maturation and self-thinning to smaller, denser stands over time. Using cross-validated estimates of the carbon storage capacity and sequestration rates for forests within the region in light of established and currently spreading invasives, we are building a more comprehensive understanding of how specific biological, ecological, demographic traits of host trees and invasive pests interact to determine rates of change and the potential for the ultimate return to pre-invasion equilibrium biomass and productivity.

Is afforestation for carbon sequestration an effective way to achieve carbon neutrality-The Case of Northwest China

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

han Zhang[1]
zongshun Wang[1], chao Yue[2], hongqiang Yang[3]
[1] School of Economics and Management, Northwest A&F University
[2] Institute of Soil & Water Conservation, Northwest A&F University
[3] College of Economics and Management, Nanjing Forestry University

Abstract: Afforestation is considered to be a promising way to mitigate climate change. However, its cost-effectiveness should be carefully evaluated, especially for regions with fragile environment and vulnerable ecosystem. This study develops a geographic-economic-ecological integration framework to evaluate the cost-effectiveness of afforestation for carbon sequestration in Northwest China. Based on the overlay model of natural factors and the economic optimization model of land use, the marginal land suitable for afforestation is identified. Then, the Richards growth function is employed to estimate the carbon sequestration potential of afforestation. Based on this, the carbon supply curve is fitted and the cost-effectiveness of afforestation for carbon sequestration is investigated. The results show that: (1) In Northwest China, 499.58×10^4 hectare of land is ecologically available for afforestation. However, only 102.71×10^4 hectare of these lands are economically feasible for afforestation, accounting for about 1/5 of ecologically available land. The lands suitable for afforestation are primarily grasslands and unused lands, which are mainly distributed in Qinghai and Gansu provinces. (2) Afforestation has a potential of carbon sinks with 9.37 million tons of CO_2 per year in Northwest China. By 2060, this potential will cumulatively be 374.88 million tons of CO_2, which can contribute 9.70%–15.06% of the region's carbon neutrality. (3) The marginal cost of forest carbon is 22.28–217.36 \$/tCO_2 in Northwest China, with an average cost of 137.52 \$/tCO_2. Compared with industrial emissions reduction, afforestation does not have cost-effectiveness to mitigate climate change in Northwest China. Additionally, afforestation would become even less cost-effective when consider the urgency of government to address climate change. These findings provide policy implications in designing and implementing carbon neutrality strategies.

LAND COVER AND CARBON STOCK DYNAMICS IN FINIMA NATURE PARK, BONNY ISLAND, NIGERIA

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

ROSEMARY UBAEKWE[1]
Uzoma Chima[2], Funmilayo Eguakun[3]
[1] 1. Department of Forestry and Wildlife Technology, School of Agriculture and Agricultural Technology, Federal University of Technology, Owerri, Nigeria
[2] 2.Department of Forestry and Wildlife management, Faculty of Agriculture, University of Port Harcourt, Port Harcourt, Nigeria
[3] 3.Department of Forestry and Wildlife management, Faculty of Agriculture, University of Port Harcourt, Port Harcourt, Nigeria

Abstract: The accurate evaluation of carbon dynamics due to land cover changes is crucial for the effective management of forest reserves as carbon sinks, particularly in a changing climate. This study analyzed the relationship between land cover (LC) changes and carbon dynamics in Finima Nature Park from 1987-2021. Thirty 30mx30m plots were randomly laid, and tree species with diameter at breast height (dbh) ≥10cm were enumerated. Tree height, dbh, diameter at the base, middle, and top were measured. Aboveground carbon (AGC) was estimated using the field data, while a model incorporating field data, spectral variables, and vegetation indices was developed to estimate AGC for 1987, 1999, 2010, and 2021, including their spatial distributions. The LC classes were dense vegetation (DV), sparse vegetation (SV), bare land, water body, and built-up, which exhibited changes over the study periods. The total tree population enumerated was 1696, of which *Anthostema aubryanum* (302) was dominant. *Pierreodendron africanum* had the highest concentration of AGC. DV and SV covered a total area of 801.76ha, and 167.92ha in 1987, 773.14ha and 170.98ha in 1999, 776.65ha and 147.34ha in 2010, 718.87ha and 189.7ha in 2021, respectively. Spatially, DV exhibited high carbon densities across most areas, while other LC types had low to no carbon concentrations. DV stored 77634.42tons, 80058.65tons, 108622.27tons and 99779.16tons of AGC in 1987, 1999, 2010 and 2021 respectively. SV stored 7853.62tons, 10428.07tons, 10480.29tons and 16562.71tons in 1987, 1999, 2010 and 2021 respectively. No AGC in other LC types. AGC storage exhibited an upward trend during 1987–2010 and a downward trend during 2010-2021. Overall, 85488.04tons, 90486.72tons, 119102.56tons and 116341.86tons of AGC were estimated in 1987, 1999, 2010, and 2021, respectively. The slight increase in DV cover in 2010 positively affected carbon density, whereas the sharp decrease in 2021 had a negative impact. Positive changes in the SV area contributed to net carbon, while negative changes had a negative effect. The LC changes in the park have influenced the concentration of AGC over the study periods. DBH and height, also contribute to this effect. Therefore, targeted management interventions are recommended to maximize carbon storage in the park.

Leaf Phenological Responses of Juvenile Beech and Oak Provenances to Elevated Phosphorus

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Marko Bacurin[1]
Sasa Bogdan[1], Ida Katicic Bogdan[1], Antonija Vukmirovic[1], Daniel Krstonosic[1], Zeljko Skvorc[1], Tomislav Karazija[2], Krunoslav Sever[1]
[1] Faculty of Forestry and Wood Technology, University of Zagreb
[2] Faculty of Agriculture, University of Zagreb

Abstract: The few studies dealing with leaf phenological responses to elevated nutrients in forest trees have given ambiguous results, i.e., while some reported delayed leaf-out and autumn leaf senescence, others reported advanced leaf phenology caused by increased nutrition. This study aimed to determine the effects of experimentally increased phosphorus (+P treatment) on the leaf phenologies of two juvenile provenances of common beech and sessile oak. Other objectives were to determine whether there were interspecific differences as well as intraspecific variations. Saplings were excavated in two mixed beech–oak stands and transplanted into four wooden boxes filled with a commercial soil substrate. Phosphorus fertilizer was added to two of the boxes, while the remaining boxes served as controls. Both species responded to +P treatment with advanced autumn leaf senescence in the first year of the experiment. Leaf senescence in common beech began significantly earlier, while in both species, the process was accelerated compared to that in the control. In the second year, the leaf senescence response to +P treatment was even more pronounced in both species. The +P effect on leafing phenology was absent in both common beech provenances and in an oak provenance. However, the other oak provenance showed advanced leafing, indicating the existence of intraspecific differences.

Leaf traits of understory species are changing in response to climate change in the Congo Basin Forests

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Yves HATANGI[1, 2, 3]
Hippolyte Nshimba[1], Piet Stoffelen[3], Benoît Dhed'a[1], Jonas Depecker[3, 4], Ludivine Lassois[2], Filip Vandelook[3]

[4] Division of Ecology, Evolution, and Biodiversity Conservation, KU Leuven

Abstract: Background– While tropical forests play an important role, in carbon sequestration, tropical species are assumed to be sensitive to rising temperatures and prolonged drought predicted to occur in the region. Plant functional traits are useful tools for understanding and predicting possible changes in plant communities.

Objective– We analysed the variation of foliar traits of woody understory species of the Yangambi Man and Biosphere Reserve and verify if this variation is potentially related to recent climate change.

Methods – Leaves of five shrub species were collected, in the 2019-2022 period in Congolese old-growth forest (Yangambi MAB Reserve, DR Congo), from different positions on the shrub to evaluate the variation within individua and as such test the possibility to use (historic) herbaria for the study of foliar traits. These leaves were compared to herbarium specimens collected in the same area in the 1935-1960 period. In both studies we assessed leaf size, specific leaf area, stomatal size and stomatal density for all species.

Results –This study shows that the variability of the functional traits of the woody understory species are independent of the position of leaves in the crown. This makes it possible to use historic herbarium for trait analyses from tropical undergrowth shrubs. Characteristics of the recently collected leaves were notably different as compared to the herbarium leaves collected between 1935-1960. Recent leaves were significantly larger, had a higher SLA, and a smaller stomata pore length as compared to historical herbarium specimens.

Conclusion – The difference in measured trait characteristics over time correlates with the upward trend of the average temperature measured in the area over the last 80 years in Yangambi, while average annual rainfall had remained unchanged.

Our results provide a first insight into the response of forest species to climate change in the forests of the Congo Basin, and how the undergrowth species and the ecosystem will react in the longer term when temperature further increases. However, as our study is based on a limited number of species and only for one region a more extensive study is needed.

Keywords: Climate change, leaf traits, understory woody species, Congo Basin Forests, Yangambi

Litter decomposition and stabilization as affected by soil fauna functional group and tree species shift in a temperate forest soil

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Anna Kellerová[1]
Veronika Jílková[1]
[1] Biology Centre of the Czech Academy of Sciences, Institute of Soil Biology and Biogeochemistry, České Budějovice, Czech Republic.

Abstract: Soil represents the largest terrestrial carbon (C) reservoir, where C is stored in the form of soil organic matter (SOM). Temperate forest soils in particular have a great potential to store C. Soil fauna generally facilitates litter decomposition and helps stabilize available C in temperate forest soils. However, the specific effects of different soil fauna functional groups (micro-, meso-, and macrofauna) are less known. Limited knowledge is also available on the effect of a tree species shift (from coniferous to deciduous) expected as a result of climate change. Here we present preliminary results of our laboratory mesocosm experiment focused on the decomposition of litter of variable quality (higher-quality beech and lower-quality spruce litter) affected by soil microorganisms and microfauna, mesofauna and macrofauna (*Armadillidium vulgare*). We also focus on incorporation of C from these litters into the SOM fractions of variable availability (more available particulate organic matter (POM) and less available mineral-associated organic matter (MAOM)) in temperate mixed forest soils and discuss possible future implications under climate change scenario.

Litterfall production and associated elemental flux in cool-temperate stands with contrasting functional types in Daejeon, South Korea

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Byung Bae Park[1]
Mark Bryan Carayugan[1], **Ji Young An**[1, 2]
[1] Department of Environment and Forest Resources, College of Agriculture and Life Sciences, Chungnam National University, Republic of Korea
[2] Institute of Agricultural Science, Chungnam National University, Republic of Korea

Abstract: Litterfall provides a dynamic pathway for carbon and nutrient entry into the forest soil, thereby influencing the movement of biomaterials within and between terrestrial ecosystems. However, our comparative understanding of litterfall and elemental fluxes in broadleaf deciduous and coniferous evergreen forests growing in similar localities remains limited. Here, we quantified the long-term litterfall production patterns and nutrient inputs at a broadleaf deciduous stand located in Daejeon (hereafter, BDF_A) and compared these estimates with stands exhibiting a different dominant functional type (CEF) and sub-canopy composition (BDF_B). Seasonal and annual litter debris, including foliage, twigs, bark, reproductive structures, and miscellaneous components, was collected for at least two calendar years using circular litterfall traps. Intercepted litter during periods of high litterfall was composited per fraction and analyzed for carbon and macronutrient concentrations. The mean annual litterfall production in BDF_A was identical to that in BDF_B and CEF, ranging from 841.47 g m^{-2} to 990.24 g m^{-2}. Foliar litter accounted for 63% to 69% of total litter debris in all three sites. Litterfall exhibited pronounced seasonal fluctuations caused primarily by relative humidity, wind speed, and solar radiation. Except for carbon, macronutrient concentrations were consistently higher in BDF_A and BDF_B compared to CEF. Macronutrient input from litterfall was the highest in N (943.76–111.14 kg ha^{-1} yr^{-1}) and the lowest in P (3.26–4.14 kg ha^{-1} yr^{-1}) across all investigated stands. BDF_A and BDF_B returned higher amounts of potassium (K), calcium (Ca), and magnesium (Mg) to the forest soil relative to CEF. Nutrient use efficiency in CEF was higher than that in BDF_A and BDF_B for all macronutrients, following the pattern P > Mg > K > Ca > N . The effect of forest functional type on nutrient cycling via litterfall is more strongly dependent on nutrient returns than litter quantity due to the differences in the mechanisms by which broadleaf deciduous and coniferous evergreen communities acquire, utilize, and resorb nutrients prior to litter formation. Our findings are relevant to the understanding of biogeochemical cycling dynamics in various cool-temperate forest zones in South Korea and other areas alike.

Long-term dynamics of the carbon budget in loblolly pine plantations

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Dehai Zhao[1]
Bronson Bullock[1], Cristian Montes[1], Mingliang Wang[1]
[1] Plantation Management Research Cooperative, Warnell School of Forestry and Natural Resources, University of Georgia, Athens, GA 30602, USA

Abstract: Intensively managed pine plantations in the southeastern US could not only meet the increasing demand for traditional wood products and biomass for energy, but also play a critical role in meeting US GHG emission reduction goals through additional carbon sequestration. Adapting forest management to mitigate climate change requires an understanding of the long-term effects of silvicultural treatments on forest production and carbon sequestration. A loblolly pine (*Pinus taeda* L.) silviculture-by-density study was initiated in 1995/96 with 40 installations across the southern US. Each installation contains 12 large plots planted at six levels of planting density (ranging from 740 – 4448 trees/ha) in combination with two levels of silvicultural intensity (operational vs. intensive management). With the long-term data from this study, we assessed the impact of site quality, cultural intensity, and planting density on temporal dynamics of aboveground net primary production in carbon (ANPPC), total carbon uptake, aboveground living tree biomass carbon (AGC) stocks, and cumulative carbon released back to the atmosphere. Silvicultural intensity and planting density significantly affected ANPPC before age 15 years. Total carbon uptake was significantly affected by site quality at early ages, and by both culture and planting density over the study period. Carbon released back was significantly affected by site quality during mid-rotation, by planting density after age 6, and by silvicultural intensity over time. AGC stocks were significantly affected by site quality at early and late ages, by silviculture intensity before age 15, and by planting density over time. After age 20, stands on higher quality sites stored higher amounts of carbon, but higher-planting density stands might store less carbon, with no significant differences between silvicultural intensities. Our results indicate that management practices that enhance growth and carbon absorption in young stands do not necessarily result in more carbon storage at later developmental stages. The relationships between management practices and carbon sequestration in plantations need more research to further develop climate-smart forest management practices.

Long-term effects of Norway spruce and European beech on soil properties and carbon stocks

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Peter Horvat[1]
Aleksander Marinšek[1], Tine Grebenc[2], Marjetka Suhadolc[3], Primož Simončič[1]
[1] Department of Forest Ecology, Slovenian Forestry Institute, Slovenia
[2] Department of Forest Physiology and Genetics, Slovenian Forestry Institute, Slovenia
[3] Department of Agronomy, University of Ljubljana, Slovenia

Abstract: Norway spruce (*Picea abies*) and European beech (*Fagus sylvatica*) are among the most ecologically and economically important tree species in Europe. Historical afforestation policies led to the extensive planting of spruce in Slovenia and other European countries. However, the species now faces severe pressure from global warming and forest disturbances. As a result, forest management strategies in Central Europe aim to convert spruce-dominated forests into mixed forests, with beech being a promising deciduous species for this purpose. Climate change is also expected to drive the migration of deciduous tree species to higher elevations currently dominated by spruce.

This study aims to compare the long-term effects of these two tree species on soil properties and carbon stocks. Forest soils play a crucial role in supporting forest growth, carbon sequestration, and climate change mitigation through long-term carbon storage. Trees influence soil properties through litter inputs, water dynamics, nutrient uptake, and other processes. Understanding the relationships between tree species and the soil environment is essential for sustainable forest management, carbon sequestration, and addressing issues like soil acidification.

This study will focus on two sites in Slovenia, one on siliceous (Pohorje area) and one on carbonate parent material (Snežnik-Javorniki plateau) with similar stages of soil development, which had the same forest stand species composition for over 50 years. Soil chemical properties (pH, cation exchange capacity, base saturation, total organic carbon (C_{org}), total nitrogen (N), dissolved C_{org}, mineral N, plant-available P and K) and soil physical properties (texture, bulk density, mechanical resistance, and water holding capacity) will be measured. The findings will enhance our understanding of the influence of tree species on soil properties and soil carbon stocks in selected areas. The results will be valuable for developing forest management strategies, improving carbon storage, and addressing undesirable soil-related phenomena. Considering the changing climate and potential shifts in forest composition, it is also crucial to assess the ecological impacts of the transition from spruce- to beech-dominated forests.

Long-term forest stability: Mode of tree mortality matters.

Abstract: The biomass in a forest is a function of the productivity and mortality rate of the trees that compose it. Under increasing abiotic disturbance (e.g., windstorms, fires) or physiological stress (e.g., droughts, pests), forests will first change in age, composition and could ultimately tip over into other ecosystems such as grasslands. We are using an ensemble of seven vegetation models to investigate the effect of changes in tree mortality rates on the resilience of forest ecosystems. These state-of-the-art demographic vegetation models explicitly resolve the size structure of trees within forests and their processes of growth, death and establishment. These models scale from leaf to population to region and are a powerful tool to explore different scenarios of forest futures. They are increasingly integrated within Earth system models to improve climate projections. Because these

models directly simulate forest structural (e.g. tree diameter classes) and dynamical variables (carbon content over time) which are widely observed in the field, it is possible to more tightly constrain their behaviour to real forest dynamics than more abstract representations of vegetation. In this study we first verify model outputs against observations from forest inventory plots across boreal, temperate and tropical forests. We then explore how the increase of mortality affects the new emerging dynamic equilibrium of these ecosystems. Our results highlight that the mechanism of mortality has a strong impact on the biomass trajectory of the ecosystem. For example, increases in stand-replacing disturbances lead to a very different level of resilience than an increase in overall background mortality rates, even for the same unit increase in tree mortality. Therefore, large-scale assessments of forest carbon balance in light of changing mortality regimes need to take account of the “how”, as well as the “how much”.

Modelling nitrogen limitation of litter decomposition

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Samia Ghersheen[1]
Stefano Manzoni[2], Marie Spohn[1], Björn Lindahl[1]
[1] Swedish University of Agricultural Sciences, Department of Soil and Environment, Sweden
[2] Stockholm University, Department of Physical Geography, Sweden

Abstract: The dynamics of belowground organic matter has been widely studied due to its association with forest management, environmental sustainability and climate change mitigation. White carbon and nutrient stocks ultimately depend on rates of input, decomposition losses are just as important in stock regulation of stocks, but are notoriously difficult to assess reliably. Different approaches have been used to address constraints on decomposition.
Mathematical modelling is one of the tools to understand and predict soil organic matter dynamics and its association with other soil processes. Most of the widely used soil organic matter models have been developed with a focus on carbon dynamics rather than on element interactions. However, in many regions of the world, particularly at high latitudes, soil organic matter decomposition is constrained by low nitrogen availability, but this phenomenon is usually not explicitly incorporated in the decomposition models. Nitrogen dynamics is pivotal in regulating aboveground productivity, and retention of nitrogen in soil may hamper availability to trees. However, the mechanisms behind belowground retention and release of nitrogen are poorly understood.
We formulated a process-based model of decomposition of plant litter to investigate the effect of nitrogen limitation on decomposition. The model describes the dynamics of a single litter unit over time, as it is decomposed by fungi. It has five pools with different C:N ratios. Unlike most other decomposition models, our model reflects the microbial (fungal) dynamics explicitly. Fungal biomass is divided into two different fractions describing the different state of fungal cells, 1) cytoplasmic cells with high decomposer activity and 2) vacuolised cells with a lower N content and lower activity. The fungus adapts to N limitation by increasing the proportion of vacuolised cells. The model is capable of predicting mass loss trajectories of a variety of litter types from information about initial nitrogen and lignin content, based on single set of global parameters. In order to predict patterns of nitrogen retention/release, decomposition of fungal necromass has to be slow, with decomposition rates more similar to those of recalcitrant lignin. The model will be used as a component in future ecosystem models with trees and mycorrhizal interactions.

No increased mortality from drought stress in thinned stands: results from a meta-analysis

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Julius Willig[1]
Julia Schwarz[1], Jürgen Bauhus[1]
[1] University of Freiburg, Chair of Silviculture

Abstract: Forest researchers are confronted with the challenge to propose appropriate and evidence-based silvicultural options that mitigate negative effects of droughts induced by climate change. Water stress may be alleviated by reducing the number of transpiring trees in a stand through thinning. So far, it has been comprehensively studied how thinning influences stem growth of trees during and after droughts. Mostly positive, but also mixed effects of thinning on growth response indicators were found but also a high dependence on confounding factors. Here, we conducted a meta-analysis on thinning effects on tree mortality after drought to assess thinning as an adaptation option fostering drought resistance. Additionally, we investigated whether thinning changed mortality patterns among tree dominance classes for a subset of studies that provided the necessary data.

We found 29 thinning experiments from 10 studies in Europe and North America that assessed mortality before and after a drought event. Our analysis indicates that mortality rate in unthinned control stands was more negatively affected by drought compared to thinned stands. Also, there was a weak negative relation between thinning intensity and mortality. However, owing to the high heterogeneity between studies due to differences in study design and forest types, we cannot provide robust evidence that there is an effect, but state that thinning does not alter mortality after drought substantially. In both thinned and control treatments mainly suppressed trees died; there was no shift in mortality to more dominant trees that are more exposed to radiation in thinned stands.

While thinning did not clearly mitigate drought-related mortality, it also did not exacerbate it. Thus thinning, which has been previously shown to improve growth in relation to drought and has other benefits such as reducing production times and risk of wind-throw, would not come with higher mortality risk. After all, our meta-analysis was characterized by high heterogeneity. To allow for more general statements and more precise identification of confounding factors a much higher sample size would be necessary. This calls for more standardized reporting of results from thinning studies to compile a global database.

Nutrient mobilisation from forest floors along four elevation-related temperature gradients in European beech forests

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

[2] University of Copenhagen
[3] Technical University München

Abstract: Slow turnover of the forest floor (FF) is often assumed to be related to immobilization of nutrients within the organic matter. However, the FF is also assumed to be an important nutrient source at sites with low nutrient concentrations of the mineral soil. Yet, little is known about the availability of nutrients present in the FF and how it is related to FF turnover.

Within the DFG-funded Research Unit FOREST FLOOR weidentify processes that control the relevance of the FF for tree nutrition as compared to the mineral topsoil in European beech (Fagus sylvatica) forests with admixtures of Norway spruce (Picea abies) and maple (Acer pseudoplatanus). Wequantify resin extractable macronutrients at lab conditions in the FF and the mineral topsoil along four elevation-related temperature gradients with different P status of the mineral soil on silicate and on carbonate rock. We hypothesize that nutrient availability in the FF at high mean annual temperature (MAT) sites is lower compared to low MAT sites due to temperature-enhanced immobilization of the nutrients by the microbial biomass and leaching into the mineral soil. Consequently, we expect a higher nutrient availability in the mineral soil at high MAT compared to low MAT sites due to faster nutrient mineralization of the litter. Furthermore, we argue that temperature dependency of nutrient immobilization depends on the P status of the mineral soil. Among the three tree species, spruce, maple and beech, we expect that the FF will contribute more to nutrient uptake in spruce than in maple, while FF in beech will take an intermediate position.

Preliminary analyses on P poor sites (< 300 g P/m2) in the Black Forest showed that higher temperatures decrease not only the stock of available P (Pres) of the FF but also the Presstock of the upper 10 cm of mineral soil (Kandel, MAT 5 °C, 10 g Pres /m²]; Waldkirch, MAT 9 °C, 8 g Pres/m²]). These first results support the crucial role of the FF for beech forest nutrition and its vulnerability under climate change.

Nutrient uptake, microstructural changes and antioxidative mechanisms in Phyllostachys vivax transplanted into coastal site

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Chunju Cai[1]
Juan Li[1], Guohua Cao[2], Shaohua Mu[1], Jian Gao[1]
[1] International Centre for Bamboo and Rattan
[2] Dongtai Huanghai Forest Park

Abstract: Chinese timber bamboo (*Phyllostachys vivax* McClure) has been successfully intro-duced to the coastal belt of eastern China. However, the mechanisms of nutrient uptake and antioxidative protection of *P. vivax* in response to salinity adaptation in coastal areas remains unclear.*P. vivax* forests were studied in their native and coastal transplantation sites within the coastal belt of China. In particular, nutrient allocation, anti-oxidative enzyme activities, biomass accumulation, water contents, water potentials, and root system morphologies vs. microstructures were evaluated in plants from the two sites.

Plant morphology adapted to the coastal saline soils by increasing root/shoot ratios and the length of large diameter rhizome, increasing vascular numbers, and lightening epidermal cells within rhizomes. The ratio of Ca^{2+}/Na^{+} increased, while K^{+}/Na^{+}, Mg^{2+}/Na^{+} decreased after transplanted to the coastal sites. Nitrogen nutrient contents were significantly positive correlated with plant growth characteristics of *P. vivax*. The Mg^{2+}, Na^{+}, and Ca^{2+} concentrations contributed more significantly to differences among organs, while N, Mg^{2+}, Na^{+}, and Ca^{2+} contents contributed more to root systems. Nutrition uptake regulation by *P. vivax* primarily occurred via tissues that limited the excessive absorption of Na^{+} and the complementary reduction of ion toxicity. The activities of superoxide dismutase (SOD), peroxidase (POD), and ascorbate peroxidase (APX) decreased, while the levels of glutathione (GSH) and ascorbic acid (AsA) increased in belowground tissues. The contributions of catalase (CAT) and proteins were higher for the principal components explaining variation among different organs, the protective enzymes played indirect roles in the growth of *P. vivax*.

Overall, our investigation shows that *P. vivax* maintained normal growth after transplantation to the Yancheng coastal beach. The root system should be protected and the water balance of root system should be maintained when *P. vivax* is transplanted to the salinity site. It is very important to maintain the nutrient content in the soil around underground root system. Nevertheless, these results are preliminary, and further investigation should be conducted to understand the adaptive mechanisms and nutrient uptake of bamboo plants in coastal belt sites, particularly over longer time scales.

Old-growth forests get nitrogen saturated – what does this imply for their climate effect?

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Per Gundersen[1]
Frederik Nygaard Philipsen[1], Lars Vesterdal[1]
[1] Dept. of Geosciences and Natural Resource Management, University of Copenhagen

Abstract: Many European forests are exposed to nitrogen (N) deposition above critical loads. In old-growth forests or forest reserves, where no N is removed in products, this may lead to N enrichment and with time N saturation.

In the longest unmanaged forest in Denmark, Suserup, soil water monitoring has shown a constant high nitrate leaching for 20 years, with N-leaching at or higher than the N-input from throughfall. Thus, this ecosystem is clearly N saturated. Since carbon (C) and N are closely related in biomass and soil organic matter, this may signal that the forest ecosystem is also C saturated. Repeated biomass inventories indeed indicate that the forest has reached its maximum biomass. Thus, this old-growth forest is likely neither a sink nor a source of CO_2.

However, with high N availability and acidic topsoil there is risk that N_2O is formed in the soil during nitrification. In a pilot study we have measured high N_2O-emision in Suserup forest (significantly higher than in a nearby managed forest) and at levels that could turn the forest into a source of CO_2-equivalents.

In this presentation we will report a full year of N_2O-emission observations from Suserup forest and a nearby managed forest to evaluate the potential contribution of N_2O-emission to the overall greenhouse gas balance of these forests. Further, we will report on short-term comparisons of N availability, nitrate leaching and soil N_2O-emissions in other paired (managed and unmanged) forests to infer if N saturation and elevated N_2O-emissions generally occur in old unmanaged forests.

Post-fire vegetation dynamics in southwestern forest at Saudi Arabia (KSA)

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Rahmah Al-Qthanin[1, 2]
[1] Biology Department, College of Sciences, King Khalid University, Abha, Saudi Arabia
[2] Prince Sultan Bin-Abdul-Aziz Center for Environment and Tourism Studies and Researches, King Khalid University, Abha 61421, Saudi Arabia

Abstract: Forests in the southwest of Saudi Arabia had severe wildfire in October 2020, endangering their natural vegetation, especially Al-Mufrah mountain. It is one of a group of mountains in Al-Soudah, has a substantial amount of flora covering it, and is the first destination for tourists visiting Saudi Arabia. Post-fire vegetation dynamics is examined over an extended timescale, to investigate the effects of fire on plant diversity and to verify the ability of plant species for regeneration naturally. Permanent plots were sampled at three locations along a gradient from 2500 to 2700 m. Plot locations corresponded to three community types: *Dodonea* sp.- *Acacia* sp. (low slope); *Acacia* sp. (mid slope); and *Juniperus* sp. (high slope). vegetation measurements were used to determine the effects of fire on the mortality and regeneration of trees, shrubs, and herbaceous species.

The findings demonstrate that mortality was greatest in the high slope position, significantly decreasing in the trees level. The mid-slope position had a lower death rate than the high-slope position, while the low-slope position had the lowest mortality. These death rates were correlated with the severity of the fire and the type of plant community. Species richness and diversity varied over the hillside gradient according to the ability of plants to regeneration naturally. The diversity of the herb-layer on the ridge greatly increased, but the diversity of the trees declined. The trees on the midslope showed little sign of alteration, although they have the capacity to naturally regenerate. Trees, shrubs, and the herb layer did not alter on the low slope. This will help to focus conservation efforts and provide a framework for research, conservation, and policy development for post-fire vegetation dynamics in the forest.

Recovery of ecosystem carbon pools 35 years after whole-tree harvesting a balsam fir – red spruce forest

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Inge Stupak[1]
Bruna Barusco[1], C. Tattersall Smith[2], Russell D. Briggs[3], Ivan J. Fernandez[4], Shawn Fraver[5], Agnė Grigaitė[1], Christopher Preece[2], Brian E. Roth[6]

[5] School of Forest Resources, University of Maine, Maine, The United States of America
[6] Roth Forestry Research

Abstract: Long-term data on the contribution of forests in mitigating the impacts of anthropogenic CO_2 emissions across different climates and site conditions is needed to inform forest management and policy. This study reports on the effect of whole-tree (WTH), stem-only (SOH) and no-harvest for a balsam fir-red spruce forest at the Weymouth Point Study Area in Maine, USA. The field work took place on various occasions from 1979 to 2016 in two adjacent watersheds with similar species composition and disturbance history. One watershed was clearcut harvested in 1981 and the other was left as a reference. Despite different levels of harvest residue inputs in WTH and SOH, there was no significant difference between the treatments for deadwood, forest floor and mineral soil C pool 35 years after harvesting, and the impacts on living biomass C was not consistent across drainage class groups. However, living biomass, deadwood and forest floor C pools of the 35-year-old forest were significantly smaller than the corresponding pools of the reference forest, while the mineral soil C pool tended to be larger. The recovery ratios for living biomass, deadwood, forest floor and mineral soil C of the 35-year-old forest were 62-67%, 38-39%, 55-64%, and 115-124% relative to the corresponding pools in the reference forest (Mean±SE135±11, 15±2, 44±3, and 78±8 Mg C ha^{-1}, respectively). Comparison with previous results from WPSA and the scientific literature across northeastern North America suggested that recovery of living biomass C is rapid, that recovery of forest floor C pools may largely take place within a single rotation of typically 80-100 years, while recovery may take longer for the deadwood C pool. The further development in the C recovery ratio will depend on the occurrence of future natural disturbances in the 35-year-old forest, and the extent to which the C pools of the reference forest fluctuate around a steady-state or a trend. It is a political decision if assessment of the climate change mitigation potential of forests is only based on the development in forest C pools, as reported in this study, or also forest product C pools, and substitution effects.

Simulating drought responses of European forests with a process-based model

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Benjamin F. Meyer[1]
Joao Darela-Filho[1], Andreas Krause[1], Konstantin Gregor[1], Qiaolin Gu[1], Christian S. Zang[2], Allan Buras[1], Phillip Papastefanou[3], Annemarie Eckes-Shepard[4], Thomas A. M. Pugh[4], **Anja Rammig**[1]

[2] University of Applied Sciences Weihenstephan-Triesdorf, Professorship of Forests and Climate Change, Freising, Germany
[3] Max Planck Institute for Biogeochemistry, Jena, Germany
[4] Department of Physical Geography and Ecosystem Science, Lund University, Lund, Sweden

Abstract: The unprecedented extent and intensity of hot and dry weather conditions in Europe in recent years is considered a new benchmark for drought conditions for the region. Additionally, the frequency and intensity of such hot drought (or compound) events are expected to be exacerbated in future conditions characterized by higher temperatures, leading to wide-spread forest decline driven by increased tree mortality. Forests store large amounts of carbon in biomass and soils and provide wood which can replace carbon-intensive materials and fuels. The protection and expansion of forests therefore is a crucial feature of climate mitigation pathways, but at the same time critically affected by climate change. Thus, understanding the negative effects of drought on European forests is of high relevance. Estimating the future impacts of drought on the carbon cycle and other related ecosystem processes and services – *e.g.*, forest regeneration and timber production, is a major challenge. The task requires robust modelling frameworks and theoretical understanding of how vegetation responds to changing environmental conditions. Here, we present the implementation of a new plant hydraulic framework in the well-established dynamic vegetation model LPJ-GUESS. It simulates the mechanism of water potential regulation of individual trees and drought-induced carbon losses from tree mortality. Hydraulic parameters for seven common European tree species were estimated from the literature and plant trait databases. A sensitivity analysis of model outputs (primary productivity, evapotranspiration, drought mortality) and a benchmark of historical model runs were performed. The model successfully reproduces carbon and water fluxes at FLUXNET sites and identifies hotspots of carbon losses during the European droughts in 2003, 2018, and 2022. We conclude that the model is suitable for evaluating future drought risks and present simulation results from a range of forest conservation, reforestation and forest management scenarios using e.g., CMIP6 climate projections. Based on these simulations we can assess the carbon dioxide removal potential of land-based mitigation efforts and identify adaptation strategies which ensure the continued provision of manifold forest ecosystem services.

Soil carbon dynamics during the first years following pseudo-steppe afforestation by Eucalyptus robusta trees on tropical highlands

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Iaviantsoa Ramanandraibe[1]
Bruno Bordron[2], Jean-Pierre Bouillet[2], Fenitra Razafindrakoto[3], Daniel Epron[4], Tantely Razafimbelo[1]
[1] Laboratoire des Radio-Isotopes, University of Antananarivo, Madagascar
[2] CIRAD - UMR Eco&Sols, France
[3] University of Antananarivo, Madagascar
[4] Kyoto University, Graduate School of Agriculture, Japan

Abstract: Afforestation is known as an efficient climate change mitigation option by the ability of forests to store carbon in tree biomass and soil. However, data on soil carbon storage, sequestration capacity and dynamics in planted forests are scarce in Sub-Saharan African countries, particularly in highlands. This work aims to assess the potential of eucalyptus plantations (EP) on soil carbon sequestration during the first years following the afforestation of grassland. EP are the primary fuelwood source in Madagascar where one of the main drivers of deforestation is the need for fuelwood. Our hypotheses were: i) soil carbon stocks increase with tree biomass ii) mineral fertilizer improves biomass production and so soil carbon sequestration iii) soil carbon contents vary spatially depending on the distance from the tree. The study was conducted in Anjozorobe in the Central Highlands of Madagascar with average annual rainfall and temperature of 1295 mm and 18.7°C respectively. The soils are Ferralsols. Natural vegetation is characterized by a pseudo-steppe dominated by *Aristida sp* grasses. A four-age chronosequence (2, 4, 5 and 6 years old) of *Eucalyptus robusta* plantation with and without mineral fertilization was selected with two controls as the initial (pseudo-steppe) and final (more than 60 years old EP) state of land use change from grassland to planted forest. These ten treatments have three replicates. In each inner plot, soil samples were collected at six depths (0 - 5 cm, 5-10 cm, 10-20 cm, 20-30 cm, 30-50 cm and 50-100 cm) at three different distances from a tree. Determination of soil carbon content and bulk density calculation will permit the estimation of soil carbon stocks in different soil layers according to the spatial position at the plot level and the fertilization application. Aboveground tree biomass was estimated by measuring circumferences at breast height and height of each tree and sampling destructively eight trees per treatment. Allometric equations were established to estimate the biomass of all aboveground tree compartments and the relation between soil carbon storage and tree biomass will be deducted. The results will give insights into the capacity of EP on tropical highlands to improve soil carbon sequestration.

SOIL CARBON, NITROGEN, SULFUR, AND C/N RATIOS IN PERMANENT FORESTS RESERVES OF TERENGGANU, MALAYSIA

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Mohd Hakeem Mohd Ibrahim[1]

[4] Forestry Department Peninsular Malaysia, Kuala Lumpur, Malaysia
[5] Dept of Forestry Science & Biodiversity, Faculty of Forestry & Environment, UPM
[6] Dept. of Forestry Science, Faculty of Agricultural & Forestry Sciences, UPM Sarawak

Abstract: Carbon and nitrogen are two vital components that play a crucial role in preserving the health and productivity of forest ecosystems. The permanent forest reserves managed by Terengganu State Forestry Department are essential in maintaining the natural habitats of diverse flora and animal species. Also, these reserves offer beneficial ecosystem services like nitrogen cycling and carbon sequestration, which are crucial for reducing the effects of climate change. However, there is a significant lack of documentation on the soil carbon and nitrogen distribution in the forest reserves including sulphur and C/N ratios. This information is essential for maintaining the health and productivity of these ecosystems. By studying the cycling of this element, we can gain insight into how these ecosystems function and how they may respond to environmental changes or the effect of logging and it will benefit the decision-makers, who need to make informed decisions about forest management strategies. Therefore, evaluating the current carbon and nitrogen distribution is crucial in making suitable plans to rehabilitate and conserve the forests. This study aims to assess the soil carbon, nitrogen, sulfur, and C/N ratio distribution as part of evaluating the soil health of Terengganu permanent forest reserves. Soil sampling was carried out at the research plots of endangered timber species. Composite soil samples were collected from 0-40 cm depth and were air-dried for 48 hours at room temperature prior to analyses. Analyses carried out include bulk density, soil pH, and carbon, nitrogen, and sulphur analyses. The soil analysis is currently underway, and the results will provide valuable insights into the distribution of carbon and nitrogen in the protected forests of Terengganu. These findings will contribute to our understanding of how these ecosystems function and respond to environmental changes, ultimately helping to maintain their health and productivity.

Soil moisture controls the partitioning of carbon stocks across a managed boreal forest landscape

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Johannes Larson[1]
Jörgen Wallerman[1], Matthias Peichl[1], Hjalmar Laudon[1]
[1] Swedish University of Agricultural Sciences

Abstract: Boreal forests sequester and store vast amounts of carbon (C), with likely important feedbacks potential to climatic warming. To understand climate change impacts on carbon stocks it is important to assess the controlling factors determining the magnitude and partitioning of different C pools within different scales. The boreal landscape is heterogonous, consisting of a mosaic of forests and peatlands with large variations in total C stocks within small distances. We quantified the total C stocks including the organic layer, mineral soil and the tree biomass in 430 plots across a 68 km^2 boreal catchment. We could show that the organic layer constituted the largest C pool, accounting for 39% of the total C storage, followed by tree and mineral C pools constituting 38% and 23%, respectively. Modelled soil moisture conditions revealed a clear increase in the magnitude of total C stocks with increased soil moisture, which was especially pronounced for the soil organic C pool (R^2=0.50). In contrast, the tree C pool followed a unimodal relationship with the highest storage at intermediate wetness conditions. The partitioning between tree and soil carbon pools were also highly dependent on soil moisture conditions, which in the small spatial scale of this study is mainly driven by topographic variation. In addition, we revealed a similar magnitude and variation in the total soil C stocks compared to those found at the national level in Sweden, suggesting that the local scale variation, primarily driven by soil moisture conditions is far more important than regional differences in climate, nitrogen deposition and parent material for C accumulation in the boreal landscape.

Soil organic carbon in high karst Dinaric fir-beech forests is influenced by site morphology, soil type and harvest intensity

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: Close-to-nature (CTN) forest management has traditionally been applied in fir-beech forests of high karst Dinaric regions. CTN management preserves soil organic carbon (SOC) through low levels of forest stand disturbance and changes in a microclimate with a relatively high amount of growing stock. SOC storage was used as an indicator for the valorization of the effects of CTN forestry management in beech and fir forest stands. The same methodology was applied to four selected plots in Slovenia and Bosnia and Herzegovina with applied different harvest intensities. The designed forest experiment resembled large-scale disturbances taking place in 2014 and 2017, such as sleet, windthrows, and consequent bark-beetle attacks. SOC varied in relation to site micromorphology and soil type. Higher harvest intensity, including 50% and 100% reduction of growing stock resulted in variations of SOC and nitrogen in the forest floor and upper mineral layer. The analysis did not confirm any significant differences in SOC storage on sites with applied low-intensity harvests (less than 20 % of the growing stock). Provided results explain soil organic carbon storage related to CTN forest management, prior to and after harvests which resemble to natural disturbances, and may serve as a reference for the future comparisons of similar highly productive forest sites.

Soil organic matter fractions and soil carbon storage as affected by forest type and climate change

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Veronika Jílková[1]
Kateřina Jandová[2], Olga Vindušková[2]
[1] Biology Centre of the Czech Academy of Sciences, Institute of Soil Biology and Biogeochemistry, České Budějovice, Czech Republic
[2] Charles University, Faculty of Sciences, Institute for Environmental Studies, Prague, Czech Republic

Abstract: Temperate forests have a great potential to store soil organic carbon (SOC). Coniferous forest topsoils generally store more SOC than deciduous forest topsoils. However, less is known about C distribution in subsoils. Also important is the partitioning of SOC into fractions of soil organic matter (SOM), which differ in terms of formation, persistence, and function. Few studies have compared the proportions of C in SOM fractions between coniferous and deciduous forest soils or the influence of C inputs of variable quality and of soil community composition on SOM fraction formation and persistence. Fraction formation and persistence might also be greatly affected by climate change, which includes an increase in temperature and a shift in the distribution of tree species. Here we present results of our field study focused on the partitioning of SOC into fractions of SOM in temperate forest topsoils and subsoils under spruce, beech, and mixed forest stands. We also discuss results of our laboratory experiments focused on the effects of C inputs of variable quality and climate change on SOM fraction formation and decomposition.

SOM-mineral association and interaction in forest floors of silicate vs. calcareous soils

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Gabriela Villalba Ayala[1]
Jörg Prietzel[1]
[1] Technische Universität München - Chair of Soil Sciences

Abstract: In forest ecosystems, the accumulation of plant residues on the soil surface creates a unique zone rich in soil organic matter (SOM) known as forest floor (FF). Forest floor SOM plays an important role in forest vitality and productivity because it drives a variety of physical, chemical, and biological soil functions. Its properties and susceptibility to mineralization are strongly affected by the extent of organo-mineral association and formation of SOM-mineral assemblages. The content of mineral compounds in FF layers can be considerable (theoretically up to 70 mass percent). The accumulation of mineral compounds in FF can be attributed to several pathways, including abiotic mineral particle deposition, bioturbation, etc. Information about the relative contribution of organic and mineral compounds in FF layers and their structural and spatial arrangement provides useful insights into the mechanisms involved in their formation and turnover, FF resistance to microbial decomposition, and FF stability in a warming climate. However, our current knowledge about inorganic FF constituents and SOM-mineral association in FF is scarce.

Within the framework of the DFG-funded Research Unit "Forest Floor" (RU 5315), we investigated the effects of parent material and climate on biochemical and/or physicochemical FF properties (SOM C speciation, FF nutrient, and mineral content, SOM-mineral association) by analyzing O layers of German and Swiss forest soils with different parent material (silicate, carbonate) and climate conditions (elevation/temperature gradient). We combined the application of a novel density fractionation method optimized for FF characterization (Prietzel et al. 2020) with a detailed chemical characterization of the different density fractions, including cutting-edge methods such as synchrotron-based XANES spectroscopy. Density fractionation has been proven a powerful method to distinguish SOM fractions with different extents of SOM-mineral interaction and/or occlusion within aggregates in mineral soil samples. However, its utilization for FF characterization at present is still limited. Our study for the first time compares SOM-mineral interaction and association patterns in O layers of silicate and calcareous soils. The results will enhance our understanding of parent material effects on FF properties and FF resilience to climate warming.

Spruce and aspen density treatments within the boreal forests and their effects on soil carbon and nutrients.

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: Mixed conifer-deciduous species forests are a promising step towards climate change adaptation and mitigation as coniferous forests are increasingly damaged by abiotic and biotic disturbances that are related to climate change. In Canada, a common forest mixture of the western boreal forests is trembling aspen (*Populus tremuloides* Michx.) and white spruce (*Picea glauca* (Moench) Voss). Key benefits to mixed-species forests include higher resilience to climate change, potential higher total biomass and enhanced long-term site productivity. Increased resilience results from complementarity in resource use, increased productivity, and the presence of aspen litterfall forming moder humus. This leads to improved mineralization and decomposition for more nutrient-rich soil. This study explores how aspen density in mixed stands affects the carbon storage potential and nutrient content above and below ground. Testing was conducted at the Western Boreal Growth and Yield (WESBOGY) Long-term Study site located in Prince Albert, Saskatchewan in Canada. This site was established in 1990 with white spruce planted in clearcut areas where aspen was regenerating. At age 5, aspen was thinned to a range of densities (0, 200, 500, 1500, and 4000 sph) along with an unthinned control. Soil samples were taken over two summers along with spruce and aspen foliage in each treatment to analyze macronutrient and soil carbon content. Comparing the different density treatments will contribute to our understanding of mixed-forest stand dynamics, nutrient cycles, and soil properties in boreal forests. The findings of this study will be used to guide forest managers to make informed decisions regarding silvicultural treatments to enhance carbon storage capacity, optimize forest health, productivity, and resilience in the face of climate change.

Stand-scale carbon dynamics modelling in deciduous temperate forests under climate change

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Frédérik Doyon[1], Évelyne Thiffault[2]
[1] University of Québec in Outaouais, Natural Sciences Department, Canada
[2] University Laval, Forest and Wood Sciences Department, Canada

Abstract: Forests ecosystems can help mitigate the effects of climate change since they can assimilate atmospheric carbon and store it in the living biomass, dead organic matter and soil. The Net Ecosystemic Productivity (NEP) of a particular forest stand can inform us on the net carbon flux that will be added or subtracted to the total Stand Carbon Storage (SCS) over time, as a positive value indicate a carbon sink and a negative value indicate a carbon source. To help estimate those values, many models have been developed over the last years to couple stand-scale forest growth dynamics to forest carbon dynamics using empiric methods. Under climate change however, these models need to integrate finer-scale processes and fluxes to correctly represent the future behavior of forest ecosystems under those conditions. The goal of this research project is to evaluate stand-scale carbon dynamics in deciduous temperate forests of Southern Québec, Canada under different sylvicultural strategies in interaction with current and future climate. We first calibrated the HETEROFOR model to simulate spatially explicit forest growth dynamics for several types of stand associations typical of the temperate forest of Québec. This model was then joined with the dead organic matter, decomposition and soil organic carbon modules of the CBM-CFS3 model and validated with long-term stand survey data to simulate long-term carbon dynamics (NEP/SCS) of forest ecosystems under numerous different factors. We used this new complete model to generate stand carbon assessments (NEP/SCS) curves over a 100-year period for several temperate forest stands under many current or alternative silvicultural strategies and in interaction with several climate variables linked to current and future climate conditions. We used an ANOVA analysis to identify scenarios with better carbon uptake and storage at any given time during the simulation and an HGAM analysis to identify which scenarios had the best total SCS for the whole simulation period. These simulations have allowed us to identify which strategies can help optimize stand NEP and SCS depending on future climate interactions and which ones should be favored to help mitigate climate change impacts in the future.

Sustaining forest carbon sequestration following disturbance: What have we learned from a quarter century of coupled field-modeling experiments?

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: Disturbances from extreme weather, insects and pathogens, fires, and harvesting are increasing worldwide, with uncertain consequences for the forest carbon cycling processes that are crucial to climate stabilization and timber production. At the University of Michigan Biological Station, in northern Michigan, USA, we have used large-scale experiments, long-term observations, and simulation models for the last quarter century to understand how climate and a variety of disturbance sources affect forest carbon cycling processes, and to identify the factors that promote ecological stability. Decades-long observations from carbon flux towers suggest that a warming climate and changing forest composition initially increased carbon sequestration. However, temperature extremes may be eroding the forest carbon sink by accelerating organic matter decomposition and soil carbon losses. Experimental chronosequence studies suggest that clear-cut harvesting significantly reduced rates of carbon sequestration for a century, but subsequent fire had no compounding effect on long-term carbon cycling processes. In contrast, stem girdling experiments and observations during insect outbreaks indicate that forests can be surprisingly resistant to slower-acting partial disturbances that disrupt vascular tissue, sustaining carbon sequestration, in some cases, at tree mortality levels of 85%. Simulation modeling of our field experiments suggests that carbon cycling responses to disturbance are modulated by climate during recovery, highlighting the importance of disturbance-climate interactions when forecasting ecological stability.

Across experiments, multiple factors promoted carbon cycling stability, suggesting a common set of mechanisms sustained carbon sequestration through disturbance. First, the retention of growth-limiting resources played a crucial role, with more abrupt and severe disturbances causing carbon and nitrogen losses through leaching or volatilization. Secondly, the retention of biological legacies in the form of residual live vegetation supported rapid compensatory growth as disturbance-impacted trees declined. Lastly, greater biological and canopy structural diversity enhanced temporal stability, buffering carbon sequestration from high interannual climate variation and age-related tree mortality. Our collective results provide three critical insights: forest carbon sequestration can remain stable following relatively high levels of tree mortality; a suite of complementary ecological properties and mechanisms support stability; and management that cultivates these properties could mitigate the effects of disturbance and climate change on forest carbon sequestration.

The context-dependent role of ectomycorrhiza in decomposition

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: Ectomycorrhizal fungi are an essential component of soil biota in northern forest ecosystems. They live in tight symbiosis with trees and are particularly sensitive to forestry practices. It is crucial to understand the consequences of changes in their abundance and community composition for belowground carbon and nutrient cycling.

Some ectomycorrhizal fungi have retained significant decomposer capabilities during evolution from free-living ancestors, whereas other species lack decomposer enzymes. When ectomycorrhizal decomposers are abundant, they may drive decomposition particularly when other decomposers are scarce. However, dominance by ectomycorrhizal fungi may also hamper decomposition if they suppress more potent, free-living litter degraders (the Gadgil effect). The role of ectomycorrhizal fungi in driving or hampering decomposition is, thus, likely to depend on the functional capabilities of other actors in the fungal communities, and thereby on the over-all ecological context.

We have found support for this theory in a series of field experiments and surveys across subarctic, boreal and nemo-boreal forests in Sweden. In a gradient from more fertile/southern to less fertile/northern forests, the contribution of litter decomposing basidiomycetes decreased, whereas root-associated ascomycetes (including ericoid mycorrhizal associates) increased in relative abundance. Depending on this overall shift in fungal communities, the role of ectomycorrhizal is likely to change from hampering in more fertile soils to driving in less fertile contexts.

Forestry-related losses of ectomycorrhizal fungi may, thus, stimulate decomposition and nutrient cycling in more fertile soils, as potent free-living decomposers become free to proliferate in the absence of mycorrhizal competition. This Gadgil effect may favor seedling establishment and growth of young trees, but can also lead to losses of belowground carbon stocks. In more harsh environments, ectomycorrhizal decomposers may be essential drivers of organic matter turnover. When they decline, their role may not be taken over by the residual community of stress-tolerant ascomycetes with relatively low decomposer capabilities. This may lead to significant accumulation of carbon below ground, but hampered nutrient cycling may put long-term ecosystem productivity at risk.

The effects of forest management on water quality: the issue of carbon

Abstract: Water scarcity and contamination are the greatest pressures on global water resources, directly impacting upon our social and economic well-being and ecosystem health. Inappropriate land use management is contributing to these pressures and so there is a need to evaluate and improve how we manage land including forested areas.

Water draining forests is generally high quality, but forest management and operations can lead to deterioration and adverse impacts upon the aquatic environment. Key concerns include diffuse pollution, harmful effects on freshwater ecology, and carbon transport.

We undertook a global review of the effects of a range of forestry activities on water quality, attempting to summarise the literature across a wide geographical area focusing on empirical studies.

The review highlighted a wide range of water quality impacts after forest operations including sediment delivery, nutrient losses, changes in water temperature and dissolved organic carbon (DOC) transport, which contributes to browning of freshwaters.

Here, we focus on the question of aquatic carbon fluxes presenting the findings from our review and data from studies investigating the effects of forestry on dissolved organic carbon (DOC) transport; we also present management practices that have been shown to mitigate impacts.

Furthermore, we highlight knowledge gaps and discuss whether forests inherently contribute more carbon from terrestrial environments to surface waters and oceans than other land uses, a subject that is currently of great interest and debate due to concerns over drinking water treatment, global warming and climate change.

The effects of tree species identity and traits on soil carbon sequestration and stability in a large mature common garden in Belgium

Abstract: The climate is changing due to elevated CO_2 concentrations in the atmosphere, therefore there is a need for climate change mitigation practices. Forest ecosystems contain vast amounts of carbon (C), and their soils have the potential to sequester C and therefore act as a C sink. Understanding the mechanisms influencing C sequestration, and more specifically its stability, are crucial for optimisation of forest management. This research aims at identifying the effects of different tree species traits and identities on C sequestration and stability. The research makes use of a Common Garden experiment, situated on loamy soils and located in the Geographical Arboretum Tervuren, Belgium. This setup provides a unique study area in which different tree species are located within a similar edaphic context, and therefore the environmental variation within the study area is limited. Twenty-two monoculture stands with unique tree species are selected and soil samples of the topsoil (0-10 cm) and subsoil (10-20 cm) are taken and analysed on their total and organic C stocks, dissolved organic C, total N, and pH. Using a density fractionation method with a density cut-off of 1.8 g/cm^3, soil organic matter is fractionated into particulate organic matter (POM), occluded POM and mineral-associated organic matter (MAOM) to determine the C stability. With the use of pyrolysis-GC/MS the molecular composition of these different fractions will be determined, to identify the effects of tree species on the stability of C. The results of this ongoing experiment will be presented. The first, very preliminary results show indications of higher soil organic C content, but less stable C fractions, underneath coniferous tree species compared to broadleaved species. Additionally, we hypothesise that the differences in molecular composition of organic matter correlate with the stabilised fractions of C, based on the properties of the functional groups and their capacities to interact with mineral surfaces. To conclude, tree species have a substantial effect on C stability, and having insight in the specifics will make it possible for forest management to choose tree species based on their ability to stabilise C and therefore help in mitigating climate change.

THE IMPACT OF CONSEQUENCES OF WAR IN UKRAINE ON CARBON-SEQUESTERING FUNCTION OF FORESTS

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: The full-scale armed aggression of the bloody regime of the Russian Federation against independent Ukraine causes irreparable losses not only to the population and infrastructure, but also leaves deep wounds in the natural environment of the country. As a result of rocket strikes and hostilities in large areas, an instantaneous loss of forest resources has occurred; the induced forest fires significantly deteriorate environmental functions (carbon sequestration, oxygen production etc.), whose restoration will take decades.

The daily war statistics testify to growing losses of forest fund in both geographical and economic dimensions. According to the data of the State Forest Resources Agency of Ukraine, as of April 1, 2023, the area of forested land affected by the armed aggression was over 1 million 700 thousand hectares. At the same time, 14.2 thousand hectares have suffered from forest fires, of which 906 hectares were crown fires. The total amount of damage and losses amounted to 42 million 242 thousand UAH.

In this research, we focused on losses of carbon-sequestering function of forest ecosystems, which is important for combatting climate change. The losses occurred because of damage to tree stands, mainly – due to forest fires.

The methodological approach to assessing losses of environmental functions of forests, caused by forest fires as a result of the armed aggression of Russian Federation, consisted in prognostic modeling of current increment in live biomass of stands based on mean biometric indices by their location (*Lakyda, 2002*), carbon content in wood (wood, bark) and photosynthesizing (foliage) crown fractions, and live ground cover (*Matthews, 1993*).

Forest areas affected by crown fires were considered as having completely lost the productivity of environmental functions, for ground fires – only a third of their total area. The results show that annual loss of the carbon-sequestering function in forests of the State Forest Resources Agency of Ukraine amounts to 12.39 thousand $t \cdot year^{-1}$ (including 2.08 thousand $t \cdot year^{-1}$ – due to crown fires, 10,31 thousand $t \cdot year^{-1}$ – ground fires). The annual losses of sequestered carbon will have a significant impact on the gas balance of the atmosphere and will decrease over time if the affected areas are afforested.

The interacting effect of climate change and herbivory can trigger large-scale transformation of European temperate forests

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

[4] Global Change Research Institute, Czech Academy of Sciences

Abstract: Climate change and natural disturbances are driving the fast transformations of many European forests. Regionally, populations of large wild herbivores exceed the environment`s carrying capacity and shift forest community composition through their foraging preference. We focused here on managed temperate forests dominated by *Picea abies,* which have been cultivated across Europe and often replaced native broadleaved forests; these forests have recently experienced an unprecedented disturbance level from wind, drought, and bark beetles. Many disturbed areas are exposed to climatic stress and herbivory, potentially leading to large-scale forest degradation, including critical loss of climate regulation function. We used the individual-based forest landscape and disturbance model iLand to evaluate the long-term impact of this combination of stressors on forest demography, carbon, and species composition.

A high browsing pressure maintained *P. abies* in species composition by reducing the competition of naturally dominating and more palatable broadleaved species. A browsing reduction or exclusion caused the fast replacement of *P. abies* by other species. This transition was accelerated by warmer and drier climates, increasing *P. abies* mortality from climatically sensitive bark beetle outbreaks. Under the reduced browsing, the forests converged to the new equilibrium characterized by an unchanged level of landscape carbon, a large number of smaller-diameter trees, higher carbon uptake, and significantly lower vulnerability to natural disturbances. On the contrary, increased browsing pressure combined with warmer and drier conditions resulted in a fast transition to the conditions characterized by reduced landscape carbon, reduced carbon uptake, and high disturbance susceptibility.

We conclude that the success of game management can make a difference between climate-adapted stable forests preserving high carbon stocks and degraded vulnerable forests with low carbon stocks and diminished provision of ecosystem services.

The responses of soil microbial characteristics to nitrogen addition and biochar amendment in a Larix kaempferi plantation

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

JINGPIN LEI[1, 2]
CHEN HU[1], ZHIYUAN MA[1], JINYU GONG[1], TIAN LI[1]
[1] Research Institute of Forestry, Chinese Academy of Forestry
[2] Hubei Academy of Forestry, Wuhan, China

Abstract: Nitrogen (N) deposition is an important environmental factor that can change soil chemical properties. It can also alter the characteristics of microbial communities. The incorporation of biochar into soils is considered a potential strategy to enhance carbon (C) storage in soil and modify the impacts of N deposition. However, the impacts of biochar on the microbial characteristics of soil after short-term N deposition in subtropical plantations remain poorly understood. Here, we investigated the effects of biochar application (0, 5, 10 t ha^{-1}) on soil chemical traits and microbial characteristics (extracellular enzyme activities, microbial community and microbial biomass) in a *Larix kaempferi* plantation in Shennongjia, China, under N addition (0, 50, 100 kg N ha^{-1} yr^{-1}) during two growing seasons. We found that simulated N deposition significant increased soil total nitrogen (TN), nitrate nitrogen (NO_3^--N) and total phosphorus (TP) concentrations, while heavy N deposition (100 kg N ha^{-1} yr^{-1}) significant decreased soil microbial biomass nitrogen (MBN) concentration and β-glucosidase (β-GC) activity. Biochar amendment significantly increased soil microbial biomass, TN and soil organic carbon (SOC) concentrations. Both N addition and biochar amendment significantly altered *Ascomycota* and *Basidiomycota* relative abundance, with biochar amendment increasing *Ascomycota* relative abundance and decreasing *Mortierellomycota* relative abundance under heavy N deposition. Fungal diversity showed a positive correlation to TN, TP and NO_3^--N concentrations, but a negative correlation to MBN. Biochar addition inhibited the increase in soil NO_3^--N concentration caused by high N addition in the plantation, and influenced the change in the composition of microbial community caused by N addition. Our piecewise structural equation model suggested that N addition affected MBN and fungal diversity directly or indirectly via its effects on soil enzyme activities and properties. In contrast, there were no significant direct or indirect effects on bacterial diversity among all factors. These results improve our understanding of the influence and mechanisms of N addition and biochar amendment on soil microbial characteristics in subtropical coniferous plantations in the short term, and can provide a valuable reference for predicting the future effects of N deposition on soils in this region's plantation.

The significance of tree retention at harvest of boreal forests on belowground storage of carbon and nitrogen after twelve years

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Tamlyn Kirstey Gangiah[1]
Andreas Lundgren[2], Karina Clemmensen[3], Björn Lindahl[1], Anders Dahlberg[3]

[2] Department of Ecology, Swedish university of Agricultural Sciences, Uppsala, Sweden
[3] Department of Forest Mycology and Plant Pathology, Swedish University of Agricultural Sciences, Uppsala, Sweden

Abstract: Management practices have significant impacts on carbon and nutrient cycling in boreal forests. In Sweden, forested land is dominated by secondary forests planted after clear-cutting, and the impacts of these practices on belowground carbon and nutrient cycling are of particular importance. On recent clear-cuts, microorganisms may encounter carbon limitation due to the loss of carbon input from roots and litter fall. This limitation can potentially lead to accelerated carbon loss and increased rates of nitrogen mineralization. On the contrary, disruption of ectomycorrhizal symbiosis in clear-cut areas could potentially hinder the turnover of organic stocks, resulting in carbon sequestration and retention of organic nitrogen belowground. To test these ideas, we established a long-term experiment in a low-productive pine forest in northern Sweden that was visited after twelve years, which comprised four levels of harvest intensity: fully clear-cut (0%), 30% or 60% of evenly distributed trees retained, and unlogged (100%) plots. In fully clear-cut plots, carbon storage was significantly lower, with partially harvested plots showing similar carbon stocks to the unlogged plots. Nitrogen stocks were marginally lower in the clear-cut plots, whereas in partially harvested plots nitrogen stocks remained more similar to the unlogged plots. Ammonium levels were consistently low across all plots (and nitrate was not detected), suggesting that any remaining trees (including saplings) and understory vegetation maintained the ecosystem in a nitrogen-limited state. Potentially contributing to the observed 1.45% and 1.32% average increase in growth post-harvest by the 30% and 60% partially harvested plots, respectively. Thus, tree retention may be a means to mitigate soil organic matter losses and promote carbon storage without limiting the availability of nitrogen for tree growth, as shown by increased tree growth post-harvest. Overall, this study highlights the influence of management practices on carbon and nutrient dynamics in northern boreal forests.

The Silva Nova Project - Restoring soil biology and soil functions to gain multiple benefits in new forests

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

[3] Mycology and Microbiology Center, University of Tartu, Estonia

Abstract: Afforestation and forest restoration are seen as key factors to mitigate climate change and biodiversity loss given that forests host a major part of the species pool. In Denmark, most of the areas intended for afforestation are former cropland, and their agricultural legacies (high nutrient availability, altered soil biota structure and function) constrain the development of forest-adapted species, tree growth and stability, ecosystem functions and biodiversity.

The central hypothesis of Silva Nova is that inoculation of former arable land with soil (including microbiome, fauna and seeds/rhizomes of understory vegetation) from old forests will improve productivity and more rapidly restore forest-adapted communities.

The project will test this hypothesis by 1) evaluating temporal and spatial responses in biomass production, soil biota and soil functions to afforestation in existing chronosequences and sites with increasing distance to other forests; 2) quantifying the effects of inoculation methods regarding donor, amount and application mode to different soil types and tree species through mesocosm experiments; 3) expanding knowledge of inoculation methods from mesocosm to new and existing field-scale experiments; 4) incorporating the landscape context into guidelines and tools for spatially explicit prioritization of areas for promoting dispersal.

Our methodologies will link results from state-of-the-art eDNA analyses for above and below-ground microbiome characterization (bacteria, fungi and insects) to vegetation analyses, forest structure (LiDAR), in-situ and laboratory measurements of soil functions (e.g. greenhouse gasses and soil metabolic activity) and soil and plant chemical properties.

The aims of Silva Nova are to resolve barriers for successful restoration and develop landscape-scale afforestation strategies that optimize productivity and biodiversity, while generating knowledge on the trees, ground vegetation, soil fauna, and microbiome nexus and its effects. Silva Nova is a collaborative effort between the universities of Copenhagen (DK), Leiden (NL) and Tartu (EE), that received a six years grant from the Novo Nordisk Foundation.

Towards a model of forest soil carbon dynamics under tree species composition shift

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Olga Vindušková[1]
Gaby Deckmyn[2], Kateřina Jandová[1], Veronika Jílková[3]

Abstract: As forest management responds to climate change, temperate forests will experience a shift from coniferous to deciduous species. Predicting the impact of such shift on soil carbon dynamics will require soil C models that include all relevant mechanisms, e.g., changes in litter quality and soil biota, belowground input quantity and distribution, stability of soil organic matter and priming effect.

To model stability of soil organic matter, advancing from the use of theoretical, kinetically defined SOM pools to empirically defined SOM fractions such as particulate organic matter (POM) and mineral-associated organic matter (MAOM) has been suggested as a way to improve C models. Both POM and MAOM decomposition may be increased by DOC inputs via the priming effect (PE) which is stronger in less-protected fractions (i.e., POM) and is also influenced by the DOC input quality. Even though PE effects could reduce SOC gains from enhanced ecosystem productivity under global change, the PE has been introduced to few models only recently; none of them, however, considers how C input quality affect the PE. The recently introduced KEYLINK model allows to model the interaction between C dynamics, soil biota and soil structure, but requires further validation with experimental data.

Here we review which mechanisms should be considered when predicting soil C dynamics under tree species composition shift and which of the currently available models of C turnover include empirically defined SOM pools (POM and MAOM), priming effect and effects of soil biota. We propose how to combine these into a model that is capable of modelling the impact of shift in tree species composition on forest C stocks.

Tree Species Composition and Carbon Stock in Biomass of Young Forests at a Post-Disturbance Area in Tatra National Park, Slovak Republic

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Bohdan Konopka[1]
Vladimir Seben[1], Jozef Pajtik[1]
[1] National Forest Centre, Forest Research Institute Zvolen, T.G. Masaryka 22, SK-960 01 Zvolen, Slovak Republic

Abstract: Long-term records in Slovakia show that the large-scale disturbances in the forests have increasing tendency since the 60's. The evidence further proved that windstorms have been the severest destructive factor in most of the years. The largest wind disturbance within the present millennium in the Slovak Republic occurred in November 2004 (windstorm Elisabeth). The wind impacted the northern and central parts of Slovak territory particularly hard, with the epicenter of forest destruction in the Tatra National Park (TANAP). The wind destroyed forests dominated by Norway spruce at elevations from 700 to 1400 m a.s.l. Since the windstorm dramatically modified the forest stands in TANAP, our research team approached to quantification of tree species composition and carbon pool in whole-tree biomass of young forest stands in 2007, 2010, and 2016. We recorded that the number of tree species was significantly greater at lower (below 900 m; i.e. foothill sites) than higher elevations (above 900 m; i.e. mountain sites). The number of species increased between 2007 and 2010, and after 2010 almost stabilized. In 2007, estimates showed an average of nearly 2.0 tons of carbon per hectare, but only 0.4 tons per hectare in the lower and the higher sites, respectively. Between 2007 and 2016, carbon stocks in whole-tree biomass grew to 11.5 tons per hectare in lower sites and 5.3 tons per hectare in higher ones, with an average for the entire area of about 8.0 tons per hectare. Our estimates also showed that the amount of carbon in whole-tree biomass before the calamity (in 1996) was 101 tons per hectare. After the wind disturbance, higher biomass stock was found among conifers (especially Norway spruce) at lower elevations and among broadleaves (mostly rowan and birches) at higher elevations. The tree species composition twelve years after the wind disturbance was more diverse than that before forest destruction. We can conclude that the current tree species composition in TANAP seems to be a positive consequence of disturbance, especially given the forest stand's resistance to harmful agents**.** We suggested that continuous monitoring of forest development based on a network of plots would be important.

Tree species diversity and size inequality of Akure Strict Nature Reserve, Nigeria

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Oladele Fisayo Falade[1]
Dami Adewale Aruwajoye[1]
[1] Department of Forest Production and Products, University of Ibadan, Nigeria

Abstract: Interaction among tree species contributes to maintenance of species diversity in forest structure. Size structure and species structure do not have the same effects on ecosystem functions and services. Understanding the coexistence of tree species diversity requires knowledge of inter- and intra- specific interaction. Therefore, this study investigated tree species diversity and size inequality in Akure Strict Nature Reserve. Eighteen and twelve plots (30m x 30m) were laid on parallel transects of 400m long in identified Old-growth and Riparian forests, respectively. Six (6) sample plots (30m x 30m) were demarcated alternatively with 30m intervals on a line transect of 400m long. Trees with diameter-at-breast-height (dbh) ≥ 10cm were counted and identified to species level. Tree diameter at base, middle and top and total height were measured using Relaskop. Tree species diversity (Shannon-Weiner, Simpson and Margalef indices) and dbh inequality measures (Gini coefficient, Gini; Coefficient of Variation, CV; Skewness Coefficient, Skewness) were computed for each plot and compared for each forest type. Stem biomass were computed and converted to carbon stock. Data were analysed using descriptive, and correlation analysis at $\alpha_{0.05}$. Fifty-five (56) tree species representing 17 families were found in the forest. Species diversity indices were higher in Riparian while size inequalities in Old-growth forests. CV correlate with skewness (r=0.810) and Shannon (r=0.735) in Old-growth while GC correlate with CV (r=0.716) in Riparian forests. The size inequality measures were strongly related with each other in Riparian while species and size inequality measures were strongly related with each other in Old-growth forests. The carbon stocks of Old-growth and Riparian forests were 117.21Mg/ha and 43.47Mg/ha, respectively. *Triplochiton scleroxylon* and *Bridelia micrantha* contained highest carbon stock in Old-growth and Riparian forests, respectively. Asymmetric mode of interaction in the absence of competition shows competition for below-ground resource, especially presence of moisture and nutrient gradient. Size inequality among different and within the same species determined coexistence tree communities in Old-growth and Riparian forests of Akure Strict Nature Reserve, respectively.

Unveiling the Role of Mistletoes as a Potential Drought Accelerator for Host Plants in Arid Environments

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: Global warming has far-reaching consequences beyond temperature rise, including increased aridity in various regions, imposing significant drought stress on trees. European mistletoe (*Viscum album*), a widespread species found throughout Europe, has exhibited an increased severity of infection in central Europe in recent decades, accelerating drought stress in its host plants.

In this study, conducted in Switzerland, we investigated the physiological responses of mistletoes and its host plants to long-term irrigation. Surprisingly, mistletoes exhibited reduced carbon assimilation compared to its host, suggesting a decreased carbon incorporation capacity under irrigation conditions. Additionally, a needle-removal experiment carried out as part of a whole crown ^{13}C pulse labeling experiment, revealed a higher presence of ^{13}C assimilates in mistletoe leaves in dry control plots compared to the irrigated, indicating that the mistletoe's photosynthetic capacity is driven by the water availability of the host. Morphologically, mistletoe displayed smaller leaf size and higher LMA, indicating an adaptive strategy to enhance water uptake capacity during dry periods. Our results signified that host needle removal not only affected source–sink carbon relationships in the girdled branch but might also result in more available water for the mistletoe due to discontinued host transpiration. The alleviated competition for water may allow the mistletoes to keep stomates more open, thus facilitating higher photosynthesis rates. However, an assessment of multiple mistletoe-host pairs with different host tree species demonstrated relatively stable leaf morphological traits for *V. album*, suggesting a more responsive nature to water availability rather than host specificity. Overall, our findings indicate that *V. album* employs aggressive strategies to maintain a stable water potential gap and higher transpiration rate compared to its host, allowing to effectively compete for water resources under drought conditions.

Our findings strongly support the notion that European mistletoe and its host plants maintain a harmonious coexistence relationship in habitats characterized by adequate hydration levels. However, as global warming is likely to drive more severe and frequent drought events across the terrestrial ecosystems, such equilibrium of coexistence relationship may become disrupted and

mistletoe would exhibit a strong potential in exacerbating the already challenging drought conditions faced by the host plants.

Warming influences the carbon-nitrogen exchange between a widespread understory shrub and its root-associated fungi

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Paul Kardol[1]
Stefan F. Hupperts[1], Kazi Samuil Islam[1], Michael J. Gundale[1], Maja K. Sundqvist[1]
[1] Swedish University of Agricultural Sciences

Abstract: Boreal forests are warming faster than other forests and are often dominated by a ground layer of Ericaceous shrubs, which are a key ecosystem components that may respond positively to warming. As a result, heightened competition from shrubs under warming could drastically modify tree regeneration and stand development. Along with woody plants worldwide, boreal shrubs form symbioses with mycorrhizal fungi, which forage for nutrients that can be transferred to the host plant in exchange for photosynthetically-derived C. The carbon-for-nitrogen (C-N) exchange between Ericaceous shrubs and ericoid mycorrhizal symbionts may underlie shrub responses to warming, but is not well understood.

We performed three parallel and complementary greenhouse experiments to investigate the effects of warming on the C-N exchange between the Ericaceous shrub *Empetrum nigrum* and its root-associated fungi. We applied different ^{13}C and ^{15}N isotope labels, including a simple organic N form (i.e., the amino acid glycine), and a complex organic N form (i.e., moss litter), and quantified the assimilation of the labels into soil, plant biomass, and root fungal biomass pools. We found that warming lowered the ^{13}C cost of glycine ^{15}N (for *E. nigrum*), but only in the short-term. This suggests that positive warming effects on the C-N exchange rate disappears when a pulse of free amino acid ^{15}N is depleted, implying that any positive effects of warming are contingent on the availability of free amino acids. In contrast, warming increased the ^{13}C cost of ^{15}N from moss, indicating that the effect of warming also depends on the form of organic N. In contrast with glycine, moss litter is highly recalcitrant and N incorporated therein first requires liberation before being assimilated.

Given that *E. nigrum* is abundant in boreal forests, the effects of warming on nutrient acquisition efficiency that we observed may have consequences for how boreal forest ecosystems respond to warming. Lower C costs for amino acid N uptake could allow *Empetrum*, and perhaps also other Ericaceous dwarf shrubs, to redirect C toward other functions such as growth, respiration, or defense. Hence, in understanding forest responses to climate change, we should not forget about the understory.

Wildfire impacts on a managed boreal forest: an interdisciplinary perspective

S1.3 Forests in a changing world – impacts on carbon and nutrient dynamics

Abstract: The interactions between forest management decisions and the impacts of wildfire have rarely been studied in the Eurasian boreal forest. Yet the increasing frequency and severity of wildfire threatens the ability of this ecosystem to continue providing the carbon sequestration, wood production and cultural services that millions of people depend on. In 2018, an extreme drought in central and northern Europe caused an unprecedented number of wildfires across Sweden. We present the results of an interdisciplinary team of researchers studying the impacts of the largest fire that year, the Ljusdal fire. In combination with the fire impacts, we investigated how forest management decisions after fire (e.g. salvage-logging versus creation of nature reserves) have affected the recovery of these forests. During the first four years since the fire we measured soil microbial dynamics, nutrient cycling, vegetation growth, tree transpiration and greenhouse gas fluxes.

Our results indicate that the stands were net carbon emitters for at least four years after fire and may take over 30 years to recover all the carbon lost during the fire. Decisions on how to replant the forest after fire had no notable impact on the rate of recovery of the forest carbon budget. However, the decision to salvage-log or leave the trees standing had a significant effect on the ecosystem greenhouse gas emissions, microclimate, soil microbial growth rates and soil nutrient cycling. Combining these findings with further experimental work, we will highlight the mechanisms influencing how wildfire and forest management decisions impact the recovery of the forest carbon budget. Our results lay the foundation for identifying best practices to sustainably manage commercial European boreal forests at risk from climate extremes.

Abstract: The effects of forest harvesting on watershed exports (i.e., streamflow and evapotranspiration) are often not predictable across catchments or time. This is likely due to subsurface storage dynamics and the complexity of climatic controls on the remaining vegetation. Moreover, watershed processes may not behave as expected following extreme wet or dry conditions, as hillslopes become hydrologically connected or plants become stressed. Here, we use data from a long-term harvesting study at the Caspar Creek Experimental Watersheds in coastal California, USA to explore the complex interactions between climate, timber harvesting, and water budgets. We present eight years of climate, soil moisture, and transpiration data from four coast-redwood (*Sequoia sempervirens*) forest watersheds exposed to 0%, 35%, 55%, and 75% reduction in pre-treatment basal area. We analyzed climate and transpiration responses to forest harvesting in this Mediterranean climate in the wet season (Dec–Mar), dry season (Jun–Sep), as well as during transitional seasons. We compared post-treatment responses (2018–2022) to the pre-treatment calibration period (2015–2017) and hypothesized that transpiration differences would be greatest during the driest periods, when soil moisture was limiting. We also expected transpiration differences among the treatment levels during the wet season when light was limiting as coast redwood transpires year-round at this site. We indeed found this to be true, but the degree of harvest did not always determine the response in transpiration. Our results suggest that many climatic and ecohydrological factors must be considered when determining the impacts of forest harvesting on watersheds.

Comparative Assessment of Forested Watersheds: A Nexus Approach for Correlates between Forest, Climate and Water Indicators

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Manisha Singh[1, 2]
Bhaskar Sinha[1], Jigyasa Bisaria[1], T. Thomas[3]
[1] Indian Institute of Forest Management, Bhopal, India
[2] Forest Research Institute, Dehradun, India
[3] National Institute of Hydrology, Bhopal, India

Abstract: Forested watersheds provide various ecosystem services, including water (quality & quantity), soil moisture, ecological integrity, biodiversity, and enhanced livelihood opportunities while moderated and influenced by climate variables. Degradation, deforestation, and changing climate variables have created severe imbalances in the already sensitive eco-hydro-meteorological phenomenon implicating the sustainable flow of water in forested watersheds. The attribution of changes in water quantity to the underlying climatic and vegetation drivers is warranted for effective water management. This entails a focus on understanding the multiple impacts of climate change on the forest-water nexus of river ecosystems. In the Indian context, the majority of Southern and Central Indian rivers are forest-fed, and the climate-forest dynamics constantly threaten their perennial flow. The Narmada River is the largest west-flowing Indian river, supporting over sixteen million people of four Central Indian states. Our study explores the nexus of forest-water-climate for two watersheds (Dindori and Barwani) with different forest cover (Very Dense, Moderately Dense), types (Tropical Moist Deciduous with Sal dominant), Tropical Dry Deciduous with Teak dominant) in the upper and middle zone of Narmada. We analysed the relationship between forests and climate change and their influence on the streamflow of the selected watershed using remote sensing and secondary datasets. Suitable indicators of climate variables (temperature, rainfall, Standardized Precipitation Index, and Standardized Precipitation Evapotranspiration Index); forest and soil (forest cover change, evapotranspiration, Normalized Difference Vegetation Index, Enhanced Vegetation Index, Soil Adjusted Vegetation Index, and Soil Moisture Index) were analysed for both watersheds from 2001-2020. Multivariate analysis using multiple hypotheses was conducted to explain changes in water quantity and attribution to associated parameters. The results suggest climate variables have a major influence on changes in streamflow for both Dindori and Barwani watersheds. Vegetation indices also influenced the stream flow in both the study watersheds. Multidimensional perspectives involving several contributing variables build a holistic understanding of eco-hydrological balance. Therefore, developing countries like India must focus on integrating biotic dynamics with climatic factors for the sustainable management of forest and water resources.

Effects of Road-Stream Crossings on the Eco-Hydrological Connectivity of Amazonian Streams

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Gabriel Oliveira Ferraz[1]
Thiago Belisario D'Araujo Couto[2], Cecília Gontijo Leal[2], Gabriel Lourenço Brejão[3], Karlmer Abel Bueno Corrêa[1], Alice Whittle[2], Marcos Ângelo Alves Filho[4], Silvio Frosini de Barros Ferraz[1]

[3] São Paulo State University, UNESP - IB, Brazil
[4] Sustainable Amazon Network, RAS, Brazil

Abstract: Road construction threatens the Amazon by driving deforestation and fragmentation of the remaining forests. The effects of these dynamics on the landscape result in various impacts on ecosystems, however, the consequences for the streams of the planet's largest river basin, the Amazon, are still poorly known. The interaction of rural and forest roads with the streams causes punctual alterations on aquatic ecosystem and its riparian zone, but the cumulative impacts to aquatic connectivity span along the hydrographic network. The objective of this study was to quantify and characterize road-stream crossing in agricultural landscapes in the Brazilian Amazon region. We used RGB Planet satellite imagery (3m resolution) to manually map roads (approx. 9.000km in extension) and thus identify crossings at 1st to 3rd Strahler's order streams in the Santarém municipality region, Pará state. We also collected field data to characterize the infrastructure associated with the road-stream crossings (e.g. structure type, presence of lentic habitat caused by the crossing, channel unevenness downstream the structure (i.e. perched culvert), etc), these data served as a basis to adjust the calculation of the Stream Continuity Index (SCI) to the reality found. We identified 2.048 road-stream crossings in the study area (approx. 11.000km²), most of which in agriculture land use. During the field validation, we found that 30% of the mapped intersections were absent, highlighting the importance of cross-checking the available imagery with the ground data. The most common structures associated with road crossings were culverts (56%) followed by single span crossings (i.e. bridge without support column) (28%). The predominance of culvert crossings threatens ecohydrological connectivity, as indicated by SCI. Moreover, the majority of culverts were perched (53%), which are particularly harmful to the movement of aquatic fauna (e.g. fish, acroinvertebrates, etc.). Advancing the knowledge about the road-stream crossings is crucial to understand and mitigate their ecological, social, and economic impacts. Both roads and streams play fundamental roles in the lives of Amazonian populations, and the harmonious interaction between these two factors is essential to ensure a sustainable future for the region.

Extensive reforestation activities lead to significant hydrological alteration in China

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Qiang Li[1]
[1] Northwest A&F University

Abstract: Over the past decades, China has implemented several large reforestation initiatives to combat land degradation, soil erosion, air pollution, and climate change. Satellite data showed that a striking increase in forest cover in China has significantly contributed to the Greening Earth. Yet, such a credible increment in forest has intensified hydrological cycles and reduced soil erosion, while reduced total runoff and increased soil moisture deficit, particularly in the Yellow River basin, a semi-arid region. In turn, the decreased water availability has negatively affected water availability for forest growth in some regions, leading to a rethinking of the reforestation programs. This talk will first synthesize the effects of reforestation on the key hydrological processes (e.g., evapotranspiration, runoff, soil moisture, and groundwater recharge) in China over different climatic zones. Then, the status quo and lessons learnt over the historical reforestation programmers will be presented. Finally, future forest management focusing on water sustainability in the context of future reforestation initiatives and climate change will be recommended and discussed.

Forest response to drought: Applying lessons learned to managing the forest-soil-water nexus for hydrologic

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

[6] University of Guadalajara, Guadalajara, Mexico

Abstract: Forests provide critical hydrologic services related to soil water storage and regulating streamflow and climate. Increases in the frequency and intensity of drought due to climate change threaten these services; however, we lack a mechanistic understanding of how drought affects the forest-water-soil nexus. Vegetation is the key mediator of water flows between the soil and atmosphere via transpiration; thus, understanding the mechanisms by which plants control water fluxes – from leaves to whole trees to ecosystems – is of paramount importance to accurately predicting forest response to drought and managing forests for their hydrologic services under climate change. Here, we present the results from six studies that examined the response of different forest ecosystems to severe drought, including two throughfall exclusion experiments that reduced throughfall by 50-100% (temperate mixed pine-oak forest; montane tropical cloud forests), one cloud reduction experiment (montane tropical cloud forest), and two studies that assessed forest response to naturally occurring droughts (tropical rainforest; paramo woodlands).

We used a combination of ecophysiological techniques (e.g., sap flow, foliar gas exchange, plant water potential, stable isotopes) together with micrometeorological and soil moisture measurements to assess plant controls on water fluxes. We also examined plant functional traits and physiological processes to enhance understanding of how drought response varies among different plant functional types and the implications for potential shifts in species composition. Finally, we synthesize our findings within the context of global research on the forest-water-soil next across diverse climate, soil and forest types, and local conditions to derive broader conclusions about the relevance for managing forest hydrologic functions in the face of drought.

Key findings include (1) tree species exert differential controls on water fluxes that reflect their water use strategies and functional traits; (2) drivers of vegetation water use dynamics vary across geographic region and forest type, with atmospheric drivers dominating in ever-wet tropical environments, soil moisture and atmospheric conditions interacting in seasonal temperate and tropical environments, and soil moisture prevailing in dry environments; and (3) knowledge of plant physiological controls on water fluxes provide insight into forest drought response and managing the forest-soil-water nexus for climate adaptation and resilience.

From the Soil to the Sky The power of the red mangrove to move up water and contribute water to the atmosphere.

[5] Biología de la Conservación, Centro de Investigación Científica y de Educación Superior de Ensenada, Baja California, México.

Abstract: Mangrove forests are great allies in combating climate change effects in coastal regions, mainly by their ecosystem services related to carbon, water, and energy processes. Even if these ecosystem services have impacts at regional and global scales, they are based on plant physiology and anatomy of the mangrove species and its continuous feedback with the micro-environment. Due to their geographical distribution, mangrove forests receive a high amount of energy by solar radiation that is transformed by plants into heat conduction and convection (*i.e.,* temperature) and latent heat (*i.e.,* transpiration). Moreover, mangrove forest must dissipate that energy without compromising their growth and maintenance at a very low water cost. Thus, during periods of high solar radiation incidence and high vapor pressure deficit (VPD), mangrove trees must regulate the water loss by transpiration and deal with water uptake by roots in a hyper-saline flooded environment, increasing, in turn, the leaf osmotic potential. Therefore, we analyzed the effect of the micro-environment on sap flow in dwarf mangrove forests dominated by red mangrove (*Rhizophora mangle* L.), during dry and rainy seasons in the Ría Celestún Biosphere Reserve, Yucatan (Mexico). In this regard, continuous measurements of air temperature, wind speed, photosynthetic photon flux density, solar radiation, and VPD were taken to characterize the micro-environment. Furthermore, sap flux density, leaf osmotic potential, and leaf–canopy transpiration were obtained using Granier's thermal dissipation method, a plant canopy analyzer, and a steady-state porometer. We found a maximum VPD and sap flux density in the dry season up to 2.88 kPa and 129.9 L m^{-2} h^{-1}, respectively; while during the rainy season, values were 1.65 kPa and 263.8 L m^{-2} h^{-1}. Greater transpiration rates and lower osmotic potential were found during the rainy season, which could have an impact on the ecohydrological processes modulation, affecting climate regulation at the local scale. Consequently, the study of water exchange and transport in mangrove forests – at leaf and canopy levels – is crucial for a better understanding of ecosystem services provided by mangroves, especially in semi-arid regions where water is for more, the most important resource for forests and societies.

impacts of native forest replacement by pinus plantations on water consumption and groundwater recharge in a Mediterranean context

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Mauricio Galleguillos[1, 2, 3]
Elizabeth Ramirez[4], Carlos Faundez[5], Oscar Seguel[4]

[5] Pontificia Universidad Católica de Valparaíso

Abstract: The continuous expansion of exotic pine plantations has replaced native vegetation such as thorny dry forests; this could have consequences in the hydrological cycle of the areas where this land cover change occurs. We aim to evaluate the effect of replacing *Acacia caven* dry forest with *Pinus radiata* plantations on actual evapotranspiration (ETa) and groundwater recharge (GWR) in a Mediterranean river basin of Chile. We implemented The HYDRUS-1D water transfers model to quantify ETa and GWR in both kinds of forest with three replications under different past, present, and future periods including climate change scenarios. We contrasted simulations against soil moisture and transpiration sap flow measurements, with satisfactory results with $R2 > 0.9$, $KGE > 0.85$ and $PBIAS < 10\%$ for soil moisture, and $R2 > 0.7$, $KGE > 0.55$ and $PBIAS < 15\%$, for transpiration. The results indicate that from 1979 to 2022, there has been a significant decrease in the ETa rate and GWR in both land covers, especially during the mega-drought period (2010-2022). The yearly differences between forests showed that ETa was between 180 to 214 mm $year^{-1}$ more in pines than in the dry forest and that the latter percolates between 184 to 237 mm $year^{-1}$ more than pines, regardless of the period analyzed. For the future climate change period, both coverages will decrease their GWR, regardless of the climate change modeling scenario. In some dry years, pines simulations showed suppression and even negative values of GWR related to the access to the local shallow water table to maintain their ETa rates. The historical replacement of shrubland by pine trees within the basin (corresponding to 7,751 ha) in the three-time period analyzed yielded amounts of 15 to 19 million m^3 $year^{-1}$ additional water consumption as ETa and between 14 to 18 million m^3 $year^{-1}$ decrease in GWR. Those amounts represent around 1.4 to 1.9 million water trucks per year, the currently available water supply for the rural population in the basin. Results reported in this study and the projected water scarcity in the region impose challenges to opting for carbon neutrality to which Chile is committed.

Influence of forest thinning on total suspended solids in headwater streams covered by Korean pine

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Sooyoun Nam
Honggeun Lim[1], Qiwen Li[1], Byoungki Choi[1], Hyungtae Choi[1]
[1] Forest Environment and Conservation Department, National Institute of Forest Science

Abstract: We examined changes in total suspended solids (TSS) after a forest thinning in headwater streams draining a Korean pine (Pinus koraiensis) plantation forest. We applied a paired-catchment analysis to treated (K_T: 0.8 ha) and control (K_C: 0.7 ha) catchments. The K_T catchment was subjected to 50% random thinning from December 2016 to March 2017, while the K_C catchment remained as a reference. Thinning operations were conducted by forest workers using chainsaws and non-heavy machinery. We conducted field observations using an automated water sampler (ISCO) and gauging stations with a V-notch (90°) at 1-hour intervals during rainfall events in the outlets of catchments. The paired-catchment analysis revealed that the TSS in the K_T catchment was increased compared with the K_C catchment within one and two years after thinning. However, the TSS in the K_C catchment appeared to decrease in three years after thinning. These results indicated the TSS could be increased due to hydrological connectivity via the magnitude of soil surface disturbance area in the immediate post-thinning period. After that, the TSS could be decreased by the protective effect of vegetation trapping and settling. Hence, forest thinning for mitigating increases in TSS can require appropriate site-specific management of land preparation with water conservation. Further study should develop essential to improve our understanding of the transported mechanisms in TSS based on process-based investigations, including the identification sources of TSS within headwater catchments.

Integration of remote sensing in watershed studies: A case study of Chawia & Fururu forested watersheds in Taita Hills, Kenya

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Abstract: Increased water demand due to population growth and climate change have resulted in drying up of springs, and a reduction in their discharge volumes in the forested Taita Hills, hence need for this study. The objective of the study was to evaluate the potential of integrating both Geographical Information Systems (GIS) and Remote Sensing (RS) in studying the status and spatial distribution of recent springs in the fragmented Chawia and Fururu forest watersheds. Physical mapping of the springs was done by demarcating the location using GPS. Data for mapping of springs was sourced from Landsat 7, 8 and Sentinel 2 which were processed and analyzed. For watershed delineation, data was examined using ArcMap GIS Hydrology tool from (ESRI), and image classification done using the Maximum Likelihood algorithm, with classification accuracy verified using the confusion matrix approach. Hydrological network was developed using Digital Elevation Model (DEM) data. From the results; ninety-one (91) springs were mapped; from which 68 were active. All the thirty-eight (38) springs in Fururu watershed were active. Six land use classes were identified within the watershed; Built-up (66.3%), Forest land (26.1%), Agriculture (7.13%), Water bodies (0.23%), Grassland (0.04%), and Bare land (0.01%). In addition, Chawia forest cover had reduced by 10% between 1987 and 2022; Fururu had increased by the same amount in the same period. From the results; the study recommends adoption of integrated forested watershed management and alternative water sources to communities for sustainability of both water and forest resources within the forested watersheds.

Interaction of forest-patch graph theory connectivity indicators with river water quality in the Caspian Sea Basin

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Mahmoud Bayat[1]
Sahar Heidari[1]
[1] Research Institute of Forests and Rangelands, Agricultural Research, Education and Extension Organization (AREEO)

Abstract: Landscape structure is one of the most important factors affecting food and organic matter in rivers and the spatial pattern of landscape patches, because differences in the length, width and gaps of patches have a great impact on food and organic matters in rivers. The present study was conducted with an aim to study the effects of forest-patch connectivity and landscape corridors on water quality in the Greater Caspian Basin. The ability of contiguous/unfractured landscapes in the promotion of acceptable water quality was evaluated with respect to ten landscape metrics and eleven water-quality indicators developed from graph theory. The degree of association between the various indices of forest-patch connectivity and water quality was determined with independent calculations of Pearson's and Spearman's correlation coefficients. Stepwise regression was also used to generate allometry-based power, exponential, and logarithmic models. The results of correlation between forest-graph theory connectivity indicators and water quality parameters showed that, several graph-theory-based indicators, dLCP (Landscape coincidence probability), dIIC (Integral index of connectivity)) had a significant negative correlation with water quality. This means that with increasing connectivity indexes, the amount of water pollution indicators is reduced and as a result, water quality is improved. The modeling results also showed that almost all selected models with acceptable AIC coefficients were nonlinear models. Therefore, the results of this study showed that graph theory indicators can describe changes in water quality parameters. As the connectivity of forest patches decreases, and the more fragmentation occurs in a watershed, the parameters of water pollution increase and the quality of water decreases, which some models, have highest level of explanation of water quality (i.e., R^2) such as CO_3 (0.82), water discharge (0.73), Ca (0.77), and TDS (Total Dissolve Solids) (0.70).

Length versus severity: The drought resilience potential of Norway spruce seedlings

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

[2] Univeristy of Innsbruck, Department of Botany

Abstract: A climate change-driven increase in drought frequency and severity is expected to have negative impacts on tree vitality. Reduced water availability can cause xylem embolism, thus blocking water transport and subsequently cause reductions in gas exchange and growth. Resistance and recovery to drought are thus decisive for tree survival during and after drought. In this study, we address the resilience of juvenile Norway spruce trees to different drought duration and severities by focusing on both, drought resistance and recovery.

In a greenhouse experiment, we continuously measured stem diameter changes, whole-tree gas exchange separated in above- and belowground, and leaf water potential in trees. To test the impact of drought duration we applied four treatments: control, short-term drought, intermitted drought, and long-term drought. Following drought release, micro-CT scans enabled visualization of persisting embolism in the xylem and thus percentage loss of water conductive xylem area.

Net assimilation, stomatal conductance, and growth rates diminished with critical water potentials. Days after drought release, water potentials and growth recovered, while gas exchange recovery was incomplete. We observed pronounced embolism in the xylem of stems, apical shoots, and roots. Prolonged drought exposure to critical water potentials resulted in slower recovery of gas exchange alongside a higher degree of embolism, while more severe yet short-term drought led to comparably less embolism and a faster recovery rate of gas exchange. In summary, this indicates that not only drought severity in terms of water potential reached before re-wetting is decisive for drought recovery, but also that the drought duration has an important impact on tree functioning and overall stress resilience.

Insufficient restoration of the hydraulic system, evidenced by reduced xylem conductive area after the recovery phase, likely resulted in incomplete recovery of gas exchange, especially during prolonged drought exposure. A limited resilience may render juvenile spruce trees more susceptible to more recurrent and/or severe droughts.

Less pronounced drought responses in ring-porous versus diffuse-porous temperate tree species

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

[3] University of Basel, Institute of Botany, Basel, Switzerland

Abstract: Tree species differ in their physiological responses to drought, but the underlying causes are often unclear. Here we explored responses of radial growth to centennial drought events and sap flow (F_s) to seasonal drought in four mixed forests on either moist or drier sites in northwestern Switzerland. While the diffuse-porous species (*Fagus sylvatica, Prunus avium, Tilia platyphyllos*) showed marked growth reductions in 1976 and 2003, two known marker years of extreme drought, growth of the two ring-porous species (*Quercus petraea, Fraxinus excelsior*) was less severely affected. During a dry early to midsummer, diffuse-porous species strongly reduced F_s at the two drier sites but not (or less so) at the two moister sites. The deep-rooting, ring-porous trees invariably down-regulated F_s to 60–70% of their maxima in response to vapour pressure deficit (VPD) and maintained similar fluxes across sites, irrespective of upper soil moisture conditions. Generalised additive modeling of F_s as a function of VPD and soil matric potential yielded a drought-sensitivity ranking led by the two insensitive ring-porous species followed by the diffuse-porous trees (ordered by increasing sensitivity: *Fraxinus excelsior* < *Quercus petraea* < *Prunus avium* < *Acer pseudoplatanus* < *Fagus sylvatica* < *Tilia platyphyllos*). In conclusion, ring-porous tree species exhibited stronger VPD-driven stomatal control over F_s, and tree-ring formation was less sensitive to severe drought than in neighbouring diffuse-porous species. Disregarding biotic hazards, our findings imply shifts in forest structure towards greater basal area of deep-rooting, ring-porous species in a drier future. With stronger reliance on deeper-lying soil moisture reserves and more frequent topsoil desiccation under drier future conditions, hydraulic redistribution may play an increasingly important role in nutrient dynamics and soil microbial activity in the upper soil horizon.

Limited connection between forest vegetation and groundwater level at Kecskemét-Méntelek study site, Hungary

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

András Szabó[1]
Bence Bolla[1], Tamás Molnár[1], Bálint Horváth[1]
[1] University of Sopron, Forest Research Institute, Department of Ecology and Silviculture, Sárvár, Hungary

Abstract: One of the most serious consequences of climate change is the decline in available water resources around the globe. Meanwhile forest vegetation as a carbon sink is considered as an useful tool to mitigate those consequences, it has generally higher water demand than herbaceous vegetation. This conflict generates a serious dilemma for decision makers according to land use policies.

This problem is also very acute at the Sand Ridge Region of the Great Hungarian Plain, where a decrease in the groundwater level is observable since the 1970's. Among other causes, the high water demand of the local forest vegetation was also mentioned behind the phenomena by various authors.

Our aim was to investigate the assumed connection between forest stands and the groundwater level decrease at our study site at Kecskemét-Méntelek. Soil moisture content at 200 cm and groundwater level (GWL) data was collected between 12.05.2021 and 12.07.2022 in every 10 and 15 minutes respectively at a study point surrounded by forests. Daily GWL changes were also calculated from the data.

According to the results there was no connection between GWL and daily GWL change and the photosynthetic activity or soil moisture content. There was also no observable recharge period although occasionally relatively high daily recharge was measured.

We concluded, that the above-mentioned factors have no impact on GWL or on groundwater recharge therefore the water-uptake or interception of the (forest or herbaceous) vegetation is negligible. This could be explained by the depth of the groundwater (approx. 8 m).

Mapping watercourses using AI – key for managing the forest-soil-water nexus

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Mariana Dos Santos Toledo Busarello[1]
William Lidberg[1], Florian Westphal[2], Anneli Ågren[1]
[1] Swedish University of Agricultural Science
[2] Jönköping University

Abstract: Small watercourses have been overlooked during mapping, aquatic research, and forest management, but new research highlights the importance of these channels as sources of greenhouse gas emissions and provisioning ecosystem services. They form the capillaries of the forest-soil-water nexus and are the largest contact area between the terrestrial and aquatic environment. Hence, whether naturally eroded or dug by humans in the form of ditches, small watercourses need to be considered during forest management in order to maintain the integrity of both water quality and the carbon balance of the boreal ecosystem.

However, a problem for practical management is that most channels less than 6 m wide are missing from traditional maps (in Sweden, only 22% are mapped). There is a gap in knowledge that not only reduces the understanding regarding the channels' placement but hinders the assessment of their environmental impact and consideration during forest management. This also concerns Agenda 2030's Target 6 about water systems protection and restoration: their management could require the filling of ditches in order to support the original ecosystem, affecting forest owners.

In this study, we combined aerial laser scanning with deep learning to develop a method for mapping small-scale watercourses, additionally evaluating several digital terrain indices as predictors. From the digital elevation model and the deep learning model, we were able to map 82% of the small watercourses across the entire boreal and nemoboreal landscape of Sweden. The method had a better performance mapping ditches – the most common channel type across the Baltic Region. Detailed mapping of the location and extension of ditches in the boreal forest is a primordial step towards supporting science-based management decisions on the forest-soil-water nexus.

Phloem carbon-isotope discrimination and carbon balance of Eucalyptus genotypes under contrasting water availability regimes

Abstract: Identifying *Eucalyptus* taxa/genotypes that show better adaptability to increasing drought conditions is critical in the context of climate change in many regions of the world. Use of physiological traits may provide insights on characterizing above and belowground (C) carbon fluxes of intensively managed plantations and their response to limitations on water resource availability. Our study evaluated the relationship between $\delta^{13}C$ and C fluxes of selected *Eucalyptus* genotypes under contrasting water availability regimes. The experiment was located in a sandy soil (Xeric Passament) in the Central Valley of Chile (37º1269´S, 72º4733´W) under a mediterranean climate with an average annual temperature of 13.8°C and annual rainfall of 1071.1 mm. The experiment was established in 2013, with a 3 x 2 m planting spacing, under a completely randomized factorial design with three blocks. Main experimental factor considered summer irrigation at 2 levels: (i) High (close to 75% field capacity) vs Low (close to 25% from wilting point to field capacity). Minor plots considered 8 genotypes: (ii) 2 *E. globulus* (high yield: EgH vs low yield: EgL), 2 *E. nitens x globulus* hybrids (high yield: EngH vs low yield: EngL), 1 *E. nitens* (En), 1 *E. camaldulensis x globulus* (Ecg), 1 *E. badjensis* (Eb), and 1 *E. smithii* (Es). Gross primary production (GPP), total belowground carbon flux (TBCF), aboveground net primary production (ANPP), wood primary productivity (WNPP), autotrophic respiration (Ra) and $\delta^{13}C$ in phloem were evaluated between 2020 and 2022 (7 to 9 years old). Results showed that under High irrigation regime GPP values reached in average of 3931 $gCm^{-2}yr^{-1}$ and a $\delta^{13}C$ of -30.2%o vs the Low irrigation regime with average GPP values of 2984 $gCm^{-2}yr^{-1}$ and -28.4%o for $\delta^{13}C$. Both irrigation regimes showed, positive and significant ($p<0.01$) linear relationship between $\delta^{13}C$ and GPP (R^2=0.63-0.79), ANPP (R^2=0.62-0.81), WNPP (R^2=0.65-0.82), Ra (R^2=0.63-0.81) and TBCF (R^2=0.36-0.63). Our results suggest that phloem $\delta^{13}C$ may provide a valuable key physiological assessment estimating C balance response of Eucalyptus genotypes and support selections under contrasting water availability scenarios.

Quantitative assessment of the impact of forest change and permafrost degradation on streamflow in Northeast China

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Liangliang Duan[1]
[1] Northeast Forestry University, China

Abstract: Forest change and climate variability are generally considered to be the two most important drivers of runoff change in forest watersheds. However, in the context of global warming, the degradation of permafrost has also become an important factor affecting river runoff. The Da Hinggan Mountains is the southern margin of the Eurasian permafrost distribution area, which is the one of the most sensitive area response to climate warming. At the same time, the boreal forest Da Hinggan Mountains has experienced a dynamic process of deforestation and forest restoration in the past few decades. The impact of the changes in forest, climate and permafrost on hydrological processes and water resources has become a scientific question that needs to be revealed urgently in this region. In this study, the meteorological, hydrological and permafrost data of the past 50 years were used to analyze the climate variability, forest coverage change, and permafrost degradation that occurred in the past few decades and their relationship with runoff. We quantitatively evaluated the relative contributions of climate variability, permafrost degradation, and forest vegetation change to changes in annual runoff. It has accurately and quantitatively revealed how river runoff in the permafrost distribution area of Northeast China responds to changes in forests, climate, and permafrost. It is of great significance to the sustainable management of regional forests and water resources in the context of global climate change in the boreal foerst regions.

REMOTE SENSING FOR FORESTRY ASSESSMENT AND QUALITY OF WATER RESOURCES: THE CASE OF DZALANYAMA CATCHMENT (MALAWI)

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Bernard Chome[1]
[1] Centre for Applied Systems Analysis

Abstract: Water quality is the measure of the chemical, physical and biological suitability of water in relation to natural effects and intended purpose which may affect human health and aquatic life. Assessment of water quality is very essential for the management of water resources as well as human health. Forestry plays a major role in protecting water resources, as forests provide 75% of the world's accessible water. Over the years forests have been under heavy depletion due to anthropogenic activities and this has also affected the quality of water in water resources originating from forest catchments. Monitoring of forests is usually done using traditional methods that are laborious and time-consuming. However remote sensing has shown that it is a reliable tool for forest monitoring and assessment. Remote sensing provides extensive spatial extent and large temporal variations. This abstract reiterates the significance of remote sensing in forest management and its impact on water quality. With the help of remote sensing methodologies, the extent of forest degradation and its effect on water quality could be measured. The anticipated results of heavy forest degradation would be an increase in harmful water quality parameters in water bodies. Some of these water parameters are; suspended solids, turbidity, and chlorophyll a. The results will then help determine the interventions that could be put in place to tackle this issue.

Remote sensing for water quality monitoring: a reservoir case study

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Teresa Albuquerque[1, 2, 3]
Cristina Alegria[1, 3]
[1] Instituto Politécnico de Castelo Branco | Polytechnic University, Castelo Branco, Portugal
[2] ICT| University of Évora, Évora, Portugal
[3] Centro de Estudos de Recursos Naturais, Ambiente e Sociedade (CERNAS), Instituto Politécnico de Castelo Branco | Polytechnic University, Castelo Branco, Portugal

Abstract: Continuous monitoring of water resources is crucial for ensuring sustainable urban water supply. Remote sensing techniques have proven to be valuable in monitoring various water quality parameters with optical characteristics. The study focused on the Marateca reservoir located in central inland Portugal. The objectives were as follows: (1) to investigate the water quality parameters at different monitoring points within the Marateca reservoir that could explain certain events; (2) to validate optical water quality parameters using the data collected from the monitoring points; and (3) to model the water characteristics of the reservoir, including its depth, trophic state, and turbidity.

The parameters of total phosphorus, total nitrogen, and chlorophyll-a were utilized to calculate a trophic level index. Sentinel-2 imagery was employed to compute spectral indices and image ratios for different bands, obtain spectral signatures for the monitoring points, and model the water characteristics. The analysis revealed that the water parameters exceeded the recommended values at the entry point of the reservoir from the Ocreza river. The trophic level of the reservoir was classified as Hypereutrophic and Eutrophic. The spectral signatures confirmed a Hypereutrophic pattern at the entry point. The modeling of the Marateca reservoir's water characteristics predicted zones of contamination issues.

The developed methodology can be readily applied to other reservoirs and serves as a valuable decision-making tool for policymakers. This study was funded by CERNAS-IPCB [UIDB/00681/2020] funding from the Foundation for Science and Technology (Fundação para a Ciência e Tecnologia-FCT); and by ICT [UIDB/04683/2020] also funding from FCT.

Restoring water-related ecosystem services by forestation: Practices in China

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Shirong Liu[1]
[1] Key Laboratory of Forest Ecology and Environment of National Forestry and Grassland Administration, Ecology and Nature Conservation Institute, Chinese Academy of Forestry, Beijing 100091, China

Abstract: Widespread deforestation has greatly degraded water-related ecosystem services provided by forests in China in the last century. The nation-wide catastrophic floods in China in 1998 is a good example of severe ecological consequence of forest loss. Since then, China has launched a series of forest restoration projects including Natural Forest Protection Program (NFPP) and Sloping Land Conversion Program (SLCP) to combat deforestation. The massive forestation makes China the country with the largest contribution to land greening on Earth in the past two decades. Water-related ecosystem services such as flood control, water supply, soil erosion control, flow regulation, and climate regulation provided by forests have been enhanced accordingly due to national-wide efforts in forest restoration in China. Here we will use the studies in the Upper Yangtze River basin and the Loess Plateau as examples to demonstrate how we restore water-related ecosystem services of subalpine and temperate forests by regional-specific forest management practices in China. These findings can provide important scientific supports for restoring water-related ecosystem services of forests by adaptive forest management under a changing environment in China and other countries.

The interaction of water and nitrogen uptake by trees from deep soil in pure and mixed stands of Douglas fir, European beech and their mixture

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Klara Mrak[1]
Christina Hackmann[2]
[1] Soil Science of Temperate Ecosystems, University of Göttingen
[2] Silviculture and Forest Ecology of the Temperate Zones, University of Göttingen

Abstract:
Planting non-native conifers and admixing them to native broadleaves is a highly interesting climate change adaptation strategy of forestry in temperate Europe. Forests here are expected to face lower water availability and altered nutrient cycles in future. The acquisition of nitrogen by trees is dependent on water flux due to mass flow, but the uptake of the two resources is not necessarily coupled. The increasingly popular introduced species Douglas fir is associated with drought tolerance and a risk of nitrate leaching on some sites, however, these traits are site-specific and have not yet been studied together.

In a mature forest experiment, we isotopically labelled water and nitrate in soil solution below the main rooting depth of Douglas fir, European beech, and their mixture on sited with contrasting soil texture. We monitor tree sap travel times using sap flow sensors installed on each tree and trace the ^{2}H and $K^{15}NO_3$ label in xylem water and in top-canopy foliage. Firstly, we expect that the strength of the coupling of water and nitrogen uptake, indicated by xylem water enrichment in ^{2}H and ^{15}N, varies with site conditions (soil texture), species identity (root characteristics) and is further modulated by species mixing (facilitation). Secondly, we expect that nitrate leaching under some Douglas fir stands, found in our previous study, is not a consequence of the trees' inability to take up excess nitrate from deep soil solution, which will be reflected in similar foliage enrichment among the stands. Thirdly, we expect to find a larger facilitation of water and nitrogen acquisition, indicated by larger cumulative tracer recovery in biomass in the mixed stands at the poorer sandy site due to the stress gradient hypothesis.

We anticipate more molecular experiments illuminating the mechanisms behind water-dependent nitrogen uptake at the root surface, which would complement our *in-situ* experiment and help understand tree resource acquisition strategies. Experiments evaluating the importance of other biotic drivers of resource limitation and excess (in the form of leaching) would also be relevant to predict this species' behavior in a changed climate, for example, the role of mycorrhiza and the rhizosphere.

The quality of water from forest landscapes under pressure in the Anthropocene

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Bishop Kevin[1]
[1] Swedish University of Agricultural Sciences, Department of Aquatic Sciences and Assessment

Abstract: Forests in a landscape are often beneficial for water quality. But contemporary forests are subject to a nexus of new influences characteristic of the Anthropocene – climate change, pollution and increasing societal demands to provide a range of ecosystem services including, but by no means limited to provision of timber, fiber and energy. This talk will examine the degree to which forests can supply water-related ecosystem services under these circumstances, with a focus on water quality in the context of Agenda 2030 and the Sustainable Development Goals (SDGs). While the availability of relevant data is not evenly spread over forest biomes, the talk will seek to take a global view of the situation. This will not only recognize the variety of different ways a forest can influence water, but also bring out the generally applicable findings that play out differently depending on the specific setting. A central issue will be the degree to which forest landscapes have already been, or will soon be impaired in their ability to deliver water with quality that can support endemic aquatic ecosystems and the drinking water for human communities. This leads to consideration of how management practices that consider water quality interact with other goals, including mitigation of climate change, adaptation to climate change and the incentives to manage forests. To conclude, payment for ecosystem services with respect to water quality will be explored in the framework of Agenda 2030 and the SDGs.

The role of terrestrial productivity and hydrology in regulating aquatic dissolved organic carbon concentrations in boreal catchments

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Xudan Zhu[1]

[7] Institute for Atmospheric Earth System Research (INAR), University of Helsinki, Helsinki, Finland

Abstract: The past decades have witnessed an increase in dissolved organic carbon (DOC) concentrations in the catchments of the Northern Hemisphere. Increasing terrestrial productivity and changing hydrology may be reasons for the increases in DOC concentration. The aim of this study is to investigate the impacts of increased terrestrial productivity and changed hydrology following climate change on DOC concentrations. We tested and quantified the effects of gross primary production (GPP), ecosystem respiration (RE) and discharge on DOC concentrations in boreal catchments over 3 years. As catchment characteristics can regulate the extent of rising DOC concentrations caused by the regional or global environmental changes, we selected four catchments with different sizes (small, medium and large) and landscapes (forest, mire and forest-mire mixed). We applied multiple models: Wavelet coherence analysis detected the delay-effects of terrestrial productivity and discharge on aquatic DOC variations of boreal catchments; thereafter, the distributed-lag linear models quantified the contributions of each factor on DOC variations. Our results showed that the combined impacts of terrestrial productivity and discharge explained 62% of aquatic DOC variations on average across all sites, whereas discharge, gross primary production (GPP) and RE accounted for 26%, 22% and 3%, respectively. The impact of GPP and discharge on DOC changes was directly related to catchment size: GPP dominated DOC fluctuations in small catchments (<1 km2), whereas discharge controlled DOC variations in big catchments (>1 km2). The direction of the relation between GPP and discharge on DOC varied. Increasing RE always made a positive contribution to DOC concentration. This study reveals that climate change-induced terrestrial greening and shifting hydrology change the DOC export from terrestrial to aquatic ecosystems. The work improves our mechanistic understanding of surface water DOC regulation in boreal catchments and confirms the importance of DOC fluxes in regulating ecosystem C budgets.

Tree water relations as drought stress indicators in a changing world

S1.4 Global water provision: Understanding the forest-soil-water nexus under forest management, climate change and increasing disturbances

Yanick Ziegler[1]
Timo Knüver[1], Franklin Alongi[1], Rüdiger Grote[1], Nadine Ruehr[1]
[1] Karlsruhe Institute of Technology (KIT), Institute of Meteorology and Climate Research–Atmospheric Environmental Research (IMK-IFU), Garmisch-Partenkirchen 82467, Germany

Abstract: Climate change is expected to increase the frequency and severity of droughts and thus affect forests and their numerous benefits globally. Limited water supply leads to temporal reductions of tree internal water reservoirs and stem shrinkage of elastic tissues typically measured with high-resolution point dendrometers (tree water deficit; TWD). When drought stress becomes severe and internal water storage depletes, embolism formation (air bubbles in the xylem preventing water flow) starts. This can cause long-term hydraulic damage to trees, loss of functionality and, ultimately, tree death. Knowing a tree's water status and its development under different environmental conditions is crucial to predict forest health conditions and helps in management decisions regarding thinning and species selection. In this work, we investigate water-related tree traits to evaluate their potential for quantifying, monitoring and projecting drought stress impacts on temperate tree species.

Two wide-spread temperate tree species *Pinus sylvestris* and *Larix decidua* were exposed either to drought-recovery cycles or to lethal drought until complete dehydration under controlled experimental conditions. To improve mechanistic understanding of tree water relations we investigated the correlations between tree water deficit, water potential and embolism occurrence (using an *in-vivo* optical method). We will provide relationships between these traits across the full range of dehydration and rehydration in order to link high-resolution dendrometer data to forest drought stress development. Further, we will highlight possible ways to integrate such relationships into an already existing process-based model to address and project drought-stress-induced forest decline and drought-recovery dynamics.

Abstract: There is a huge and growing legal and illegal international trade in Himalayan medicinal plant products. In Nepal, as many as 300 species are traded annually in tens of thousands of tons worth hundreds of millions of USD. Evidence shows that past and current attempts at promoting sustainable management in Nepal through a centralised approach to resource monitoring and trade regulation have failed, leaving species vulnerable to commercial harvesting and threatening rural household incomes and government revenues. The purpose of this paper is to develop a theory of change to allow an explicit move towards sustainable management of medicinal plant resources in Nepal as part of the bioeconomy. Building on a systematic review of proposed interventions in the literature and annual dialogue meetings with key stakeholders in 2016, 2017, and 2018, we characterised interventions by type (supply-side, transactional, demand-side), governance approach (centralised vs decentralised), and choice of institutional arrangement (positive vs negative: incentives for changed behaviour vs punishments for breaking restrictions). We identified five foundation stones upon which to build future interventions (e.g. a long tradition of successful community management of natural resources) and grouped existing interventions into five explicitly described development pathways to increase sustainability: increase cultivation, strengthen local management, support domestic industries, improve sector governance, and establish regional collaboration. Each pathway consists of a number of mechanisms: actions (from 2-5 per pathway) that lead to outputs (2-4) and outcomes (2-6), e.g. the "strengthen local management" pathway can be pursued through hand-over of high-altitude areas to local communities (action) leading to an increased area under local management (output) and better resource monitoring (outcome). We identified pathway assumptions and feedback loops. This draft theory of change was then discussed and finalised with key stakeholders in 2023, resulting in prioritised pathways and mechanisms to promote sustainable management and trade as part of the bioeconomy.

Assessing the timber harvesting potential of Europe's forest

S2.1 Governance of a Bio-resource-based Bioeconomy in the Global South

Christoph Pucher[1]
Hubert Hasenauer[1]
[1] Institute of Silviculture, Department of Forest and Soil Sciences, University of Natural Resources and Life Sciences, Peter Jordan Strasse 82, A-1190 Vienna, Austria

Abstract: Forests cover around one third of Europe's land area and are beneficial to society by providing numerous goods and services such as water supply, biodiversity, recreation, and welfare. They are further of increasing importance for mitigating climate change effects due to their potential to store carbon and to provide the renewable material wood. Europe, in order to achieve the climate targets and reduce greenhouse gas emission from the combustion of fossil fuel, is aiming to transform towards a sustainable bio-economy. Wood, especially in the form of long-lived wood products, will play an integral part in such an economy and an increase in the demand for wood is expected. In our study we assess the timber harvesting potential of Europe's forest by combining terrestrial information from repeatedly observed forest inventory plots with remotely sensed net primary production (NPP) and other European data. With these data we assess the availability of Europe's forest for wood supply and estimate increment, a key figure regarding sustainable harvesting. The results show that around 75 % of the total forest area in Europe has the potential to be harvested under current economic and technical harvesting conditions and can thus be considered as 'forest available for wood supply' (FAWS). The estimated growing stock in FAWS is around 25 billion m^3. Preliminary results suggest that around 600 million m^3 are potentially available for sustainable harvesting.

Bioeconomy in countries of the Mekong region and its role in forestry sector

S2.1 Governance of a Bio-resource-based Bioeconomy in the Global South

Radek Rinn[1]
Martin Jankovský[1], Petra Palátová[1], Sandra Paola García Jácome[1], Nataša Lovrić[2], Alice Sharp[3], Prasit Wangpakapattanawong[4], Vu Van Manh[5], Doan Thi Nhat Minh[5], Bounheuang Ninchaleune[6], Inta Chanthavong[6], Kongchan Douangmala[6]

Abstract: The approach to the bioeconomy concept is relatively much explored in developed countries, especially in Europe and North America. In other parts of the world, it deserves more scientific and practical attention.

The aim of our research was to analyze, evaluate and compare the status of the bioeconomy concept in the Mekong region in three countries, namely Thailand, Vietnam and Laos. The research questions were focused on the perception of the bioeconomy concept by representatives of the administration and industry, on the barriers to its development and on the prerequisites for its development in the region, and also determined whether it is reflected in the official related strategic existing documents.

Our study used a combined methodology that included qualitative document analysis and an online questionnaire distributed to public and private sector representatives in all countries. The results showed that while the bioeconomy is recognized in many institutions in Southeast Asian countries and is closely linked to sustainable development and the circular economy, a clear vision of the bioeconomy is lacking, resulting in the absence of specialized bioeconomy strategies in these countries. The results showed that the bioeconomy concept is an emerging concept in these countries and was perceived as the most important obstacle to its development. Unfortunately, there is limited bioeconomy expertise and insufficient support from the state, followed by low technological development. The study also highlighted the irreplaceable role of the forestry sector in the bioeconomy concept. We propose further research into the economic valuation of the bioeconomy to support its adoption, as well as greater involvement of key politicians in individual countries for its further development, specifically in Thailand, Vietnam, or further comparison with selected European countries.

Exploring Scientific Discourse on Climate Change and Forest Governance in Indonesia

S2.1 Governance of a Bio-resource-based Bioeconomy in the Global South

Andita Aulia Pratama[1, 2]
Daniela Kleinschmit[1], Ahmad Maryudi[2]
[1] Chair of Forest and Environmental Policy, University of Freiburg
[2] Sebijak Institute, Faculty of Forestry, Universitas Gadjah Mada

Abstract: Climate change is causing rapid changes and profound uncertainties that pose a threat to human life. Considering its complexities and urgency, a wide range of mechanisms has been undertaken, from global to local, involving a variety of actors and stakeholders. As a powerful discourse, it also shapes the way forests are governed. Indonesia, which harbors large tropical forests, has forest governance heavily driven by international discourse, including climate change. We analyzed scientific discourse on climate change and forest governance and found 218 articles using the Scopus Database, combining the keywords 'forest', 'climate change', and 'policy and governance' within the Indonesia region. The results were further scrutinized by employing categorization that reflects the storyline of climate change and forest governance, following the logic of discourse. Subsequently, we employed sub-categorization to explore the linkage of the scientific discourse to more specific themes, such as governance design and internationality. The results show rising trends in climate change and forest governance research starting from 2007 onwards, with both strong theoretical and empirically-driven research. The major research theme in Indonesia is found to be dominated by REDD+ research. The latest research trends imply that research problematization is underpinned by Indonesia's Forest and Other Land Use (FOLU) Net Sink strategy to correspond to the Nationally Determined Contribution (NDC) commitment. Through a discourse perspective, the results suggest that the scientific discourse of climate change and forest governance in Indonesia is profoundly endorsed by international concern that has been institutionalized nationally. This may lead to limited scientific narratives of climate change and forest governance and reduce scientific options in the science-policy-praxis nexus. Consequently, newer research themes, such as sustainable development and bioeconomy, are relatively absent in climate change and forest governance research in Indonesia due to lacking institutionalization in Indonesia's context.

Keywords: climate change, forest governance, discourse analysis, systematic literature review

Fixing the meaning: discourses and network analysis in the bioeconomy policy processes in Argentina and Uruguay

S2.1 Governance of a Bio-resource-based Bioeconomy in the Global South

Julián Daniel Mijailoff[1, 2]
Sarah Lilian Burns[1, 3]
[1] Research Lab in Ecological and Environmental Systems (LISEA), La Plata National University
[2] National Scientific and Technical Research Council (CONICET)
[3] Chair of Tropical and International Forestry, Technical University Dresden, Germany

Abstract: The concept of bioeconomy has spread globally as a floating signifier leading to multiple policies and strategies. As an ambiguous and polysemic concept, bioeconomy policy agendas at national levels draw on a variety of discourses and visions later reshaped by the particular political and social contexts of each country or region. From the broad boundaries of the overarching bioeconomy meta-discourse, local dominant discourses emerge, created and transformed by supranational and national social actors in the frame of power relations displaying discursive struggles. Understanding the body of social dimensions of forest-based bioeconomy, particularly from less studied Global South countries, remains crucial for the critical comprehension of ongoing bioeconomy policy processes. In recent years, efforts to develop bioeconomy and forest-based bioeconomy strategies and related policy-making were observed in Argentina and Uruguay, two neighbouring countries with similar forest sectors development. Against this background, our study aims to explore these ongoing forest-based bioeconomy policy processes. In order to do so, discourse analysis tools were used to identify current dominant visions regarding bioeconomy. Additionally, the main social agents dealing and promoting forest-based bioeconomy as well as discourse coalitions were identified with social network analysis techniques. Our findings revealed general scarce activity of bioeconomy policy debate in medias, predominantly conducted by a narrow number of legitimatized actors. Whilst in Argentina private sector and interest groups appears as main actors promoting forest-based bioeconomy, in Uruguay the predominant type of actors were the government and political parties. Dominant visions reproduce elements from the European bioeconomy as a strategy to incorporate new forms of enunciation and authority argumentations, namely the pro-growth economic visions driven by local current forestry model sustained in industrial forest plantations silvicultural paradigm. International actors were found to be strongly related to Uruguay forest-based bioeconomy development, while the Argentinian forest-based bioeconomy is embedded in the national agricultural bioeconomy discourse. Dominant storylines on both countries reproduce the power situations of the forestry policy subsystem where central actors not only exert structural power indicated by their network centrality as a parameter of their social capital but also prominently generate dominant information excluding alternative actors and their visions.

Future scenarios for forestry sector within Turkey's sustainable circular bioeconomy transition

S2.1 Governance of a Bio-resource-based Bioeconomy in the Global South

Mehtap Koç[1]
[1] Istanbul University-Cerrahpasa, Faculty of Forestry, Department of Forestry Economics

Abstract: Sustainable circular bioeconomy is accepted by many nations as a boundry concept and is supported by relevant strategy documents. In various countries, especially in those subject to European Union implemantation, the process progresses rapidly and even renewed strategy documents are encountered. As a country that is in the process of preparation for EU harmonization laws, Turkey has been seen as a preparation stage of bioeconomy strategy in various international processes for many years. However, when the local reflections of national efforts are examined, they do not cover all relevant bioeconomy sectors. In addition to the observation of the leadership of the agricultural sector and related actors in Turkey, this research was designed on the need to create future scenarios about the effectiveness of forestry sector actors in circular bioeconomy strategies. The process of creating future scenarios was carried out by examining all relevant policies, strategies and reports of forestry sector actors like industry representatives using wood products, forest resource managers, forestry academia, non-governmental organizations, biomass-based renewable energy representatives. Twenty influential factors determined in the STEEP category and with their interaction matrix, active, passive, dynamic and buffering factors were determined. Wood material supply and demand, national circular bioeconomy knowledge infrastructure, wood value chains and innovations and finally climate change factors and alternative projections of these factors with various assumptions were taken into account. Four plausible scenarios were developed around two uncertainty axes with the 2x2 scenario development technique. The first of the selected uncertainty axes was determined as Turkey's adaptation to the circular bioeconomy and the second was the participation of the forestry sector, future scenarios for 2035 were created. These scenarios, named as biotransformation of forestry (1), missed opportunity for forestry (2), forestry potential in the shadows (3), unchanging future (4), contribute to Turkey's national strategy preparation processes. It will be beneficial for the relevant stakeholders to integrate the forestry sector potential into their decision processes. It also contributes to Turkey's forest based circular bioeconomy scientific discussions.

Governance of the bio-based bioeconomy in Latin America: considerations from Uruguay with a focus on the forestry sector

S2.1 Governance of a Bio-resource-based Bioeconomy in the Global South

Amalia Margarita Stuhldreher[1]
Lucía Morales[1], Claudia Ramos[1]
[1] Instituto de Desarrollo Sostenible, Innovación e Inclusión Social. Sede Tacuarembó. Universidad de la Rrepública

Abstract: This analysis presents the results of an R+D project funded by the Sectoral Commission for Scientific Research of the UDELAR (Uruguay) from a governance perspective with a multilevel and multistakeholder approach, which implies a highly political process.

At international level, governance frameworks related to the bioeconomy paradigm have not been developed as such, although it is undeniable that the paths of bioeconomic transformations tend to involve various transboundary effects with global effects. However, there are some approaches that outline possible future governance schemes or regimes, framed within the needs and strategies developed by many countries in order to respond to the challenges of sustainable development.

In Latin America there are no bioeconomy regimes in a strict sense, although there are some national bioeconomy strategies, with different proposals and policy documents that promote the transition towards greater sustainability. In this context, the bioeconomy as a political project within the government agendas is framed according to the actions, interests, values and visions of diverse actors, whose discourses represent a primary factor in the implementation and development of public policies.

In the Southern Cone, Argentina and Brazil are key players. In Uruguay, the concept of bioeconomy has become increasingly important. This represents a challenge, including the implementation of possible guidelines for a National Bioeconomy Strategy.

The Uruguayan State has played a fundamental role in this process: through public policies to promote the bioeconomy and inter-institutional cooperation among different ministries and government agencies, considering diverse perspectives and initiatives of non-State actors. The private sector and foreign investment have been drivers of the development of certain bioeconomic sectors. In the debate on the bioeconomy in Uruguay forestry is a fundamental sector. Studies regarding the coalitions of actors that emerge around sustainability issues linked to this sector, identify a so-called "weak sustainability coalition", that prevails in this discussion. In contrast, the so-called "strong sustainability coalition" emerged in the late '90s, made up of certain sectors of the 'critical' academy and environmental non-governmental organizations.

Governing Bioeconomy Pathways: regional analysis, engagement and dialogues in East Africa, Southeast Asia and Latin America

S2.1 Governance of a Bio-resource-based Bioeconomy in the Global South

Francis X. Johnson[1]
Monica Trujillo[2], Alphayo Lutta[3], Ivar Virgin[4]
[1] SEI-Asia Centre, Stockholm Environment Institute
[2] SEI-LAC Centre, Stockholm Environment Institute
[3] SEI-Africa Centre, Stockholm Environment Institute
[4] SEI-HQ, Stockholm Environment Institute

Abstract: The *core* of a *modern* and *sustainable* bioeconomy is found in the *cross-cutting*, *value-adding*, *innovative* perspectives and approaches that are integral to long term sustainability transformations through the use of bio-resources and the application of biological processes. The wide variety of stakeholders involved in shaping future bioeconomy *pathways* seek to translate their *visions* of the bioeconomy into concrete programs to develop the *bio-resource base* into new bio-based products, biological processes and ecological services. As different localities, countries and regions develop strategies and policies, they must also develop the means for effective *implementation* and *governance.* The *contested* objectives, difficulties of *measuring* sustainability and the sometimes *conflicting* bioeconomy visions must be reconciled through analysis, dialogue, mediation and synthesis. Although bio-resources may be seen as local, transnational transfer of technologies, resources, knowledge and regional capacities remain critcal for advancing a global bioeconomy. Bioeconomy governance is therefore a *multi-level* undertaking encompassing all scales from local to global.

We employed the above conceptual model in assessing the terrestrial (land-based) bioeconomy in a five-year program of research, stakeholder engagement and policy dialogue in the global South, entitled "Governing Bioeconomy Pathways" in East Africa, SE-Asia and Latin America. In this paper, we present key results, using the framework of bioeconomy visions and pathways to analyse and compare developments in the three regions and in selected countries. Our analysis has three inter-linked levels, namely micro, meso and macro perspectives. At *micro* level, we undertook selected sustainability case studies on the transformation of bio-resources into value-added bio-based products and services, including croton in East Africa, acai in Latin America, sugarcane in SE-Asia, embedding these within forest, agricultural and mixed landscapes. At the *meso* level, we compared bioeconomy strategies and evaluated enablers and barriers in the means of implementation in the three regions. At the *macro* level, we considered the three regions in a global context and with particular reference to key global goals for biodiversity, climate protection and sustainable land use. By conducting analysis and engagement across multiple landscapes, themes, institutional levels and geographical regions, we developed a broad comparative assessment and synthesis on the governance of bioeconomy pathways.

How do multinational enterprises shape the socio-technical regimes in the Global South? - Case pulp industry in Uruguay

S2.1 Governance of a Bio-resource-based Bioeconomy in the Global South

Veera Tahvanainen[1]
Anu Laakkonen[1], Ossi Pesälä[1], Lucía Pittaluga[2], Teppo Hujala[1], Jouni Pykäläinen[1]
[1] University of Eastern Finland (UEF)
[2] University of the Republic, Uruguay (UdelaR)

Abstract: The pulp and paper industry is one of the largest industries in the world. The industry's main actors comprise of a few multi-national enterprises traditionally from Global North, who operate in global markets. The industry is increasingly moving its production to the Global South. This alters the global pulp value chains and more so the national socio-technical regimes of target countries of these massive investment operations. In addition to industry-internal activities, the operational environment changes too, thus challenging the pulp and paper industry's current operations. These factors are for example the sustainability paradigm and the transition to bioeconomy. We analyzed scientific, technical, and popular documents and conducted semi-structured research interviews through the multi-level perspective framework to investigate the pulp industry in Uruguay and how the Finnish multinational enterprises have influenced the developments within the Uruguayan regime. Our aim was to study 1) how the local socio-technical regime in Uruguay has developed since the emergence of the multinational enterprises until 2018 when the data was collected, and 2) what is its role in the global pulp industry's value chain. Our findings suggest that the emergence of the pulp industry in Uruguay has changed the national socio-technical regime dramatically. The developments within the Uruguayan regime were highly influenced by the Finnish multinational enterprises and the way they organized their global value chains. Uruguay's role in the global pulp industry value chain is to produce raw material. The integration of the industry to local research, innovation and education actors is rather weak and the emergence of industry has not improved the innovation capacity of the country and thus it has not led to the development of a strongly sustainable bioeconomy. We suggest that a transition to a sustainable bioeconomy or pulp industry regime in Uruguay would require steps forward in the immaterial resource base with closer cooperation between the industrial and the national research and education actors. Thus, the Global South should not directly adopt the regimes and ways of operating in the Global North, but a deeper collaboration between the global value chain actors is needed.

Inherent complexity of conflicts creates uncertainty for forest based bioeconomy

S2.1 Governance of a Bio-resource-based Bioeconomy in the Global South

Irmeli Mustalahti[1]
[1] University of Eastern Finland

Abstract: Globally, since the beginning of the 2000s there has been a rapid expansion of community forestry, small and medium-scale commercial tree growing. The increasing demand for timber has attracted both local inhabitants and translocal investors to capture this new resource frontier. The context of forest landscape has radically changed because of the expansion of forestry activities while also the interest towards carbon sequestration and forest conservation is growing. The increased occurrence of conflicts between the various actors has created challanges for forest governance. The inherent complexity of forestry related conflicts creates uncertainty, the issue, which impacts transformation to a sustainable bioeconomy. My experience is based on 20 years field data collection in Global South to map a diverse range of interpretations related to forest governance in general and to community forest and small and medium-scale commercial tree growing specially. A mixed method research design integrates individual interviews, focus group discussions (FGDs), direct participant observations, the expertise of a co-researcher and going back method. The underlying driving forces for forest conflicts are related to ambiguous and conflicting social processes in forest management and conservation. The conclusion is that there is an uncertainty of collaborative actions to discuss the causes, the effects, and the prevention of conflicts between the different actors. Actors know the causes of the conflicts and the measures needed to prevent the conflicts but too differently.

Integrating new environmental paradigms to ensure sustainable management of forest ecosystems: What opportunities for the bioeconomy in Africa?

S2.1 Governance of a Bio-resource-based Bioeconomy in the Global South

ADJONOU Kossi[1]
HOUNKPATI Kossi[1], SEGLA Kossi Novinyo[1], SCHEPERS Stefan[2], KOKOU Kouami[1]
[1] Faculty of Sciences, University of Lome
[2] Centre CONDORCET asbl

Abstract: In recent years, circular economy and bioeconomy have become predominant approaches to encourage sustainability, gaining traction and uptake by an ever-increasing community of governments, non-governmental organizations, civil society organizations and businesses. In this new paradigm of sustainable and responsible growth, Africa has an important potential and several major opportunities to increase circular economy based on ecosystem service, cultural services, regulating services, supporting services, provisioning services, etc. Considering forests as the most important biological infrastructure and main source of renewable biomaterials and bioenergy as well as the main host for biodiversity and terrestrial carbon sink, Africa has then a high potential to build a sustainable and circular economy. Globally, forest conservation has the potential to create a total of ~16 million jobs. With Africa's share of the world's forest standing at 17%, forest management could generate about 3 million jobs across the continent. Africa has a great asset to create green jobs. In spite of all these potentialities, it is noticed, a weak actively promoting of bioeconomy notably by the deficiency of collective agenda and drive ambitious action in favour of circular economy. In addition to the governance problems, there is a poor involvement of scientific actors and research institutions on circular economy issues in Africa. The adoption and implementation of policies that can accelerate the transition to a circular economy are still in their early stages in African countries. Even if several African countries have integrated the promotion of circular economy principles at some level in their national sustainable development or 'green economy' strategies, policies, and legislation real action on the ground, however, remains irrelevant. Despite all these, the sustainable use of these forest and tree products and services such as building materials, food and energy therefore provide unique opportunities for a transition to a sustainable circular economy in Africa.

Land and feedstocks availability for liquid biofuel production and associated emission in some eastern Africa countries: a review

S2.1 Governance of a Bio-resource-based Bioeconomy in the Global South

Miftah F Kedir[1]
Doirs Mutta[2]
[1] Ethiopian Forest Development
[2] African Forest Forum

Abstract: Liquid biofuel utilization is required to keep global warming below 2°C as stated in 2015 Paris agreement. In eastern Africa, countries like Ethiopia, Kenya, Tanzania, Sudan and Uganda have great potential of liquid biofuel production. The objective of this review was to show suitable land and feedstock availability for biofuel crop production and in turn to determine their role in emission reduction. Data was obtained from published and unpublished country documents. In Ethiopia, 23.3 million ha land area was suitable for biodiesel crops and 333,500 ha for bioethanol crops. Sudan has more than 60 million hectares of cultivable land for biofuel crops. In Tanzania, about 435,000 ha of land was allocated for biofuel production. In Uganda, 50% of the arable land area was suitable for sugarcane production. In Kenya, 20% of the poten-tial arable land was suitable for croton and jatropha. However, poor productivity of jatropha diverted attention to ethanol production from sugarcane. Soon after the launch of the strategy, in 2009, Kenana Sudan Sugar Company (KSC) launched 65 million liters annual ethanol production. Tanzania produced jatropha biodiesel for electricity. Uganda commercially produced ethanol from sweet sorghum. Increasing productivity was needed to obtain sufficient food and biofuel crops. Ethiopia and Tanzania can produce 35.588, and 7.089 billion litres of lignocellulosic ethanol from crop residues, respectively which is higher than their annual import of petroleum. Then eastern Africa countries have no problem of land and feedstock competition with agricultural practices for biofuel production. Biofuels could reduce deforestation and GHG emissions by 10 to 90% when compared with fossil fuels. Therefore, land and feedstock are widely available in eastern Africa to produce more biofuel crops for clean energy development.

Optimizing the Forest Bioeconomy: Balancing Biological Limits and Empowering Local Communities.

S2.1 Governance of a Bio-resource-based Bioeconomy in the Global South

Diana Carolina Huertas Bernal[1]
Miroslav Hájek[1]
[1] Czech University of Life Sciences, Faculty Forestry and Wood Sciences, 165 00 Prague, Czechia

Abstract: Climate change raises significant concerns for global economies as the current economic model assumes unlimited resources, leaving them increasingly vulnerable to the impacts of global warming. In response, the bioeconomy has emerged as a sustainable alternative that prioritizes responsible production, use, and conservation of renewable biological resources, encompassing knowledge, science, technology, and innovation. However, the bioeconomy faces a significant challenge in meeting the growing demand for biomass, which leads to adverse effects such as overexploitation of natural resources, agricultural expansion, competition for land use, soil erosion, deforestation, and biodiversity loss. These issues are more pronounced in certain regions where legal frameworks for ecosystem protection and sustainable management are lacking. Consequently, some countries prioritize exporting large quantities of low-value commodities, significantly transforming natural ecosystems. Notably, the production of soybeans, palm oil, and other crops in the Amazon region exemplifies this situation. Regrettably, economic considerations often precede environmental concerns, leading to unsustainable practices that harm ecosystems and the quality of the services they provide. To address these challenges, this study builds upon previous research and proposes improvements in circular bioeconomy strategies through a systematic literature review and qualitative content analysis. Preliminary findings underscore the importance of empowering local communities to restore a harmonious balance within ecosystem limits. Close-to-nature and agroforestry practices are highlighted as effective approaches.

Additionally, it is crucial to establish clear boundaries to prevent the over-exhaustion of natural resources and to respect biological cycles and regeneration processes. Addressing these critical issues is vital for understanding the implications of unsustainable biomass utilization and providing valuable information to policymakers. By promoting more sustainable practices within the bioeconomy, we can protect ecosystems, safeguard our planet, and ensure the well-being of its inhabitants.

Renowned concepts, new players? How the bioeconomy is politically formulated in African countries as compared to the Global North.

S2.1 Governance of a Bio-resource-based Bioeconomy in the Global South

Michael Boecher[1]
Lena Riemann[2], Daniela Kleinschmit[2], Daniel A. Córdova[2], Sarah Schmitt[1]
[1] Otto von Guericke University Magdeburg, Chair of Political Science and Sustainable Development
[2] University of Freiburg, Chair of Forest and Environmental Policy

Abstract: Since the early 2000s the term “bioeconomy” has been rapidly taken on by politics, science and industry in the Global North. In the tradition of ecological modernization discourses, it describes an innovation-based transformation to a sustainable economy based on renewable resources. As such the dominant bioeconomy narrative is grounded in the ecological modernization discourse. Slowly, the bioeconomy is gaining popularity in African countries. The paper presents a comparative analysis between selected bioeconomy strategies from Africa and the Global North (Europe, Germany, Finland). Aim is to find out whether common narratives from the Global North are repeated or new specific approaches are gaining political attention in Africa. In the analysis, special attention is given to definitions of bioeconomy and its resource basis, as well as it is being associated with buzzwords such as “sustainability” and “green growth”. We also investigated how the forest sector is being addressed. We found that there are similarities in the definition of bioeconomy as well as in the framing of problems and proposed solutions. Regional differences exist in the type of biomass to be used as the basis for the bioeconomy as well as in the instruments that are suggested for bioeconomy implementation. Social aspects of the bioeconomy and conflicted goals related to issues such as land use and access to bio-resources, are not addressed in the African bioeconomy policies. The political focus on economic growth is mirrored by many recent scientific publications on bioeconomy coming from African countries. There are few critical voices in science who demand the inclusion of local and indigenous knowledge in bioeconomy approaches. European-African collaborations exist in form of joint scientific projects and development cooperation, e.g. for the elaboration and implementation of existing African bioeconomy strategies. The findings lead us to the assumption that there are indications that the European concept of bioeconomy serves as a role model for new bioeconomy approaches developed by African countries. This must be discussed critically since the bioeconomy model from the global North itself is very contested and follows an economy-driven approach whose contribution to sustainability has lead to controversial debates.

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

Advancing Technologies for Sustainable Forestry and Workforce Development

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

Woodam Chung[1]
Jay Kim[2], Kevin Lyons[1]
[1] College of Forestry, Oregon State University, Corvallis, OR 97331, U.S.A.
[2] College of Health, Oregon State University, Corvallis, OR 97331, U.S.A.

Abstract: Forest-dependent rural communities in the United States face significant challenges in replacing lost jobs, effectively managing forestlands, and fostering economic development. Outdated forest practices and a fragmented supply chain often result in operational inefficiencies and waste of resources. The forestry workforce is aging, and the demanding and hazardous nature of the job, coupled with low wages, discourages new entry into the field. While various industries have embraced technology advancements, the forest sector has been slower to adopt innovative technologies.

This presentation highlights ongoing research efforts focused on modernizing forest production systems, enhancing health and safety of forest workers and providing advanced training for the forest workforce using cutting-edge technologies. Key areas of discussion include: 1) Safety, efficiency and environmental impact of mechanized harvesting operations on steep slopes, 2) machine vision technology for real-time tree detection and measurement, 3) assistive wearable devices designed to reduce forest workers' fatigue and injury, and 4) digital tools for enhancing workforce education and training. By exploring these key areas, this presentation provides insights into ongoing developments and their potential to drive sustainable growth, economic revitalization and the development of the next-generation forest workforce through the adoption of advanced technologies.

Co-creating the Future of Forest Work: A multidisciplinary methodology for the Youth Visioning Workshop

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

Scott Francisco[1]
Sarah Jane Wilson[1, 2]
[1] Pilot Projects Collaborative
[2] University of Victoria

Abstract: A major challenge for those working at the nexus of environment and development is gaining a holistic, systemic understanding of the decisions and practices of people and communities in relation to their environment. This paper describes how diverse fields, such as *systems thinking*, *design thinking*, organizational development *architecture, urbanism and design education*, can contribute to methods of engaging local people about global issues in a meaningful and culturally relevant way.

Our focus issue is the outmigration or disengagement of young people from forest communities to cities, a reality which calls into question the future of community-driven forest management, conservation, and restoration. The Future of Forest Work and Communities (FoFW) community of practice was established to better understand the perspectives of young people with regard to employment, life goals, migration and the forests they live in or near to. It also aims to engage youth in a transformative process, and co-create new awareness, interest and exciting opportunities for working in and with forests, especially relative to the emerging global demand for forest conservation. In this paper, we describe the structure of and theory behind the "Youth Visioning Workshop", a methodology developed for the FoFW project. Within the workshop we look at the role of co-design as a means of expanding the sphere of dialogue, opening up latent ideas and perspectives, shaping new ideas and perspectives in concert with peers, and responding to new information from local and global leaders and sources. Results from the 14 workshops held to date led to a high level of engagement from participants, rich diverse data, and deep insights into the perspectives of these young people. It also engendered a high level of engagement and collaboration on the part of the leaders, coordinators and facilitators of the workshops, strengthening the FoFW community of practice. We conclude the paper with examples of the outcomes of the Youth Visioning Workshops that demonstrate the effectiveness of this methodology, and with some challenges and learning opportunities for further development.

Developing smart forest logistic strategies in serious-game-based simulation workshops

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

Christoph Kogler[1]
Peter Rauch[1]
[1] University of Natural Resources and Life Sciences Vienna

Abstract: A sustainable development based on renewable raw materials demands increasing amounts of wood, but the supply security is massively threatened by climate change and frequent forest calamities. Smart forest logistic strategies are needed to manage supply chain risks, uncertainties and complexities resulting in transport, storage and handling bottlenecks. Consequently, serious-game-based simulation workshops were developed to innovate forest education, transfer knowledge between science and industry as well as train the forest workforce to apply digital technologies and quantitative decision support models for the development of sustainable, resilient and efficient logistic strategies.

Scientific discrete event simulation models for forest logistics, storage as well as unimodal, multi-echelon and multimodal transport were further developed to provide intuitive usability for practical decision support in serious-game-based workshops. Discrete event simulation provides an excellent methodology for the digital representation of forest supply chains focusing on straightforward business processes to facilitate stakeholder participation and establish credibility through visualization and animation. Didactically sophisticated, hands-on game-scenarios challenge stakeholders to develop smart logistical strategies and directly assess their performance on the basis of key performance indicators such as lead and queuing times, transshipment volumes, emissions, utilizations and costs. This simulation setting allows experiencing effects of taken decisions as well as their complex interrelations with other supply chain actors to reflect on the achievement of self-set goals. The virtual simulation setting establishes a sustainable learning process through playing a serious-game without having to fear negative, dangerous and costly real-world effects, which commonly occur during crisis and uncertain system environments, where simple trial and error approaches still dominate business practice.

Consequently, the innovative simulation workshops drive the establishment of collaborative supply chain management through digital simulation technologies and smart logistic strategies. The competence-oriented, cooperative serious-game settings can be applied in scientific, educational and managerial environments to set the stage for advanced risk management (analyse and prepare), contingency planning (decide and act) and knowledge management (reflect and learn). This showcases a sustainable innovation path, where latest scientific findings are directly passed to target groups, which apply quantitative decision support models to implement smart forest logistic strategies enabling an environmentally, economically and social sustainable development.

DEVELOPMENT OF QR CODE SYSTEM FOR TROPICAL RAINFOREST TREE SPECIES IDENTIFICATION

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

Bukola Onyekwelu[1]
Grace Alo[2], Flourish Echefu[2], **Meshach Aderele**[3], Olaoluwa Adetula[2]
[1] Department of Mathematics and Computer Science, Elizade University, Ilara Mokin, Ondo State, Nigeria
[2] Department of Forestry and Wood Technology, Federal University of Technology, Akure, Nigeria
[3] Department of Landscape Design and Ecosystem Management, American University of Beirut, Lebanon

Abstract: Trees are an essential part of our natural environment, they provide a wide range of benefits to humans, other living organisms, and the environment. An accurate method of tree species identification and description will improve their management and conservation, it is also crucial for genetic study, biodiversity conservation measures, inventories, regeneration strategies, among others. The conventional methods of tropical rainforest tree species identification require examining and knowing their morphological, physiological and phenotypic characteristics. Due to the large number of tree species in tropical rainforests, the conventional method of tree identification is time-consuming, laborious, expensive, and requires a high level of expertise. Consequently, it has become imperative to develop a more efficient and easy means of tree identification. To address this problem, we developed a QR code system for tropical rainforest trees identification. Tree data was collected from two tertiary institutions in Akure, Nigeria with high concentration of trees. The QR system was built around a three-tier architectural model. PostgresSQL was used as the Relational Database System, which is the back engine and the lowest tier. The Middle tier was the Web Server, which is the Apache HTTP Server. Php 8.1 was the scripting language used to communicate with the database. For the highest tier, which is the Client tier, HTML, CSS, and Javascript were used. The barcode generator system was developed using PHP 8.1. A QR code library was utilized by the PHP script to generate the QR code image. The QR code is linked to the website and database which contains all tree species information. The generated QR codes were attached to trees, and when scanned with smartphone camera or barcode reader, the website is automatically launched and the tree information displayed. The results of end-users survey conducted within the 2 tertiary institutions revealed that the QR codes are accurate, easy to use, and made tree identification more interesting and engaging. This will, in turn, increase the interest and knowledge of people about trees, improve tree management and make it easy for people to easily identify tropical rainforest tree species.

Keywords: Tree identification, QR code, Database, Management, Tropical rainforest.

Economic Behaviour and Livestock Production in the Forestry Zones of Abuja, the Federal Capital Territory of Nigeria.

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

Michael Oke[1]
[1] Michael Adedotun Oke Foundation and Federal Capital Territory Agricultural Development Programe

Abstract: Agricultural practices can be carried out in a variety of ways that lead to results that are focused, as well as by combining various technologies to lower production costs and maximize profits. Agricultural practices are not well-documented and most farmers are unaware of the technology underlying the various practices, these practices are becoming increasingly important. The needs for the general use of land for animal production, which is now challenging. Since these innovations have the ability to "address various urban concerns such as young unemployment, environmental protection, income generation and social inclusion, and shortage of land for farming operations, they should be duplicated throughout the majority of the forested Zone. The world's growing cities can be transformed into cleaner, healthier environments by utilizing a variety of clever agricultural approaches. From enhancing environmental conditions and reforesting flood-prone areas to figuring out how to manage food waste, agricultural production, the development of green cities, and the expansion of forest zones. That can Initiative gives each community the chance to empower its people by utilizing local expertise and exchanging best practices. We must make urban living and livestock farming sustainable if they are the future's dominant lifestyle choices. Through observation and oral interviews. Additionally, I was able to find a small wooded area where residents were involved in cow and sheep farming activities. These activities included varied mixes of farming, forestry, and housing in addition to several other economic tasks including feeding the cattle, sheep and giving the animals a place to live. Eat and sleep outside, and the farmers also create their own unique farm dwellings for themselves. This encourages cooperation, multipurpose technology, and the use of animal manures like as feces, as well as the knowledge of the kinds of animals that are being produced. Mr Sule, 32, who has been using the forest zones for his livestock production claims, "With this knowledge, my sales have increased, and I've been able to establish its and in selling. I was able to feed my family through the livestock production. other agricultural practices

Effects of trees to radio wave propagation in forest areas

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

Tsuyoshi Kajisa[1]
Yukio Teraoka[1]
[1] Kagoshima University

Abstract: Smart forestry is not enforceable if moble network doesn't work.In Japan,there are no network on half of a forest area. Therefore, it leads to less secure of work environment and low productivity.that's why it is important to know and develop the connection environment in forest area for smart forestry. this report shows the effect of trees to radio wave propagation in forest area, the good practice of communication, and information communication technology tools to share locational information for safety works. we measured the signal strength of with distance, trees between propagation line. We showed that the signal strength depends on the distance and the wood dense. we also analize the effect of radio wave frequancy to communication. the low frequancy radio wave reached on longer distance than high frequency radio wave. finally, we show the one of smart forestry application for safe working environment. this is the system to share the worker's location and the noticed information. this report conclude that smart forestry need the network communication and some alternative communication are also available in forest area.

Experimental Native Tree Seedlings Establishment for Restoration and Agroforestry in Burkina Faso: effect of irrigation and soil amendment

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

Lassina SANOU[1]
[1] CNRST/INERA

Abstract: This study aims to generate knowledge that supports forest recovery on fallows to enhance ecosystem services and goods accrued from restored forests. The effect of four treatments on survival and growth of seedlings of twelve native species was tested in degraded land in Burkina Faso. A total of 504 seedlings were planted in randomized complete block design with three replicates combining four treatments: control, irrigation, manure and manure+irrigation. Soil samples were taken from the holes prior to tree planting (2012) and after 4 years' growth (2016). Survival and growth rates evaluated beyond 4 years were significantly higher using manure+irrigation, irrigation compared with the manure and control. Survival rates of plant species planted using manure+irrigation were 100% for *Piliostigma reticulatum* and *P. thonningii*, 99.07% for *Balanites aegyptiaca*, 94.44% for *Prosopis africana* and *Tamarindus indica*. Survival rate of *Detarium microcarpum* was 25.92%, 29.17%, 39.81%, 44.44%, respectively control, irrigation, manure and manure+irrigation. These results showed that except *D. microcarpum*, the other species can be considered and recommended as the suitable candidates to restore degraded land. Results for comparison between sample taken in 2012 and 2016 revealed an increase in total C, N, P, K and exchange cation capacity confined to the different soil layers. These results testified that reforestation impacted on soil properties and contributed to increase soil fertility. Furthermore, our results showed that restoration of degraded soil by native seedlings plantation is possible and could permit at long term biodiversity conservation, soil fertility, availability of forage, carbon sequestration and mitigate climate change.

Forest workers for the future – young students' view of their working life in a transforming forestry sector

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

Ann Grubbström[1]
Stina Powell[1]
[1] Swedish University of Agricultural sciences

Abstract: The young generation of forest workers is a crucial group for the transition towards more sustainable forest futures. Despite young people's decisive role as agents for change, few studies have addressed their view of the challenges and opportunities connected to future work in the forestry sector. In Sweden, where clear-cut forest management is the dominant practice, there is a need to increase understanding of how this practice affects young people's view of the future and the meanings and norms that are associated with the continuation of such practices. The study is based on seven focus groups of high school students in their first, second and third years of a programme with a particular focus on forestry. It emerges from the study that the ideas and norms of clear-cutting are challenged during their education, even though the view that Sweden is a leading country in sustainable forestry remains. A main challenge for future operators of tree harvesters is the stress generated from having production goals. The students also recognise the potential health problems from sitting still for long periods and that working alone in the forest could make them vulnerable in case an accident or technical incidents occur. Together with late and long working hours, this imagined work situation made most of them think that they could only work as tree harvester operators for a limited time. To attract more young people and change the gender-coded division of work in the forest sector, students suggest more targeted initiatives towards primary school pupils. This should include a broader view of possible work tasks, where pupils are able to visit forests and try out different practical tasks. The results show that the dominant practices create challenges: new operators of tree harvesters have to be constantly trained for only a few years in service. Education and training of the future workforce need to address the challenges facing students in a clear way. Moreover, the study suggests a close collaboration between education and forest companies to develop long-term sustainable and attractive forest employments, as an important contribution towards the transformation to sustainable forestry.

GNSS through the trees: Smartphone capabilities under forested conditions

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

Krista Merry[1]
Pete Bettinger[1]
[1] University of Georgia, Warnell School of Forestry and Natural Resources

Abstract: Smartphones are pervasive in today's society serving as communication devices, navigation systems, and data collectors. Recent graduates of forestry and natural resource programs as well as young professionals in the field will undoubtedly be a generation very savvy with smartphone technologies. Workforce training and education about the GNSS systems in these devices would likely benefit from incorporating and promoting technologies that are familiar to these digital natives. As GNSS antennas and capabilities of smartphones improve, these non-traditional GNSS receivers may be approaching a level of accuracy that makes their integration into field data collection and analysis a reasonable alternative to traditional handheld GNSS receivers. Modern smartphones are often equipped with more than one transmission frequency in recent years, some allow access to raw GNSS data for post-processing differential correction, and some have the capability of being coupled with external antennas which potentially can increase positional accuracy of data collected with these devices.

An extensive research effort is underway to investigate the horizontal positional accuracy of two types of smartphones, an iPhone 13 Pro and a Google Pixel 6 Pro, to understand potential positional error encountered under both leaf-on and leaf-off forested conditions. In addition to independent data collection with these devices, the iPhone 13 Pro will also be connected to a Juniper Geode antenna using bluetooth technology, turning the smartphone into an interface for collecting GNSS data with the antenna. Early results from this research suggest that smartphone technology may now provide sub-meter positional accuracy in forested conditions, improving efficiency and safety in forest management as well as possibly reducing the costs associated with mapping-grade GNSS technology. More extensive results will be provided during the presentation. Understanding the positional accuracy smartphone devices provide, and the associated uncertainty, is important as they become more commonly used in natural resource management. Continued assessments of smartphone GNSS technologies, as they evolve, benefit not only researchers but those professionals who use smartphones for normal work activities.

Integrated forest and wildlife management – a prerequisite for climate-smart tree species mixtures in natural regeneration

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

Magdalena Langmaier[1]
Gyula Kovacs[1], Herbert Kohlross[2], Horst Leitner[3], Paula Klück[3], **Silvio Schueler**[1]
[1] Federal Research and Training Centre for Forests, Natural Hazards and Landscape (BFW)
[2] Unternehmensberatung Forstwirtschaft D.I. Dr. Herbert Kohlross
[3] Büro für Wildökologie und Forstwirtschaft e.U.

Abstract: Sustainable forest management includes not only the preservation and management of tree populations, but also the management of the various game species belonging to the forest habitat. This dual management regularly leads to conflicts of objectives between hunters and foresters, as the type and intensity of hunting has significant effects on natural regeneration, tree species composition and biodiversity in the forest. Moreover, the selective browsing of specific tree species might affect the suitability of the next tree generation and thus the vulnerability of the regenerated forest.

Austrian harbours a broad range of forests types ranging from low elevation mixed hardwood forests up to high elevation Alpine forests. Several forests types already face signs of climate change induced disturbances and forest pest. Natural regeneration is therefore seen as an efficient nature-based solution to support mixed species forests and to reduce the vulnerability of forest to climate change based forest hazards. The objective of the present study is to disentangle the role of prerequisites for climate-smart natural regeneration in terms of adult species compositions, forest management and structure, wildlife habitat and game management. Across 21 pilot forest areas, detailed assessments of forest structure, regeneration ecology and wildlife ecology were undertaken using grid-based inventories. The recorded composition of natural regeneration was tested for its vulnerability to future climate using tree species distribution models. Moreover, hunters and forest owners were interviewed for their management behaviour, management objectives and cooperation as integrated forest and wildlife management.

Our results demonstrate that on average, tree species diversity decreased from the adult stage to the natural regeneration. Moreover, intensive browsing on species which are less vulnerable to climate change further reduced the diversity of the future forest, despite common interests and significant efforts of both forest managers and hunters. The most successful pilot areas showed a long-term commitment to active forest management and hunting as supporting service. Such cooperations not only reached high tree species diversity but also higher wildlife habitat quality. We conclude that climate-smart tree species mixtures from natural regeneration are not likely to be reached without strong cooperations among forest managers and hunters.

Single-tree level optimization model for cable-based forest operations planning in steep terrain

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

Francesco Sforza[1]
Michael Starke[1], Patrick Dietsch[1], Peter Thür[1], Emanuele Lingua[2], Martin Ziesak[1]
[1] Bern University of Applied Science
[2] University of Padova

Abstract: A common challenge in planning forest operations with cable-based systems in steep terrain is to maintain the expected harvesting efficiency such that the revenues exceed logging costs. One of the difficulties in realizing a positive economic marginal return is the spatial distribution of the trees selected for harvesting. Indeed, selection scheme, generally must comply with strict silvicultural constraints, also limiting the volume of timber to be harvested. Using spatial optimization at single-tree level can address the operational problem maximizing the profit under given constraints.

In this study, a decision-support optimization model based on integer programming (IP) was implemented to select trees to be harvested, according to economical and spatial objectives. To create a base to apply the optimization approach, field data and StanForD 2010 data from a Mounty 5000 cable yarder were used to develop efficiency and productivity models using multiple linear regression method. Tree parameters, as spatial input scenario, describing a specific forest stand, were derived by means of high-resolution airborne laser scanning at individual tree level. Trees were further rated by financial value and then connected with the productivity models to run the optimization process.

Our preliminary results show that an improving in key-performance indicators of forest operations, such as the economic marginal return, could be achieved by pre-selecting the most suitable trees to cable-based harvesting system, while still respecting the timber volume reported in the harvest plan.

Keywords: Cable yarder, optimization, integer programming, airborne LiDAR

The development of artificial intelligence and visualization technology promotes the application of smart forestry

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

HUAIQING ZHANG[1]
TINGDONG YANG[1]
[1] Research Institute of Forest Resources Information Techniques, Chinese Academy of Forestry

Abstract: Artificial intelligence and visualization technology, as core technologies driving the digital transformation of the modern forestry and grass industry, will continue to deeply integrate with and empower the business, widely applying in areas such as forestry and grassland resource monitoring, biodiversity conservation, and forestry and grassland disaster prevention and control, promoting the high-quality development of forestry and grass industry. The report introduces the latest research progress and application prospects of artificial intelligence, 3D visualization, digital twins, and metaverse technology in the three-dimensional modeling of forestry and grassland resources, intelligent monitoring of flora and fauna, intelligent supervision of forest resources, national park construction, ecological industry development, and digital cultural heritage protection. The report elaborates on the integration between Artificial Intelligence Generated Content (AIGC) and the forestry and grassland metaverse, especially in the generation of virtual environments and scenes for forestry and grassland, the creation and generation of digital content for forestry and grassland, real-time interaction and natural interaction generation, forestry and grassland simulation, prediction, and decision-making generation, which can provide content generation for forest structure optimization, quality improvement, ecological protection, and industrial development, enabling intelligent analysis, comparison, optimization, and improving decision-making capabilities. AIGC can provide the forestry and grassland metaverse with richer and more diverse creative and generative capabilities, accelerating the development of the metaverse.

Visualizing forestry Linked Open Data and producing biodiversity annotations with EducaWood

S2.2 Smart Forestry – Transforming Forestry and the Future Forest Workforce

Guillermo Vega-Gorgojo[1, 2]
Irene Ruano[1], Miguel L. Bote-Lorenzo[2], José M. Giménez-García[2], Felipe Bravo[1]
[1] Instituto de Investigación en Gestión Forestal Sostenible (iuFOR), ETS de Ingenierías Agrarias, Universidad de Valladolid, Avda. de Madrid 44, 34004 Palencia, Spain
[2] Group of Intelligent and Cooperative Systems, Universidad de Valladolid, Spain

Abstract: EducaWood is a web application designed for environmental education and the creation of biodiversity repositories. It can be used to support learning activities based on the social annotation of trees and other ecosystem structures; it also allows the exploration of forestry information in an area of interest. EducaWood exploits existing semantic datasets of land use and dendrometric information from Spain and Portugal that we have released as Linked Open Data (LOD). Teachers can check these sources to propose contextualized activities of environmental education, e.g. find a holm oak in a nearby dehesa and annotate it. Students can then go to the target site and perform the proposed activities with their mobile phones. EducaWood provides an interactive map with typical navigation controls like panning or zooming to easily explore the zone of interest. Beyond the visualization of forestry data, registered users of EducaWood can create new trees or enrich existing ones with new annotations. A geolocation annotation is always required, while the rest of annotation types are optional and include species, dendrologic measures, photos and tree status. To define the necessary terms we reuse some forest ontologies (species, locations, measures) and we have developed the Simple Tree Annotation (STA) ontology to allow social annotation of trees. STA supports multiple and possibly inconsistent annotations from multiple users, including primary properties that are purposed for conflict resolution. Annotations are introduced through simple web forms, thus hiding the intricacies of ontologies and data formats to users. All produced annotations are published as LOD and shared for the community of EducaWood. As a result, the application enables the creation of a crowdsourced biodiversity dataset that expands beyond the areas covered by institutional forest inventories, e.g. urban forests. This dataset can also be exploited in follow-up learning activities such as virtual field trips or citizen science projects. We have tested a first version of EducaWood with a reduced set of users. With the collected feedback, we are currently completing a production version that will be released soon. Future plans include pilot studies in forestry courses at University level and the integration of environmental data from OpenStreetMap.

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Sustainability Beyond Functionality – A Study Of Past 25 Years In Central Indian State Madhya Pradesh

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Dr Ajit Kumar Shrivastava[1]
Dr ramendra Tiwari[2]
[1] Principal Chief Conservator of Forests,Forest Department of Madhya Pradesh, India
[2] Working Plan Sagar

Abstract: The Central Indian state of Madhya Pradesh is having the largest forest area in the country. The forest management is based on sustainability and yield from forest which is regulated by selective felling along with regular plantations in the suitable areas. Other than timber production the non-timber forest products are a major activity along with multiple uses of them.

Since 1992, Rio summit for sustainability till 2016 the timber production has reduced almost to half in past 25 years. Dwindling forest wealth is attributed to many factors such as over exploitation, over grazing, illegal encroachments, unsustainable practices and forest fires.

During this period the state had many management and legislative changes like, World Bank added project, Joint Forest Management, Forest Rights Act, Green India Mission and Biodiversity Act.

The study reveals that although the production has shown a down trend, the management of forests has continuously changed towards participatory and decentralized decision making. Still there is insufficient economic promotion of forest goods and services. Additional resources are required for environmental education, awareness and women participation along with understanding of indigenous knowledge. The conservation of bio resource along with the needs of the society and ecology are at the cross roads for the future adaptation of the natural wealth.

The revenue generation from the production forestry is vanishing with time vis a vis the social needs and the role of forest wealth is increasing for the present need of climate change and for the betterment of the people living and surviving in and around the forests and dependent on the forest wealth.

The paper deals with the critical analysis of the local issues along with the priorities of the National Policy draft and the International Conventions. The paper also critically analyze the risks of the socio ecological conflicts arising due to the present and future need of the precious forest wealth and the ever increasing pressure of the people's needs and urbanization.

A Brief Overview of the Marketing of Firewood in the Federal Capital Territory of Abuja, Nigeria

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Michael Oke[1]

[1] Michael Adedotun Oke Foundation and Federal Capital Territory Agricultural Development Programe

Abstract: The numerous needs to improve the forestry industry, the necessity to rethink the various marketing and distribution strategies of the various firewood products, and involvement in the manufacturing of charcoal, chewing sticks, and sculptured wood items. As a result, Nigeria possesses approximately 600 potential timber species. Less than 300 are currently being commercially utilized for international trade. However, if the informal firms of tiny wood-based industries were conducted with official inclusion into the national economy, the industry could contribute significantly to local and worldwide trade. These businesses include diverse craftspeople, cabinet manufacturers, and timber converters who sell various types of firewood. More research is required to provide varied costs; information; networking; seller connection; and documentation of best practices in firewood marketing. If there are better ways of enhancing and assisting persons involved in various uses, such as residential and industrial, The numerous investigations were carried out in two regions of the Federal Capital Territory of Abuja, namely Gwagwalada and Municipal, and the varied methods of marketing the various firewood's were observed. According to the findings of the field survey, the firewood. was being marketed in an open setting, divided into different sizes, and assembled. However, there is no precise information regarding the various prices. This article so advocated the necessity for re-strategizing the style of marketing the various types of forestry products; techniques of presenting; community seller involvement and cooperative society building; and the need for reforestation and forest protection programs.

Keywords: Firewood, Marketing, Selling, Federal Capital Territory

An Estimation of National Charcoal Production: the case of Ghana.

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Joseph Asante[1, 2]
[1] Tropenbos Ghana, Kumasi – Ghana
[2] Kwame Nkrumah University of Science and Technology, Kumasi – Ghana

Abstract: Accurate data on the production and sources of woodfuels is necessary to ensure sustainability. National level data is scanty in most sub-Saharan African countries. This research aimed to provide accurate data on charcoal production in Ghana and to develop, and put fort a methodology that could serve as an inspiration for future assessments, in Ghana and beyond. The study compiled data over two years from Ghana Forestry Commission's records on charcoal quantities transported on the road (Charcoal Conveyance Certificates). This data was validated by mounting sentries 24 hours daily for two weeks in 2016 and 2018, respectively, along major charcoal transport routes to capture charcoal being transported without the certificate. Charcoal production not captured through the Charcoal Conveyance Certificate and the sentries was quantified from field observation and expert panel validation. Using these three methods, the study estimated a total annual production (2018) of 1 100 000 tonnes of charcoal for Ghana. This corresponds to 15.7 million m 3 of round wood equivalent. The comprehensiveness and robustness of the methodology hints of possibility of a more accurate data to inform decision making and planning on charcoal production and trade. This however requires improvement in the Charcoal Conveyance Certificate regime by the Ghana Forestry Commission to capture more of the charcoal conveying vehicles and their load (carrying capacity). This can be done through periodic mounting of sentries as demonstrated in this study to monitor the charcoal conveyance data. We suggest that the proposed method could serve as inspiration for regulatory bodies in Ghana, notably the Ghana Energy Commission and Ghana Forestry Commission, to generate regular updates on annual charcoal production and consumption, perhaps in tandem with estimates obtained through other methods, for example consumption studies. Finally, it is suggested that the method demonstrated here can serve as inspiration beyond Ghana, in countries where national permit systems are implemented, but only capture a share of the total production and movement.

Assessment of stocking, productivity, and aboveground biomass of tree species used as fuelwood in Rwanda's agricultural landscapes

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

ELIAS NELLY BAPFAKURERA

Abstract: Trees-based systems (TBS) in the agricultural landscape have the potential to supply wood biomass as the source of cooking energy to the local communities in Rwanda, but there needs to be more information on the current most cultivated tree species suitable for fuelwoods supply and available wood biomass. We assessed the most cultivated species preferable for fuelwoods supply and their aboveground biomass (AGB) stock in five TBS, which are home gardens, mixed cropping, intercropping, live fences, and woodlots, through a survey of 130 transects covering an area of 130 ha, systematically distributed in Musanze and Bugesera Districts. Considering the total inventoried tree species, tree density covered 132 trees/ha in Musanze and 74 trees/ha in Bugesera. In Musanze, Eucalyptus spp were the most cultivated trees in all TBS constituting 68.3% of all trees. In Bugesera, 6251indivudual trees were found, of which eucalyptus spp was the most common tree (31.9%) ,followed by senna spectabilis (28.5%).Overall, the total AGB was 2.77t/ha in Musanze and 1.08t/ha in Bugesera. AGB was higher in intercropping in both Musanze and Bugesera (0.86t/ha and 0.36t/ha). The four species that contributed the most to the total AGB were Grevellia robusta (0.34t/ha), Eucalyptus spp (1.97t/ha), Alnus acuminate (0.42t/ha), and Markamia lutea (0.04t/ha) in Musanze District while in Bugesera District were Grevellia robusta (0.79t/ha), Eucalyptus spp (0.20t/ha), Senna spectabilis(0.06t/ha) and Markamia lutea (0.03t/ha).

Combined application of biochar and deficit irrigation enhanced growth of commercial agroforestry woody species seedlings in the drylands

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Gebremariam Yaebiyo[1]
Emiru Birhane[1], Tewodros Tadesse[2], Solomon Kiros[3], Kiros Meles Hadgu[4], Yemane G.Egziabher[5], Solomon Habtu[1]

[3] Science and Technology, Addis Ababa University, Addis Ababa, Ethiopia
[4] World Agroforestry Center (ICRAF), Addis Ababa, Ethiopia
[5] Department of Dryland Crop and Horticultural Sciences, Mekelle University, Mekelle, Ethiopia

Abstract: Water availability is the main problem for the growth and expansion of commercial agroforestry woody species in drylands. Biochar (B) and deficit irrigation (DI) can be used to enhance soil moisture in drylands. Growth of commercial woody species seedlings were evaluated for about two years using the combined effect of B and DI treatments. Biochar was applied to the plantation pits during plantation with a rate of 10 ton ha^{-1}. The irrigation applied covered 59.6% (459 mm) and 35.2% (459 mm) of the dry season crop evapotranspiration for *Citrus sinensis* and *Yushinia alpina*, respectively. Combined application of B and DI significantly increased growth of both the species. New culms of *Y. alpina* were increased by applying both B and DI. The species differed significantly in height and diameter relative growth rate (RGR) and physiological responses. *C. sinensis* had higher height and diameter RGR than *Y. alpina*. Transpiration rate was significantly higher in *C. sinensis* than in *Y. alpina*, but vice versa in water use efficiency. Combined application of B and DI significantly enhanced the height and diameter RGR of the species in dry months through gas exchange enhancement. Both the species attained their maximum height growth rate at the end of the rainy seasons. Combined application of B and DI and DI alone significantly increased biomass of *Y. alpina*. Hence, combined application of B and DI is essential for successful establishment of *C. sinensis* and *Y. alpina* seedlings in farmlands of dryland areas.

CONTRIBUTION OF BRITISH AMERICAN TOBACCO (BAT) TO TREE PLANTING IN KENYA

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Peter Kimani[1]
Joram Kagombe[1], Miriam Gathogo[1], James Mwaura[1], Celestine Ingutia[1], Stanley Nadir[1]
[1] kenya forestry research institute

Abstract: Tobacco industry has been associated with improvement of livelihood as well as claims of degradation. A study in 2016 addressed the environmental impact of tobacco growing, paying special attention to tree planting and loss of vegetation in Kenya. The objective of the tree census was to evaluate the effect of afforestation programs by BAT tree planting project to its contracted farmers in Kenya that is Eastern, Western and Nyanza regions. The study targeted 517 farmers sampled from the total number of farmers estimated at 5500. Tree inventory, consultative and participatory survey approaches mainly targeting key informant interviews, documents reviews, questionnaires and focus group discussions were used. These targeted various levels of BAT customers/beneficiaries. Desk reviews on existing secondary data and documents were undertaken for study preparations, methodologies, benchmarking with other similar studies and to develop a comprehensive report. The study suggests three triggers that lead to vegetation loss associated with tobacco growing namely forest degradation and deforestation due to tobacco curing clearance for more growing land. The study noted that, although the global share of agricultural land used for tobacco growing is less than 1%, its impact on global deforestation is 2–4%, making a visible footprint for climate change. The key tree planting support that BAT gave to farmers and institutions was provision of free seedlings. In Western, the survival rate was higher for trees issued by BAT compared to trees sourced elsewhere, contrary to Eastern and Nyanza regions. The major reasons for mortality amongst tree seedlings include drought, poor season timing and pests attack, especially termites. The possible interventions for the challenges were watering trees during dry seasons and provision of pesticides/ termiticides. The company should supply tree seedlings in good time. Study recommended approaches to enhance tree cover initiatives that include increased tree nurseries for contract farmers, pest and disease monitoring, proper timing for tree planting and continued collaboration with key partners.

Key words: Tree census, tree planting, Participatory, tobacco growing, degradation, deforestation

Does intensive forest biomass harvest require nutrient compensation for sustainable biomass production?

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Ulf Sikström[1]
Lars Högbom[1]
[1] Skogforsk (The Forestry Research Institute of Sweden), Uppsala Science Park, S-751 83 Uppsala, Sweden

Abstract: The use of forest derived biofuels as an energy source has increased substantially during the last decades not least in Sweden. Whole-tree harvesting includes extraction of, except for stems, tops and branches used for energy purposes. This is a large-scale practice and recycling of the produced wood-ash is undertaken at some sites. There are only a few available field experiments with ash addition, especially when added in clear-cuts following whole tree harvesting. Therefore, to increase requested knowledge on how whole tree harvesting and ash recycling affect growth of Norway spruce (*Picea abies* L. Karst.) three field experiments were established to test the following hypotheses: (i) the growth is reduced after WTH, (ii) at fertile sites the growth is enhanced by ash addition, unaffected at medium-productive sites, and reduced at low-productive sites, (iii) the reduced growth by WTH is compensated for by ash addition at fertile sites only. The study includes monitoring of survival and tree growth measurements in the three field experiments located on sites of different fertility. The experimental design is treatments randomized within blocks (n = 5). At all sites the following treatments are included: (i) harvest of stems only, (ii) whole-tree harvest, (iii) harvest of stems only + 3 tonnes (dry matter) of self-hardened crushed biofuel ash, and (iv) whole-tree harvest + 3 tonnes (dry matter) of self-hardened crushed biofuel ash. Each study plot is sized 20 m × 20 m and included 64 seedlings at planting. The experiments were established between 2011 and 2015. Results on survival and growth over 8-10 growing seasons will be presented and the need for nutrient compensation after WTH will be discussed based on these results and the general knowledge on tree growth responses of WTH and different nutrient compensation regimes.

Does traditional agrisilvicultural systems benefit farmers? - A benefit-cost analysis of Grewia optiva on pea fields of northwest Himalayas

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Tara Kumari[1]

[2] Wildlife Institute of India, P.O. Chandrabani, Dehradun-248001, India
[3] Institute of Green Economy (IGREC) C2/24, First floor, Lord Krishna Enclave, Sushant Lok I, Gurugram 122009

Abstract: *Grewia optiva*, a multipurpose tree species, is widely preferred by farmers in traditional agroforestry systems in the northwest and central Himalayan regions of India. This species is retained deliberately by farmers on the farm bunds on account of its utility as fodder, fuel, fiber, and other purposes. The selection of intercrops depends mainly on edapho-climatic conditions of the area. The present study is aimed to assess the benefit-cost analysis of the *Grewia-based* traditional agrisilvicultural system in Chakrata tehsil of Dehradun district in the north-west Himalayan state of Uttarakhand during the winter season. We chose pea (*Pisum sativum*) as a representative rabi crop for the agricultural component of the study area as it is a major and most preferred crop of the region. The Two-stage random sampling was adopted for the selection of the primary sampling units, i.e., households. Villages were selected in the first stage and households in the second. At least 10% sampling intensity was maintained to randomly select the villages and a representative household survey was conducted following a pre-structured questionnaire in the selected villages. We calculated the benefit-to-cost ratio (B/C ratio) at a discounted rate of 7% for a period of 5 years by incorporating all the input and output costs associated with this tree-crop combination. A high 3.6 B/C ratio indicates multifold benefits gained from *Grewia-based* agri-silvicultural fields. The said benefits include the daily requirement of fodder and fuelwood during the lean winter season besides the main income generated from agricultural crops.

Driving Sustainable Economic Growth in Mountain Forest Communities through the Implementation of Charcoal Production Chains

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Alessio Mencarelli[1]
Rosa Greco[1], Raffaele Cavalli[1], Stefano Grigolato[1]
[1] Department of Land, Environment, Agriculture and Forestry, University of Padova, Viale dell'Università 16, Legnaro (PD), 35020, Italy

Abstract: Based on FAO data, most of the charcoal consumed in Europe is produced in non-European Union countries, particularly tropical regions. This reliance on imported charcoal raises concerns as it often contributes to illegal logging practices and forest degradation, posing significant environmental and sustainability challenges.

The use of local wood resources for charcoal production guarantees several benefits. Firstly, it reduces the dependence on imported charcoal from foreign countries, ensuring self-sufficiency and promoting local economic growth by generating additional income for forest owners and communities. Beyond its traditional use as a cooking fuel, charcoal has also several applications in industries such as metallurgy or pharmaceuticals.

Therefore, charcoal production and its distribution at the local level could represent an effective solution to reduce wood charcoal importation and at the same time add value to the local wood supply chain in the frame of the circular economy.

In this frame, a case study located in the north-eastern part of Italy has been analyzed considering: 1) wood harvesting efficiency, 2) potential availability of logging residues suitable for charcoal production; 3) charcoal production process efficiency; 4) charcoal quality compared to products already available in the market.

The study will present the consideration to implement a charcoal-production chain at a small-scale in terms of socioeconomic and environmental benefits.

Factors influencing adoption of energy conservation and production technologies for wood fuel resources in Makueni County, Kenya.

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Emily Kitheka[1]
Kazuki Shibasaki[2], Rahab Wanjau[1], Linet Muindi[1], Valentor Okul[1], Rufo Jilo[1], Celestine Ingutia[1], Franciscah Henry[1], Josephine Musyoki Musyoki[1], Albert Luvanda[1], James K. Ndufa[1], **Nellie Oduor**[1]

[2] Japan International Forestry Promotion and cooperation center

Abstract: Abstract

In Kenyan, wood fuel is an important sector in the economy. Increased population, rapid urbanization, changes in lifestyles, high poverty levels and high cost of alternative fuels for cooking and heating have contributed to increased demand for wood energy. This has resulted in increased deforestation of public, private and community forests. Production and utilization of woodfuel resources is characterized by selective and unsustainable harvesting methods, overexploitation of preferred species and use of inefficient production and utilization technologies. A socio-economic survey undertaken in Makueni County to evaluate woodfuel resources, preferred, alternative fuels sources, and socio-economic factors influencing adoption of energy conservation and production technologies. The results revealed that energy mix and stacking is a replica of the national situation with fuelwood being the most preferred source of energy, followed by charcoal, kerosene, gas and crop residues respectively. Availability, cultural preferences, health and safety, cost of technology and sustainability of the fuel influenced choice. Decreasing indigenous trees on community forests and private farms, and increased planting of exotic trees for timber, fruits and aesthetic were the major factors contributing wood fuel scarcity. Availability of alternative fuels, scarcity of fuelwood, high cost of charcoal and convenience in use has influenced changes in types and quantities of energy used at household and institutions. There was a significant correlation between family sizes and energy consumption. Major challenges in obtaining fuelwood included: scarcity of firewood resources, long distance and time taken for collection, high cost of production, labor intensity, ban on charcoal production, inefficient production and climate change. Indigenous trees were the most preferred fuelwood sources though the tree are getting overexploitated. Acacia and Terminalia species were the most preferred. Adoption of energy conservation technologies was constrained by land and tree ownership, income level, education level, cultural values, lack of expertise, availability of alternative fuels and ignorance. The study concluded that bioenergy is a major source of cooking fuel for rural population. We recommend capacity building of community, groups and institutions on sustainable bioenergy production, utilization, environmental conservation and afforestation using indigenous species as way forward.

Keywords: bioenergy, technologies, energy sources, preferred species. Environment, biodiversity

Geographical variations of woodfuel supply and trade in northeastern Bangladesh: The question of sustainability

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Md. Habibur Rahman[1]
Kaoru Kitajima[1], Yohei Mitani[1]
[1] Graduate School of Agriculture, Kyoto University, Kyoto 606-8502, Japan

Abstract: We surveyed woodfuel vendors in 112 markets within 30 km from the borders of Khadimnagar National Park (KNP subregion) and Lawachara National Park (LNP subregion), evaluating how two subregions differ in relation to market attributes (degree of urbanization, population density), environmental attributes (tree coverage, seasonality), vendor characteristics, and woodfuel sources utilized by the vendors. A total of 206 woodfuel vendors were interviewed, including 58 wholesalers, 22 mixed wholesalers, and 126 sawmills. Principal component analysis (PCA) was used to summarize the relationships between environmental factors and market attributes. Survey results revealed that 101 rural market vendors sold higher quantities of woodfuel compared to 94 semi-urban market vendors. In the KNP subregion, the average woodfuel sold across 74 markets was 243 ± 283 t/yr, while the LNP subregion saw 333 ± 316 t/yr of woodfuel sold across 38 markets. Sawmills in the two subregions had significantly greater woodfuel sales than the wholesalers and mixed wholesale vendors. There was a significant seasonal fluctuation in woodfuel sales, with lower sales during the wetter monsoon months (July-October) and higher sales in the winter months (November-February). Findings showed a positive correlation between the annual woodfuel sold in each market and market attributes, such as the surrounding population density. Non-forest sources, such as homestead forests, roadside plantations, tea estates, and sawmills supplied 73% of the total woodfuel sold. Moreover, the Multinomial logit model revealed significant effects of specific vendor attributes on the selection of utilized woodfuel sources ($p < 0.01$). Significant variations were observed in both the woodfuel selling price and vendor's net income between the two subregions. The findings highlight the importance of homestead forestry and roadside social forestry plantations in achieving sustainable woodfuel supply for Bangladesh's forest and energy sectors' sustainable development goals.

Governance of landscape approach applied to woodfuel value chains in Democratic Republic of Congo: Experiences from Yangambi landscape (North-eastern)

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Muvatsi Lwanga Kasereka[1]
Jolien Schure[1], Georges Mumbere Kiwanza[1], Abdon Awono[1]
[1] Center for International Forestry Research-World Agroforestry Centre (CIFOR-ICRAF)

Abstract: In the Democratic Republic of Congo (DRC), woodfuel is used by households as a primary source of domestic energy for cooking, with an increasing demand by urban centers. This situation calls for reconsideration of the balance between socio-economic and environmental outcomes of woodfuel value chains and potential of sustainable management.

Woodfuel production is often presented as one of the drivers of deforestation and forest degradation. However, this sector is part of more complex links and often a by-product of shifting cultivation practiced throughout the Congo Basin region. Previous efforts to formalise the woodfuel sector in the DRC have not sufficiently incorporated a landscape approach that considers these interlinkages with other uses and users in the supply chain. This paper shows how the landscape approach could be effectively applied to woodfuel value chains in order to contribute to biodiversity conservation and livelihood improvement for local communities. The analysis is based on a literature review and empirical data collected from producers, sellers and households in Yangambi landscape located in North-eastern in DRC.

Governance through the landscape approach helps to explore the formal and informal opportunities for the sustainability of woodfuel value chains linked to other livelihood activities.

In Yangambi landscape, this integrated approach through a participatory process resulted in bases for sustainable socio-ecological systems of woodfuel production (agroforestry, improved carbonisation techniques and valorisation of wood waste) and consumption (promotion of using improved stoves) based on local context.

Key words: Landscape approach, woodfuel value chain, Yangambi landscape.

Supporting Transitions to Sustainable Woodfuels in sub-Saharan Africa with New Tools and Novel Policies

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Rob Bailis[1]
Adrian Ghilardi[2]
[1] Stockholm Environment Institute
[2] Universidad Nacional Autónoma de México (UNAM)

Abstract: Roughly 2.4 billion people in Global South rely on wood, charcoal, and other biomass as their primary source of energy. These fuels are typically burned in open fires or simple devices and are associated with a range of development challenges including profound health impacts, forest degradation, climate-forcing emissions, and gender inequities. Some regions are transitioning from woodfuels to cleaner options like cooking gas or electricity, which have fewer negative impacts. However, in the absence of major investments and shifts in policy, hundreds of millions of families will use biomass for years to come. Indeed, the WHO estimates that the woodfuel-dependent population in sub-Saharan Africa will **increase by 400 million people** in the next two decades.

Many countries in sub-Saharan Africa are trying to address these challenges by introducing new policies and seeking investment that would initiate or accelerate a transition away from traditional woodfuels. Indeed, thirty-eight countries in the region have included provisions in their Nationally Determined Contributions (NDCs) to the UN Framework Convention on Climate Change seeking to either make woodfuel consumption more sustainable, reduce woodfuel dependence, or eliminate it entirely. However, achieving those targets will be incredibly challenging. There are very few examples of successful woodfuel transitions in the region and the investments made in the sector have been woefully inadequate.

In this panel presentation, we will discuss recent efforts to promote sustainable woodfuels and introduce alternative sources of household energy in sub-Saharan Africa. Our presentation will examine both analytic tools and policies. The analytic tools we introduce are computer-based models that help us understand the nature and magnitude of the impacts that unsustainable woodfuel consumption has on the environment and society including forest degradation, greenhouse gas emissions, and health risks. Quantifying these impacts is critical to understand the full costs and benefits of transitions and to catalyze the necessary investment. The policies we examine have either been introduced or are under development and are intended to shift countries to more sustainable energy pathways. Specifically, we are advising the government of Uganda to develop a new Clean Cooking Strategy and cut woodfuel demand in half by 2025.

Sustainability of woody biomass feedstock for bioenergy sector in China- A case study of Guangxi

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Ya Gao[1]
[1] FSC International, Adenauerallee 134, 53113 Bonn, Germany

Abstract: Guangxi is a forest resource rich province, with 62.2% of the land covered by forests. Half of it used for timber production, of which 10% are certified under FSC or PEFC. Guangxi supplies more than 40% of China's domestic timber. Guangxi's forest-based industries are amongst the largest in China, characterized by high level of integration, reliance on regional wood supply and interdependence between different value chains. It contrasts with other Chinese forest industry clusters that rely on imported raw material.

The study aims to evaluate the availability, sustainability and traceability of woody biomass feedstock for bioenergy. We mapped out value chains, identified sectors that supply woody biomass residue (WBR) and sectors which compete for WBR with bioenergy generation. Sustainability, and traceability of the WBR for bioenergy sectors are evaluated based on FSC FM and CoC standards.

Harvesting, sawmilling and plywood industries generate WBR that feed into the production of fiberboard, particleboard, wood pellet and biomass power generation. Given the large plywood production capacity, processing residue from plywood constitute the main source of WBR. A smaller portion comes from sawmilling industry. Harvesting residue, due to high cost of labor and transportation, is utilized at low rate. Large production capacity of fiberboard and particleboard compete fiercely for WBR with wood pellet and biomass power generation industries. The sustainability of WBR is largely ensured by theSFM principles and criteria which are embedded in China's recently revised forest law. Another layer of sustainability comes from WBR that are generated from FSC and PEFC certified supply chains. The main sustainability risks include over and false utilization of fertilizer and herbicide, worker safety and rights of immigrant workers. Traceability of WBR poses the biggest challenge because of high consolidation of sawmilling and plywood production industries.

Guangxi provincial government highly recognizes the contribution of forest-based industries to local economic development. Policies are in place to further catalyze the development of forest-based industries. Bioenergy industry as an integral part of the local bioeconomy and a sector that utilizes residues of mechanical wood producing industries have a key role to play in driving sustainability and traceability in the sector.

Sustainable Wood Fuel Production for Dendroenergy Generation – Challenges and Learnings Through Economic and Environmental Dimensions

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Parthiban K.T.[1]
Jawahar Vishnu M.V.[1], Revathi S[1], Arasakumar E[1], Akshay Fakkirappa Madiwalar[1]
[1] Forest College and Research Institute, Tamil Nadu Agricultural University, Mettupalayam

Abstract: The demand for energy particularly the renewable energy is gaining potential attraction among the developed and developing nations. Among the renewable energy resources, the significance of biomass energy generation is very well witnessed due to its role in decentralized energy generation, rural employment coupled with its role in carbon sequestration. Hence, studies were conducted in the state of Tamil Nadu, India to assess the status and opportunities of dendroenergy generation coupled with suitable research interventions to sustain the availability of biomass resources. The study considered the actual potential and demand of wood to meet the raw material requirement of various biomass industries coupled with policy directions on blending biomass in coal powered plants. This besides, the current availability of biomass has been reviewed and presented with the challenges and constraints which detracts the attraction of biomass energy generation. The paper also indicated the potential and viable opportunities to establish commercial and sustainable dendroenergy plantations through technological and organizational interventions. The development and deployment of High Yielding Short Rotation (HYSR) clones (100 tonnes/ha in 2-3 years) with improved thermo-chemical properties (Calorific value ranging between 3800 and 4500 Kcal), site-specific dendroenergy models (HDEP), value addition technology viz., wood chips (<10 mm, 20-40 mm), briquettes (70 mm & 90 mm) and pellets are the technological interventions which attracted dendroenergy generation. The establishment of suitable linkages among various stakeholders from the entire Production to Consumption System (PCS) in a consortium approach is proved to be very lucrative and attractive both for the growers and consuming industries. In a holistic analysis, the current paper describes the potential options for sustainable wood production through Forestry and Agroforestry options towards generating clean and green energy.

The Potential of Efficient Charcoal Production and Briquetting in Improving Livelihoods and Combating Climate Change

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Timothy Namaswa[1, 2]
Nellie Oduor[1], Joseph Githiomi[1], Emily Kitheka[1], Peter Ogutu[1], James Kimwemwe[1], Nathan Maitha[1]
[1] Kenya Forestry Research Institute (KEFRI), P. O. Box 20412-00200 Nairobi, Kenya
[2] School of Biological Sciences, University of Aberdeen, St Machar Drive, Aberdeen, Scotland, U.K. AB24 3UU

Abstract: Unsustainable woodfuel production in fragile ecosystems is responsible for increasing deforestation and widening woodfuel supply-demand deficit. This is threatening the livelihood of communities while accelerating climate change. This study aimed at validating and upscaling efficient charcoal production and provision of briquettes for sustainability and improved livelihoods. The study determined efficiency and productivity of kilns, quality of charcoal and briquettes, greenhouse gas emissions, and profitability of efficient charcoaling and briquetting. The study was conducted using stems and withies from Prosopis, maize cobs, rice husks and bagasse. Pyrolysis technologies validated were traditional earth mound (baseline), improved earth mound, portable metal, top-lid up-draft box, modified drum and cylindrical husk Carbonizer. The kilns and accessories were fabricated and validated with community interest groups (CIGs). Key informant interviews and laboratory tests were conducted. Emission factors were obtained from published literature. Results indicated that portable metal kiln had the highest efficiency (35.3%) with annual profitability increase of 19.6% in relation to baseline kilns. Charcoal from improved traditional earth mound recorded the highest fixed carbon (77.5%) and least ash content (3.1%). Traditional earth mound kiln recorded higher average monthly CO_2 (1.3 tons) and CO (0.3 tons) emissions compared to other kilns. Briquetting technologies showed conversion efficiency above 25% on feedstocks tested. Briquettes from bagasse carbonized using modified drum kiln and mixed with gum arabic recorded the least ash content (9.1%) whilst briquettes from Prosopis withies carbonized using the same kiln and mixed with gum arabic recorded the highest fixed carbon content (67.4%) and calorific value (25.4 MJ kg^{-1}). It was estimated that a CIG producing briquettes using bagasse via a motorized machine could make the highest monthly profits (US$ 477), with the potential to make 5.1 tons of charcoal equivalent fuel monthly. Therefore, efficient charcoaling and briquetting can improve people's livelihood and combat climate change.

“Before, when we were poor…” - how a market driven afforestation changed trajectories in socio-economic and environmental resilience in Ethiopia

S2.3 Sustainable Woodfuel Production in Sub-Saharan Africa - Social, Economic and Environmental Dimensions

Erik Karltun[1]
Asmamaw Alemu[2], Getachew G. Tiruneh[1], Jennie Barron[1], Fantaw Yimer[3], Linley Chiwona Karltun[4]

[2] Dept. of Forestry, University of Gondar, Ethiopia
[3] Wondo Genet College of Forestry and Naturals Resources, Hawassa University, Ethiopia
[4] Dept. of Urban and Rural Development, SLU, Sweden

Abstract: A rapid market driven land-use change from agriculture to forestry is occurring in the Amhara region in Ethiopia. Farmers have introduced an agro-forestry system with production of charcoal from fast growing *Acacia mearnsii* in a 4 to 6 year rotation, with high economic returns and impacts on landscape ecosystem features. The *Acacia* is intercropped with teff and grass during the first and second year of the rotation. This system largely replaced traditional annual cropping systems. Between 2002 and 2017 the area proportion of traditionally managed cropland reduced from 67% to 36% in the Fagita Lekoma district while the *Acacia* plantations went from less than 1% to 38% (25 000 ha in 2017). The value chain of the charcoal creates significant economic activity. Based on trade statistics from the district office we estimated annual export of charcoal in the order of 5.3 million bags yr^{-1} of charcoal (July 2018 – June 2019). This charcoal represents a market value in Addis Ababa of 450 million Birr (15 million USD). This has led to monetary income along the value chain including farmers, charcoal makers, local labourers, seedling producers, brokers and transporters. The seedling producing activities are substantial. Just to replant the harvested *Acacia* stands, in the order of 100 million seedlings/yr needs to be raised only in the Fagita Lekoma district. The income generated from the value chain is unequally distributed between men and women with higher pay for activities dominated by men. Wealth indicators indicate rapid improvement in household income for many families. The plantations has led to a significant increase in carbon sequestration, mainly attributed to the increase in *Acacia* above and below ground biomass while soil carbon has not increased. There has been an evident increase in the canopy cover of adjacent natural forests since the onset of the plantations, which we interpret to be a result of reduced collection of fuel wood and reduced free grazing. Studies on the effect on the water balance indicate higher infiltration rate in the stands than in the adjacent cropland which can explain farmers’ observations of reduced erosion due to the *Acacia* plantations.

S2.4 Unlocking the bioeconomy for nontimber forest products

Comparative transcriptome analysis of high temperature stress response in Mitragyna speciosa (Rubiaceae)

S2.4 Unlocking the bioeconomy for nontimber forest products

Abstract: Plants have primary and secondary metabolisms, whereby primary metabolism produces metabolites essential for plant growth cum development, and secondary metabolism produces compounds involved in plant defence system. Throughout human history, plant secondary metabolites have been a treasure throve of therapeutic agents in treating diseases, alleviating symptoms and for pain relief. Many prospective plants for drug discovery are yet to be discovered from the forest. Kratom (*Mitragyna speciosa*) is a unique psychotropic tropical plant of the Rubiaceae family. It has been used as a traditional remedy to treat various ailments as well as a stimulant to boost energy. It has many medicinal properties, owing to its opioid-like, analgesic, and antitussive effects. As studies have shown that high temperature increases the production of secondary metabolites in some plants, we hypothesised that high temperature stress would increase the mitragynine content in Kratom leaf. Mitragynine is the major alkaloid of Kratom, an important pharmacologically active compound besides 7-hydroxymitragynine. The high-temperature treatment of *M. speciosa* plants was conducted in a growth chamber. Results from the phytochemical analysis of the control and treated leaf samples supported the hypothesis, in that the mitragynine content quantified was significantly higher in treated samples. Subsequently, RNA sequencing was conducted for the control and treated samples using Illumina platform. The sequences were assembled using a reference genome that generated 72,885 transcripts of 70,406 known genes and 2,479 novel genes. From the comparative transcriptome analysis, a total of 16,003 differentially expressed genes were identified, of which 6,894 were up-regulated and 9,109 down-regulated. A total of five genes related to the MG biosynthesis pathway were successfully validated by RT-qPCR.

Diversity and Importance Value Index (IVI) of Tree species with Non-Timber Forest Products attachment in Niassa Special Reserve, Mozambique.

S2.4 Unlocking the bioeconomy for nontimber forest products

Gerald Lubega[1]
Falcao Mario Paulo da Silva[1], Joseph Ssekandi[2], Ribeiro Natasha[1]
[1] Department of Forest Engineering, Faculty of Agronomy and Forest Engineering, Eduardo Mondlane University, P.O.Box 257, Maputo, Mozambique
[2] Department of Agricultural Sciences, Faculty of Agriculture and Environmental Sciences, Kabale University, Kabale, Uganda

Abstract: Assessment of Tree species composition and structure was carried out in Niassa Special Reserve, Mozambique. Data on anatomy, botany, physiology and flowering/fruiting phenology of the various tree species used as source of Non- Timber Forest Products (NTFPs) was collected through community meetings, literature from local, regional and national sources, and key informant interviews. Key informant interviews were conducted with Wildlife Conservation Society (WCS) officials, traditional healers, and local leaders to help in identifying the different places where these tree species were being harvested. ,Two Linear transects having 500m long each per community/village were laid. Along each transect five composite plots of $2500m^2$ were established where data on tree species with NTFPs Attachment was collected. The distance between two different transect was determined after producing the village maps by the community members. Identification of different tree species with NTFPs attachment along each transect was based on visual assessment of physiognomic and ecological characteristics. The main parameters taken in account were dominant tree species, indicator species, tree density, height, and degree of disturbance. A total inventory of the different NTFPs Tree species was done from all the plots within each transect. A total of 56 different tree species and 25 families were identified. The family of *Fabaceae* had the highest number of species (17). Tree species were measured and the data was used to calculate Relative Abundance, Relative Dominance, and Relative Frequency. Their results were used to derive the Important Value Index (IVI) which determined the dominant tree species of the entire area under study. *Diplorhynchus condylocarpon* (29,03) had the most Importance Value Index followed by *Julbernadia globiflora* (26,82), *Burkea africana* (25,75), *Terminalia sericea* (22,42) and *Combretum apiculantum* (16,99). The tree species were harvested from the Leaves, Roots, Back, Fruits, seeds, and flowers and were harvested for Medicine, Firewood, Traditional/Cultural Attachment, Forage, Poles, Ropes, Honey production, Fishing, Food, Crafts and making canoes. The Niassa Special Reserve management should design programmes that will create awareness to people around and within the Reserve to realise the need of conserving the flora and fauna species most especially those with several uses but with low diversity.

Does income from environmental products have potential to eradicate poverty among forest-dependent communities? The case of Ophiocordyceps sinensis.

S2.4 Unlocking the bioeconomy for nontimber forest products

Sanjeev Poudel
Ram Pandit[1]
[1] University of Western Australia

Abstract: This paper examines whether the income from caterpillar fungus trade helps local communities to move out of poverty. Considering *Pupal* pasture and associated local communities from *Dhorpatan* Hunting Reserve as a case study, we applied socio-ecological system's perspective to examine the research question. We surveyed 223 caterpillar fungus collectors during May-June season of 2019 using a survey instrument. Findings suggest that the collectors earned on average USD 3,090 PPP from fungus collection in a season, which is about 80% of the household income. Average expenditure to collect fungus is about USD 736 PPP. This suggests that earnings from caterpillar fungus collection substantially contribute to reduce income poverty among the community of Eastern *Maikot* – who are the primary collector of fungus at Pupal pasture. If resource is managed sustainably, this income could be sustained in the long run which could potentially alleviate the poverty among forest dependent communities of Maikot.

Fostering transition pathways towards the sustainable integration of non-timber forest products to a bioeconomy: learning from the case of baobab

S2.4 Unlocking the bioeconomy for nontimber forest products

Kathrin Meinhold[1, 2]
Dietrich Darr[1, 2]
[1] Rhine-Waal University of Applied Sciences
[2] Sustainable Food Systems Research Centre

Abstract: Many non-timber forest products (NTFPs) have great potential for higher-value processing and commercialisation, fostering more sustainable land-use practices and contributing positively to livelihoods. This is especially relevant for (semi-)arid regions, where many priority NTFPs are located. Their sustainable integration into a bioeconomy can offer a viable alternative to prevailing (agricultural) practices in such regions, which are already severely threatened by today's global challenges such as climate change or biodiversity loss. Frequently, however, the collection, processing, and trade of NTFPs remains on a small scale, creating only limited benefits. Thus, this paper aims to contribute to a better understanding on how such change could occur, e.g. how possible transition pathways could be framed, how NTFP value chains be mainstreamed into the economy, and associated challenges tackled; topics, which so far have only been insufficiently assessed. Besides drawing on conceptual underpinnings highlighting the necessity of a holistic, systems approach to aid transformation processes, we would like to illustrate how such a transition can occur in practice, by exploring the case of the baobab (*Adansonia digitata* L) tree in (semi-) arid regions of sub-Sahara Africa. The value chains of this species have already advanced quite substantially towards a stronger bioeconomy integration via the creation of a variety of innovative bio-based products, considering principles of cascading use. Baobab products are nowadays commercialised in different sectors and markets, from regional to international. This offers substantial lessons to be learnt for promoting an increased NTFP integration into the bioeconomy more generally, e.g. in terms of value chain structure and functioning, policy and institutional changes required, or the role of research. Drawing on these lessons, we aim to illustrate a holistic and participatory research and development approach which may help foster similar transition processes for other priority NTFPs in (semi-)arid regions.

How emerging non-timber forest products markets transform gender division of labour? Learnings from açaí (Euterpe oleracea) in the Amazon

Abstract: The economy based on non-timber forest products (NTFPs) often relies on informal actors and activities, based on specific logics and worldviews. While the effects of these new markets on traditional societies and lifestyles have been studied, gender is rarely addressed. However, authors have shown that the inclusion of traditional products in markets, including NTFPs, tends to dispossess women of resources and of their activities, making the poorest fringe of the world's population even more vulnerable. We hypothesise that by understanding the changing roles of women and men in the markets for one NTFP, açaí, we can explain how, and under what conditions, women manage to be part in the supply chain and thus become economic stakeholders in their own right. The method is based on monographic studies conducted between 2014 and 2019 in the states of Pará and Amapá (Brasil), and in French Guiana, in different marketing contexts: home sales, short circuits, export. Practices surrounding the harvesting, processing and consumption were described and supplemented by historical interviews on traditional practices and know-how, as a reference time preceding the marketing of açaí.

Our results show that fruit-gathering was not a gendered activity, but was carried out by young people regardless of their sex, or on specific occasions when people were going out into the forest (hunting for instance). The urbanisation of lifestyles, combined with the loss of links with the forest, seems to have accelerated the process of masculinisation of fruit-gathering. Processing used to be carried out by women - although not exclusively; it is now the preserve of men in Brazil, including in micro-processing units. In French Guiana, while the açai economy is still invisible, processing is dominated by women, including for large volumes. Permanent control of processing, for commercial purposes, is systematically accompanied by financial independence (enabling the purchase of equipments). Our study also shows that the gendered specialisation of gathering can be accompanied, conversely, by the permanence or appearance of new forms of young men precariousness. These results may contribute to unlock the bioeconomy for non timber forest products.

Linking ecosystem, food systems and community for sustainable governance

S2.4 Unlocking the bioeconomy for nontimber forest products

Huidan Xue[1]
Qing Li[2]
[1] School of Economics and Management, Beijing University of Technology, Beijing 100124, China
[2] Beijing-Dublin International College, Beijing University of Technology, Beijing 100124, China

Abstract: With the development of agroforestry and urbanization, ecosystems, food systems, and communities are interacting more and more actively, especially in areas with high forest coverage. The global pandemic, reduction in biodiversity, and lack of resilience of food systems have alerted that countries should make efforts to establish a global governance framework with integrated ecosystems, food systems, and local communities. This research constructs a systematic framework to analyze the connections and interlinkages between the ecosystem, food systems, and local communities, and then conducts a qualitative study of the discourse coalition and actions of different stakeholders in the breeding and farmed wildlife industry of China using discourse analysis and actor-oriented approach. It finds that discourse and actions have had drastic turns in the pre-, early, and post-COVID-19 era. Government and stakeholders of the ecosystem and consumers in food systems tended to form discourse coalition in terms of disease control, ecosystem protection, and food safety, yet producers, processors, and other stakeholders in the food systems involuntarily joined discourse coalition and reroute actions initially as their economic conditions and livelihood were heavily affected. However, local communities and food systems have the self-repairing capacity in the long-term by “up to down” and “down to up” discourse architecture and grass-root collective actions after disruption and chaos occurred. Discourses regarding livelihood, poverty alleviation, and breeding wildlife for traditional Chinese medicine and economic growth of rural communities are found to be significantly weakening in the early COVID-19 era, yet distorted discourses and actions that isolate the connections between ecosystem, food systems, and communities have been gradually amended in the post-COVID-19 era. Social media, governments, and residents in the local communities play a key role in discourse coalition and emendation, yet social media, and online public opinions to some degree distort discourse and actions. It also finds that communities in the forestry areas are a core node that integrates farmed wildlife industry into the ecosystem, food system, and community network. This research reflects on achieving sustainable development by putting systematic, integrated, and inclusive policies and approaches to governing the ecosystems, food systems, and community at the core.

Non-timber forest products and the European bioeconomy: status and transition pathways

S2.4 Unlocking the bioeconomy for nontimber forest products

Marko Lovric[1]
Sven Mutke[2], Elena Górriz Mifsud[3], Inazio Martinez de Arano[1], Davide Matteo Pettenella[4], Enrico Vidale[4], Robert Mavsar[4]

[4] University of Padova, Italy

Abstract: In Europe, Non-Timber Forest Products (NTFPs) are important for forest recreation, rural income, cultural heritage, and as industrial commodities. Although widely collected and consumed across the continent, national statistical and scientific data are limited. Combined with short and underexplored value-chains, the cross-sectoral nature of the legislative framework, and complex institutional arrangements, NTFPs remain on the fringes of European forest policy and management practices. The bioeconomy inherently implies strong reliance on natural resources, and ignoring NTFPs would impede the bioeconomic transition. Based on the literature, we review (i) the current knowledge on NTFPs collection, consumption, and trade in Europe, (ii) the institutional and legislative structures governing their use, and (iii) discuss how to realise their market and bioeconomy potential. We found (i) their value comparable to the value of annual roundwood removals, (ii) that in Western Europe they are primarily connected to forest recreation and in Eastern Europe to household consumption and income generation, and (iii) that complex and restrictive legislation frequently drives the commercialisation of NTFPs towards informal markets. We present legislative, economic, and information-based recommendations on integrating NTFPs into the bioeconomy. A priority should be strengthening of formal markets and developing value-added products.

The anatomy of a sustainable Himalayan bioeconomy

S2.4 Unlocking the bioeconomy for nontimber forest products

Carsten Smith-Hall[1]
[1] University of Copenhagen

Abstract: An enormous global bioeconomy is built on environmental products – plant, fungus, lichen, and animal products from managed and unmanaged habitats – harvested and sold by poor people in lower-income countries. This environmental income prevents harvesters from sinking deeper into poverty while also presenting a rare opportunity to increase the welfare of some of the poorest people in the world. Yes, connecting pro-poor economic growth and sustainable renewable resources in lower-income countries receives little attention, e.g. the Intergovernmental Platform on Biodiversity and Ecosystem Services (IPBES) conceptual framework connecting nature and people does not emphasise such linkages. The emerging bioeconomic theory and literature provide a structured point of departure to address this shortcoming. This presentation presents the anatomy of a sustainable Himalayan bioeconomy, using the example of commercial medicinal plants from Nepal. This case is particularly interesting due to its (i) scale, encompassing 300 traded species harvested for tubers, bark, leaves, etc., with an annual trade value of tens of millions of USD, (ii) dynamics, with the domestic processing industry evolving from 20 to 300 companies in the past two decades, annually processing thousands of tonnes of raw materials, (iii) absolute importance, as Nepal's most valuable export commodity even if it remains unrecorded in official statistics, and (iv) complexity, spanning from resource base management to demand drivers. Findings are based on a unique panel dataset covering 1997-98, 2014-15, and 2021-22, involving quantitative and qualitative interviews with hundreds of harvesters, traders, wholesalers, and processors. This data document the products' economic importance to rural households and national development and identify sustainable development pathways within a bioeconomic framework. What happened to many whale, fish, and timber species need not happen to medicinal plants or other groups of species. This speak focuses on how to get it right.

Transitioning to an inclusive forest-based bioeconomy.

S2.4 Unlocking the bioeconomy for nontimber forest products

James Chamberlain[1]
Carsten Smith-Hall[2]
[1] USDA Forest Service, Virginia, United States
[2] University of Copenhagen, Copenhagen, Denmark

Abstract: The bioeconomy is rapidly evolving to become the economic strategy to address the global challenges – climate change, poverty, biodiversity loss - of the 21st century. In general, the essence of bioeconomic strategies has been using biomass to reduce the need for fossil fuels. Nontimber forest products are absent from early iterations of the bioeconomy model, even though more than ¼ of the world's population directly consume products from forests other than wood, and many of those people live in abject poverty. The more than 50000 plant species used for products other than wood add much to the forest biodiversity of the world, yet few of them are managed for sustainable production. Many nontimber forest products have long histories of contributing to nations' economies, yet are not accounted for in bioeconomies. So why are these products and the people that harvest and consume them not included in bioeconomies? What will it take to include them in progressive bioeconomy strategies? We address these questions. Fundamentally, the global bioeconomy community needs to move rapidly beyond thinking of this strategy as a way to increase efficiencies of wood uses to address major global challenges, and embrace the many other products and services from forest biodiversity that can contribute to these aspirations. A truly integrated forest-based bioeconomy represents a way to reconsider and redefine forestry and the forest products industry to increase the value of these natural resources for greater biodiversity conservation to benefit a larger portion of society. Transition pathways for inclusive forest-based bioeconomies are not easily determined. They will require changing priorities that reflect motivations of sectors that have not been considered part of the forest products industry. Cultural values and informal market economies are essential elements of successful pathways. New and novel economic, social and biophysical research and technology opportunities abound in support of the transition to an all-inclusive forest-based bioeconomy.

S2.5 Scaling up the exchange between forest science and business

S3.1 Assisted migration for adapting forests to climate change

Accounting for phenotypic plasticity and local adaptation in species distribution models to support prescriptions on assisted migration

S3.1 Assisted migration for adapting forests to climate change

Katharina J. Liepe[1, 2]
Mirko Liesebach[1], Ernst van der Maaten[2], Marieke van der Maaten-Theunissen[2]
[1] Thünen Institute of Forest Genetics, Grosshansdorf, Germany
[2] Chair of Forest Growth and Woody Biomass Production, Technische Universität Dresden, Tharandt, Germany

Abstract: The most common tool to predict future changes in species range are occurrence-based species distribution models. However, these models often underestimate the potential future habitat, as they do not account for phenotypic plasticity and local adaptation. These highly important processes in the response of tree populations to climate change are considered in trait-based models combining reaction norms of quantitative trait variation as a function of past climate experienced at seed source origin to which populations are genetically adapted, and simultaneously as a function of current climate experienced at the planting site to which they show plastic responses.
We make use of extensive provenance trial series of Norway spruce and European beech to model future height growth potential and compare these predictions with classic species distribution models. For Norway spruce, both the occurrence-based and the growth-based model show a significant retreat towards northern latitudes and higher elevations (-55 % and -43 % by 2080). However, thanks to the species particularly high phenotypic plasticity, the decline is delayed. Increasing summer heat coupled with decreasing water availability limits performance, while a prolonged frost-free period enables an increase within the remaining area. Signals of local adaptation along climatic gradients are low, as they are masked by a strong influence of latitude. The latter reflects population differentiation for the Baltics, but does not capture the high phenotypic variation associated with heterogeneity in Central European mountain ranges and postglacial migration history. The model is used to provide recommendations for optimal provenance selection under future climate. In essence, seed transfer cannot mitigate the projected range decline of Norway spruce, but it can help to exploit potential opportunities for better growth associated with warmer climate conditions. A comparable model for European beech is currently under development and results will be presented.

Assessing Carbon Storage and Habitat Characteristics in Jeju's Semi-Mangrove Ecosystems, South Korea

S3.1 Assisted migration for adapting forests to climate change

[2] Pointworks

Abstract: A research team was first tasked with finding a solution to the need for more creative ways to contribute to natural carbon capture and storage solutions to meet South Korea's national climate change objectives of reaching net zero by 2050. It was through this and the unique properties of Korea's southern islands that true mangroves and mangrove associates (semi-mangroves) were suggested as possible candidates that could promise high carbon absorption rates, and adaptability to continue to provide ecosystem services through climate change. Some pre-existing native habitats of semi-mangrove species (e.g., Hibiscus hamabo, Paliurus ramosissimus) on Jeju Island had already demonstrated comparatively higher carbon absorption abilities than other broadleaf species as measured by photosynthesis rates and soil carbon storage performance. This study investigates the distribution of carbon storage and the characteristics of semi-mangrove habitats based on the Lidar 3D imaging. This includes also evaluating their carbon uptake capabilities in order to forecast projections on the carbon storage and carbon absorption performance of selected species. This study is an opportunity to contribute further knowledge towards global carbon reduction and climate change mitigation objectives, especially given the high concentration of highly vulnerable or at-risk populations in the Asia-Pacific.

Assisted migration needs of northern red oak (Quercus rubra)

S3.1 Assisted migration for adapting forests to climate change

[2] College of Biological Sciences, University of Minnesota, St. Paul 55108 MN, U.S.A.

Abstract: Intensifying climate change exacerbates droughts, heatwaves, and extreme weather events, endangering global forest health and biodiversity. Assisted migration is increasingly recognized as a management strategy for safeguarding forest species. But simply moving tree populations towards expected future mean annual temperatures does not account for increased extreme weather events nor incorporate trees' phenotypic plasticity.

In 2019, we planted a replicated provenance trial with 19 populations and 118 open-pollinated families of northern red oak (*Quercus rubra*) spanning 10°C mean annual temperature (MAT 4.1°C - 14.2°C). The provenance trial sites are located near the northern seed collection limit (Ford Center and Forest, MAT 4.4°C) and at a central location (W.K. Kellogg Experimental Forest, MAT 8.8°C). To assess the performance of populations within and beyond their natural distribution, we measured annual growth, tree and leaf morphology, leaf and root physiology, foliar metabolites, pest and pathogen damage, plant phenology, and frost damage. We assessed phenotypic plasticity by comparing measured traits at both sites within families as well as traits measured on the same trees over time.

Initially, warmer, southern populations outperformed northern populations in above-ground biomass accumulation at the northern site. Unseasonable cold events in fall 2020 and spring 2021 caused extensive tree dieback in southern populations. Northern populations had higher photosynthetic capacity and chlorophyll A levels; southern populations had lower optimal quantum efficiency. Traits related to physiology showed some phenotypic plasticity, allowing trees to adapt to varying environments. At the central site, trees from northern populations did not perform as well as central or southern populations.

These results indicate that moving trees against the direction of climate change harms tree performance and that assisted migration north may soon become necessary. While extreme weather events had minimal effect on populations shifted a few degrees Celsius north, trees from much warmer seed sources suffered during unseasonal frost events since their phenology was not adapted to the longer northern winters. Northern seed sources exhibited conservative growth strategies, while southern populations adopted acquisitive strategies that often led to bush-like growth after multiple rounds of frost damage to the leading shoot.

Assisted migration of European beech populations - options and limitations

S3.1 Assisted migration for adapting forests to climate change

Andreas Bolte[1, 2]
Shah Rukh[1, 2], Tanja Sanders[1]
[1] Thünen Institute of Forest Ecosystems, Eberswalde, Germany
[2] University of Göttingen, Dept. Silviculture and Forest Ecology of the Temperate Zones, Germany

Abstract: European beech (*Fagus sylvatica* L.), the major native decidous tree species in Central Europe is known to be drought sensitive. In particular, the reoccurrence of two extreme drought events in 2003 and 2018–2020 in Central Europe, in a time span shorter than 20 years, caused severe deterioration and decline of tree crowns as well as growth reductions. This loss of vigor might persist as legacy effects, including lagged post-drought responses. These may hamper tree recovery, due to carbon depletion through reduced photosynthesis as well as hydraulic dysfunction, which, if persistent over time, can lead to mortality. In particular, on sites with low soil water storage capacity (SWC) beech trees run into the risk of lethal hydraulic failure if climate change aggravates drought and heat extremes; in Germany, the centre of beech native range, one third of today's beech forest area grow on drought-exposed sites with less than 90 mm soil water storage capacity within 1 meter soil depth. Assisted Migration (AM) may provide a solution towards more adaptive forests with beech, moving seed sources or populations of European beech to a location not accessible by natural dispersal. This is aimed at introducing better drought-adapted or adaptive beech genotypes and thus improving the resilience of forests. The high variation of beech populations within its recent native range in sensitivty to drought and cavitation enables adaptation options using AM, in particular using marginal population from the drought-induced range edges. However, phenotypic and epigenetic plasticity of beech and in-situ adaptation processes may also provide successful adaptation options. Based on own and compiled study results we discuss the options and limitations of AM versus in-situ adaptation of European beech in Central Europe and further needed steps to manage future forests with dominant or admixed European beech.

Assisted migration: a climate-adaptive and rehabilitation tool for degraded forests

S3.1 Assisted migration for adapting forests to climate change

[3] Université Laval

Abstract: Rehabilitation of degraded forests can mitigate the effects of global change through enhanced carbon sequestration. It can also improve the forests adaptive capacity by promoting resilience to disturbances through functional diversity. In this project, we assessed assisted migration, the deliberate displacement of tree species or populations to locations with suitable future climate conditions, as both adaptive and rehabilitation tool in degraded mixedwood forest.

We assessed seedling survival and growth of 9 species through abiotic (e.g. microclimate) and biotic (e.g. browsing, competing vegetation) filters in mixedwood plantings established 120 km northwest of Quebec City (Canada) in sub-boreal mixedwood natural stands high graded by diameter-limit cutting. The factorial experimental design comprised canopy cover (clearcut vs partial cut), cervid exclusion (excluded vs non-excluded) and competing vegetation (removed vs non-removed) treatments. In 2018, we planted species expected to have unfavorable (*Picea glauca, Picea rubens, Thuya occidentalis),* and favorable *(Pinus strobus, Pinus resinosa, Acer saccharum)* future habitat conditions, and species with potential new habitat in the area *(Quercus rubra, Prunus serotina, Carya ovata*). Seedlings were grown from seeds of locations associated to three climate analogues: current climate, projected climates for mid-century and end of century.

Cumulative basal diameter growth of all species, except for *Acer saccharum,* was larger in open conditions than under partial cover after 3 growing seasons. The understory vegetation control treatment by mechanical release benefited *Pinus* and *Picea* species, although the effect was only significant within the clearcuts for *Picea* species. Planting under partial cover contributed to acclimate southern species such as *Quercus rubra*, which suffered frost damage during the Spring 2020 and 2021, mostly in clearcuts. Overall, 3-yr species survival varied from 78% (*Carya ovata*) to 93% (*Picea glauca*). Survival tended to be lower for the end of century analogues of southern species such as *Acer saccharum* and *Prunus serotina*, but remained relatively high (beyond 75%), hinting that an assisted migration approach based on climate analogues can be potentially viable for restoring forests altered by past inappropriate cutting practices.

Desired REgeneration through Assisted Migration (DREAM): implementing a research framework for climate-adaptive silviculture.

[8] Département de Géographie, Université Laval, 2405 Rue de la Terrasse, Québec, QC, G1V 0A6, Canada

Abstract: Assisted migration (AM) is a climate-adaptation strategy that may ensure that forests established today are adapted to expected future climate conditions. Although many pilot AM efforts are underway, managers lack 1) access to decision-support tools to guide choices of seed sources for species and/or genotypes, 2) confidence in the ecophysiological tolerances of putatively future-adapted stock and 3) the silvicultural strategies necessary to regenerate future-adapted species in an assisted migration context. These shortcomings represent a critical problem because establishment of potentially poorly-adapted selections and/or inappropriate silvicultural strategies creates major risk to management time and financial resources.

The Desired REgeneration through Assisted Migration (DREAM) framework is an international collaboration that uses basic and applied research to reduce these uncertainties and derive climate-informed planting approaches. DREAM is self-reinforcing in that each step in the process informs and strengthens subsequent phases. Namely, it sources seed in a climatically informed manner, experimentally tests this sourced stock to probe for physiological maladaptation under controlled settings, grows the stock in the field under a range of silvicultural scenarios, and finally forecasts long-term outcomes using models parameterized from the controlled- and field-tests. Through these steps, the DREAM approach specifically addresses knowledge gaps necessary to successfully plan and execute assisted migration plantings.

Here, we describe the DREAM framework illustrate aspects and challenges of its implementation drawing from two experimental sites: one in Québec, Canada and one in Wisconsin, USA. Moreover, we present data from our suite of syntheses, lab, and field trials to accentuate how

operationalizing FAM effectively will require more than matching species or populations with expected future climates. Rather, it will require a deeper understanding of the context-dependencies at the outplanting site including, current climatic conditions, plant-soil feedbacks, and herbivory that may ultimately regulate establishment success.

Does earlier bud break in drought adapted tree species and provenances lead to a competitive advantage?

S3.1 Assisted migration for adapting forests to climate change

Barbara Moser[1]
Anoucha Perret-Gentil[1], Ingrid Jansen[1], Daniel Scherrer[1], Thomas Wohlgemuth[1], Yann Vitasse[1]
[1] Swiss Federal Research Institute WSL

Abstract: Rapid increase of temperature and dryness leads to novel climate in Central Europe. Experiments that test the performance of multiple native and non-native species under future climate as well as across different soil types are rare. To address this gap, the Polytunnel Greenhouse Experiment was set-up as an interdisciplinary research platform in autumn 2021. The experiment is located in three extant forest communities on the Swiss Plateau and simulates novel forests with future tree species, including native silver fir, European beech and sessile oak, and non-native Atlas cedar, Douglas fir and Turkey oak, each from four different seed sources (at least one from warmer/drier climate). The 4-yr-old seedlings grow in a climate that is warmer and drier than the current climate on the Swiss Plateau. We will model the growth performance of individual tree species and provenances in relation to their leaf-out phenology, climate (current climate, warming in the absence of drought, warming in the presence of drought), and soil type. Higher temperatures have advanced leaf out by 9–18 days in the first two years, depending on species and seed provenance. This increase in growing season length might lead to higher growth rates, while drought is expected to negatively impact growth and survival. Consequently, the combination of warming x drought will exacerbate trade-offs between fast seedling growth to compete with surrounding vegetation and slow resource use to resist drought. How native and assisted non-native tree species respond to these trade-offs in a heterogenous landscape is largely unknown. Our results will indicate how assisted migration of more drought and heat adapted provenances or tree species will change the competitive outcome between species in a future climate.

Does provenance matter? Surprising lessons learnt from two drought experiments in common gardens of two common shrub species in Belgium

S3.1 Assisted migration for adapting forests to climate change

Kristine Vander Mijnsbrugge[1]
Liselotte De Ligne[2], Victor Mihaila[2], Joris Van Acker[2], Jan Van den Bulcke[2]
[1] Research Institute for Nature and Forest, Belgium
[2] University of Ghent - Woodlab, Belgium

Abstract: Assisted migration is a much-debated topic in forest-adaptation to climate change. Most of the research, however, is focussing on commercial tree species, and little attention is given to shrubs.

In this study, we tested two shrub species in two common garden experiments.

In the first experiment, we twice withheld water from rooted cuttings of three provenances (Italian, local Belgian, and Swedish) of *Frangula alnus* in summer. Counter-intuitively, the Italian provenance displayed earlier symptoms and stronger effects of water limitation than the others. A higher transpiration was suggested based on larger shoot growth, larger leaves and higher stomatal density. In the second experiment (same genotypes, other ramets), we studied reproductive traits. The local Belgian provenance produced more ripened berries than the Italian and Swedish provenances, both in water-limited as in control plants. The next spring, the germination percentage of the stones from the water restricted mother plants was significantly higher than the controls for all three provenances. The timing of seedling emergence reflected the timing of bud burst of the mother plants, including a counter-gradient effect for the Swedish provenance, corroborating the suggestion that seedling emergence and leaf phenology may have a common genetic basis.

We also studied the responses to a summer water withholding, followed by rewatering, in a common garden (local Belgian and Pyrenean provenance) of *Cornus sanguineum*. We showed that the timing of autumnal leaf senescence was earlier than the controls for plants that displayed no to little leaf desiccation due to the experienced drought. On the contrary, plants suffering from heavy to total leaf desiccation resprouted after the drought and displayed a delayed leaf senescence. No shift in timing of leaf senescence was observed for plants with intermediate leaf desiccation, suggesting two different post-drought recovery strategies (acclimation vs damage repair), depending on the severity of the drought stress, that cancel each other for plants with intermediate symptoms. Results suggest that the first strategy was activated earlier in the Pyrenean provenance, whereas no difference in timing was detected for the second strategy.

In all, assisted migration from southern to western Europe might not always follow the expected patterns.

Enhancing resilience and adaptation of native European beech and sessile oak forests to climate change: assisted migration in practice

S3.1 Assisted migration for adapting forests to climate change

Erik Szamosvari[1]
László Nagy[2], Heino Konrad[1], Norbert Móricz[2], Lambert Weißenbacher[1], Marcela van Loo[1]
[1] Austrian Research Centre for Forests BFW, Vienna Austria
[2] Forest Research Institute – University of Sopron SOE ERTI, Sárvár, Hungary

Abstract: Climate change exerts impacts on forest growth, productivity, tree vitality, and species composition at both global and local scales. Due to limited natural migration capacity and local adaptation caused by the warming climate, some species will face significant loss of habitats and decreased distribution. In light of these concerns, the science-based and practice-oriented bilateral project REIN-Forest ATHU150 focused on two dominant deciduous forest tree species, *Quercus petraea* and *Fagus sylvatica*, in the Austrian-Hungarian border region. The project aimed to maintain the present forest cover, preserve biodiversity, and safeguard future economic benefits by selecting suitable, resilient, and potentially adapted provenances (seed sources). In each country, three provenance trials ranging from 1.2 to 2 hectares were established to assess, monitor and validate the benefits of these provenances compared to local ones. The future climate-adapted provenances were selected for the RCP 8.5 climate change scenario using previously developed model-based information on the current and future prospects of these forests in the study area and forest decision support systems: Forest Vulnerability and Seed Transfer Tool and SusSelect (SUSTREE project). During the establishment of the six provenance trials, forest reproductive material (FRM) from ten local and fifteen adapted to the future climate seed stands were planted, originating from seven different countries. In the winter of 2022, one site in each country was afforested with local and adapted sessile oak provenances, another with local and adapted European beech provenances, and the third site with a combination of local European beech and adapted sessile oak provenances, considering the predicted loss of beech dominance in the future. In the next fifteen years, the performance of the different FRMs will be evaluated by monitoring parameters such as survival, phenology, abiotic and biotic damage, quality and growth. Genetic monitoring may also be assessed to compare and validate the concept of assisted migration with future climate-adapted provenances alongside the transfer system recommendations. This presentation aims to share the practical experiences acquired during the establishment of the trials, highlight challenges and obstacles encountered during the import of FRM, and present first results on survival rates between the two groups of FRM.

Models and Motivation for Sustainable Mangrove Management in Ban Tha Bo Ko Mangrove Forest, Nakhon Si Thammarat Province, Thailand.

S3.1 Assisted migration for adapting forests to climate change

Sutida Maneeanakekul[1]
[1] Sutida Maneeanakekul

Abstract: The aims of this study were 1) to determine the appropriate model for Ban Tha Bo Ko Mangrove Forest Management with community participation. 2) to create appropriate motivations to encourage communities living in Ban Tha Bo Ko Mangrove Forest participated in sustainable management of mangrove forests and 3) to publicize and return information on sustainable management of mangrove forests under climate change and incentive measures to participate in appropriate mangrove forest preservation in study area.

The secondary data collections, site surveys, focus group discussions, and interviews were used to collect and analyze data on current patterns of mangrove utilization and management of communities living in Mangrove Forest. Incentive measures needed by the community to enable participation in the preservation and sustainable management of mangrove forests to support the REDD PLUS mechanism encountered in the management of each area by key informant groups, namely representatives from people living in the area involved in the utilization and management of Ban Tha Bo Ko Mangrove Forest, as well as evaluating opinions from using a questionnaire on community representatives and relevant officials about measures and guidelines to create incentives for sustainable management of mangrove forests.

The results shown that the important forms of proper mangrove forests management are mangrove planting activities, aquatic animal release activities, cooperation in preventing illegal fishing, jointly solving garbage problems, and protection against deforestation.The relevant agencies should set up appropriate incentive measures in four aspects: regulations and agreements, financial, social, and incentive support including assigning agencies /related agencies that should be responsible to carry out concrete work. The opinions of the local participants were evaluated at 5 levels on the measures and guidelines for motivating sustainable management of mangrove forests according to the REDD+ Mechanism in all 4 aspects: regulations and agreement, financial, social, and incentive support with 35 respondents.

Practitioner-focused, soil-sensitive decision support for assisted migration of tree species

S3.1 Assisted migration for adapting forests to climate change

Colin R. Mahony[1]
William H. MacKenzie[1]
[1] British Columbia Ministry of Forests

Abstract: Accounting for climate change in reforestation practices has the potential to be one of the most efficacious adaptation strategies for maintaining future forest ecosystem services. There is a rich literature projecting spatial shifts in climatic suitability for tree species and strong scientific evidence for the necessity of assisted migration. However, there has been limited translation of this research into operational reforestation, due in part to mismatches to the information needs of practitioners. To address this need, we have developed a practitioner-focused climate change informed tree species selection (CCISS) framework to support reforestation decisions in British Columbia (BC). CCISS projects the climate change redistribution of bioclimate units from the multi-scaled Biogeoclimatic Ecosystem Classification (BEC) system with machine-learning for an ensemble of modelled future climates. It leverages the reforestation knowledge from BEC to make site-specific species projections of reforestation feasibility with climate change uncertainty metrics. We present 21st-century feasibility projections for a comprehensive set of tree species native to western North America. Some general trends are evident: augmentation of the portfolio of feasible species in sub-boreal regions due to the rapid expansion of feasibility for temperate species; attrition at low elevations in southern BC due to declines in the feasibility of native species with little compensation by non-native species; and turnover at mid-elevations as declining feasibility for subalpine species is compensated by uphill expansion of climatic feasibility for submontane species. Edaphic (soil) factors are important; feasibility declines are higher on relatively dry sites than on wetter sites for most species. Our analysis emphasizes that changes in feasibility are species-specific, spatially variable, and influenced by edaphic site factors. In addition to our modeling results, we will present our recent work on integrating modeled results with observational evidence from assisted migration trials. By employing the multi-scaled BEC system that currently informs operational reforestation, CCISS translates research into actionable assisted migration guidance for practitioners.

Searching for drought-resistant genetic variants in Quercus cerris for future Austrian climate

S3.1 Assisted migration for adapting forests to climate change

Agathe Hurel[1]
Jonathan Feichter[1], Berthold Heinze[1]
[1] BFW - Austrian Center For Forest Research

Abstract: In the current context of global change, forest ecosystems are among the most endangered.

The main objectives of our study are (1) to identify the genetic variants associated with drought stress resistance across *Quercus cerris* natural distribution, and (2) to screen the Austrian populations for such genetic variation. We plan on a phenotype-genotype association analysis of tree-ring width on dry years as a proxy for drought resistance, by means of ca 90 K SNPs detected with Single Primer Enrichment Technology (SPET). The first step of this analysis is to find regions in the current distribution of *Q. cerris* where the climate is comparable to predicted future conditions in Austria (IPCC climatic scenario RCP8.5). We established partnerships with research institutions in 14 countries, providing 40 locations of interest. In addition, we included 6,348 locations distributed evenly over the natural range of *Q. cerris* into our dataset. To represent Austria, we selected 34 locations where *Q. cerris* has high probability of presence in 2095 according to RCP8.5. Mean annual temperature, continentality, summer temperature, total annual precipitation and accumulated growing degree days are among the most important climatic variables for *Q. cerris*. The CHELSA dataset delivers data observations from 1981-2010 as well as predictions for RCP8.5 in the timeframe 2071-2100. We retrieved the observed variables for the locations of interest and the predicted variables for the 34 Austrian locations. Using the Elbow method, we established k=4 as the optimal number of clusters for this dataset. Interestingly, using Ward's clustering algorithm with Euclidean distance, we observed that 3 of these clusters were represented in Austria. In sum, we report a meaningful approach to select relevant sampling locations to investigate the genetic variants underlying drought resistance in climatic regions similar to the future of Austria, bringing us one step closer to ensuring forest ecosystems sustainability.

Selection experiments of southern origins of Pedunculated oak (Quercus robur) and development of related planting technology

S3.1 Assisted migration for adapting forests to climate change

Sandor Horvath[1]
Viktoria Papp[1]
[1] WOODTECH PLC, Hungary

Abstract: The effects of climate change, which is increasingly affecting our time, also have a significant impact on the health of European oak stands. On the one hand, the decrease and shift in the amount of annual precipitation, and on the other hand, summer heat waves make it difficult for young oak trees to survive. In addition to abiotic effects, the role of biotic pests is becoming more and more important. The Oak lace bug (Corythucha arcuata) has been causing more and more damage to oak stands, especially to the acorn crop, in recent years. During our research, we are investigating container planting of healthy oak acorns from southern climates. During planting, we place the acorns in different directions, as this can also have a significant effect on the root structure. We also examine the effect of different nutrient media and nutrient solutions on growth. The purpose of the tests is, on the one hand, to determine the growth and survival rate of acorns from different climates, and on the other hand, to create stronger seedlings compared to traditional forestry planting methods. Seedlings grown from acorns from southern climates are expected to adapt better to the rapidly changing climate, research is aimed at creating climate-resistant propagating material and at the development of planting technology.

Survival and growth of Acacia senegal (L.) Wild. (Senegalia senegal (L.) Britton) provenances depend on the rainfall at the site of origin

S3.1 Assisted migration for adapting forests to climate change

Oulimata Diatta[1]
[1] Department of Agroforestry, Assane Seck University of Ziguinchor (UASZ), BP 523, Diabire, Ziguinchor,

Abstract: Context: Several studies have shown important differences in adaptive properties among provenances (origins) of African savanna tree species, but there is a lack of studies on how these differences are expressed in different environments and age and to what extent they reflect local adaptation.

Aims: This study investigates the survival and growth of trees from 15 African *Acacia senegal* (*Senegalia senegal* (L.) Britton) provenances tested in two environments and relates the differences among provenances to the climate at their site of origin and tree age.

Methods: The study is based on 14 years growth in a common garden trial at two sites (Bambey and Dahra, Senegal) that differ in water availability, followed up by later assessment after 23 years at one of the sites.

Results: The variation among provenances in survival, height, and diameter was significant, and differences could be partly explained by the climate at their site of origin. In general, provenances from dry sites survived better at both sites. However, we observed genotype-by-environmental interactions where provenances from dry sites on average performed relatively poorer in height and diameter at the wettest site (Bambey) compared to the drier site (Dahra), while the opposite was the case for provenances from wetter sites.

Conclusion: The results support that divergent selection creates and maintains local adaptation of *Acacia senegal* provenances in relation to growth (height and diameter) and survival in areas with different water availability. This has important implications for choice of appropriate planting material for tree planting and for conservation of genetic variation among natural populations, but also for prediction of the effects of climate change.

Three-North Shelterbelt Program

S3.1 Assisted migration for adapting forests to climate change

Guangsheng Chen[1]
[1] Zhejiang A&F University

Abstract: The Three-North Shelterbelt Program (TNSP) is one of the world's largest afforestation projects, which involves in over 42.40% of China's total land area. The project has implemented over 40 years and the statistical data showing an increased forest area of 3014 ha (13.57% forest coverage), and many studies have assessed the ecological, economic and social benefits of this project. However, most of these studies are based on the statistical forest area released by the government and it is still unclear how much forest actually exists and what the spatiotemporal forest recovery pattern is in the TNSP region. This is partially because the harsh environmental condition in this region has caused the death of large area of planted trees right after planting. The existing geospatial land use and cover products failed to reflect the actual recovered forest area in the TNSP region due to various reasons. Based on time-series Landsat satellite images, LandTrendr change detection algorithm, machine-learning method and dense sampling plots, our study developed an integrative method to detect the spatiotemporal forest recovery patterns in the TNSP region during 1990-2022. The detected results were further evaluated against sampling plot data, inventory data and other geospatial land use and cover datasets using the metrics of overall accuracy (OA), Kappa coefficient, regression coefficient and Root Mean Square Error (RMSE). In addition, the forest growth status was also monitored and assessed based on the generated various vegetation indices. Our study not only provides a high-precision and resolution forest recovery dataset, but also assesses the forest health status under climate change, which could further help more accurately evaluate the long-term advantages or disadvantages of the implementation of TNSP.

Tree species choice tool supporting climate-smart forest management

S3.1 Assisted migration for adapting forests to climate change

Margaux Casier[1]
Ellen Desie[1], Wim Smits[2], Wim Buysse[2], Gudrun Van Langenhove[2], **Bart Muys**[1]
[1] Division Forest, Nature and Landscape, Department Earth and Environmental Sciences, KU Leuven, Belgium
[2] Agentschap Natuur en Bos, Brussels, Belgium

Abstract: *Context*

In response to climate change, tree species tend to migrate to more suitable climate zones. However, the current speed of climate change is generally too fast, which may result in local loss of species and related ecosystem services. Alternatively, assisted migration can be implemented, defined as human-facilitated species migration to regions with more suitable environmental conditions. This study focuses on enhancing forest resilience to climate change, using the principles of **"resilience trait-based assisted migration"**, which seeks to maximize functional diversity and redundancy through assisted migration. In this context, a tree species selection tool for Flanders, the northern region of Belgium is developed.

Methodology

A list of relevant native and non-native tree species is created, using national forest inventories and (inter)national studies on tree species distributions, followed by three evaluation steps:

1. Climate suitability: species are selected and ranked based on their suitability for present and future regional climatic conditions. Species distribution models are simulated for future climate scenarios, using the CHELSA dataset for IPCC climatic scenarios, and its BIOCLIM+ variables.
2. Risk assessment: potential risks linked to species introduction are considered. Species with unacceptable potential risks related to their introduction, are excluded. This exclusion stage can consider risks of drought, invasiveness, etc.
3. Feasibility: a wide variety of functional traits and ecosystem services derived from freely accessible databases are added to the tool to allow further species ranking and selection for restoration projects.

During this project, the methodology and results of this study are systematically discussed with an expert panel comprising experts in climate, nature conservation, and forestry. Field experience is included through interviews with experienced practitioners.

Results

This project results in a tool, consisting of a database with tree species that are ranked based on their potential to thrive in Flanders under a wide range of future climatic scenarios, as well as several functional traits, potential risks, and ecosystem services. This database can be used by the government as a decision support tool for policymaking, and in forestry and nature restoration for

the selection of tree species for plantation, based on desired traits and climate resilience.

Funding: Klimaatbomenproject ANB, Flemish Community.

Using assisted migration to design and adapt the next generation Scots pine seed orchards in Sweden to future climate conditions

S3.1 Assisted migration for adapting forests to climate change

Mats Berlin[1]
Henrik Hallingbäck[1], Curt Almqvist[1], Torgny Persson[1], Sven Tegelmo[1], Ulfstand Wennström[1]
[1] Skogforsk

Abstract: Climate adaptation is an important challenge for future forests with rapidly altering growing conditions that may cause tree maladaptation leading to reduced growth, increased risk of damages and mortality. One way of addressing this issue is to select genetically improved seedlings and deploy them so that their high performance can be fully exploited. To enable that, Skogforsk has developed a decision support tool, Planter's guide, for Scots pine that ranks all contemporary and productive seed orchards according to the predicted volume production over a rotation. The latter is calculated from transfer effect models for survival at the establishment phase in the current climate, and growth at mid-rotation in a future climate, allowing for assisted migration.

Contemporary seed orchards span from 1g to 1.5g, whereas 2g seed orchards are currently being planned and established. However, 2g seed orchards established today will start to produce seedlings after 15-20 years and have an expected life span of 30 years. This means that the seedlings produced in such orchards will face a warmer climate at establishment and a substantially warmer climate at mid-rotation (30-50 years after planting). Not considering this, we risk designing the 2g seed orchards so that they will be maladapted to their intended seed zone when in full production.

We have used the Planter's guide model platform to analyze the performance of different 2g seed orchards designs in a pilot study that includes a Swedish forest company, SCA. We used their planned regeneration sites for the period 2050-2090 and maximized the yearly annual growth over all sites given a set of fictive 2g seed orchards with different designs. If we were to establish the 2g seed orchards with the same clonal composition as the current orchards, it would result in a substantial maladaptation of the optimal deployment area compared to the intended seed zone. Thus, a selection of clones from milder, more southern, conditions provided a better match to the intended seed zone. Furthermore, seed orchard design with high selection effort on survival in harsh conditions were less competitive compared to seed orchard design with more focus on growth.

S3.2 Restoring forests and trees: Balancing goals, interests and trade-offs

A history-based critique on the global forest restoration project

S3.2 Restoring forests and trees: Balancing goals, interests and trade-offs

Wil De Jong

Abstract: Restoring tree and forest cover is hailed as options to solve climate chang, biodiversity conservation, and development challenges. Multiple supra-national initiatives have sprung up to achieve forest restoration in large areas, here referred to as the global forest restoration project. They pursue ambitious targets and have adopted discourses hailing multiple benefits, not the least to 'deprived' residents in locations where restoration is to happen. A look at forest restoration histories reveals that in the past, centres of economic and political hegemony promoted and engaged in forest restoration, but also adopted discourses that have parallels with those of the contemporary global forest restoration project, including benefits to climate, biodiversity and to local people. The parallels between historic and contemporary trans-national forest restoration interests, discourses and projects intrigue. My elaborations will identify similarities and differences between past and modern transnational forest restoration, and reflect on these, including on whose interests are being addressed and are negated.

An economic view on the costs and benefits of forest restoration

S3.2 Restoring forests and trees: Balancing goals, interests and trade-offs

Pablo Pacheco[1]
Craig Beatty[1], Jwalin Patel[2]
[1] WWF
[2] IDinsight

Abstract: Debates on the benefits of forest restoration tend to neglect the disparities of costs and benefits across different restoration options, and variations across contexts. These variations should be at the center when considering restoration futures, potential benefits, and who pays the costs and reaps the benefits. Drawing on a review of available studies and data across six different restoration options, we provide key findings and knowledge gaps regarding economic and financial costs and benefits of forest restoration. We show that while financial costs and benefits vary widely across and within forest restoration options, almost all forest restoration options are financially attractive. Natural regeneration options are the least costly options, followed by tree plantations in monocultures. While agroforestry systems are most costly and require higher upfront investments, comparatively they yield higher economic and ecological benefits depending on the agroforestry system. We observe significant variations in costs within similar forest restoration options suggesting that several contextual factors, including biophysical and political economic conditions, may explain some of this variability. In addition, economic cost-benefit analysis suggests that benefits outweigh the costs, particularly under longer restoration time horizons, and when looking at a wider range of benefits. Finally, we argue that there are several tradeoffs associated with forest restoration, mainly regarding the financial, socioeconomic, and environmental benefits, which also have a temporal dimension since benefits accrue over different timeframes, and many may only accrue in the long run.

Forest restoration governance: institutions, interests, ideas and their interlinked logics

S3.2 Restoring forests and trees: Balancing goals, interests and trade-offs

[6] IRD

Abstract: High expectations have been raised that Forest Landscape Restoration (FLR) will provide an answer to climate change and biodiversity loss and support human wellbeing. Numerous local to global FLR initiatives have evolved over the past decades if not centuries, engaging a diverse set of actors and employing or encountering diverse logics and arguments related to (re)planting trees. We analyse these (de)legitimizing narratives of FLR (win-win, implementation, critique) and the underlying institutions and interests in which their discursive power rests. Based on the 3Is (institutional path dependency, interests and ideas), we identify and critically discuss three key distinct logics that to varying degrees drive FLR policy and practice today : (i) the global sustainability logic: planting trees to meet international challenges, (ii) the community logic: restoring or creating forests for local livelihoods and fostering empowerment, and (iii) the production logic: forest plantations and bioeconomy. We conclude that if the inherent historical power structures in FLR design and implementation are not recognized and addressed, then the currently dominant FLR logics—with a focus on global sustainability and production arguments—are likely to produce many "win-lose" or "lose-lose" projects.

Forest restoration strategies, ecosystem service delivery and trade-offs at site and landscape level in Ethiopia

S3.2 Restoring forests and trees: Balancing goals, interests and trade-offs

[6] No affiliation

Abstract: Deforestation and forest degradation are becoming a global concern especially under current climatic changes and human population growth trends. Forest landscape restoration however, offers an opportunity to ameliorate impacts, end poverty, build climate resilience and enhance biodiversity. For this to happen, there is need to evaluate the context-specific success and failure factors in order to enable adaptive management. For many restoration projects worldwide, it is shown that there is a lack of knowledge and capacities for local forest restoration implementation, for example with regards to suitable seed sources and plant material, establishment techniques, as well as long-term tending of the restored forests. Furthermore, the goals and importance of ecosystem services differ among stakeholders leading to trade-offs and possible governance conflicts. We compare contributions of passive and active approaches, and evaluate perception of actors on societal benefits from restoration.

We conducted a rigorous assessment of biophysical and socioeconomic factors affecting restoration in Ethiopia as part of the FLESRA project. Forest and soil inventory of active and passive restoration sites, and identification of contextual factors was done. Data from 1,519 plots representing 7 forest stand types, 145 key informants and 371 farmer interviews across Oromia and Southern Nations regions was collected. Analyses of this data is expected to help to derive recommendations for best practices, and develop suitable tools for successful implementation and management of restoration.

Preliminary results show that management and soil properties play a key role in the performance of restoration especially among the active strategies. Active restoration strategies perform better especially in timber production and biomass, while passive restoration strategies are better in terms of plant diversity improvement at site level. At landscape scale, active restoration approaches contribute greatly to overall observed plant diversity. Also, among the strategies, timber and fuel are the most ranked direct services, while carbon absorption and erosion control are the most perceived indirect services. Surprisingly, actors do not perceive biodiversity as important across strategies.

Results suggest the importance of adoption of a mixture of passive and active restoration approaches in landscapes for multiple benefits, implementation of proper management and increased actor participation in restoration.

Introducing the IUFRO-WFSE book: Restoring forests and trees for sustainable development - Policies, practices, impacts and ways forward

S3.2 Restoring forests and trees: Balancing goals, interests and trade-offs

Pia Katila[1]
[1] Natural Resources Institute Finland

Abstract: This presentation presents the IUFRO-WFSE project's new book "Restoring forests and trees for sustainable development - Policies, practices, impacts and ways forward" and the process for developing it. The book provides a comprehensive overview of forest and forest landscape restoration and the different understandings, drivers, goals, and related commitments, approaches, and achievements. It presents the current state of knowledge and range of ideas regarding interacting social, economic, political, and ecological aspects of restoring forests and trees. The book focuses on the linkages between forest restoration, biodiversity, and ecosystem services, and addresses forest restoration from the point of view of socioeconomic development, justice, equity, and governance considerations. It provides science-based information for developing sustainable restoration policies and programs, guiding the planning and implementation of restoration efforts in different contexts, and developing pathways and approaches to mitigate the social, cultural, economic, and environmental risks associated with restoration.

Land use Landcover responses to Forest Landscape Restoration interventions: A case of Malawi

S3.2 Restoring forests and trees: Balancing goals, interests and trade-offs

Tonthoza Uganja[1]
[1] Bangor University

Abstract: This paper analyses the impact of land use and land cover changes (LULC) on forest landscape restoration targets in Malawi, a country facing challenges such as deforestation, soil erosion, and declining forest resources exacerbated by population expansion. Understanding the relationship between land-use changes and their impact on forest landscape restoration targets is crucial in addressing challenges such as deforestation and declining forest resources in Malawi. The most practical method for monitoring forest change over large areas is using remotely sensed data. For operators and other practitioners looking to monitor land use land cover change (LULC) using free and open access data and maps becomes practical and inexpensive. However, achieving accurate monitoring remains challenging, especially in Africa where there is limited access to resources for ground truthing data. To assess LULC since the Bonn pledge in Malawi, we estimated tree cover gain/loss using Sentinel-2 data from ESRI's living atlas. We estimated tree cover gain and loss for the period 2017-2022 to ascertain whether Forest Landscape Restoration (FLR) Targets are being met. We then completed accuracy assessments and area estimation using reference data obtained from the Nation Forest Monitoring Unit who use a cluster stratified random sampling method to collect National Forest Inventory (NFI) point data. We used a confusion matrix to graphically summarizes the occurrence of individual classes being correctly identified and the occurrence of individual classes being misclassified. The confusion matrices for extracted Sentinel-2 2020 annual map when compared against NFI validation data for the same year (2020) depicted huge discrepancies. The results indicated that in LULC estimation, Sentinel-2 played a limited role in discerning land use classes correctly; the rangeland class achieved highly different results to the other classes as it fell within the description of three other land use classes (Shrubland, grassland and cropland) based on the land use schema of Malawi. The three land use classes are critical and have significant implications because continuous monitoring and validation efforts are essential to assess negative trends promptly and implement necessary interventions, ensuring that restoration targets are met.

LANDSCAPE RESTORATION FOR LOCAL DEVELOPMENT: HOW TO MAKE FLR WORK FOR FOOD SECURITY, LIVELIHOODS AND WELL-BEING OF LOCAL COMMUNITIES

S3.2 Restoring forests and trees: Balancing goals, interests and trade-offs

Houria Djoudi[1]
Ida N. S. Djenontin[2], Carol J. Pierce Colfer[1, 3]
[1] CIFOR-ICRAF
[2] Penn State University, USA
[3] Cornell Institute for International Food and Agricultural Development

Abstract: Forest landscape restoration (FLR) is increasingly recognized as a people-centred approach to restore millions of hectares of degraded forested and agrarian landscapes by 2030. It holds promise as a solution to address global socio-environmental challenges, including environmental degradation and climate change. However, the current focus on environmental and ecological outcomes, despite acknowledging the importance of achieving both ecological and social outcomes in FLR, limits the potential of FLR to provide a wide range of ecosystem services for socio-ecological benefits. This situation highlights the ongoing challenges and trade-offs in balancing local social needs with global goals.

In order to avoid compromising global goals while meeting local needs, it is crucial to prioritize social equity in the design and implementation of FLR interventions. This chapter aims to draw attention to the significance of social equity in FLR processes on the ground. By exploring three key questions, we can preemptively address the equity implications of neglecting local social and human well-being in FLR interventions.

Firstly, we examine the potential of FLR to benefit local livelihoods and well-being. Secondly, we analyze the current challenges and trade-offs associated with integrating restoration efforts with local livelihoods and well-being. Lastly, we explore pathways towards collaborative management and identify ways to increase the benefits and co-benefits of FLR interventions for local development and livelihoods.

By addressing these questions, we provide recommendations to better incorporate local development and livelihoods into FLR processes and outcomes. This will help ensure that FLR interventions contribute to the well-being and sustainable development of local communities.

Participatory restoration planning in Abancay – Apurímac Model Forest, Perú

S3.2 Restoring forests and trees: Balancing goals, interests and trade-offs

Natalia Ruiz-Guevara[1]
Augusto Ramírez Vicencio[2], Jaime Valenzuela Trujillo[3], Rosendo Echevarría[4], Hernán Sanchez[4], **Juan Pablo Rodríguez Garavito**[1]
[1] Red Latinoamericana de Bosques Modelo
[2] CEDES Apurímac
[3] SERNANP – Santuario Nacional del Ampay
[4] Comisión Ambiental Regional de Apurímac

Abstract: Model Forests (MF) are multi-stakeholder landscape governance processes. The Abancay-Apurímac MF (AAMF), located in the Apurímac region, Southern Andes of Peru, covers 80,030 hectares, with biodiverse high Andean ecosystems of forests, scrublands, wetlands, grasslands, “puna”, forest plantations, and agricultural mosaic. It is affected by expansion of the urban and agricultural frontier, and bad productive practices. The recent intensification of climate change with higher temperatures and incidence of droughts increased agricultural vulnerability and the incidence of forest fires. The Apurímac Region has a Restoration Strategy (2018), which identified 12,836 priority hectares to be restored within the scope of the AAMF.

We participatory facilitated a compreahensive Action Plan, for the implementation of the Strategy. 51 people participated in a sequence of workshops, interviews and surveys. We began with a stakeholders mapping and restoration initiatives. Subsequently, an online collaborative spatial analysis was carried out, using the Google Earth tool, as well as an analysis of human-cultural, physical-natural, economic-financial and sociopolitical resources and gaps. Finally, a set of actions for landscape restoration was proposed, prioritized, and validated.

Among the results are: 1) identification of 1,280 hectares to be restored in addition to those identified in 2018; 2) list of promising ecological and productive restoration practices, including: agroecology, community based conservation, and ecological restoration for the recovery of hidrological ecosystem services; and 3) the determination of 14 actions for landscape restoration, categorized in: good governance (GOB), capacity building (CAP), technical actions (TEC) and financial management (FIN). Political advocacy, territorial planning, capacity building and preparation of technical files by sector are key to unlock political and financial limitations. The next steps are the scheduling of activities and inter-institutional commitments.

Reforestation potential assessment to determine the suitability of degraded land for proactive large-scale nature-based reforestation.

S3.2 Restoring forests and trees: Balancing goals, interests and trade-offs

Koen Kramer[1, 2]
Benjamin Bishop[1], Veronica Nooijen[1], Ignacio Martin-Andres[1], Quinten Vermissen[1]
[1] Land Life Company
[2] Wageningen University and Research

Abstract: Large areas of degraded land are vulnerable to further degradation and desertification because of overexploitation and climate change. The rate at which these areas reforest by natural regeneration is often too slow e.g. due to lack of seed sources, overgrazing, fire, and drought. However, significant parts of these degraded areas are potentially suitable for proactive reforestation by seeding or planting trees, thereby preventing further loss of vegetation and soil erosion. Nature-based reforestation is vital to establish forests with adaptive capacity to adjust to future circumstances and allow forest succession. Whilst large-scale reforestation is required for the supply of multiple forest ecosystem services for cost effectivenes and to meet stakeholder's demands.

We developed a tool that allows to assess:

1) the Goldilocks zone within which the land is neither too degraded or too vulnerable to future degradation so that a forest is an unfeasible goal, nor that active reforestation is unnecessary because of ample natural regeneration ('degradedness'),

2) the Forest Management Approaches (FMAs) that could be applied in the area, targeting different forest ecosystem services thus expressing the degree of nature-based reforestation of the FMA considered ('naturalness') and,

3) the spatial extent that allows combining FMAs thereby meeting multiple stakeholder demands ('scale').

The suitability of an area of degraded land for large-scale nature-based reforestation is first assessed at a 3-point decision scale for its Degradedness, Naturalness, and Scale. If the area falls within the acceptable range of these indicators, the assessment produces the following results:

- the Degradedness assessment provides potential reforestation targets expressed as a species pool and set of functional traits of the forest,
- the Naturalness assessment provides an overview of potential FMAs, given the constaints provided by Degradedness. We follow the approach developed by Dunkler et al. (2012) who characterize FMAs as Passive (Unmanaged forest nature reserve), Low (Close-to-nature forestry), Medium (Combined objective forestry), High (Intensive even-aged forestry), and Intensive (Short rotation forestry),
- the Scale assessment finally provides the distribution of FMAs over the area as the outcome of cost assessment and stakeholder demands.

We’ll present a case study applying the reforestation potential tool in a stakeholder consultation process.

Supporting land manager decision making for natural colonisation as an effective strategy for expanding forest cover and biodiversity recovery

S3.2 Restoring forests and trees: Balancing goals, interests and trade-offs

Bianca Ambrose-Oji[1]
Maddy Pearson[1], Katy Spencer[1], Elliot Colley[1], Matt Guy[1], Kevin Watts[1]
[1] Forest Research

Abstract: There is a global drive to increase forest cover to protect biodiversity and help combat climate change. Tree planting is widely used to restore forest cover, but there is growing interest in using natural colonisation. However, predicting the outcome of natural colonisation is challenging as it is a highly variable process and evidence is sparse, especially in temperate landscapes. In the UK the responsibility for achieving national targets will fall mostly to private landowners and managers who own the majority of available land, and have been responsible for the most recent tree cover increase (e.g., across the UK, 97% of new trees were planted on privately-owned land in 2019). We present three years (2021-24) of empirical socio-ecological research using mixed methods (semi-structured interviews, site visits, and deliberative workshops) with c.150 land managers and advisors in different ecological and land use contexts and sites across the UK. We show that the perceived risks and opportunities associated with natural colonisation are linked with three broad identity types, with each identity type rating the bundle of risks and opportunities for restoration and biodiversity differently. Rather than a polarisation between ‘tree planters’ versus those using natural processes emerging, our research demonstrates the majority of land managers, across identities, appreciate a blend of active and passive approaches to meet their own objectives. Many also realise that hybrid approaches (i.e. applied nucleation) may actually assist natural processes, and reduce the risks of unexpected or unwanted species assemblages. “Story lines” and narratives associated with natural colonisation influence land managers decision making, but are not fully evidenced by ecological research. Critical analysis reveals that: i. the use of language which reflects identity types, ii. guidance and tools which demonstrate likely outcomes and risks, iii. financial support that reduces perceived risks, are all fundamental to encouraging uptake of natural colonisation and applied nucleation. We end by drawing important lessons and principals, from ways in which this research is being integrated into on-going policy development processes in the UK. We show how these are useful for other regions using natural colonisation for expanding resilient forest cover and biodiversity recovery.

The role of forests in land-based mitigation: reconciling different approaches, capacities and interests

S3.2 Restoring forests and trees: Balancing goals, interests and trade-offs

Francis X. Johnson[1]
Stefan Boessner[1], Maria Xylia[2], Monica Trujillo[3], Yudi Yepes[3], Mathieu Mal[1], Kuntum Melati[1], Eileen Torres Morales[2], Mbeo Ogeya[4], Alphayo Lutta[4]
[1] SEI-Asia Centre, Stockholm Environment Institute
[2] SEI-HQ, Stockholm Environment Institute
[3] SEI-LAC Centre, Stockholm Environment Institute
[4] SEI-Africa Centre, Stockholm Environment Institute

Abstract: The recently completed Sixth Assessment Cycle of the Intergovernmental Panel on Climate Change (IPCC) suggests that it will be extremely challenging to meet the goal of limiting the global average tempterature increase to 1.5C or even 2C under many scenarios. The lack of progress in reducing GHG emissions across most sectors has led to expectations that a significant level of negative emissions will be needed, through land-based, ocean-based or industrial systems that insure net carbon removal from the atmosphere. Forests are envisioned to play a critical role among land-based mitigation strategies, not only because of their high capacity for carbon sequestration but also because of the many other benefits that forests provide, including biodiversity, air quality improvement, water quality regulation, ecosystem health, and social and cultural benefits. Although there can be co-benefits and even synergies between climate mitigation and other sustainability goals, there may also be trade-offs. The significant differences in both the biophysical and socio-economic context for forest management across different world regions - as well as across different means of management and governance - results in a fairly complex decision-making field for local, national and global stakeholders. These stakeholders also have quite different capacities and different priorities or interests.

We discuss here the results of a multi-year project of land use modeling, institutional analysis and stakeholder engagement on land-based mitigation across four world regions - East Africa, Southeast Asia, Latin America (Amazonas countries) and the Nordic countries. We had a particular focus on the central role of afforestation, reforestation and forest management in land-based mitigation portfolios, including differing approaches and priorities, and different implications for climate ambitions. We also considered the relation between local, national and regional perspectives and especially the opportunities for regional engagement to enhance climate ambition and co-benefits through scaling up and replication from national to regional levels. We present conclusions or recommendations on how competing interests might be reconciled and climate ambitions better articulated through an improved understanding of how enhanced capacities and means of implementation can be harnessed at regional as well as national level to better exploit co-benefits and synergies in achieving the aims of the Paris Agreement.

S4.1 Building international initiatives to strengthen forest adaptation strategies in a changing climate

Addressing national forest monitoring R&D gaps through the Global Forest Observations Initiative

S4.1 Building international initiatives to strengthen forest adaptation strategies in a changing climate

Daniela Requena Suarez
Martin Herold[1], Frank Martin Seifert[2]
[1] GFZ German Research Centre for Geosciences, Potsdam, Germany
[2] European Space Agency, Frascati, Italy

Abstract: Effective monitoring of tropical forests plays a vital role in understanding their health, dynamics, and the ecosystem services they provide. With their critical contribution to climate change mitigation, there is a growing need to support national forest monitoring, particularly within the framework of Reducing Emissions from Deforestation and Forest Degradation (REDD+) and voluntary carbon markets, as outlined in Article 6 of the Paris Agreement. While countries are making progress in enhancing their forest monitoring capacities, significant technical gaps persist in their national forest monitoring systems.

The Global Forest Observations Initiative (GFOI) is a collaborative partnership involving international organizations, governments, and research institutions, with the primary objective of strengthening national forest monitoring capabilities through the provision of technical assistance, tools, and knowledge-sharing platforms. The GFOI R&D community has recently made substantial efforts to address research gaps related to national forest monitoring. Here we will highlight the latest advancements achieved by the research community in relation to the five GFOI R&D priorities: regrowth and degradation monitoring, biomass estimation, deforestation alerts, land use and greenhouse gas (GHG) monitoring, and uncertainty analysis. We will emphasize the key research initiatives undertaken by the GFOI R&D community, leveraging the increased availability of Earth Observation (EO) based data and derived products. Additionally, we will demonstrate context-specific applications of these new data sources to enhance national forest monitoring systems. Furthermore, we encourage researchers, practitioners, and interested parties to engage in future discussions and collaborations on these research priorities.

Cases of China-Europe cooperation in planted forest management and adaptation to climate change in Guangxi, China

S4.1 Building international initiatives to strengthen forest adaptation strategies in a changing climate

Hui Wang[1]
[1] Ecology and Nature Conservation Institute, Chinese Academy of Forestry

Abstract: The societal expectations from forests have changed fundamentally, over the past few decades. It is well recognized that forests have a very wide range of ecological, economic and societal functions that can be broadly classified as supporting, provisioning, regulating and cultural. Increasingly societies, particularly those which are better off economically, demand more from forests than mere forest products, thus bringing about a huge challenge to the forest scientists and managers considering the multifunctional forest ecosystem management imposed on the practitioners.

Guangxi Zhuang Autonomous Region of China has the largest planted forest area and the largest timber output of China. In the last 15 years, I involved in two international cooperation projects supported by China's Ministry of Science and Technology, and carried out cooperative studies with European partners from University of Freiburg, Dresden University of Technology, INRA, and Austrian Research Centre for Forests – BFW. The topics included the carbon stability and forest management, tree species richness and ecosystem functions, and the effect of experimental warming on soil carbon fluxes.

Main points and highlights of the international cooperation included (i) concept and practice of multifunctional forestry in Chinese and European research regions; (ii) adaptive tree species mixed silviculture strategies and techniques for multifunction increases; (iii) tree species diversity and forest ecosystem functions enhancing; (iv) response of soil warming and throughfall decreasing on the forest ecosystem carbon sequestration.

Several suggestions for the further cooperation could be (i) Sharing advanced idea in the joint research platform and laboratory; (ii) reducing the risk of climate change impacting the plantation production and ecological functions; (iii) increasing the resilience and adaptive capacity of the forest ecosystem to changing environment.

Climate-driven variations in functional strategies of forest ecosystems across USA and Europe

Abstract: Functional strategies play a crucial role regulating forest capacity to cope with water stress. However, current understanding on community-level functional strategies of forest ecosystems and how they vary with geographic patterns is limited. We combined eight functional traits (i.e., leaf nitrogen content, xylem conductivity, leaf area to sapwood area ratio, leaf mass area, xylem water potential at 50% loss of conductivity (P50), slope for the curve between P50-P88, leaf turgor loss point and wood density) with forest inventory data across temperate regions in the USA and Europe (n=12,332 grid cells aggregated at 0.5° resolution) to identify functional strategies with respect to water stress and to analyse their relationships with water and temperature gradients. Principal components analysis suggests that functional strategies at species-level can be captured at community-level. Acquisitive-conservative strategies loaded along the first dimension, while the water storage and isohydricity strategies loaded along the second dimension. Spatial patterns of community-level strategies showed more explanatory power with temperature than aridity, suggesting that interfaces with other aspects of plant strategy may be strongly influencing the strategy adopted to handle water stress. This was accompanied by an increase in the diversity of strategies with respect to water stress as aridity increased, with more mesic forests converging on a

relatively narrower region of strategy space. Our findings promote the understanding of forest responses to drought across temperate regions and provide a basis for improving the ability of ecosystem models to predict the patterns of tree mortality and forest biomass accumulation.

CRAAFT, a new international initiative on the adaptation of forests and agroforests to climate change

S4.1 Building international initiatives to strengthen forest adaptation strategies in a changing climate

Philippe Rozenberg[1]
Alexia Stokes[2], Ivan Scotti[3], Murielle Trouillet[4]
[1] INRAE ONF BIOFORA LIA FORESTIA DRI, France
[2] INRAE UMR AMAP, France
[3] INRAE UR FM, France
[4] INRAE DRI, France

Abstract: The CRAAFT initiative originated at INRAE's general management level, with the support of CIRAD, in France. A French working group of 10 members, later enlarged to 30 international experts from various regions of the world, drew up a concept note designed to present the context, objectives and approaches of the initiative.

This initiative is dedicated to forest and agroforests social-ecosystems. The project considers the trees as the foundation species of theses ecosystems, but add all other types of living things, plants and animals, as well as microorganisms, and human beings.

While during the first 20 years of climatic change its effects were not obviously harmful, or were even sometimes found to be beneficial, things then changed rapidly: forest started to respond with more and more frequent and severe declines and diebacks, observed in all types of climates and forests.

Therefore, critical questions are addressed now to scientists: to which extent the natural mechanisms of local adaptation can allow forests to recover from the extreme events, which are a direct or indirect consequence of climate change? How to help them to regain rapidly a stable viable state, i.e. to show resilience? How can they continue to provide all categories of ecosystem services, both market and non-market?

Among the things that severely limit our ability to answer these questions is the uncertainty that accompanies future climates prediction. Future climates are increasingly dependent on large-scale political decisions that are beyond the control of the scientific community. Another major difficulty is our ability to consider the complex interactions between the different variables that directly and indirectly affect forest evolution.

Initiatives trying to imagine and test adaptive management interventions that could increase the resilience of forests to extreme climate events are highly needed. They require involvement of social and economic actors, and the high level of challenges and threats calls for extensive international exchanges of knowledge, innovation and solutions, in order to increase the power and the significance of experimentation. CRAAFT is one of these international initiatives, taking on some of the most urgent and relevant research actions.

Effectiveness of partnerships and regional cooperation in addressing forestry challenges.

S4.1 Building international initiatives to strengthen forest adaptation strategies in a changing climate

BETTY PRISSY NJOKI NDUMA[1]
Josephine Wanjiku[1], Paul Tuwei[1]
[1] KENYA FORESTRY RESEARCH INSTITUTE

Abstract: Forestry sector, faces numerous challenges such as deforestation, climate change, illegal logging, and habitat degradation. Addressing these challenges requires a collective effort that goes beyond individual capabilities. Partnerships and regional cooperation has been adopted globally as a tool that can enhance joint articulation and tackling of forestry challenges and issues.

Partnerships provide a platform for governments, non-governmental organizations, local communities, and businesses to collaborate, share knowledge and jointly seek/pool resources. A key advantage of partnerships and regional cooperation is exchange of knowledge and expertise. Regional cooperation allows stakeholders to share best practices, research findings, and innovative technologies. By learning from each other's experiences, partners can develop comprehensive strategies that take into account local contexts and global trends. Partnerships and regional cooperation also enhance the conservation of natural resources especially those shared across borders. By working together, stakeholders establish protected areas, promote reforestation initiatives, and implement sustainable harvesting practices. Sharing resources and expertise can help optimize the allocation of limited funds and ensure that conservation efforts are targeted and impactful. Moreover, collective action increases the influence and effectiveness of advocacy efforts, encouraging policymakers to prioritize sustainable forestry. Example illegal charcoal trade challenges cut across East Africa Countries and a regional cooperation approach has potential benefits in enhancing regulation and Trans-border trade. Another significant benefit of partnerships is their potential to support local communities. In many regions, forests are intricately linked to the livelihoods and cultural identities of rural communities. For Example more than 70% Sub Saharan Africa communities depend on wood and forests. Collaborative initiatives provide opportunities for these communities to participate in decision-

Above all Regional cooperation facilitate access to funding and investment opportunities. The pooling of resources and expertise increases the attractiveness of forestry projects to financiers and donors, leverage public-private partnerships, secure grants, and attract. Collaborative initiatives leverage public-private partnerships and attract private sector investments.

This paper will present 3 selected cases on regional cooperation that include the KEFRI social Forestry regional trainings on climate change among others to showcase effectiveness of partnerships and regional cooperation in addressing forestry challenges.

Enhancing the role of forests and trees in transformational adaptation to climate change

S4.1 Building international initiatives to strengthen forest adaptation strategies in a changing climate

Antoine Libert[1]
Amy Duchelle[1], Annika Cobb[1], Virginie Peccoud[1], Houria Djoudi[2], Aster Gebrekirstos[2], Vincent Gitz[2], Inge Jonckheere[1], Alexandre Meybeck[1], Maria Nuutinen[1], Marggiori Pancorbo Olivera[1]
[1] FAO
[2] CIFOR-ICRAF

Abstract: The Intergovernmental Panel on Climate Change (IPCC) *Sixth Assessment Report* calls for upscaling and disseminating tried and tested adaptation measures that are recognized for their high feasibility and synergies with mitigation and the Sustainable Development Goals (SDGs). One of these measures identified by the IPCC is "forest-based adaptation", an ensemble of climate actions that employ forests and trees in support of climate change adaptation and resilience, including sustainable forest management, forest conservation and restoration, reforestation, silvopastoral systems, trees on farms and trees in cities.

Forests and trees provide ecosystem services which minimize exposure, reduce vulnerabilities, and strengthen capacities, thus contributing to adaptation and resilience. However, these adaptation services depend on forests being resilient to climate change. As such, forests and trees can sustain society's efforts to adapt to climate change, yet they also require society's contributions to maintain their resilience.

Building upon previous work in the field, FAO has been working with partners to highlight the contributions of forests and trees to fulfilling country commitments for climate change adaptation and resilience building. The FAO technical paper *Forest-based adaptation: transformational adaptation through forests and trees (2022)* unpacks the concept of forest-based adaptation and describes policy spheres that could bolster the role of forests and trees in providing adaptation and resilience benefits. It introduces a set of ten principles for using forests and trees to promote transformational adaptation, which were developed with leading experts from the Center for International Forestry Research and World Agroforestry (CIFOR-ICRAF) and other partners. It describes the policy implications of each principle and draws on examples from diverse forest ecosystems and management practices to illustrate their application in practice.

Building on this work, we have facilitated a series of global and regional dialogues with international researchers and practitioners, adaptation and forestry country representatives, and climate finance actors to bolster cross-sectoral collaborations around emerging priorities, including to: promote mitigation-adaptation synergies; integrate forests in cross-sectoral adaptation strategies; assess the resilience of forests and trees to climate change; monitor adaptation progress; and mobilize finance for adaptation. This presentation will highlight the results of this collective work and indicate ways forward.

Forest management and biodiversity conservation in a changing climate: consequences and the way forward

S4.1 Building international initiatives to strengthen forest adaptation strategies in a changing climate

Claire Depardieu[1]
Philippe Rozenberg[2]
[1] Canada Research Chair in Forest Genomics, Institute for Systems and Integrative Biology, Université Laval, Québec, QC, Canada
[2] ECODIV, INRAE, France

Abstract: Understanding forests functioning and how forests respond to climate disturbances is a major challenge for any forestry research programme in the 21st century. We still lack a clear understanding of the complex interactions between the different components of forest systems, the role played by the different levels of biodiversity, and the behaviour of unbalanced systems.

The geographical scale of the dangers posed by climate change to agroforests and forests far exceeds national borders. Also, forests are social-ecosystems where humans and non-humans cohabit, generally with conflicts of interest affecting certain beneficiaries of ecosystem services, both human and non-human. As a consequence, there is an urgent need for large-scale transdisciplinary international projects taking into account socio-ecological contexts, to ensure that multiple values are well considered.

In this presentation, we outline the opinion defended by the CRAAFT project, a new international initiative on the adaptation of forests and agroforests to climate change. We support the idea that research projects aiming at better characterizing (1) the response of forests to climatic disturbances and (2) the interactions between the different components of forest systems at large geographical scales are urgently needed. We propose to explore transformative strategies[1] in addition to adaptation or incremental strategies, and to provide new scientific knowledge to help decision-makers avoid insufficient, unsuitable or unsustainable options for future forest management. In particular, we believe that the highly needed research on natural adaptation and its mechanisms must be multidisciplinary and combine human and social sciences with biology and ecology to lead to effective adaptive management.

During this conference, we will show how current knowledge can be used to suggest the most promising avenues for research, i.e. those that will help preserve biodiversity and ensure sustainable forest management in the face of ongoing climate change.

[1]A transformative strategy is designed to create transformative change, which involves a fundamental shift in the functioning and dynamics of forest-landscape systems.

Improving the Sustainable Management of the Brazilian Cerrado

S4.1 Building international initiatives to strengthen forest adaptation strategies in a changing climate

E Maria Gomes Vale[1]
Aldicir Scariot[2], Eraldo Matricardi[3], Carlos Torres[4], Melanie Feurer[5], Dietrich Darr[1], Kathrin Meinhold[1], Dietrich Schmitd-Vogt[5]
[1] Hochschule Rhein Waal
[2] Brazilian Agricultural Research Corporation, Genetic Resources and Biotechnology Center
[3] Universidade de Brasília
[4] Universidade Federal de Viçosa
[5] Albert-Ludwigs-Universität Freiburg

Abstract: The Brazilian Cerrado is a savanna of global importance that is severely threatened by agricultural expansion and forest conversion into intensively managed pastures. While autochthonous silvopastoral systems offer a more sustainable alternative, they are currently less financially profitable compared to the intensively managed systems.

Our research alliance is a German-Brazilian initiative to improve the sustainable management of the Cerrado through quantification and valorisation of ecosystem services provided by silvopastoral systems. One potential pathway to enhance profitability compared to other land uses is by monetizing these services through various means, such as product labels, certification, value-added processing of non-timber forest products, and carbon credits. By recognizing and assigning value to the ecosystem services, we can create economic incentives that promote the adoption and continued support of silvopastoral systems in the region.

We combine household-level primary data with data collected through a market survey, and secondary sources for econometric modelling on the determinants of silvopastoral system adoption in the Cerrado region. We assess the factors determining silvopastoral system adoption and management, and aim for an improvement of rural livelihoods and household nutrition. Concluding, we stress the importance of building the capacity of extension agents, scientific community, and local government to facilitate a more sustainable management of the Cerrado.

Jurisdictional REDD+: A Comprehensive Literature Review on Opportunities, Challenges, and Potential

S4.1 Building international initiatives to strengthen forest adaptation strategies in a changing climate

Youjin Jung[1]
Joonsoon Kim[2]
[1] Deparment of Forest Management, Kangwon National University
[2] Division of Forest Science, Kangwon National University

Abstract: REDD+ stands for Reducing Emissions from Deforestation and Forest Degradation, which encompasses all activities aimed at protecting forests from deforestation. Within the realm of REDD+, jurisdictional projects emerge as a distinctive approach. In comparison to project-level REDD+, jurisdictional-level REDD+ offers several advantages, including a reduced risk of inflated baselines and over-crediting, as well as the ability to address the issue of leakage. This paper aims to undertake a comprehensive literature review to provide an in-depth understanding of the current state of research on subnational REDD+, shedding light on both the opportunities and challenges associated with this approach. Specifically, we will emphasize the pivotal role played by local stakeholders in the successful implementation of subnational REDD+ initiatives. Moreover, we will underscore the significance of establishing robust governance structures and institutional frameworks, which serve as key pillars for the effective execution of subnational REDD+ programs. Additionally, the necessity of implementing efficient monitoring and verification systems will be emphasized, as they are critical for ensuring the credibility and efficacy of subnational REDD+ endeavors. Furthermore, this paper will explore the potential for scaling up subnational REDD+ initiatives to a national level, evaluating their capacity to contribute to the overarching goals outlined in the Paris Agreement. By elucidating the complexities and nuances surrounding subnational REDD+, this study will provide valuable insights for policymakers and practitioners engaged in climate change mitigation efforts.

Linking Fruit and Forest tree communities: the FRUITDIV European initiative

S4.1 Building international initiatives to strengthen forest adaptation strategies in a changing climate

Veronique Decroocq[1]
Dalibor Ballian[2], Katja Sonnenschein[3], Martin Lascoux[4], Phil Aravanopoulos[5]
[1] INRAE Univ. Of Bordeaux, UMR BFP, France
[2] UNSA, Univerzitet U Sarajevu, Bosnia-Herzegovia
[3] GIS Gozdarski Institut Slovenije, Slovenia
[4] Uppsala Universitet, Sweden
[5] Aristotelio Panepistimio Thessalonikis, Greece

Abstract: Crop wild relatives (CWR) are wild plant taxa closely related to a crop. They represent an important source of genetic diversity for the improvement of agronomic traits and they are still available as tree species within the European forests. In the context of the One Health Initiative, temperate fruit trees are essential for human nutrition and health, yet CWR resources have hitherto been underused. Moreover, fruit tree long lifespan and a current production dominated by a few cultivars make them particularly vulnerable to the effects of global changes. To address this challenge, the FRUITDIV project will monitor, characterize, use, and conserve the diversity of emblematic fruit tree CWR, with a particular emphasis on Malus, Pyrus and Prunus, by linking horticulturists, forestry officers and citizens.

To better characterize the genetic and phenotypic diversity of CWR fruit trees and identify favourable traits for future introgression into cultivars, FRUITDIV will use a combination of floristic, ethnogeography and population genomics on genebanks and historical European hotspots of diversity. We will then develop new multiomics-based breeding strategies that combine marker assisted introgression for traits of interest (e.g. resilience, resistance to pests and diseases, fruit quality) with pangenomic prediction and a reduction of CWR-associated genetic load.

In addition to breeding programs, FRUITDIV will also work with networks of farmers and associations to help characterize CWR progeny in various pedo-climatic conditions in Europe. An European-wide online platform that provides genotyping and phenotyping data for free will be implemented to promote the use of CWR genitors by breeders and farmers and help disseminate plant material of interest for various usages and cultivation systems.
Overall, the FRUITDIV multi-actor approach involving geneticists, forestry officers, germplasm curators, farmers and citizens, will foster the in- and ex-situ conservation of Fruit tree CWR and promote sustainable agricultural and forestry practices across Europe.

FRUITDIV is by essence inter-disciplinary, gathering experts in horticulture, forestry, ecology, genetics and population genetics, genomics, bioinformatics, mathematics and social sciences. It is made of 27 partners from 10 EU countries and 4 non-EU countries. The above 5 authors will represent the consortium at the IUFRO conference.

TF on monitoring global tree mortality: opportunities and challenges of internationalization of research on forest adaptation to climate change

S4.1 Building international initiatives to strengthen forest adaptation strategies in a changing climate

Henrik Hartmann[1, 2]
[1] Institute for Forest Protection, Julius Kühn-Institute, Federal Research Institute for Cultivated Plants: Quedlinburg, GER
[2] Max Planck Institute for Biogeochemistry, Jena. GER

Abstract: Forests are threatened by climate change in many regions across the globe. During the last decades, increased tree mortality and forest decline in response to drought and heat have been observed in all forested biomes and documented on a global map. However, the underlying observations in forests are often carried out in proximity to research institutions and-or in countries with forest assessment programs, leaving many blank spots on the global mortality map. It thus remains uncertain whether such a map represents a consistent trend in forest condition, but this information is crucial for evaluating forest damage from and also forest adaptation to climate change.

International and interdisciplinary research is needed to fill this blank, by creating synergies between forestry agencies, research plot networks, remote sensing analysts and vegetation modellers on the one hand, and field experts like forest ecologists, ecophysiologists, entomologists and pathologists ont the other hand. The IUFRO task force on monitoring global tree mortality has been aiming to foster such interdisciplinary research internationalization.

In this talk I will present experiences of six years of networking activities to create such synergies, and I will highlight both opportunities and challenges that lie within internationalization of forest research activities. While not specifically mandated to address forest adaptation to climate change, experiences collected during the lifetime of the IUFRO task force on monitoring global tree mortality can be valuable to other futue internationalization initiatives.

TreesAdapt: a global partnership platform to leverage forests, trees and agroforestry solutions for cross-sectoral adaptation

S4.1 Building international initiatives to strengthen forest adaptation strategies in a changing climate

Vincent Gitz[1]
Houria Djoudi[1], Aster Gebrekirstos[1], Peter Minang[1], Christine Lamanna[1], Thuy Pham[1], Ramni Jamnadass[1]
[1] CIFOR-ICRAF

Abstract: Forests, tree commodities and agroforestry systems -as well as their value chains- are and will be strongly affected by climate change. Moreover, forests and trees are key to buffer impacts of climate change on agriculture and other sectors, including water, infrastructures, cities and on the most vulnerable populations.

Actions mobilising the potential of forests and trees for adaptation have multiple benefits, mitigating climate change, contributing to the achievement of the SDGs as well as contributing to biodiversity and land restoration agendas. Adaptation of and with forests and trees is increasingly mentioned in NDCs and NAPs. There is also an increasing demand for cross cutting, systemic adaptation. This requires both the capacity to synthetize and organize issues and options inside a sector and to relate to other sectors and to broad challenges at national level. This is particularly important for transformative adaptation that changes the fundamental attributes of a system to respond to climate change and its effects.

There is a demand for evidence and knowledge to ground design and selection of options, for methods, tools, technical support capacity building for implementation of adaptation measures of/with forests and trees. There is also a key need to design and develop an appropriate enabling environment and appropriate learning loops and communication.

It is to answer these demands and needs that CIFOR-ICRAF, building upon a strong and diversified body of knowledge and track record, has organized a coordinated answer in partnership, to leverage the roles of forests, trees and agroforestry for cross-sectoral adaptation: ***TreesAdapt.***

Adopting a concrete entry point, forests and trees, ***TreesAdapt*** is a transformative partnership platform that targets implementation on the ground of climate change adaptation solutions with forests, trees and agroforestry. It aims to constitute forests and trees as a binding object that can trigger intersectoral dialogues, facilitate the elaboration of a shared understanding of issues and the co-construction of locally-adapted solutions. ***TreesAdapt***, because of its cross-cutting nature, is also a great vehicule for introducing system thinking in broad adaptation planning.

The ***TreesAdapt*** platform and its advances will be presented, and ways to engage and to partner will be discussed.

Why forestry science should go (really) global? Needs and challenges to have a significant impact on knowledge, scientists and forests worldwide

S4.1 Building international initiatives to strengthen forest adaptation strategies in a changing climate

María Elena Fernández[1]
Javier Gyenge[1]
[1] CONICET-INTA UEDD IPADS, Forest Ecology Group Tandil, Argentina

Abstract: There is ample consensus about the interrelated global challenges faced by humanity, associated to a growing human population, pressing on natural resources, and climate change. Forests are in the center of those challenges, as recipients of the negative impacts of climate and land use changes, and as providers of key ecosystems services (food, fibers, energy, biodiversity, carbon sequestration, water regulation, etc.) to contribute with their solution. The world may be rather simplistically divided between what is called “the Global North” and the “Global South”, which refers mainly to the socio-economic development of the nations within them. High-income countries (mostly on the geographic North, except Australia or New Zealand) have a high per-capita (or total) consumption of natural resources and are responsible of most of the greenhouse gas emissions. The low-income countries (mostly in the geographic South) have low per-capita impacts but are those with the highest world deforestation rates nowadays (mostly to provide commodities to the North, which pays more for them than for the missing forests` services). However, there are not only socio-economic differences, but environmental ones, with different combinations of climatic drivers and soil types unique to each continent. Studies focused on new regions may expand the current fragmentary knowledge we have about how the forests function now and could function in the future. To fill the gaps in knowledge, forest science should go really global. But this demands a new ethic in data generation and sharing and in scientists´ exchange and participation to build a fair and balanced scientific framework. Pairs and colleagues from all over the world should be part of the debates and decisions within the scientific community, for instance by forming part of research nets and editorial and academic boards, and recipients of long-term funding for forest data generation and curation. However, beyond the efforts to build a better frame for forestry scientists and generate better forestry knowledge, the possibility of forest science to contribute to global solutions demands new dialogues outside our community and forms of knowledge construction. It is time for us, therefore, to be more fair, open and creative.

S4.2 Forest Policy and Justifying Role of Science in Tropical Countries. A High-Level Policy Panel Dialogue

Inclusive science to inform forest policy in the tropics

S4.2 Forest Policy and Justifying Role of Science in Tropical Countries. A High-Level Policy Panel Dialogue

Pablo Pacheco[1]
[1] WWF

Abstract: The tropics continue to show trends of growing land occupation, unequal access to public services, and persistent rural poverty. Much of the economic wealth generated from land, forest, and minerals' resources use and extraction is concentrated and poorly redistributed. The dominant pattern of economic development has prompted natural forest loss and degradation, contributing to carbon emissions and biodiversity loss. The resilience of forest ecosystems, people's livelihoods, and local economies is growingly under threat due to compounding and cascading climate disturbances. While climate science has alerted on climate change and its consequences, it has done from a biophysical and ecological perspective, and there are major gaps related to translating scientific findings to inform local responses, including indigenous and local knowledge to understand forests and social behavior changes and adaptation, and approaching solutions in more integrative ways by building on a more inclusive science. Until today, policy and practice in the tropics is informed by scientific paradigms, which guide mainstream conservation, sustainable management and land use approaches that struggle to embrace more plural and holistic perspectives of understanding. However, increasingly, there are efforts to co-produce knowledge aimed at better connecting global trends and local socio-ecological and climate dynamics, understanding the socio-diversity of local contexts, and co-designing options to advance collective actions. I will argue that for overcoming the climate challenges, in the face of the economic and governance challenges facing the tropics, a more integrative science is needed, that builds on plural explanatory perspectives including those of indigenous and local knowledge, a better understanding of the climate and socio-institutional linkages shaped by context, and a more comprehensive acknowledgement of the responses potential that considers explicitly the needs and aspirations of the tropics' multiple stakeholders.

Science policy interface and tropical forests

S4.2 Forest Policy and Justifying Role of Science in Tropical Countries. A High-Level Policy Panel Dialogue

Robert Nasi[1]

[1] Center for International Forestry Research / World Agroforestry

Abstract: Researchers are increasingly being forced to consider how their research findings can result in tangible impacts thereby presenting a considerable challenge to those seeking to achieve those impacts as a consequence of policy changes. The policy change process is subject to a bewildering array of social, economic and political influences, and policy decisions are taken largely independently from the actions of scientists and research institutes. To assume that conducting research on policies relating to forests and disseminating the findings will lead to changes in the policies themselves is unrealistically naive and grossly overestimates the role of knowledge acquisition in policy change processes. A role exists nevertheless.

Through successful case studies from tropical countries, we will demonstrate the transformative potential of forest science in driving positive change. It will showcase examples of sustainable forestry practices, community-based initiatives, and innovative conservation strategies that have emerged from scientific research.

We hope to underscore the pivotal role of forest science in the conservation and sustainable use of tropical forests. By integrating scientific evidence, interdisciplinary collaboration, and inclusive approaches, it becomes possible to develop effective policies and practices that ensure the long-term health, resilience, and equitable benefits of tropical forests for present and future generations.

The Politics of Numbers in Global Forest Governance

S4.2 Forest Policy and Justifying Role of Science in Tropical Countries. A High-Level Policy Panel Dialogue

Maria Brockhaus[1]
[1] University of Helsinki

Abstract: Scientific information - and scientists - are assumed to play a key role in global forest governance based on the idea that rigorous scientific information can lead to more effective, efficient and equitable forest policy outcomes. Data and information are central to forest policy processes, in framing the policy problem, designing and implementing policy 'solutions', and evaluating impacts. Better data and information infrastructures are expected to lead to better policies and outcomes, for example, by enabling transparent decision making and enhancing capacity and accountability. Scientists are expected to engage in diverse policy processes and science policy interfaces (SPIs) aiming for scientifically informed policy in forest related policy arenas, which often involve a multitude of actors with conflicting values and interests. In this context, scientists and their evidence are supposed to be striving for credibility, relevance, and legitimacy of the produced evidence while navigating these complex, politicized webs of public policy making. Yet, the collection, selection, representation, framing and application of data are not merely technical and apolitical procedures. Data and information are socially constructed, and their interpretations are shaped by the contexts in which they emerge – an observation not very popular among scientists and decision makers alike - as it easily can be misread as an effort to undermine claims of the research community to speak 'truth'. Dominant beliefs in the transformative power of new data and technologies, cannot explain why, often, new information does not translate into policy change and desired action. Despite this dissonance, it seems that the theories of change underlying the design of forest policy SPIs continue to assume that knowledge is the missing piece for policy makers and private sector actors, and for entrepreneurs to do 'better' – and hence to move effectively (measurably) away from an unsustainable business as usual. Acknowledging 'power and politics of numbers' in our contemporary and often highly contested forest policy arenas, will be a very important step when producing and assessing evidence, and designing and assessing the impacts of SPIs. Who counts and what is counted, counts in forest policy and practice.

Uncertainties and trends in the forest policy framework in Sierra Leone: an overview of forest sustainability challenges in the post-independence era

S4.2 Forest Policy and Justifying Role of Science in Tropical Countries. A High-Level Policy Panel Dialogue

Moses Fayiah[1]
[1] Department of Forestry, School of Natural Resources Management, Njala University, Sierra Leone

Abstract: Sierra Leone is part of the Upper Guinean Forests with a climate that enhances great floral biodiversity. The relationship between forest exploitation and plantation forest decline is broadly assumed to be influenced by population growth, weak forest policies, legislatures, forest management and monitoring policies over the past century. The paper examines forests status and forest resources policy evolution since the pre-colonial era but pays particular attention to policies developed from 1988, in the post-colonial era, and the challenges facing their implementation. The paper highlights major challenges facing the healthy and sustainable growth of forest resources in Sierra Leone. The challenges range from the attachment of the Forestry Division to the Ministry of Agriculture, Forestry and Food Security (MAFFS), the overlap in ministerial mandates about forest protection, corrupt government officials, poverty, illegal logging, inadequate funding and staff, natural disaster and outdated forestry instruments. Natural factors such as climate change, drought, and landslides are considered among the issues affecting the sustainable expansion of forest resources in Sierra Leone. A flowchart of forest sustainability challenges in Sierra Leone was designed, and classified forest challenges into natural and man-made causes. The inability of the Forestry Division to become an independent body and the continued reliance of the Division on the 1988 Forestry Act to make informed decisions in the 21st century is serving as a major barrier in sustaining forests resources in Sierra Leone. Improving forest management in the country requires the collective efforts of both national and international forests protections entities and organizations. Sound forests conservation policies and adequate funding and staffing can strengthen the Forestry Division in enforcing its constitutional mandates. Adopting the best practices models from countries such as China, India and the USA will help towards the goal of managing forest resources sustainably for current and future generations.

S4.3 International Forest Governance: A Comprehensive Global Review

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

A peri-urban forest conserving challenges in West Africa

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Blandine Marie Ivette NACOULMA[1]

[2] Ecole Nationale Des Eaux et Forêts, Dinderesso 01 BP 1105 Bobo-Dioulasso, Burkina Faso
[3] Institut des Sciences et Technologies, Ecole Normale Supérieure, Koudougou, Burkina Faso

Abstract: Urban forests have played crucial role of urban centers in West Africa. However, the growing population and rapid urbanization occasioned by demographic switch from rural to urban society is outstripping the planning and carrying capacity of municipal authorities in West Africa. Thus, evaluating the governance and the dynamics of peri-urban forests is fundamental to guide management and conservation policies. This study aimed to analyze the spatio-temporal dynamics of the "*Forêt Régionale du Centre*" (FRC) in Burkina Faso. Focus group surveys with local populations and foresters, combined to Landsat satellite images analysis for a period of twenty years from the study site were used. The results show that the FRC undergoes increasing degradation of plant resources characterized by landscape modification. Local populations perceive the regression of the forest, which is classified as in high degraded state by 93% of informants with the disappearing of the 10 most useful trees species such as *Parkia biglobosa, Lannea microcarpa* and *Bombax constatum*. The main identified drivers included the forest governance in which all stakeholders blame each other, human activities, demographic explosion, and climate variability. The analysis of the satellite images confirmed the regressive dynamics of the FRC. In twenty years, about 50% of the vegetation area was lost at the expense of bare soils and illegal habitations. To save the FRC, forestry administrations have to consider it as a specific component in its own right, by involving local populations in it management and protection.

A regenerative approach to forestry

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Dr. Mónica Hernández-Morcillo[1]
Prof. Dr. Carsten Mann[1]
[1] University for Sustainable Development, Eberswalde, Germany

Abstract: Today, as the multiple planetary crises converge irrupting our daily life and threatening our existence, we are increasingly becoming aware of our interdependence with nature. A core cause of the unprecedented degradation of the planet lies in our inner perceptions as separated from nature. Yet, most of the current sustainable forest management efforts are dedicated to transforming the external world of forestry policies, economies, or ecosystems, overlooking the inside dimensions of individuals and their deep transformational potential. There is growing recognition that addressing the inner dimensions and integrating the values and perceptions underpinning human-forest connections is essential for pursuing permanent changes in the outer dimensions.

In this paper, we introduce a regenerative approach to forestry, advancing the current sustainable forest management practices by including the inner dimensions of individuals, values, and perceptions to enable a long-term co-evolution with forests. The regenerative approach to forestry is based on the concept that all systems, human and natural, are interlinked and can influence each other. This means that each forestry project or community should always be considered within the context it is part of and its impact on its proximity. We contribute to the empirical corpus of regenerative forestry evidence through a case study in Algezur, Portugal. We found three main aspects where a regenerative forestry approach could add value to sustainable forest management. First by unfolding the transformative potential of forests within their local contexts, second, by cultivating the capacity in individuals to perceive and embody a whole living systems perspective, and third by reestablishing the reciprocal contributions between forests' benefits to people and people´s benefits to forests.

Actor centered power mapping for mangrove protected area governance

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Md Nazmus Sadath[1]
Md Saifur Rahman[2], Ariful Alam[1]
[1] Forestry and Wood Technology Discipline, Khulna university, Bangladesh
[2] Ministry of Environment, Forest and Climate Change, Bangladesh Government

Abstract: The effective governance of mangrove-protected areas is crucial for the conservation and sustainable management of these valuable ecosystems. However, power dynamics among different actors within these governance systems often play a significant role in shaping decision-making processes and policy outcomes. The Sundarbans, the world largest single tract mangrove forest was chosen for the study. This study aims to develop an actor-cantered power mapping framework to analyze and understand power relations within mangrove-protected area governance. The proposed framework integrates elements from social network analysis, power theory, and stakeholder analysis to identify key actors, their relationships, and the distribution of power among them. By utilizing qualitative and quantitative data, including interviews, surveys, and policy document analysis, the study examines the formal and informal power structures that influence decision-making processes in mangrove-protected areas. By mapping power relations, the framework provides insights into the influence of actors on policy formulation, resource allocation, and implementation. The findings of the study contribute to a deeper understanding of power dynamics and their implications for mangrove-protected area governance. This study creates a complete policy actor network for the Sundarbans protected area governance using the snowball sampling technique. Bangladesh forest department appears as the most powerful actor however shipping ministry, Mongla port authority and BIWTC are also among the powerful actor in the wider intersectoral policy decision making process. The study also reveals that the policy outcome satisfies the interest of the Bangladesh forest department, but the action fails in the implementation steps as the core interests of other powerful actor from outside the forest sector are not in synergy with BFD's interest. The study also reveals that equal share of decision-making responsibilities was not achieved in the Sundarbans protected area governance as the forest users have little influence in determining the policy outcome.

Adaptation through planting fast-growing broadleaves among private forest owners in Sweden

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Caroline Rapp[1]
Louise Eriksson[1]
[1] Umeå University, Department of Geography, Sweden

Abstract: Forest damages are increasing and there is a need to adapt the forest to climate change, at the same time as forests need to deliver a range of ecosystem services. To meet upcoming challenges, many advocate for a diversification of forest management strategies and tree species. Fast-growing broadleaves (FGBs) adopted as part of forestry or agroforestry include hybrid and native species and may contribute to diversifying forests currently dominated by conifers. Yet, knowledge gaps remain regarding their economic viability, as well as impacts on biodiversity and recreational values. To ensure that climate adapted forestry is not creating new conflicts between stakeholder groups with different interests, and facilitate convergence with policy, we must understand reactions and decision-making processes of diverse stakeholder and rightsholder groups in different places.

Comparable to many other countries in Europe and the United States, a large share of the productive forest land in Sweden is owned by private forest owners (also called family forest owners), making them a key actor for climate adaption in forests. This study examines forest owners' adoption of FGBs with a specific interest for the role of place (social and ecological characteristics) and decision-making processes. Since adopting FGBs is only one way to diversify, this decision is contrasted with willingness to adapt in other ways (e.g., other broadleaves). Based on data from a large survey of a random sample of private forest owners in Sweden (n = 5000), this study explores how owners in different municipalities and regions, with varying climate conditions but also ownership structures and access to sawmills processing broadleaves, vary in their interest in FGBs. In addition, analyses cover to what extent decisions to adopt is motivated by problems associated with current management (including appraisals of future damages) versus the emotions and beliefs associated with FGBs specifically. By considering decision making processes in relation to place characteristics covering both the social and ecological dimensions, this study provides insights on the drivers and barriers of adaptation among forest owners. This knowledge is key for an understanding of how the forest will be adapted to climate change.

Addressing wildfire risk. A review of approaches to design decision and criteria spaces and support adaptive forest management planning

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Jose G. Borges[1]
Dagm Abate[1], Susete Marques[1], Liliana Ferreira[2], Miguel Constantino[3]
[1] Forest Research Centre, School of Agriculture, University of Lisbon
[2] Departamento de Matemática Escola Superior de Tecnologia e Gestão, Instituto Politecnico de Leiria
[3] Departamento de Estatística e Investigação Operacional, Faculdade de Ciências, Universidade de Lisboa

Abstract: Wildfires pose a challenge to forest management planning. The provision of a wide range of ecosystem services in contexts of global change requires often the conversion of forest types. Yet the impacts of these management options on that provision are not immediate. They rather take place over extended temporal horizons and may thus be affected by the occurrence of wildfires. In this context, addressing the wildfire challenge requires models and methods that may design effectively both the forest management planning decision and criteria spaces. This will be influential to estimate the impact of management options on the provision of ecosystem services and to analyze the tradeoffs among the latter. This presentation reviews and classifies models and methods according to the support provided to the design of decision and criteria spaces in forested landscapes. It further reviews and discusses approaches to facilitate the engagement of decision-makers and stakeholders in the exploration of the criteria space. The potential of models, methods and tools to address wildfire risk and support adaptive forest management planning is illustrated by an application to a forested landscape extending over 14 thousand ha and involving multiple decision makers and stakeholders.

Adopting robust actions in forest management planning in protected areas – insights from Slovakia

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Yvonne Brodrechtova[1]
Róbert Sedmák[2]
[1] Technical University in Zvolen, Faculty of Forestry, Department of Economics and Management of Forestry
[2] Technical University in Zvolen, Faculty of Forestry, Department of Forest Resource Planning and Informatics

Abstract: The rapid and turbulent changes in our world create significant uncertainties on myriad factors, which present themselves in many ways, such as the climate, market conditions, legal frameworks, and their impacts. Faced with an unpredictable and fast-changing world, maintaining and promoting sustainable forest management in Slovakia in the coming decades will be a challenging task. Therefore the forest sector needs to think and act strategically. Developing robust strategies that are relatively insensitive to future uncertainty is an attractive way. Yet, the application and adaptation of forest management to uncertainties under climate changes or other developments (e.g., ecological, societal, economic, and technological demands) have been addressed just now. If it should be integrated into forest management planning, the non-probabilistic approaches are necessary to explore the future in plausible scenarios. In other words, the scenarios are not prognoses. Thus, they do not try to forecast the most probable future development but create variants of possible plausible future development. An important area of application of scenarios is strategic planning, the basis of which are critical decisions taken under uncertainty. This could be applied to general forest management planning and protected areas. As national parks are considered a key to conserving forest ecosystems and biodiversity, stakeholders' participation in forest management planning may help to improve and mitigate environmental, economic, or social inequalities. So far, forest management planning has been rather a technical task to match capacity with goals and a political one to give experts the responsibility of developing the plan. As a result, the research project's goal is to present an alternative to current planning processes in finding robust (participatory set) actions for the future. These robust actions will be determined using an innovative approach in which various methods (e.g., stakeholder analysis combined with social network analysis, scenario analysis combined with multicriterial optimization) will be integrated. As the demand in national parks in Slovakia for alternative forest management increased after recent institutional changes, now more than ever, there is a call for robust (participatory set) actions in general and in protected areas in particular.

Allocation of tree species under climate change uncertainty: optimizing reforestation for resilience using Modern Portfolio Theory

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

William H MacKenzie
Kiri Daust[1], Colin Mahony[1]
[1] Future Forest Ecosystem Centre, British Columbia Forest Service, Victoria , British Columbia, Canada

Abstract: Modern Portfolio Theory (MPT) mathematics underpin modern financial strategies to optimize investment performance under market uncertainty. This approach can be applied to the challenge of accounting for climate change uncertainty in the choice of tree species and provenance for reforestation. We developed a climate change informed species selection (CCISS) analysis to forecast future trends in the suitability of tree species under a wide range of global climate model – carbon scenarios for the province of British Columbia, Canada, where 300 million seedlings are planted yearly. CCISS generates site condition specific tree species suitability trends in 20-year periods out 100 years and delivers an output that meshes with the decision-making framework used by reforestation professionals. A challenge with this analysis is that the modelled outcomes rarely produce clear agreement in species suitability ratings across the modelled futures and time periods. Instead, each climate future has a different tree species suitability profile for each plausible future reflecting the uncertainty in climate futures. For decision-makers this complicated outcome, while providing a useful perspective on climate change implications to current reforestation standards, is difficult to interpret, optimize, and fully incorporate into decisions.

To provide clearer guidance to practitioners, we apply the concepts of MPT to CCISS predictions to generate climate-change optimized species ratios areas for reforestation. We use modelled changes to species suitability as a proxy for tree stress and forest health risks, and modelled tree growth rates (based on site index by site condition) for returns. The MPT analysis generates a range of portfolio options, from one or two species mixes with maximum potential return (but higher risk) to more species diverse portfolios with higher resilience. This MPT output allows forest managers to choose a risk-return level they deem appropriate for management goals and identify the species portfolio that optimizes the balance between forest productivity and climate change resilience.

Ambiguity, value of information and forest rotation decision under storm risk: a theoretical model and an experimental test

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Marielle Brunette[1]
Stéphane Couture[2], Patrice Loisel[3]

[3] MISTEA, Université Montpellier, INRAE, Institut Agro, Montpellier, France. patrice.loisel@inrae.fr

Abstract: Natural hazards represent the major threat for forest worldwide, especially storm. However, due to the more or less pessimistic scenarios of future climate change, storm frequency is now ambiguous and only partially known (i.e., scenario ambiguity). Furthermore, within each scenario, the quantification of storm frequency is also ambiguous due to the differences in risk quantification by experts, creating a second level of ambiguity (i.e., frequency ambiguity). In such an ambiguous context, knowledge of the future climate through accurate information about this risk is fundamental and can be of significant value. In this paper, we question how ambiguity and ambiguity aversion affect forest management, in particular, optimal cutting age, using both a theoretical model and an experimental test. Using a classical Faustmann framework of forest rotation decisions, we compare theoretically three different situations: risk, scenario ambiguity and frequency ambiguity, also considering the preferences of the forest owner. We show that risk and risk aversion significantly reduce the optimal cutting age. We also show that both scenario and frequency ambiguities reinforce the effect of risk. Inversely, ambiguity aversion has no effect. The value of information that resolves scenario ambiguity is high, whereas it is null for frequency ambiguity. In addition, we test these theoretical results through experimental economics. We realize an online experiment with a population of private forest owners from Grand-Est Region in France. We quantify risk and ambiguity aversion through classical Multiple Price List methodology. We then ask the forest owners to indicate the optimal cutting age in the various scenario. The experiment will be carried out during March and the data analysed thereafter.

Application of Risk-Based Approach for Sustainable Forest Management Assessment in Ukraine

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Pavlo Kravets[1, 2]
Yevhenii Khan[1, 2], Oksana Pavlishchuk[1, 2]
[1] National University of Life and Environmental Sciences of Ukraine
[2] FSC Ukraine

Abstract: One of the most robust ways to implement sustainable forest management is through voluntary certification standards that encourage the best available practices in forestry and actively develop new areas such as anti-corruption policy, gender equality and ecosystem services. In this regard, comprehensive approaches to certification are changing and necessitate more open data on forest management to cover, which will reveal existing and potential conflicts.

The study that was conducted during 2021-2023 provides insights on how different categories of open data and targeted stakeholder engagement can be applied for a third-party evaluation of an organization's compliance with FSC standards. In addition, the results of the study identify the potential use of this data in the organization's self-assessment and due diligence procedures.

The developed tool is in alignment with the risk management system in accordance with ISO 31000:2018 and ISO 9001:2015. At the same time, this tool enhances the ability to identify risks at different management levels, analyze and evaluate them, and determine mitigation measures. In this case, the developed risk matrix is based on the most relevant issues (for example, commercialization of thinning and sanitary felling) of forest management identified by experts. The matrix includes risk factors, risk designation (low or specified risks), links to the FSC National Forest Stewardship Standard requirement, data sources and relevant comments. The specified risk leads to applying risk-adjusted audits by certification bodies, in particular, by engaging an expert, using remote sensing methods and technologies, increasing the sample for field visits to forest areas and the frequency of assessments.

The application of the proposed tool is based on consolidating various datasets - public summaries of FSC forest management reports, media analyses, and forest management data - to enhance the flow of information within forest management units. In 2022-2023, some of certification bodies operating in Ukraine tested proposed matrix and recommendations. It helped them identify critical assessment points in forest management, optimize evaluation procedures, and promote adaptation to modern challenges, aiding forest conflict prevention.

The study demonstrates that a risk-based approach can be applied to evaluating sustainable forest management under diverse socio-ecological expectations and unpredicted challenges.

Changes of Protected Areas Policies in China

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Gang Yang[1]

[1] School of Agricultural Economics and Rural Development, Renmin University of China

Abstract: Protected areas policies in China has been changing for nearly 70 years and becoming increasingly complicated. A policy system led by the Regulations on Nature Reserves and complemented by other laws, regulations, outline plans has been established. After the State Council's institutional reform in 2018, the State Forestry and Grassland Administration is responsible for supervising and managing all types of protected areas, partly solving the overlapping management issue. However, during the policy implementation, there are still issues such as the unbalanced powers and responsibilities assignment, insufficient human capacity, and the lack of inspection. By using historical institutionalism, this paper examines the structure and historical changes of protected areas policies in China. It is found that: economic, ecological and international impacts have influenced the protected areas policies; policy changes could be found in policy issuing subjects, policy implementing subjects and policy objectives; the Central Environmental Protection Inspectorate is a key approach to promote the implementation of protected areas policy. This paper suggests to promote the revision of the Regulations on Nature Reserves and the enactment of the Law on Protected Areas, with a comprehensive consideration of economic, ecological and international factors. It is also necessary to enhance the capacity of management agencies to manage various protected areas by staff training and technology investment, so as to promote the change of policy implementation subjects; improve legislation related to environmental protection inspection, so that the inspection mechanism can be standardized and normalized.

Climate change induced risks for forestry and forest owners' willingness to join the voluntary carbon schemes

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Emmi Haltia[1]
Jussi Leppänen[1], Jussi Lintunen[1], Mikko Peltoniemi[1], Esa-Jussi Viitala[1]
[1] Natural Resources Institute Finland

Abstract: Forest carbon sinks can play an important role in mitigating climate change globally. The voluntary carbon schemes are a promising policy tool for incentivizing forest owners for increasing the carbon sinks. The success of the voluntary scheme is, however, dependent on the forest owners' willingness to join the scheme. According to the earlier studies, forest owners are interested in increasing the carbon sink in their forest for monetary compensation, but long contract periods or other limiting contract features may reduce the interest substantially.

The attractiveness of carbon scheme depends on forest owner's monetary and nonmonetary preferences, but also on her/his risk attitude. While the scheme may increase the earnings from forestry, the changes in management may increase the risk of natural disturbances like wind damages and insect outbreaks. Since the increase in expected earnings is associated with increased risks, the forest owners' risk attitudes can influence the willingness to join the scheme.

In this study we examine the impact of the forest owners' risk attitudes and their other characteristics on their willingness to join the voluntary carbon schemes. We compare the impact of these factors on two different types of the compensation schemes: in the first one the forest owners are compensated for lengthening the rotation period and, in the second one the compensations are based on the amount of carbon sequestered into the forest. In the first compensation scheme, the forest owners know the amount of compensation they get for certain measures. In the latter scheme, forest owners can choose the measures to increase the amount of carbon in their forest, but the future compensation is not known for sure.

The survey data will be collected in June 2023. The electronic survey questionnaire will be sent to 10 000 forest owners randomly sampled from the Finnish Forest Centre's database. In the survey, we use both contingent valuation and choice experiment methods to evaluate the forest owners' willingness to accept compensation for the carbon scheme. The results of the survey will be presented in the conference.

Community Perception Towards the Major Drivers for Deforestation and Land Degradation of the Afro-alpine Ecosystem

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Zelalem Gebew[1]
Aklilu Agidie[1], Tewachew Worku[1], Sintayehu Gete[1]
[1] 1Ethiopian Forest Development, Bahir Dar Center, Po.box:2128

Abstract: The Choke Mountains have several endangered and endemic wildlife species and provide important ecosystem services. Despite their environmental importance, the Choke Mountains are found in dangerous conditions. This raised the need for an evaluation of the community's perception of deforestation and its major drivers and suggested possible solutions in the Choke Mountains of northwestern Ethiopia. For this purpose, household surveys, key informant interviews, and focus group discussions were used. A total sample of 102 informants was used for this survey. A purposive sampling technique was applied to select the participants for in-depth interviews and focus group discussions. Both qualitative and quantitative data analyses were used. Computation of descriptive statistics such as mean, percentages, frequency, tables, figures, and graphs was applied to organize, analyze and interpret the study. This study assessed smallholder agricultural land expansion, Fuel wood collection, population growth; encroachment, free grazing, high demand of construction wood, unplanned resettlement, unemployment, border conflict, lack of a strong forest protecting system, and drought were the serious causes of forest depletion reported by local communities. Loss of land productivity, Soil erosion, soil fertility decline, increasing wind velocity, rising temperature, and frequency of drought was the most perceived impacts of deforestation. Most of the farmers have a holistic understanding of forest cover change. Strengthening forest protection, improving soil and water conservation, enrichment planting, awareness creation, payment for ecosystem services, and zero grazing campaigns were mentioned as possible solutions to the current state of deforestation. Applications of Intervention measures, such as animal fattening, beekeeping, and fruit production can contribute to decreasing the deforestation causes and improve communities' livelihood. In addition, concerted efforts of conservation will ensure that the forests' ecosystems contribute to increased ecosystem services. The major drivers of deforestation should be addressed with government intervention to change dependency on forest resources, income sources of the people, and institutional set-up of the forestry sector. Overall, further reduction in anthropogenic pressure is urgent and crucial for the recovery of the afro-alpine vegetation and the interrelated endangered wildlife in the Choke Mountains.

Coping with disturbance impacts in European forests: implications for forest multifunctionality and adaptive strategies

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Andrey Lessa Derci Augustynczik[1]
Mykola Gusti[1], Andre Deppermann[1], Andre Nakhavali[1], Fulvio di Fulvio[1], Nicklas Forsell[1], Pekka Lauri[1], Petr Havlík[1]
[1] International Institute for Applied Systems Analysis

Abstract: Forest disturbances are becoming a main driver of forest dynamics in Europe and further interactions with climate change are expected to intensify disturbance activity in the future. This will require forest managers to anticipate disturbance and climate change impacts and act to promote forest resilience and the maintenance of ecosystem services in the region. Still, uncertainties remain on the impacts and vulnerability of European forests towards multiple disturbance agents under changing climatic conditions. Here we address this issue and evaluate the implications of climate change to forest growth in European forests, considering the influence of future windstorm and insect outbreak events on forest dynamics and ecosystem services. To this end, we apply an enhanced version of the process-based model 3PGmix, coupled with windstorm and bark beetle disturbance modules, under multiple climate change scenarios. We assess disturbance and climate impacts on the provision of multiple ecosystem services, including wood production, carbon sequestration and biodiversity. Furthermore, we evaluate different management strategies to mitigate negative impacts of disturbance events, including changes in species and harvesting intensity. Our results show that climate change will have profound impacts on future forest dynamics in European forests. The direction of changes in forest productivity is context dependent, with majorly positive influence of climate on forest productivity in the boreal zone, while more negative impacts are expected in Mediterranean forests and in Eastern Europe. Furthermore, disturbances are expected to increase forest damage in the future, reaching close to 80 million m^3 per year by the end of the century. Forest management, however, can be leveraged to mitigate climate change and disturbance impacts, while considering the increasing focus and contribution of European forests to climate and biodiversity protection goals.

Determinants of Forestry Insurance Adoption among Private Forest Owners: A Choice Experiment Approach

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Fanny Claise[1]

[1] Bureau for Economic Theory and Application, INRAE, France

Abstract: Forestry insurance adoption by private owners is crucial for mitigating the financial risks associated with climate change and other hazards. Climate change is expected to have significant impacts on forests, including more frequent and severe natural disasters such as wildfires, storms, and pest outbreaks. However, the adoption of forestry insurance by private owners can be low in some European countries due to factors such as perceived cost, lack of knowledge, and low perceived risk.

Within the framework of the European project *Eco2adapt*, this study uses a choice experiment methodology to understand the preferences of forest owners and investigate the decision-making factors that influence the adoption of forestry insurance coverage in the context of climate change. A survey was conducted with private forest owners in European countries, where participants were presented with hypothetical insurance scenarios. The results show that the factors that most influence private owners' adoption of forestry insurance are perceived risk, insurance coverage, and cost, as well as the potential impact of climate change on forest risks. The results also suggest that private owners are willing to pay a premium for comprehensive insurance coverage. These findings can inform the development of forestry insurance policies and marketing strategies that are better tailored to the needs and preferences of private forest owners and can help to promote more sustainable and resilient forest management practices in the face of climate change.

Economic consequences for Norway Spruce of storm damage in German forests under climate change

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Robin Bourke[1]
Barry Gardiner[1], Rasoul Yousefpour[1], Marc Hanewinkel[1]
[1] Chair of Forestry Economics and Forest Planning, University of Freiburg

Abstract: Wind storms pose a significant threat to European forests and may increase in frequency under climate change (Mölter et al. 2016).

We investigate the future storm damage risk under changing climate in the forests within Germany, simulating their future development over 30 years with the forest growth model 3-PG Mix (Forrester & Tang, 2016) and comparing their potential storm damage risk using two storm damage risk prediction models, Forest Gales (Gardiner et al. 2000) and Lothar (Schmidt et al. 2010). Forest Gales is a mechanistic damage model, while Lothar is a statistical model, calibrated from storm-damaged forests after the Lothar storm in 1999. The simulations were run using RCP 8.5 climate data. Four management strategies were simulated: a "Business as usual" thinning regime and intense, light and no thinning interventions. The simulations were initialised from national forest inventory data. An economic analysis of the 30 years of forest growth was undertaken, where the net present value, value at risk (VaR) and conditional value at risk (CVaR) were calculated.
Using Lothar, storm risk probability closely mirrored the past damage distribution of the historical Lothar storm in Baden Württemberg, where the most severe risk is predicted in the westerly region of the state. In contrast, Forest Gales showed less localised damage and was more spread across the entire region. Differences in the damage predictions are attributed to the differences in the risk calculation. While both models consider current stand parameters (height and diameter), the statistical nature of the Lothar model means there is more weighting of the probability on previously damage areas and topographic exposure. In Forest Gales, however, damage probability is more related to stand attributes and wind climate.

In all cases, considering changed climate, an intensive thinning strategy was found to provide the most favourable results in the worst case, i.e. the VaR and CVaR was the highest under this strategy. This applied when wind storm damage was and was not considered.

Therefore, under the growth conditions posed by extreme climate change, in addition to predicted storm damage risk, extreme losses could be mitigated by a more intensive thinning strategy.

Faustmann Model Expansion under Policy Uncertainty

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Yanzhen Hong[1, 2]
Bangni Li[1]
[1] School of Economics and Management, Fujian Agriculture and Forestry University, Fuzhou 350002, China
[2] Research Center for Reform and Development of Collective Forestry, National Forestry and Grassland Adiministration, Fuzhou 350002, China

Abstract: Faustmann Model Expansion under Policy Uncertainty
Forestry policies have certain uncertainties which bring adverse expectations to farmers' harvesting. The Faustmann model focuses on the optimal rotation period for forest management, whereas the Faustmann model on uncertainty focuses on the exploration of market uncertainty, and policy uncertainty is less studied. We develop a new index of forest policy uncertainty (FPU) based on three certain newspapers and policies released on forestry department websites. We rely on natural language processing tools to help select policy-relevant terms. The obtained contents were classified according to three key phrases: uncertainty U, forestry F, and policy P using natural language processing tools, and the resulting forestry policy uncertainty index was used to extend the Faustmann model under policy uncertainty.

Keywords： Faustmann；Forestry policies; Uncertainty; Foresty Policy Uncertainty index; Natural language processing

Forest adaptation strategies to climate change under socio-, economic and ecological uncertainties - a case study from Serbia

Abstract: In the German-Serbian bilateral research cooperation project ANKLIWA-DS, we showcase how we tackle to overcome major “science gaps” to develop and implement adaptation strategies to climate change focusing on beech and oak forest management. Deviating from business-as-usual forest management requires extensive knowledge and scientific data on several levels regarding species suitability, profitability and social demands etc. A combination of site mapping, dendrochronological field measurements, inventory data and the calibration of forest growth simulators is leading to maps of productivity and dynamic tree species distribution. Risk and uncertainties in productivity, tree species suitability and distribution are analysed applying scenarios of climate change. Economic evaluation and optimization of simulation outputs is conducted. Intensive communication with stakeholder accompanies the project aiming at a better understanding on demands, needs and possibilities on both sides. Policy instruments are developed for the governance and implementation of smart climate change strategies in Serbia based on multi-level stakeholder analyses, expert interviews and surveys ("Climate Smart Forestry"). After a thorough risk evaluation, developed action alternatives combined with adequate policy programs are assessed that not only provide ecologically feasible and economically efficient but also socially acceptable and thus “robust” adaptation strategies under climate change.

Harmonizing the Ecosystem Symphony: Exploring the role of vital Actors in Payment for Ecosystem Services and Navigating the Challenges Ahead

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Mona Nazari[1]

Abstract: Payment for Ecosystem Services (PES) has been identified as an important mechanism to close the gap between the demands of society and the service providers. PES is where buyers are beneficiaries paying for ecosystem services, sellers are land and resource managers ensuring service supply and intermediaries facilitate scheme implementation.

Despite the extensive implementation of PES cases worldwide, there remains a need for a more comprehensive understanding among
policy and decision-makers regarding the optimal design features of future PES initiatives that are more likely to achieve
successful outcomes. This study aims to provide a systematic understanding of the roles of different actors in the PES scheme, identifying the most enabling actors for a sustainable program, and examining the critical challenges encountered throughout the program process.

As a primary data source for this research, a database of 145 implemented cases from 46 different countries was compiled based on
2 sources of databases from the NOBEL and SINCERE projects and reviewing the lessons learned. The information was synthesized
according to specific case study actors' groups such as type of intermediary, buyer, and sellers. In-depth interviews were
conducted with selected cases, to derive a detailed picture of the project´s challenges and underlying motives.

The study highlights the significant impact of actors and their different roles in the PES schemes. Trusted intermediaries in 90
percent of the cases, mostly NGOs, actively participated throughout the project. Government and Business companies are involved in
40 percent of reviewed PES cases involving as buyers. Local communities and landowners emerged as the primary providers in 50
percent of the identified PES schemes. The main barriers identified are the lack of market information, participation avoidance, and mistrust.

In conclusion, enhancing the capacity of locally based intermediaries holds great promise in addressing the issue of mistrust
among rural communities. It can play a vital role in increasing program awareness. Moreover,

strengthening these networks is
essential for fostering alternative livelihoods that encourage greater participation. However, by collaborating with government
entities, the potential for success in PES initiatives can be significantly enhanced, paving the way for sustainable environmental conservation and community development.

How can ambiguity influence the optimal management of a forest? An approach with Multi-Model Markov Decision Processes

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Stéphane Couture[1]
Marie-Josée Cros[1], Régis Sabbadin[1]
[1] University of Toulouse, INRA MIAT

Abstract: In a context of climate change, it becomes difficult for private forest owners to optimize their decisions for the management of their forest. Indeed, climate change is not predictable in a perfect way, and the risks of fire threats on forests, strongly linked to climate change, will also evolve. Forest owners must therefore act in a situation of ambiguity. In addition, private forest owners are very heterogeneous in terms of objectives, attitudes and behaviors in their forest management, but also in terms of perception and defiance to ambiguity. It is therefore essential, in any given framework, to take this heterogeneity into consideration. Providing recommendations to private forest owners that take into account their preferences regarding ambiguity is a fundamental societal challenge in the face of climate change. This study aims to provide some answers in this context of ambiguity in order to optimize forest owners' decisions and find optimal policies. We define a maximization approach to obtain optimal forest management policies considering ambiguity and ambiguity aversion in order to explicitly consider climate change and the various possible fire risks. We adopt an infinite-horizon stationary Multi-Model Markov Decision Processes (MMDP) framework to model this problem. The main contribution of this work is to design a MMDP model to evaluate forest management policies in an ambiguous context due to climate change, and to generate the forest management policies evaluated under several parameters of forest owner's ambiguity preferences, according to two decision criteria, the α-MEU model or the smooth ambiguity model.This enables the forest owners to develop insights into the economic forest management under climate change. The MMDP framework is applied to a non-industrial private forest owner located in southwestern France facing a fire risk. Ambiguity and ambiguity aversion amplifie the effects of risk aversion and further reduces the optimal cutting age.

How prevention, supression and restoration actions my help to design resistant and resilient forested landscapes? The Portuguese Living Lab example

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Abstract: Managing forests has been demonstrated to be an efficient strategy for fragmenting fuels and reducing fire spread rates, severity, and extreme wildfire events (EWE). Landscape managers and policymakers are facing a significant challenge in shifting the paradigm to integrate prevention, suppression, and restoration activities into fire and forest management. The FIRE-RES project proposes to implement innovation actions:1) demonstrate the use of tools (e.g. fire behavior simulators) and techniques (e.g. optimization approaches) in order to obtain optimal landscape configuration and fire management policies to minimize expected losses from EWE. 2) Designing strategic networks of managed areas to improve suppression efforts thru the implementation of a multi-criteria decision analysis and mathematical optimization, to define how to allocate fuel breaks to mitigate the impact of large fires and facilitate suppression efforts. And 3) Designing post-fire restoration strategies, also implementing a spatial multi-criteria decision analysis system to define which areas within a large fire perimeter should be prioritized for restoration actions. The innovation actions will be implemented in Living Labs such as Greece, Catalonia, Chile, and Portugal. We will present some results from the implementation of this LL Portugal in the case study area, Vale do Sousa, Northwest Portugal.

How socio-demographic factors affect perceptions of the relevance of forest ecosystem services?

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Abstract: This paper assesses the priority of forest ecosystem services (FES) and defines a socio-demographic profile of people who consider particular services an essential function of forests. The research material consists of the results of a questionnaire survey conducted on 1402 citizens in Poland. Twelve different types of FSE were valued, to which respondents assigned a relative priority (Ps) on a five-point Likert scale. The significance of differences in the importance of individual FES was tested using analysis of variance, while a logistic regression model was used to profile visitors in terms of differences in perception of the particular ecosystem service. Regulatory functions were considered the most important (Ps 3.35-3.63), followed by cultural functions (3.09 - 3.23) and least important provision functions (1.72-2.97). The trend in societal demand towards FES during the last decade was upward. The most significant increase occurred concerning regulatory functions, the smallest in the case of provisions, except for the provision of animal products in relation to which demand decreased. Regulating functions are seen as very important by people with higher education, satisfied with financial status, and women. Cultural functions are most valued by those satisfied with their material status and older people over 40. Provision functions are perceived as very important primarily by rural residents, often with low material status, with the provision of animal products being more appreciated by men and the supply of mushrooms and berries by women. Identifying the links between the condition of forest ecosystems and socially useful functions plays an important role in the planning process for sustainable forest development and ecosystem services. Our results allow us to understand public expectations for forests and better manage public forests

Index insurance for coping with drought-induced risk of production losses in French forests

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Abstract: Drought-induced risk of forest dieback is increasing due to climate change. Insurance can be a good option to compensate potential financial losses associated with forest production losses. On the one hand, forest insurance markets focus only for storm and/or fire risks. On the other hand, literature on index insurance against drought focused on the agricultural sector in developing countries. In this context, we developed an ex ante index-based insurance model to cope with drought-induced risk of forest dieback. We applied this model to beech and oak forests in France. We defined and then compared different indices from simple ones relying on rainfall indices to more complex ones relying on the functional modelling of forest sensitivity to water stress. After the calibration of the contract parameters, an insurance scheme was optimized and tested. We showed that optimal insurance contracts generate low gain of certain equivalent income, high compensation, and a high basis risk. The best contract was not proportional to the complexity of the index. There was no clear advantage to differentiate contracts based on species. Results highlighting the various perspectives of this first approach are discussed: in particular, contracts and indices are tested by simulating them for two climate change scenarios (RCP 4.5 and RCP 8.5) using three global climate forecasting models, in order to adapt insurance contracts to the context of increasing risk related to climate change.

Integrating wind disturbances into Forest planning: A stochastic programming approach

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Abstract: Forest disturbances challenge our ability to carefully plan for sustainable use of forest resources. As forest disturbances are stochastic, we cannot plan for the disturbance at any specific time or location, but we can plan for the possibility of a disturbance. Thus, mitigating disturbance impacts requires the incorporation of the potential range of disturbance intensity and frequency when examining alternative plans for the forest.

This study uses stochastic programming to integrate wind intensity and wind event frequency into the forest planning process. A small coastal Finnish forest landscape of 286 ha was used to demonstrate the potential of the approach. We use the mechanistic HWind model to quantify the critical wind speed for tree felling and a Monte Carlo framework to develop wind intensity and frequency scenarios. A stochastic programming model was applied to maximizing the expected forest net present value or minimizing expected conditional value at risk to meet predefined harvest targets. To evaluate the impact of improperly identifying wind intensity and frequency, we compare the outcomes of planning for the assumed correct vs incorrect wind assumptions.

The results of this study highlight the importance integrating wind disturbances into planning for specific management objectives. When maximizing the net present value, the impacts of misidentifying wind intensity and frequency have a minor impact on the expected net present value. This is likely caused by harvesting trees rather quickly. Alternatively, when minimizing the expected conditional value at risk, incorrectly identifying wind intensity and frequency severely impacts on the ability to meet the required harvest targets and reduces the expected net present value.

Incorporating wind disturbances into the planning process is possible and can provide useful guidance on how forest managers can effectively manage the risk preferences of a specific forest owner. However, the utility of incorporating wind disturbances into the planning process depends on the specific planning problem.

Living with the "riparian forest engineers": social perception and management alternatives for Eurasian beavers in Central Italy

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Abstract: Conflict between released Eurasian beavers *Castor fiber* and human activity may arise following forest ecosystem modifications. In our project, we aimed at assessing the social perception towards the presence of the Eurasian beaver in Central Italy through direct questionnaires for the local human population. Moreover, we identified the areas where beaver populations are most likely to arrive in the next future in Italy. We surveyed the human population through standard methods commonly used in social science. Our questionnaire was planned to measure whether and how citizens, fishermen, and farmers perceive the presence of the beaver was administered to 1114 respondents. All surveyed people have been and will be over 18 years old and able to fill the questionnaire autonomously, and they should agree to participate in this research. All on-site questionnaires were implemented on paper, were anonymous, and conducted through autocompletion to avoid potential influences by operators. To monitor potential range expansion, we developed spatially-cross-validated species distribution models to identify the areas with the highest suitability for the model species. Then, we used connectivity modeling to assess the possible expansion routes in Italy.

We recorded a comprehensive awareness of the presence of the beaver in the study area (92.3%) and a general high knowledge of issues related to the presence of the beaver (i.e., potential effects on forests). The majority of the population was in favor of reintroducing beavers, and only 1.2% was firmly against it. The majority of interviewed people was against the removal of beavers from Italy, whereas only 3.7% was in favor, as fearing impacts on riparian forests.

We found wide areas with high environmental suitability in central Italy and in foothill areas of northern Italy. The connectivity model showed a high potential for expansion from records of central Italy to surrounding areas, while records of northern Italy seem to be more isolated. Our results can help environmental managers to understand where to focus both future monitoring of beaver populations and actions to prevent and mitigate possible human-wildlife conflicts, which could arise from the expansion of an environmental engineer such as the Eurasian beaver.

multi-level remote sensing and Forest Insurance in Japan

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Masayoshi TAKAHASHI[1]
Hideki SAITO[1], Seishiro TAKI[1], Shingo OBATA[1], Tomohiro NISHIZONO[1]
[1] Forestry and Forest Products Research Institute

Abstract: Forest owners and managers face various risks associated with meteorological phenomena such as strong winds, heavy rain and snowfall, drought, freezing, and flooding. Forest insurance is one of the ways to hedge against such risks. When a disaster strikes forests, the extent and severity of the damage must be assessed before insurance payments can be made. Multi-level remote sensing supports rapid, safe, and accurate surveys. Satellite remote sensing is useful to assess extensive forest damage. UAS remote sensing is suitable for precise surveys of forest damage. We will explain the advantages and disadvantages of platforms and sensors, and the combined use of diverse remote sensing through the case studies to assess catastrophic forest disturbance caused by typhoons.
In Japan, forest insurance is provided according to the Forest Insurance Law, which has existed for more than 80 years. Since 2019, the forest insurance center, which is responsible for forest insurance in Japan, has been using remote sensing technology to assess damages for insurance payments. Accurate disturbance data derived from remote sensing will assist in a comprehensive understanding of forest risk. In the context of the current state of forest insurance, we will discuss risk communication and its challenges in the forest sector in the changing world.

Multi-objective forest management – an ecological-economic optimization approach

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Abstract: How to meet economic objectives of timber harvesting while maintaining the functioning of diverse forest ecosystems? Answering this question requires ecological-economic models that can be easily applied and generalized for uneven-aged mixed-species forests. Here, we develop a dynamic ecological-economic optimization model, which integrates a state-of-the-art demographic forest model with a continuous cover forestry harvesting model to optimize efficient and sustainable timber harvesting. As a proof-of-concept, we apply the model to a beech-dominated forest in the Hainich, Germany, with the goal of optimizing multiple objectives such as timber yield and the biodiversity value of the forest. The ecological module is the Perfect Plasticity Approximation (PPA) demographic forest model that simulates forest dynamics based on individual tree growth and survival rates in the understory layer and the canopy layer, respectively, as well as recruitment rates. We used repeated forest inventory data from a 28-ha permanent forest plot to quantify these demographic rates and validated the predictions of the ecological module against the structure of old-growth beech forests in Europe. The economic module includes constant marginal harvesting costs and timber prices to maximize the net present value of timber profits, and can be constrained by the number of retained habitat trees (>70 cm diameter) as an indicator for the biodiversity value of the forest. The forest model delivered good predictions of the size distribution, basal area, and maximum diameter of old-growth beech forests. When only timber yield was maximized, trees were harvested when they reached 65 cm in diameter. This is similar to current management practices in beech forests. There is a trade-off between maximizing timber harvest and biodiversity value. Initially, with a small number of retained habitat trees, timber harvest decreased modestly, yet as the number of habitat trees increased, timber harvest decreased sharply. We established a generic ecological-economic modeling framework that reliably represents forest dynamics as well as optimal forest management. The framework can be extended to mixed-species forests and support forest management for diverse ecosystem services.

People and forests in local Cambodian communities: perspectives from community-based forest management

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Ayako TOKO[1]
Thusitha DILSHAN[2]
[1] School of Arts and Science, TWCU, Tokyo Woman's Christian University
[2] Graduate school of Toyo University

Abstract: The important role of local communities in sustainable forest management has been increasingly acknowledged since the 1980s, as many studies indicated that community-based approach would promote self-organized governance in which the rules are devised and modified by the resource users and mutual monitoring is enforced (Ostrom, 1990; Agrawal and Ostrom, 2001; Pretty and Ward, 2001; Agrawal, 2003). This study seeks to identify challenges and opportunities of community-based forest management (CBFM) by focusing Cambodia, where 1) forest resources are critical assets for local people, owing to the fact that nearly 76% of people still rely on fuel wood and 8% rely on charcoal for daily cooking (National Institute of Statistics, 2014); and 2) forests were historically inhabited by small groups of hunters and gatherers as well as isolated farming communities (Poffenberger, 2013), and this type of livelihood is still predominant. In this studay, a case study method is applied with literature review and field research including participant observation, interviews with key stakeholders, and questionnaire survey for local communities. Results from two different cases in Chambok and in Kampot showed that environmental education effects to the local communities, and that promotion of self-organized governance, mutual monitoring and benefit sharing system by CBFM. It is also indicated that motivations for forest management are derived from local people's perception from real experiences such as increase of fish caught by mangrove reforestation. Although substantial positive aspects for local community were found in this study, large and small challenges were also identified as: massive logging concessions by industries are on-going, tourism development is threathning CBFM site, and illegal loggers breaking into community's protected forests even from neighboring villages or countries have been witnessed (Poffenberger 2013). Despite efforts in CBFM, these external and considerable factors are endangering the welfare of forest resources and local communities. Further research for addressing these external factors is also needed to contribute to real sustainable CBFM schemes.

Robust management strategies promoting ecological resilience and economic efficiency in a temperate forest under the risk of severe drought

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Juan Carlos Zamora-Pereira[1]
Marc Hanewinkel[1], Rasoul Yousefpour[1, 2]
[1] Chair of Forestry Economics and Forest Planning, University of Freiburg, Tennenbacherstr. 4, 79106 Freiburg, Germany
[2] Institute of Forestry and Conservation, John Daniels Faculty of Architecture, Landscape, and Design, University of Toronto, 33 Willcocks Street, Toronto, Ontario M5S 3B3, Canada

Abstract: Robust decision-making in forestry seeks solutions that reduce the risk of environmental damage and economic losses, which matters for designing forest adaptation measures. Droughts have had severe consequences in temperate forests, such as reduced resilience, which forest owners do not notice for some time, exacerbating stress-related mortality. Moreover, adapting forests to the effects of dry conditions is an option that owners and managers had explored to deal with increasingly frequent drought events. Nevertheless, effective adaptation to expected droughts depends on e.g., the ability of managers to understand how dry conditions affect forest development, the costs of adaptive measures to regulate the affectation, and the attitudes of foresters toward the risk of the decision to adapt. In that sense, the use of process-based modeling approaches provides an evident solution to cost-efficiently support adaptive forest management, facilitating the consolidation of knowledge from the processes behind forest adaptation. In this research, we propose a novel methodology to identify robust drought adaptive strategies aimed to find suitable solutions that would continuously perform satisfactorily over a wide range of plausible scenarios. First, we used a process based-model with an ensemble of climate change scenarios to simulate managed forest dynamics. Second, we quantified the ecological resilience and financial return as net present value (NPV), applying business-as-usual (BAU) and alternative adaptation strategies to regenerate the overstorey layer (trees ≥ 30 cm dbh) of the forest (e.g., “active”, “reactive”, and “do-nothing”). Afterward, we analyzed robustness by searching for the strategy with minimum worst-case losses of ecological and economic signposts. Our analysis found a reduced forest drought resilience under BAU and “do-nothing” strategies, determining a high probability of economic failure (~ -49% and ~ -67% loss in NPV respectively). While, an early “active” strategy would increase the NPV (~ +10%), and a highly-intense “reactive” strategy would have minimal losses (~ -2%). Finally, we found that local conditions influence the signpost performance magnitude but do not vary the robust solution. We conclude that our methodology facilitates applying a robustness analysis in forestry, and drought adaptation should occur rather sooner than later, considering constant revision.

Social Concerns and Opportunities for Intensively Managed Tree Plantations: Learnings from The Forests Dialogue

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Gary Dunning[1]
Violet Low-Beinart[1], Liz Felker[1]
[1] Yale University, The Forest School at the Yale School of the Environment, USA

Abstract: Over the past 23 years, The Forests Dialogue (TFD) has convened and facilitated numerous multi-stakeholder dialogues to explore best practices and challenges as well as the complex social landscape surrounding planted forests. Via the "Tree Plantations in the Landscape" (TPL) Initiative, TFD has most recently convened 1 scoping and 3 field dialogues, specifically in South Africa, Chile, New Zealand, and Brazil. In June 2023, TFD held its 5th TPL dialogue in Indonesia. The current TPL Initiative builds on extensive previous work under TFD's Initiative on "Intensively Managed Planted Forests" (IMPF) which took place between 2005-2008.

Social issues in particular have regularly risen to the top of participants' priorities to be addressed in dialogues. In response, TPL dialogues have explored socially related issues such as 1) approaches to enable good governance and inclusive development, 2) land tenure and community rights and 3) learnings from indigenous techniques and strategies. Dialogues have also covered other topics such as 1) the design and implementation of planted forests in the context of jurisdictional and landscape approaches, and 2) the diversification of the forms and species composition of planted forests among other issues. Learnings from each of the dialogues have been varied depending on geography and context but have coalesced around:

1. the importance of recognizing local communities' land and access rights,
2. the relevance of indigenous techniques and strategies,
3. successful local engagement processes and grievance mechanisms related to tree plantations,
4. sustainable intensification techniques,
5. nature-based solutions.

At the IUFRO Congress, TFD can offer either an individual speaker presentation or a panel event to discuss the knowledge gained through both the TPL and IMPF Initiatives, specifically drawing upon the latest learnings from the June 2023 dialogue in Indonesia. If a panel event is preferred, panelists will be drawn from dialogue organizers and participants to form a balanced group that encompasses a wide range of perspectives on critical social concerns related to planted forests.

Starting from forest stakeholders' perspectives to prevent non-adaptation: A participatory approach to foster the implementation of adaptive practices

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

Timothée Fouqueray[1]
Jean-François Bissonnette[2], Mathieu Jonard[3], Quentin Ponette[3], Christian Messier[1], Jérôme Dupras[1]
[1] Université du Québec en Outaouais, Institut des Sciences de la Forêt Tempérée, Canada
[2] Université Laval, Faculté de Foresterie, de Géographie et de Géomatique, Canada
[3] Université catholique de Louvain, Earth & Life Institute, Belgium

Abstract: The biggest risk brought by climate change may not be the lack of experimental feedback (what could happen? what could we do?) or of risk management policies (what should we do?), but the actual lack of adaptive change in forest management. Therefore, the goal of this study was to identify potential obstacles and levers to forest adaptation by directly addressing socio-economic hurdles and behavioral barriers.

Focusing on non-industrial private forest (NIPF) owners, we led a comparative analysis of two regions in Western Europe and Northern America, dominated by temperate forests. Building upon the "Actors, Resources, Dynamics and Interaction" framework, we conducted participatory, in-person and collective workshops with 46 foresters around a simple question: "how can we help NIPF owners in adapting to climate change?". Step by step, NIPF participants were asked to draw a diagram indicating the most important actors and resources for their adaptation, and how actors and resources interact. This resulted in network representations of participants' perspective on how to implement adaptation to climate change. As NIPF owners' behaviors proceed from complex relationships with other forest stakeholders, we replicated these workshops with forest advisors, public forest managers, elected officials in charge of municipal forests, members of environmental organizations, and representatives of the timber industry. The speeches, interactions, prioritization lists and diagrams allowed for a comparative analysis across categories and regions.

In this session, we will present five highlights of our analysis on non-adaptation and maladaptation risks: (1) the low risk of non-adaptation; (2) the shared understanding of balancing different forest uses and forest ES prioritization (ex: timber production vs. recreative uses); (3) the distribution of adaptive power among foresters (power to change practices by oneself, power over other stakeholders to restrict or foster behavioral changes, and empowerment); (4) the way local and national authorities try to develop adaptation policies accounting for behavioral, social and economic levers; and (5) the potential contribution of participants' differing strategies to the design of more inclusive and effective adaptation policies.

Strengthening Inter-sectoral Convergence in Ecological Mangrove Restoration of Abandoned Brackish-water Fishponds in the Philippines

S4.4 Socio-ecological conflicts in forest management: risks of (not) adapting?

John Benrich Zuniga[1]
Alvin Gestiada[2], John Rommel Manahan[2], Carmelita Villamor[2]
[1] Department of Science and Technology - Philippine Council for Agriculture, Aquatic and Natural Resources Research and Development
[2] Department of Environment and Natural Resources - Ecosystems Research and Development Bureau

Abstract: Rehabilitation of abandoned brackish-water ponds in the Philippines is often problematic due to
uncoordinated institutional policies and conflicts in ownership. Ecological Mangrove Restoration (EMR), which puts a premium on restoring natural hydrology to restore abandoned fishponds, has been applied in several countries but is not fully practiced in the Philippines. This study was done to pioneer ecological mangrove restoration in the Philippines, identify gaps in the current institutional arrangement, and recommend the roles of key stakeholders in the implementation of EMR. The selection of abandoned brackish-water fishponds was coordinated with national government agencies such as the Department of Environment and Natural Resources (DENR) and the Bureau of Fisheries and Aquatic Resources (BFAR). Other sectors involved in the implementation of EMR include the Local Government Units, Academe and Research Institutions, People's Organization and local community members. The identification of the lead and cooperating agencies and their roles in each step of the EMR process were determined based on their mandates and technical capacities. Suggested modifications in the EMR process are presented such as sustainability mechanism options and the combination of natural regeneration with active planting for better applicability in the Philippine setting. The results are seen to contribute to policy recommendations to mainstream EMR in mangrove rehabilitation projects and initiatives.

S4.5 Session of Nordic-Baltic Ministers

S5.1 Forest Futures

Potential leakage of biodiversity risks under the EU Biodiversity Strategy 2030

S5.1 Forest Futures

Franziska Schier[1]
Richard Fischer[1], Eliza Zhunusova[1], Sven Günter[1], Susanne Iost[1], Jörg Schweinle[1], Holger Weimar[1], Matthias Dieter[1]
[1] Thünen Institute of Forestry, Thünen Institute, Germany

Abstract: The EU Biodiversity Strategy 2030 (EUBDS) aims to regain biodiversity through enhanced forest conservation and protection in the EU. Existing studies already suggest that this may lead to increased timber harvest in non-EU countries. The effects of such increased harvest and roundwood production on forest biodiversity elsewhere have not yet been evaluated. We aim to identify potential leakage of biodiversity risks as induced by the implementation of EUBDS. We set up a biodiversity indicator framework and quantify vulnerability with country-wise values for 26 biodiversity indicators, mainly from publicly available databases. For risk assessment, we weight single indicator values with country-wise modelled figures on changed timber production under EUBDS implementation. Nearly 80% of the indicators point to higher vulnerability in the affected non-EU countries. Roundwood production would be transferred to countries with, on average, lower governance quality, political awareness, forest coverage and biomass and with less sustainable forest management. These countries still have more natural habitat and intact forest landscapes, but higher risks of species extinction and lower shares of protected areas. Only a few indicators point to lower vulnerability and biodiversity risks outside the EU. We conclude that safeguards are needed to ensure that implementation of EUBDS does not cause harm to ecosystems elsewhere. In this regard, the EU regulation on deforestation free supply chains might have limited effects because it hardly considers the sustainable management of persisting and even expanding forests. But as long as forest management is less sustainable and as long as forest protection status is lower outside EU, sustained roundwood production in the EU is needed to avoid placing more pressure on more vulnerable ecosystems elsewhere. Decreasing species and habitat indicator values nevertheless call for conservation and protection schemes. Effective land use planning is needed to balance conservation schemes with roundwood production.

S5.2 Harnessing Effective Communication: Building a Bolder Narrative for Forestry and Forest Science

S5.3 How to incorporate indigenous and local knowledge in forest education, back to the roots

Application of indigenous knowledge in sustainable utilization and management of mangrove forest in Lamu County

S5.3 How to incorporate indigenous and local knowledge in forest education, back to the roots

Henry Komu[1]
Leilah Ndalilo[1], Emmanuel Kenga[1]
[1] Kenya Forestry Research Institute, Kenya

Abstract: Mangroves have played a long and important role in the history of human activity in the East
African coast and in particular Lamu, Kenya. Mangrove forests in Kenya cover about 61,271 ha, with 67% occurring in Lamu County. The various goods and services derived from mangroves support the livelihood of about 80% of Lamu County's mangrove-dependent communities. However, over-exploitation of wood products, high poverty levels, lack of alternative livelihood, minimal community involvement, and poor governance has enhanced the degradation of mangroves hindering sustainable forest management. This has led to a series of presidential bans imposed on the exploitation of mangrove forests. The latest ban in 2018 had adverse effects on the livelihoods of mangrove-dependent communities prompting the government to lift the ban in Lamu, a year later. The community asserted that they have been sustainably utilizing and managing the mangroves for ages applying indigenous technical knowledge and hence shouldn't be denied user rights.

Inadequate information to support the role of indigenous knowledge in sustainable use and management of mangroves to apprise government decision-making informed this study. The overall objective was to document indigenous knowledge-based practices associated with mangrove utilization and management for integration into conventional management strategies for sustainable management of mangrove resources in Lamu County. Household surveys, Key Informant Interviews, and Focus Group Discussions were used to collect data in five sites with high mangrove dependents namely: Ndau, Faza, Pate, Mkunumbi, and Amu. The results indicated that traditional knowledge and associated practices are widely applied in mangroves' utilization, conservation, and management. The community practices selective harvesting of mangroves using non-destructive hand tools. The community also promotes mentorship and knowledge transfer from the elderly to young mangrove cutters for sustainability. Mangrove harvesting is also conducted on a rotational basis guided by monsoon wind patterns. This system allows controlled harvesting, enhancing the growth and recovery of already harvested areas. These traditional knowledge-based practices have contributed to the sustainable utilization and management of mangrove resources in Lamu County. The study recommends the integration of indigenous knowledge-based conservation strategies into conventional mangrove management strategies to enhance conservation interventions.

Bànglày at gàba: The Role of Traditional Shifting Cultivation Practices in Forest Conservation among the Molbog people of Balabac, Palawan

S5.3 How to incorporate indigenous and local knowledge in forest education, back to the roots

Aureneil Natividad[1]
Krisandra Mariano[1]
[1] Department of Social Forestry and Forest Governance, University of the Philippines- Los Baños

Abstract: Abstract

Shifting cultivation, commonly known as *kaingin* in the Philippines, is a traditional technique that consists of a crop cultivation phase that lasts for a year and involves clearing and burning primary or secondary forest, followed by a fallow phase. For centuries, indigenous communities have relied on this farming practice for subsistence. In the islands of Balabac, Palawan, the Molbog people have managed to continue practicing *Bànglày,* their own traditional swidden farming. With the country's policies prohibiting cutting in natural and residual forests, their freedom to practice their traditions and rituals are under threat. Using ethnographic methods such as in-depth interviews, participant observation, informal focus group discussions, and chaine operatoire with purposive sampling of informants, the researchers document the chain of operations in their practice of *Bànglày,* describe the conflict between this practice and current forestry-related policies, and situate the role of *Bànglày* in forest conservation within their ancestral domain. The findings of this study reveal that the rotation of the clearing, planting and resting period of *Bànglày* play a significant role in conserving their remaining forests. Contrary to the *incipient type* of shifting cultivation practiced by lowlanders and migrants in upland communities, the Molbog people still perform rituals before clearing the forest, a symbol of respect to every organism that will be affected by their activity. In spite of the exemption to the law for indigenous people in light of the Indigenous Peoples' Rights Act of 1997, policy implementers and indigenous leaders should be strategic in demarcating whether the current *Bànglày* practices contribute to the conservation of *gàba,* their forest.

Keywords: Shifting cultivation, traditional, forest conservation, indigenous peoples, indigenous knowledge

Evaluation of university forestry curriculum for job competencies and emerging job opportunities for forestry graduates in Nigeria

S5.3 How to incorporate indigenous and local knowledge in forest education, back to the roots

Alex Bimbo Onatunji
David Ayoola Shonowo[1, 2], Folaranmi Dapo Babalola[1, 3]
[1] Department of Forest Resources Management, University of Ilorin, Nigeria
[2] International Forestry Students' Association (IFSA)
[3] International Union of Forest Research Organizations (IUFRO)

Abstract: Current job markets seeks graduates who meet the desired specifications for an advertised role. However, the level to which forestry education imparts the required knowledge and skills to graduates is not well known. The study, therefore, employed an exploratory behavioural interview model to evaluate the post-forestry education of fifteen forestry graduates between 2010 -2016 across eight Nigerian universities. The study aims to determine if the forestry curriculum is sufficient to prepare graduates with skills to meet job requirements. The majority of the interviewed graduates were males, and they completed their bachelor's degrees when they were between the ages of 22 and 28 years. Most of the respondents did not choose to study forestry at the university. Competencies related to the forest field were sufficiently covered in the syllabi. However, forestry graduates in Nigeria did not gain adequate working experience from their academic studies. Consequently, getting a job, especially in forestry, often took longer years. We recommend properly revising the Nigeria forestry curriculum to develop entrepreneurship skills and prepare forestry graduates for broader employment opportunities. The forestry curriculum should also pay more attention to developing students' professional skills to meet emerging job opportunities.

Fungal Pathogens Affecting the Red Pod Terminalia Flowers, Fruits and Seeds in Drylands, Kenya

S5.3 How to incorporate indigenous and local knowledge in forest education, back to the roots

Michael; Okeyo[1, 2]
Jane Njuguna[3], Gilbert Obwoyere[4], Dickson Makanji[4], jackline Atieno[4], Joseph Machua[3], Prisila Kimani[3], Arnold Mosongo[5]

[5] 4Moi University, P.O. Box 3900 - 30100 ELDORET, KENYA

Abstract: The Red Pod Terminalia (*Terminalia brownii Fresen*) is in the Combretaceae family, it's a multipurpose agroforestry tree species widely grown in Arid and Semi-Arid Lands (ASALs) of East Africa. However, it has been over-utilized and its products such timber, posts, curving wood and seedlings are not available in the required quantities. Poor seed germination is attributed to fungal and insect infestation during flowering and fruit development. The study investigated the effect of fungal pathogens on viability of *T. brownii* seed. This study was carried out in three sites representing distinct ecological regions in agrosilvopastoral systems where *T. brownii* trees are naturally distributed in drylands of Kenya. The study sites were Nduumoni, Kimose and Kendu Bay, in Kitui, Baringo and Homa Bay counties; which are next to existing research experimental plots under the Kenya Forestry Research Institutes (KEFRI). The study investigated incidences of fungal disease infection in flowers, fruits and seed during their growth. Flower buds, flowers, and immature and mature fruits were sampled for culturing from 30 trees selected randomly within 5.0 hectares per site. Samples of 100 flower-buds, flowers, immature and mature fruits and seeds were surface sterilised using 40% hydrogen peroxide for 2 minutes and rinsed with distilled water. These were plated on Malt Extract Agar (MEA) and incubated at 28±2ºC for seven days. Fungal colonies were evaluated and sub-cultured to obtain pure cultures, and pathogens were identified using morphological characteristics and PCR techniques. Statistical analyses were done using the Kruskal-Wallis and Bonferroni multiple comparison tests to determine the differences among the sites. Common fungal pathogens isolated were *Fusarium* spp (42-49%), *Alternaria* spp (29-33%), *Bostryosphaeria* spp (4-12%), *Cladosporium* spp (38%) and *Pestalotia* spp (7%). There were significant differences ($p<0.05$) in fungal infection between flower buds, flowers, immature, mature fruits and extracted seeds but not across sites. Flower buds had minor fungal diseases, thus indicating that infection took place during and after flowering. Fungal pathogens were isolated from flowers, fruits and seed, thus reducing seed viability across study sites and affecting field natural regeneration *T. brownii*. *Terminalia brownii* seed should be dressed with appropriate fungicides to promote their germination.

Manejo forestal comunitario en ecosistemas altoandinos ante el cambio climático: caso de comunidades en la cuenca de Apacheta Ritipata, Ayacucho, Perú

S5.3 How to incorporate indigenous and local knowledge in forest education, back to the roots

Aurea Erica Castro Aponte[1]
Walter Víctor Castro Aponte[2], Tulia Demetria García León[3]
[1] Conservation & Management of Ecosystems for Sustainability (COMAES)(Perú)
[2] Universidad Nacional Autónoma de Huanta, UNAH (Perú)
[3] Centro de Desarrollo Agropecuario, CEDAP (Perú)

Abstract: In recent years, farming communities around the world are playing an increasingly important role in managing forests, conserving ecosystems and preserving local traditional knowledge. In the Andes, since pre-Columbian times and as a product of community experience, Quechua peasant communities have a particular vision of the world, which is maintained to this day (Murra, 2004). This worldview, shaped by individual and community experience, shapes forest management strategies at the community level, ensuring food security, sustainability of local livelihoods, and resilience to climate change. The presentation seeks to generate knowledge about the way of managing natural resources based on technical and social aspects that the Quechua communities of Chuschi and Canchacancha, settled in the Apacheta-Ritipata and Chikllarazu basins in the Ayacucho Region, have been carrying out. The applied methodology is descriptive, qualitative and participatory. The local NGO CEDAP identifies community agroforestry systems, the use of water, rescue of customs, knowledge, techniques and traditional practices as key to the sustainable management of Andean resources. These practices also condition the organizational structure, power relations and collaboration schemes in the communities. When Peruvian state agencies are unaware or ignorant of such norms and practices, community social practices erode and conflicts arise. Finally, the findings suggest a model of sustainable forest management at the community level and local governance based on case studies of the Chuschi and Canchancha communities by monitoring organizational and cultural aspects in addition to ecological ones in the management of high Andean ecosystems through of sustainable community forest management.

Poor people in the community forestry landscape disproportionately burdened from crop raiding and livestock depredation

S5.3 How to incorporate indigenous and local knowledge in forest education, back to the roots

Conghe Song[1]

[2] Department of Forestry and Environmental Resources, North Carolina State University, Raleigh, USA

Abstract: Community forestry has become a major innovation in forest management in low- and mid-developing countries, aiming at forest conservation and livelihood improvement for forest-dependent people. Forest conditions have improved as a result of community forestry, providing ecosystem services that benefit the whole world, such as carbon sequestration and biodiversity conservation. The improved forest conditions also enhanced the habitat quality for wild animals, which generated negative externalities. Little attention has been paid to the unexpected disproportionate burden put on the poor people by crop raiding and livestock depredation by wild animals coming from these improved habitats as a result of community forestry. This paper presents findings from a study in the Middle Hills of Nepal, where community forestry originated in the country on the impacts of crop raiding and livestock depredation on local people's livelihood. We found that a large proportion of the rural households in the community forest landscape suffered losses from crop raiding and livestock depredation. Moreover, the poor households lost a much larger share of wealth from these negative externalities than the better-off households. No effective mechanism exists for these households to seek compensation to offset the losses despite the valuable global ecosystem services these forests provide.

Social and knowledge diversity in forest education: vital for the world's forests

S5.3 How to incorporate indigenous and local knowledge in forest education, back to the roots

Mika Rekola[1]
Terry L. Sharik[2], Sandra Rodriguez- Piñeros[3], Pipiet Larasatie[4]
[1] University of Helsinki, Finland
[2] Michigan Technological University, USA
[3] Universidad Autonoma de Chihuahua, Mexico
[4] University of Arkansas, USA

Abstract: An assessment of forest education was made 2020-2022 for the first time in global scale considering the status of tertiary, vocational, and technical forest education and training. The assessment utilizing online survey had 2741 respondents, of which 38 percent were women and 11 percent identified themselves as racial and/or ethnic minorities. However, it is likely that the digital survey did not reach various relevant groups living without modern communication facilities.

While exceptional institutions existed in many regions, several global level deficits were found. Coverage of *forest services and cultural and social issues* was weak in the curricula of many programmes. Inclusion of traditional and Indigenous knowledge was frequently poor or absent. Gaps were found in enrolment at tertiary education levels with respect to diversity in gender, race/ethnicity, and other societal groups. Based on the assessment one of the main results was that forest education programmes were lacking *knowledge and social diversity*.

Recognition and inclusion of traditional and Indigenous forest-related knowledge were particularly poor or absent as reported by students, recent graduates, teachers, and professionals in most parts of the world. This deficit in *knowledge diversity* is resulting in forest professionals missing invaluable opportunities to learn from a variety of knowledge systems and from the unique capacities of traditional and Indigenous cultures around the world.

The assessment identified gaps in tertiary education enrolment. Many hesitate to enroll in forest education and training programs and experience difficulties in finding decent employment in forest-related fields. Some lack opportunities to access formal education. *Social diversity* shortfalls in programmes are resulting in sectoral underrepresentation and underservice in education, practice, and policy. Examples include under-recognition of forest economic activities that principally involve women, unsafe working environments for women, and lack of representation amongst state officials governing lands used by Indigenous Peoples.

If unaddressed, forest researchers, professionals, and workers will continue to lack distinct knowledge systems and inclusive representation. Improvements in forest-education-related research, monitoring, policy, curriculum, recruitment, and promotion are recommended. Without remedial action to build a representative, skilled and knowledgeable workforce, prospects for forests to meet local, national and global goals are at risk.

The Fire and the Forest other views from Abya Yala

S5.3 How to incorporate indigenous and local knowledge in forest education, back to the roots

Ana Maria Monsalve Cuartas[1]
Adriana Maria Walker S[2], Agapito Chuctaya Alccamari.[3]
[1] Lisbon University. Agronomic Superior Institute. Portugal
[2] Indigenous University Project. Freiburg University. Alemania .
[3] Salamanca University Science and Technology Studies Institute . España

Abstract: Colombia and Peru have approximately half of native forests in the hands of Indigenous Peoples and Local Communities, these lands are important to safeguard biodiversity, for adapting and mitigation face to climate changed and for conservation of local knowledge (Monsalve, 2021)

The disconnection between human being and native forests is growing in our times. It should be noted that the distance between one and the other has not been physical (we have never depended on trees and forests as much as now).The disconnection is emotional and spiritual. We do not see them as the amazing organisms that enable our life on earth. Most people identify forests as an inexhaustible object or resource that provides us with material to satisfy our individual and collective needs. (Jara 2018)

The profound lack of interest that many individuals of our species show towards the extraordinary kingdom of trees has led us to place such complex organisms on the same level as plastic bags: on the shelf of the useful but inert.

Many indigenous communities from Colombia and Peru don’t have separation between ‘forests’ and ‘people’. However, this true is very hard to understand by forest scientists and policy makers. Other example is the concept and management of fire in indigenous communities lands, where fire is a spirit that can help as a tool for clean and build new forest spaces and new human bodies. This article is a reflexive and critical approach to understanding the present state of knowledge, its foundations, conditions, and practices related with fire into a forest indigenous territories in Colombia and Peru.

The knowledge about fire and forest territories under other perspectives, offers a unique opportunity to study and learn about the biophysical and social materialization of complex multidimensional relationships and processes in the identification, recognition and management of fire in forests and indigenous territories.

The perception, knowledge and spiritual management of fire for three ethnic groups in Colombia and Peru can help to understand and support information about ecological, cultural, and social values, traditional knowledge, and rights of Indigenous Peoples and Local Communities (IPLCs) in forest programs.

THE IMPORTANCE OF INDIGENOUS TECHNICAL KNOWLEDGE ON VARIOUS USES OF NATURAL FOREST PRODUCTS; CASE STUDY OF LOIMA HILLS, TURKANA COUNTY

S5.3 How to incorporate indigenous and local knowledge in forest education, back to the roots

Roxventa Ongugo[1]
Patrick Mwenja[1], Basil Kaudo[1]
[1] KEFRI

Abstract: Indigenous knowledge is the local knowledge - knowledge that is unique to a given culture or society. It is the basis for local-level decision in agriculture, health care, food preparation, education, natural resource management, and a host of their activities in rural communities. Many forest communities possess considerable knowledge of the natural resources they use. Such knowledge can potentially inform scientific approaches to management, either as a source of baseline data to fill information gaps or to provide alternative management approaches from which scientists and managers might learn. However, little attention has been given to the relevance of such knowledge for resource management. Traditional institutions are generally instrumental in natural resource management and rural development processes at large. A study was conducted in Loima forest in Turkana County to document practices indicating the use of local knowledge on various uses of natural forest products, document the link between traditional custodianship and use of natural products to enhance community livelihoods and to document the socio-economic factors influencing local practices, use of natural products and traditional institutions. The study used household questionnaires and Focus group discussions for data collection and a total of 150 respondents were interviewed for household questionnaires and 13 key informants for the FGDs. Results indicated that there were trees species and other forest products of importance to the community. These species were *Vachellia tortilis* pods used for food and fodder especially during dry seasons, *Salvadora persica* roots, leaves and fruits used as medicine, water coolant and food, *Aloe turkanensis* leaves used as medicine for stomach issues, the gum is used for Malaria treatment, *Cordia sinensis* was used in traditional wedding ceremonies, to make the traditional stool used by the men known as '*Ekicholon'* and *Zizyphus Mauritania* used for food and fodder, the twigs are also used to light fires. The community also has Ekwars which are pieces of land which have specific species protected for grazing during dry seasons and are normally found along the river banks. Data collected indicates that traditional knowledge plays a huge role in conservation and livelihood improvement among communities adjacent to forests.

The role of local institutions in sustainable forest landscape management

S5.3 How to incorporate indigenous and local knowledge in forest education, back to the roots

Agnes Sirima[1]
[1] Sokoine University of Agriculture

Abstract: In recognizing the importance of indigenous groups and local communities in forest management, governments are shifting the forest tenure systems to local and indigenous communities. This relatively new innovative approach serves as an opportunity for sustainable forest initiatives and economic development for some of the marginalized communities. This paper examines the role of local indigenous institutions in the management of Community Forests. Qualitative study was carried out in Tanzania to ascertain the claim. A total of 46 individuals participated, out of these, 17 were females and 29 were males. Review of practical examples else where was drawn to enrich the selected case. Thematic analysis was conducted and several themes were generated during the analysis. Results indicate that Community Forests are managed under a complex set of power structure with several local institutions actively engaged in the management of forest resources. There are internal conflicts among institutions, each questioning the role of the other. However, local institutions still play a strong role in the community conservation efforts by creating awareness and building capacity among members. Local institution also ensure that users are identified and the benefits are shared among the right users. It is therefore important to build capacity of local institutions to enable them to effectively contribute to forest conservation and management.

What Makes Your Forest Unique?

S5.3 How to incorporate indigenous and local knowledge in forest education, back to the roots

Wening Idzatilangi[1]
Annie Biju[1]
[1] International Forestry Students' Association

Abstract: What Makes Your Forest Unique? is a participative project from forestry students around the world to capture the diversity perception of forest valuation paradigm. It compiles case studies from the field about cultural issues, forest management history, local ecological knowledge, movements, and Free, Prior, and Informed Consent of IPCLs. We see that in regard to forest valuation, monetary mechanisms such as timber or carbon trade can't provide justice solutions to many stakeholders including Indigenous People and Local Communities (IPLCs). Current valuation mechanism suggests an unbalanced sharing benefit and interest between capitalist and the communities (Mathur et al, 2013; Saunders et al, 2002). It is because the communities lack appropriate recognition in regards of land tenurial, human capacities, and financial resources (Robinson et al, 2014). While current forest valuations are the interim and calculable solutions to conserve the forest, it also brings threats of reducing the respect of IPCLs existence even erasing their livelihood (Rights and Resources Initiative, 2009; Renwick et al, 2014). Hence, the connection of IPCLs with the forest or the land over generations creates local important knowledge such as agricultural practice, medicine, and the cycle of climate change (Salim et al, 2023). In the era where the data spread so fast, any kind of effort like research, advocacy, and policy making for encouraging IPCLs to achieve its inclusivity is advanced (Valijärvi and Kahn, 2023). Combining that privilege and providing a platform where young foresters can take part in the effort of preserving the work continuation can be an advance work. The result of this project is aligned with the effort of documenting the local ecological knowledge to make the forest management become more diverse and based on local needs (Rai and Mishra, 2023). It also hoped any cultural issue in the forest can get more attention not only about describing it in textbooks but also to advocate the values and be one of the development intervention plans to revive the IPCLs interventions in decision making activities (Wiersum, 1997).

S5.4 In practice of a gender equal and inclusive forestry sector

A Sector Wide Approach to Shifting the Workplace Culture to be More Welcoming to All People - A Case Study

S5.4 In practice of a gender equal and inclusive forestry sector

Kelly Cooper[1]

[1] Centre for Social Intelligence Inc.

Abstract: Starting in 2018, the Centre for Social Intelligence and the Canadian Institute of Forestry joined forces to lead the development of a sector wide national action plan that aimed to increase the number of women in senior executive roles and in technical positions in Canada's forest sector.

This public-private funded partnership brought together representatives from the public, private, not-for-profit, academia and Indigenous communities to unite their efforts toward this goal and to create a new shared vision for the sector – one where Canada has a diverse and inclusive workforce that provides the foundation for a thriving forest sector and healthy communities. The national action plan was broken down into three main pillars of work:

- Building the evidence base (gathering data on gender and diversity in Canada's forest sector workforce)
- Fostering an inclusive culture (through training materials)
- Repositioning the sector (through communications)

Now in its second phase, and due to the online interest during the pandemic, the focus of engagement has recently shifted from a national to a global audience and is now considered a *movement*. It provides the opportunity to:

- sign on to a "declaration of intent" (i.e. commitment)
- participate in training webinars
- provide practical online training modules and
- communication shareables that everyone can use.

Online training topics include:

1. Explains why forest companies and organizations need to take action on diversity and inclusion
2. How to be an effective ally
3. How to create an inclusive culture
4. How to overcome barriers and resistance to diversity and inclusion

Strength – Unity across the sector with a common message and mandate. Strong leadership.
Weakness – Need greater funding to make a greater impact.
Research – Could develop social indicators to allow organizations to track gender diversity data for labour market needs across the sector.
Next Step – Engage leaders in the forest sector globally. Have people sign up for training modules to allow greater knowledge and understanding on the reason why action should be taken and how to

go about it.

Come and learn how you can join this movement and contribute to making the forest sector a magnet for top talent.

Equal chances in forestry - making forestry more equal and inclusive

S5.4 In practice of a gender equal and inclusive forestry sector

Iza Pigan[1, 2]
[1] Women in Forest Association
[2] National Forest Holding the State Forests

Abstract: The project founded by EEA and Norway Grants was realized in 2021-2022 by Women in Forest Association (Poland) together with Norway and Iceland partners. Main goal was to improve women's situation in forestry and draw attention to existing inequalities. The addressees were people associated with the forestry industry, in particular female employees and managers in the national Forest Holding the State Forests.
The project has been divided into four complementary areas:
1. Diagnosis and recognition - a research study of equal treatment in Polish forestry was carried out, with particular emphasis on the gender context. Over 4000 surveys were collected, with nearly 3900 completed by employees and close to 200 by HR departments. Respondents worked mainly in the State Forests, few answers came from national parks and forest departments.
2. Anti-discrimination education, addressed mainly to women - conducted as part of four editions of anti-discrimination workshops, attended by 60 women. The participants worked both in the State Forests and in other institutions. Additionally three conferences, dealing with the issue of equality activities in global forestry and in other institutions, in particular uniformed services, also had an educational value
3. International cooperation – study visits of female foresters in Norway and Iceland and revisit of partners in Poland, allowing to share experiences and know-how
4. Solutions: formulated as Good Practices Guideline - a study that is the sum of the experience gained during the project and long term activity including observations during study visits, conferences' discussions, networking and anti-discrimination workshops and recommendations resulting from the research part of the project. It is a short list of indications aimed at improving the situation of forestry workers in the area of equal treatment.
Additional part of the project was also development support for Women in Forest as an organization. It helped to improve strategic management and strengthen international links. Mutual cooperation and project synergy allowed to establish an umbrella organization connecting entities with a similar profile in other countries: Women in Forestry International.

Forstfrauen – an association for Women in Forestry

S5.4 In practice of a gender equal and inclusive forestry sector
Dagmar Karisch-Gierer[1, 2]
Elisabet Johann[1, 2]
[1] Forest Training Center Pichl (Project manager)
[2] Forstfrauen (Chairwoman)

Abstract: In the early 2000s, women in the very traditionally oriented Austrian forestry were very rarely active in the sector, be it as a forest owner or as an employee. Apart from (difficult to prove) professional disadvantages, the unique selling point "woman" and thus a special visibility based solely on gender was also associated. This visibility, which is not self-chosen, is sometimes perceived as a burden. Having a space where women are not "the only one" was the main reason for starting a network for women in forestry. Started in 2001 with 10 women the network soon started growing and in 2003 the association "Forstfrauen" ("Women in Forestry") was founded with 46 members.

Today (May 2023) "Forstfrauen" count approx. 150 members – in a small sector, in a small country. Why is the network successful? The short version: GAIN

- **G**oals: From the beginning, the goal was to network and strengthen women in forestry, i.e. a supportive approach. We wanted to make a difference for women and for forestry as a whole. This positive approach is appreciated both inside and outside.
- **A**ctivities: Networking takes place in a variety of ways – digitally (Newsletter, Website, LinkedIn), in presence, at events or on an individual level.
- **I**ntegration: "Forstfrauen" were increasingly perceived as part of the forest actorship, especially since the 2010s. Today "Forstfrauen" are represented in committees (e.g. PEFC), are partners in projects and are seen actively and specifically as an information hub, e.g. for media inquiries or job advertisements.
- **N**etwork & Members:
    - Since membership is not tied to relevant professional training, the members contribute a wide range of skills in addition to their professional background - from trainers for strategic communication to tax consultants.
    - Numerous members of the first hour have climbed the career ladder, others are at the beginning of their careers. Members in a wide variety of positions can get in touch with each other over short distances
    - Men were always invited to join the network – 6% of the members are men.

The challenge for the future is to keep our finger on the pulse - for people and forests.

Gender dimensions to climate resilience of cocoa farming systems in West Africa

S5.4 In practice of a gender equal and inclusive forestry sector

Elizabeth Asantewaa Obeng[1]
Christophe Kouame[2], **Mavis Akuffobea-Essilfie**[3], Julie Weah[4], Charles King[5], Aguilar Francisco[6]
[1] CSIR-Forestry Research Institute of Ghana
[2] World Agroforestry Center

[4] Foundation for Good Governance and Democratic Initiatives
[5] Liberian Central Agricultural Research Institute
[6] Swedish University of Agricultural Sciences

Abstract: Through a meta-analysis of the scholarly and development literature we examine how the adoption of agronomic-oriented agroforestry practices, and gender-focus policy interventions can advance the sustainability of cocoa farming systems in West Africa. We explore the capacity of these interventions in advancing Sustainable Development Goals ‘5: Gender Equality’, ‘8: Decent Work and Economic Growth’, and ‘15: Life on Land’ and SDG specific targets. We point to the importance of combining regulatory approaches that can enhance *de jure* conditions (such as laws limiting female land ownership), and engaging in a participatory process to improve norms that might limit full female access to credit (effectively in a *de facto* conditions that discriminate against women). During our review we identified the challenge of gender-aware statistics as well the opportunity of tailoring extension programs that explicitly consider gender issues. We complement this work with the analysis of survey data collected across Cote d’Ivoire, Ghana and Liberia to assess how agroforestry practices can enhance climate resilience by eliciting farmer-level capacity to cope with drought. Results show how gender disparities arise although we point to the challenge of quantitatively determine gender-based causality. Our research highlights the value of qualitative and quantitative assessments in examining opportunities to enhance the climate resiliency of cocoa farming in West Africa through agronomic and gender-centered interventions.

Gender equality in practice and theory

S5.4 In practice of a gender equal and inclusive forestry sector

Alice Ludvig[1]
Pipiet Larasatie[2], Gun Lidestav[3], Stephen Wyatt[4], Maureen Reed[5]
[1] University of Natural Resources and Life Sciences (BOKU), Vienna and EFI-FRPN
[2] University of Arkansas at Monticello, USA
[3] Sveriges lantbruksuniversitet, Sweden
[4] Université de Moncton, Canada
[5] University of Saskatchewan, Canada

Abstract: Since the Beijing Declaration in 1995, several international and national initiatives have sought to enhance women's participation in and experiences of working in male dominated sectors such as forestry. However, the framing of these initiatives differs depending on the overarching gender equality policies as well as the specific country or industry context. Typically, we are observing a shift from framing gender equality as a human rights issue to it being seen as a business advantage that enhances productivity and competitiveness. In such a framing, benefits to the workforce, organisations and society are emphasized over the benefits to women themselves, potentially leaving women vulnerable to future changes in economic conditions. Government and organisational policies typically reflect the dominant framing within that jurisdiction, in turn influencing programs and legislative measures that are used (or not used) to promote (or discourage) women's participation in these sectors. Distinct from such framing and policies, an increasing number of women-led networks and grass-roots initiatives are addressing the inequality of women and advocating and supporting the place of women in forestry.

Several theoretical approaches help us to understand the origins of gender inequality, as well as the ways in which it is maintained or challenged, including homosociality and inequality regimes. These concepts help us understand how individuals and complex organizational practices and processes create and maintain inequalities. Using theory to recognize the patterns and processes that apply to an organization allows us to question their legitimacy and supports realigning practices with the changing culture, policies, and norms of society.

The contributors to this panel have been promoting women's participation in forestry in the Global North (Sweden, Austria, USA and Canada) and the Global South (Indonesia). Their experiences with framing, policies, networks, and on-the ground initiatives helps us see how to move gender equality from theory to practice.

Gender justice through climate resilient green initiatives in Nepal

S5.4 In practice of a gender equal and inclusive forestry sector

Srijana Baral
Kanchan Lama[1]
[1] ForestAction Nepal

Abstract: The climate change associated risks and vulnerabilities have gender dimensions that increases inequalities and risks. In the current era, low carbon solutions are devised so as to mitigate climate change however; there is paucity of academic scholarships linking the potential synergies between women's economic empowerment and low-carbon transitions. This research is based on action research project that was designed and implemented to support the women to build social, economic and ecological resilience through forest-based solutions. Taking the case of two women entrepreneur groups- bio cup and plates the study analyses – i) how will the green jobs created enhance women's resilience; ii) how the nature based entrepreneurial solutions lead to ecological resilience, and iii) analyse how adoption of low carbon technology empowers women and gender justice in climate actions. 60 women entrepreneurs involved in were surveyed and four policy dialogues participated by 150 individuals were carried out to assess opportunities and challenges of forest based low carbon enterprises in economically empowering women. The results reveal that the target women groups are land-poor/landless who often get excluded from any land based economic activities consequently lack access to financial institutions. Engaging them in the small scale forest-based enterprises are accepted and welcomed by women for building climate resilience- social, economic, cultural and ecological resilience. It has been creating direct employment from collecting *Shorea robusta* (Sal) leaves, preparing *lapha**[1]*** preparation, operating machine and marketing their products. Use of bio-cups and plates economy is preferred over plastic economy having adverse impact on the women health. Moreover, use of low carbon technology has proven- efficient, reliable, time saving and easy to operate. Though the return from the forest based enterprises is moderate, these actions do not demand for detachment from their families. Hence, the use of low carbon technologies in the small-scale enterprises are economically and culturally appropriate to women groups as they rejoice their care economy while also contributing to the climate justice.[1] Lapha is the set of leaves arranged together to form be pressed to form the plate or bowl.

Joining forces and tackling problems: developing a national forum for gender equality in Swedish forest sector

S5.4 In practice of a gender equal and inclusive forestry sector

Elias Andersson[1]
Staffan Norin[2]
[1] Swedish University of Agricultural Sciences
[2] Swedish Forest Agency

Abstract: For more than a decade, gender equality has been of the agenda for the Swedish forest sector. Different types of actions and measures has been implemented on various levels. However, since the national gender equality strategy for the forest sector was launched in 2011, there has been an identified need for a forum for collaboration and coordination to support the work. In the beginning of 2022, as a response to this, the Swedish forest agency (SFA) initiated the Forest Sector´s Gender Equality Council in dialogue with the sector. Later the same year, a national forum was formed, which comprise of about 60 representatives, both gender equality experts and top management, from about 35 forest organizations (companies, forest owners associations, universitates etc.). The work is supported by the secretariat consistent of SFA and the Swedish University of Agricultural Sciences. Its aim is to contribute to the national Sweden's gender equality policy goals with the focus on three areas: education, working life and individual forest ownership. The work with these areas is developed by three working groups consists of 8-10 representatives from the council. The purpose of the council is to jointly develop both individual organizations' and the sector's overall gender equality work by e.g.:

- Identify and address common problems and challenge.
- Initiate strategic, long-term and integrated processes.
- Create a knowledge-based foundation for interventions and follow-up.

Providing a basis for a systemic and collective development of gender equality actions, on both sectorial and organizational level, constitute the main strength of the initiative, while the initiation by governmental agencies contributes to challenges in terms of creating active participation, sense of agency, ownership and responsibility of the council and its work. The high dependence on the participation and commitment of the represented organizations constitutes both a strength and challenges, while future expansions of activities and efforts of the council will require additional funding/resources.

Mainstreaming Gender within the Forest Stewardship Council (FSC) system

S5.4 In practice of a gender equal and inclusive forestry sector

Anakarina Perez Oropeza[1]
Marion Karmann[2], **Sinta Dewi**[2]
[1] FSC International, Strategic Advisor & Global Advocacy Lead
[2] FSC International, Adenauerallee 134, 53113 Bonn, Germany

Abstract: After an extensive two-year process, FSC approved the "FSC Strategic Framework on Diversity and Gender" in 2022. This Framework serves as a roadmap for FSC, enabling it to navigate complexity, maintain focus, and align with ongoing strategic efforts to mainstream diversity and gender (D&G) within FSC by 2026. Four focus areas for activities are laid out: human rights and access to resources, tenure, and use; active participation and decision-making by all stakeholders, including all genders and all levels of seniority; the gender gap; and rights-based climate and biodiversity action.

The Framework recommends striving for the full recognition of the multifunctionality of forests driven by the active and equal participation of all actors, including those in forest education, resulting in gender transformative change. As part of the implementation efforts, a gender action plan will provide more concrete interventions considering different levers and time horizons. An important development will start in 2024 as the revision process for the "FSC Principles & Criteria for Forest Stewardship" (P&C) will commence. These P&C form the foundation of FSC's global forest management certification. Currently, gender issues are addressed through a specific criterion within principle 2, which pertains to the social and economic well-being of workers. Acknowledging that gender mainstreaming requires a broader scope and perspective, the strategic framework calls for the incorporation of gender considerations into the outcome-oriented revision of the P&C, as well as the ongoing processes for revising specific indicators (performance requirements) in national forest stewardship standards.

We will also show how and when gender and diversity specialists and researchers can engage in FSC processes to ensure that gender considerations are effectively integrated in the FSC system and implemented in FSC-certified forest operations.

Situation of Gender Equality in Community Forests of Nepal

S5.4 In practice of a gender equal and inclusive forestry sector

Mathura Khanal[1]

[1] Mahila Hit Samaj, Nepal

Abstract: Abstract

Community Forestry is one of the most popular participatory forest management practices in Nepal started in 1970 after realization of the people's participation in the sustainable development by the government of Nepal. Community forests are national forests handed over to the local user groups for protection, management and utilization according to the Forest Act, 1993. Since 1970, the handover process of the CF have been increasing in the hilly region as well as in Terai. In Nepal, around 34% of the country's National forests as community forests are managed by more than 22,000 community-forest user groups. Although it is said that CF is a participatory process, active participation of different groups of the community is still lacking. In particular, women's involvement in many aspects of CF is still lacking far behind. Many amendments have been made in forestry sector policies and strategies for gender equality and social inclusion but leadership by women and Dalits in CF management become very challenging. Current forest policy has made mandatory to hold one of the major key posts (Chairperson, Secretary and Treasurer) in the CF executive committee. Therefore, main position of CFUC is occupied by female members however; the task has been performed by male members of their family or other male members of the committee. However, female are the main participants in conservation and harvesting of the forest products. Elite domination is still remaining in most of the CF leadership and weak institutional development exist.

Keywords: Community Forestry, Gender equality, Civil society, Conservation, Dalits.

The Brazilian Forest Women Network: promoting gender equity in the forest sector

S5.4 In practice of a gender equal and inclusive forestry sector

Barbara Bomfim
Ana Flavia Neves Mendes Castro[1], Fernanda Rodrigues[1], Giovanna Marcolin[1], Maria Harumi Yoshioka[1], Mariana Schuchovski[1], Nathália Granato[1], Patricia Nazario[1]
[1] Rede Mulher Florestal (Brazilian Forest Women Network)

Abstract: Rede Mulher Florestal (the Brazilian Forest Women Network) is a non-governmental organization created in 2018 with the mission of promoting respect for diversity and equal opportunities for women in the forest sector by discussing gender. The organization currently has over 180 individual members from all five regions of Brazil, as well as from other countries, and 30 legal entity members that represent over 50,000 people employed in the forest sector. The organization's creation was inspired by the question of "Where are the women in the Brazilian Forest Sector?" Based on this questioning, Rede Mulher Florestal organized the Gender Panorama of the Forest Sector in 2019, a pioneering initiative aimed at researching, identifying, and disseminating forest sector data focused on gender. The Gender Panorama had its second edition in 2021, and the third is scheduled for 2023. Companies with expertise in paper and cellulose, log and sawn wood, panels, and laminated floors, among others, participated in the research. In all editions, we found that there was a predominantly male participation in almost all positions surveyed, with emphasis on executive positions, where female participation was 8.1% in 2019 and 15.9% in 2021. On the other hand, organizations have been seeking to implement policies aimed at reducing inequality. In 2019, 45.8% of organizations had a specific policy or declaration committing to non-discrimination and promoting gender equality, and in 2021, this percentage increased to 63.2%. These gender-focused data suggest that achieving gender equity is still a long process, but the creation and ongoing work of the Network are fundamental steps towards progress. Based on the data generated by the Gender Panorama of Rede Mulher Florestal, organizations in the forest sector have an opportunity to improve or expand their policies related to gender equity, enabling a future with more gender equity in the Brazilian forest sector.

The changes of women's role in the succession of private forest ownership in Japan: using life course theory

S5.4 In practice of a gender equal and inclusive forestry sector

Miho Iwano Yamamoto[1]
Eriko Chino[2], Uichi Hayashi[1]
[1] Utsunomiya University, japan
[2] Kanto District Forest Office, Forestry Agency

Abstract: In Japan, private forest owners own not only forests but also farmlands, residences, and various other assets, and their presence and actions have influenced each community. The basic premise of this generational succession is the existence of women who have spent much of their lives supporting their families and relatives through marriage, childbirth, and child rearing. However, their behavior, which have been important factors in the social relations in farming and mountain villages and in the inheritance of private forests, have changed dramatically after a certain generation. Particularly since the mid-2010s, there have been cases of men inheriting forests and aging single, single women taking over forests, and children who have moved to the cities selling their forests along with their houses and graves. For Japan's private forests, which are often located in mountainous areas, this situation poses a land conservation problem. This study aims to clarify the role of women in the inheritance of Japan's private forests and its changes, and to develop a vision for the future. Cohorts are identified using life course theory. A "life course matrix" will be created for each person born in each year of the 200-year period from the 1800s, the period of Japan's early forestry, and compared to historical events to construct a basic data set. The following two points will be considered: 1) In the case study, the last generation of direct family members, led by the head of the family and his wife, who worked in the forest, farmland, village events, and community work, was born in the 1920s and 1930s. 2) Their children (born between 1947 and 1949) were the first generation of 'Rinken Forest Group' to organize a women's club and actively lead the group's activities. 3) The combo of these two generations is distinguished by the women (born in 1964 and later) who have worked in civil service forestry since Japan's Equal Employment Opportunity Law (1986), and the members of the "Forestry Women's Association" (born in 1987-90s) in the 2010s. At each of these life stages, relationships with local communities are being renewed and constructed.

S5.5 Integration of gender and diversity perspectives in knowledge production

A critical assessment of recognitional justice in urban forestry knowledge production

S5.5 Integration of gender and diversity perspectives in knowledge production

Lorien Nesbitt[1]
Jessica Quinton[1], Daniel Sax[1], Amber Grant[2], **Robert Kozak**[3], Lindsay Campbell[4], Leila Harris[5]
[1] University of British Columbia, Department of Forest Resources Management, Canada
[2] Toronto Metropolitan University, Department of Geography and Environmental Studies, Canada
[3] University of British Columbia, Department of Wood Science, Canada
[4] United States Forest Service, Northern Research Station, United States
[5] University of British Columbia, Institute for Resources, Environment and Sustainability

Abstract: Globally, cities are looking to their urban forests to improve climate resilience and liveability. Alongside this interest, there is an increasing focus on environmental justice in research and practice, with multiple cities incorporating equity provisions in their greening policies. Approaches typically reflect dominant discourses in urban forestry and environmental justice, namely the ecosystem services framework and distributive justice. And yet, urban forestry is motivated by and enacts diverse epistemologies, particularly at the grassroots scale. Recognition—respect for identities and cultural difference, and the ways in which agents, ideas, and cultures are valued in discourses, practices, and experiences—is a central and necessary component of environmental justice in urban forestry. However, it is understudied in research and poorly understood in practice.

To address this gap, we conducted a critical scoping review across academic literatures related to urban forestry. Our review (i) investigated the diverse ways in which relationships between human and non-human nature are expressed, and (ii) characterized these according to the Life Framework of Values to demonstrate how recognition of different epistemologies and associated environmental values occurs within the literature. Our results showed that most research advanced values related to 'living from' (the environment as a resource) and 'living in' (the environment as a place for recreation and other social activities) life frames, reflecting the dominance of ecosystem-services thinking. Research with a stronger ecological focus also commonly advanced the 'living with' frame (non-human nature as important others who coexist with humans). Less common within the literature was the 'living as' frame (the more-than-human as self, oneness, and kinship), which was most common in literatures from Indigenous and feminist scholarship, civic green space stewardship, and biocultural diversity.

Our findings show that recognitional injustice related to underrepresented epistemologies is commonplace within urban forestry literature. Urban forestry practices informed by existing research risk perpetuating environmental injustice by reproducing dominant discourses and 'only way' approaches. There is a clear need for urban forestry research to expand beyond ecosystem services and distributive justice to incorporate diverse and underrepresented perspectives. Such a move would support urban forestry practice that truly enables environmental justice and supports resilient, liveable cities.

Adaptive Collaborative Management and Gender in Forestry

S5.5 Integration of gender and diversity perspectives in knowledge production

Carol J. Pierce Colfer[1]

[1] Center for International Forestry Research

Abstract: This contribution will focus on a) the importance of incorporating the views, knowledge, and motivation of both community women and men into forestry research planning and conduct; and b) the necessity to implement a longer term approach like Adaptive Collaborative Management in order to do that. Specific emphases will include established (if variable) difficulties working with women, such as their

- lower literacy levels,
- less traditional power and authority,
- fewer available resources (money, land, rights),
- more domestic responsibilities, and
- more norms interfering with communication between women and outsiders,

on the part of women themselves; and avoidance of women by outsiders (related variably to

- fears about other people's suspicions of one's motivations [potentially sexual],
- unfair and unrealistic dismissal of women's relevance, or
- genuine dangers of working with women, in a few contexts).

This discussion will also touch on the importance of noting men's variable ideals about their own masculinity, which can be a potent force interfering with the empowerment of women – and resulting access to women's views, knowledge and motivations (in short, their potential contributions to forestry research and management).

The talk will also briefly introduce current work that builds on research done in the 1970s. This research examines what an American school was teaching children and youth during that era, and suggests the implications of those lessons for present-day adult scientists and policymakers in forestry research.

Anthropogenic climate change around forest ecosystems implications for gender equality

S5.5 Integration of gender and diversity perspectives in knowledge production

Ndirangu Ngunjiri[1]
[1] University of Nairobi

Abstract: The article also discusses the gendered impacts of climate change on forest ecosystems. Climate change exacerbates existing gender inequalities and can increase women's workload and reduce their access to forest resources. The main objective of the study is to critically examine the relationship between gender equality, climate change, and sustainable development. Both secondary and primary data were employed, with a combination of qualitative and quantitative research methods. Household surveys were conducted to gather quantitative data on the impact of climate change, gender equality, and sustainable development in Kenya. The population target was 2,000 people in 47 counties, the respondents were 1, 470, and the period of the study was 2019 to 2022. Projected climate change poses a serious threat to gender equality and sustainable development; it acts as a threat multiplier for instability in some of the most volatile regions in Kenya; projected climate change adds to tensions even in stable regions. Climate change-related shifts in rainfall patterns and increased frequency of droughts have led to resource scarcity and competition, exacerbating existing social and economic vulnerabilities, especially on women Local authorities lack the resources, capacity, and coordination needed to effectively manage the impacts of climate change on gender equality. The study findings reveal that climate changes are led by human actions such as population pressure, political motives influencing occupation of the forest land, growth of subsistence agriculture, logging, charcoal making, and rural-urban development. To address the climate change threat to sustainable development and gender equality in Kenya, gender-sensitive adaptation strategies are needed. International support is critical to addressing the climate change threat to gender equality in Kenya. While dealing with climate change issues, national policies are guided by taking into consideration addressing sustainable growth dimensions as a major threat to forest lands. The study concludes that the areas around the forests are experiencing rapid climate changes, including recurrent and persistent drought periods and rainfall variability. These changes in the local climate pose unprecedented implications for the sustainable development of the country and the region that depends on the forest complex.

Beyond Knowledge and Information: Addressing disjunctures in knowledge production and communication

S5.5 Integration of gender and diversity perspectives in knowledge production

Seema Arora-Jonsson[1]
[1] Swedish University of Agricultural Sciences

Abstract: Rights and control over forests are at the centre of conflictual relations all around

the world and have given rise to public debates that focus on biodiversity, sustainability and issues of democracy in relation to development and environmental governance. Political decentralization and the participation of local people in local development and management of resources that was on the agenda in the previous decades has given way to a rhetoric of the importance of new actors especially private interests. The need for knowledge and the free flow of information has been advocated as important to be able to meet the challenges for sustainable environmental management.

However, there are problems with the assumption that this would automatically lead

to better management. In my intervention, I advocate a different perspective and take up

three different and yet interrelated issues. Firstly, there are different kinds of knowledge

usually represented as most important by different groups of people. These are by no means

hermetically sealed but also need to be able to relate to each other for people to be able to

communicate on particular environmental issues. A second related issue is that the same body

of knowledge can look very different from different perspectives: knowledge for what and for

whom? Lastly and importantly, communication and deliberation about environmental

issues is not enough if we come from different structural positions. Using examples from my past research, I discuss how attempts at local management of forests brought up

these three issues poignantly from cases across the world. In part I will discuss how unequal (gender) relations made the idea of dialogue and discursive democracy limiting. Greater expert knowledge or greater information was not helpful for marginalized groups if it there was not at the same time a change in the structural basis of power relations.

Beyond notions of technicality: Forest science is need of plural conceptualizations of knowledges & practices

S5.5 Integration of gender and diversity perspectives in knowledge production

Kalpana Giri[1]
[1] World Resources Institute

Abstract: Forest science, in academic spaces, has largely been positioned as a technical science. This framing, while useful to build technical knowledge, also creates a narrow epistemological entry-point to better elucidate the larger social, political, financial, gendered playing field in which forests and people interact. Forest practice, on the other hand, remains plural, and shows a diversity of ways several social actors including women, marginalized groups, development practitioners generate and practice forest knowledge. Yet, these operate in distinct spaces, allowing lesser learning, reflection, and opportunities for integration. Using existing literature, case studies, and ethnographic reflection, I argue the need to connect these two spaces, and offer pathways to do so. These discussions are aimed to generate a better understanding of forest science and knowledge from diverse actors' perspectives and their relational connection to forests.

Changes in cyclist patterns in a State Park: a gender perspective

S5.5 Integration of gender and diversity perspectives in knowledge production

Emerson Soldado[1, 2]
Gabrielle Abreu Nunes[1], Vânia Loureiro[3], Nuno Loureiro[3], Teresa Magro-Lindenkamp[1]
[1] University of São Paulo, Brazil
[2] Federal Institute of São Paulo, Brazil
[3] Polytechnic Institute of Beja, Portugal

Abstract: During global health crises like the COVID-19 pandemic, there has been a significant increase in the demand for natural spaces, leading to a growing interest in outdoor recreational activities such as cycling. However, despite this overall increase, gender disparities persist as a significant feature, related to access to protected areas. This study aimed to assess gender inequality in bicycle usage among men and women in the post-pandemic period (2021-2022) in the Juquery State Park, São Paulo, Brazil. Our database was Strava Metro, which compiles data from the sports application Strava, with information collected from January 2018 to December 2022, excluding the months of 2020 and 2021 when the park was closed. The results showed a significant increase, $t(29.47) = -5.63$, $p < 0.00001$, in the average per month in the number of post-pandemic cyclists ($M = 214.60$) compared to the pre-pandemic period of 2018-2019 ($M = 138.65$), as well as a gender disparity. In the pre-pandemic period, male cyclists accounted for over 90% of the total while the female proportion was less than 10%. In the post-pandemic period, the proportion of female cyclists increased, but gender inequality remained noticeable. The proportion of female cyclists reached a maximum of only about 23% of the total individuals. A chi-square test for proportions confirmed a significant change for this data, $X^2(1) = 91.921$, $p < 0.0001$. Conversely, the proportion of male cyclists decreased from 90.98% to 83.97% post-pandemic. Although the post-pandemic dataset showed a general increase in the number of cyclists and, mainly, in the proportion of female participants, the frequency of male and female individuals is far from similar. These findings highlight the persistent gender disparities in access to natural spaces and recreational activities, emphasizing the need for managers to consider the underlying issues behind this inequality and incorporate them into the planning of these areas. One of the hypotheses we will work on is related to the safety of cyclists, if the risks are real, or if they are imposed by gender. Furthermore, understanding the reasons that led to the increase in the number of female cyclists in the protected area studied is an important future development.

Drawing the Line in Gender Blind Land Restoration: Case studies from the Savanna Parklands of Ghana and Burkina Faso.

S5.5 Integration of gender and diversity perspectives in knowledge production

Gloria Kukurije Adeyiga[1, 2]
Tim Pagella[2], Emilie Smith Dumont[3], Katrine Turner[4], Ana-Maria Peaz-Valencia[5]
[1] Forestry Research Institute of Ghana (FORIG)
[2] Bangor University, Wales, United Kingdom
[3] Independent Consultant, Lisbon Portugal
[4] Independent Consultant , Copenhagen, Denmark
[5] Alliance Bioversity-CIAT, Costa Rica

Abstract: The parklands of northern Ghana and south central Burkina Faso comprise mosaic landscapes of forest and farmland. The tree systems at the interface between these two systems play a critical role in supporting smallholder livelihood systems and providing ecological restoration pathways to address degradation. Degraded landscapes attracts several restoration initiatives, often focused around vegetation increases, seeking to address increasing climate vulnerability to food security. Trees play an important role in meeting the livelihood needs of woman, particularly in critical food gap months when many households have exhausted farm supplies. Despite the prominence of trees in woman's livelihood systems, their access to tree products is often constrained by underlying gender norms that limit their access and agency in terms of how trees are managed across a landscape. This imbalance is often neglected in restoration initiatives resulting in inequitable outcomes for woman despite women's livelihood being directly tied to tree resources and tree products directly underpinning household livelihood security. This study used gendered participatory mapping of the forest-farm mosaic and household surveys to collect data on land use access and valuation for ecosystem services. Results show a heterogeneous parkland landscape with several complex land use access regimes restrictive to women. Land uses with the highest livelihood potential for woman were a low priority for restoration initiatives forcing woman to travel longer distances (at greater risk) to access tree products. Distinct gendered norms that have evolved these complex gendered access and control regimes gives men control over valuable which was shown to influence men and women's valuation of key provisioning ecosystem services in both countries. The paper outlines the case for rebalancing restoration intervention design and planning by explicitly engaging with the underlying gender norms that maintain access restrictions to enable more equitable (and effective) outcomes of land restoration.

Equal chances in forestry - case study

S5.5 Integration of gender and diversity perspectives in knowledge production

Iza Pigan[1, 2]
Wieslawa L. Nowacka[3], Irena E. Kotowska[4], Ewa Lisowska[4], Iga Magda[4], Anita Abramowska-Kmon[4], Wojciech Latkowski[4]
[1] Women in Forestry Association
[2] National Forest Holding the State Forest
[3] Warsaw University for Life Scinces
[4] Warsaw School of Economics

Abstract: The project has been conducted in Poland by Women in Forestry Association together with partnering organizations from Norway and Iceland. Its aim was to fill the knowledge gap and prepare recommendations for good practices in gender equality.
The part of the project was to run a survey on gender equality making use of the Gender Index (GI) approach. GI approach was previously elaborated to evaluate gender differences
in work place. It was used in several organisations, also in forestry (in 2012). The current study makes it possible to find out changes over 10 years as regards women's and men's position in forestry. The CAWI survey has been run in the State Forests, main employer in Polish forestry, managing 75% of all the forest area.
Over 4 000 questionnaires were collected. The survey data have been analysed both in total (total GI) and domains distinguished (seven domain-specific gender indicators).
Since 2012 a visible increase of female employees in the State Forest has been observed up to nearly 30%. The share of women in decisive managerial positions remains very low (3%).
Despite some measures undertaken in the State Forests there are no significant changes for the better. Additionally, there is a strong regional diversity in the GI, which is difficult to explain considering a high unification of internal regulations of the State Forests.
The most gender inequality refers to protection against mobbing and harassment, while the access to training reveals the best gender equality indicator. The crude gender pay gap is relatively high (10%) while the adjusted pay gap is 2.7%. The wage difference between women and men results mainly from job segregation and retirement age by sex.
The main problem of management practices is unawareness and neglecting the area of gender inequalities.
Results of our study made it possible to formulate a broad range of recommendations, showing the most important measures to improve the situation.
They may be grouped as follows:
monitoring regarding women's share on different levels of the professional hierarchy and a gender pay gap
trainings for managers and employees
cohesive gender policies
supporting and promoting women

Five archetypes to discuss gender, gender roles and forest fires in the context of extractivism and climate change

S5.5 Integration of gender and diversity perspectives in knowledge production

Marien González-Hidalgo[1]
Ana Cabana Iglesia[2]
[1] Swedish University of Agricultural Sciences, Uppsala, Sweden
[2] Universidade Santiago de Compostela, Spain

Abstract: In our collective imaginations, forest fires are still “male” issues. However, it is evident not only that women participate actively and diversely in the event of a fire, but that they are also present in daily work to prevent them, both in the past and in the current context of environmental and climate change. Based on the question "What different roles do women have in forest fires?", in this communication we will present our work in progress that critically analyses, on the one hand, the publications on the subject. On the other hand, we will present field observations of the role of women in contexts of forest extractivism based on tree plantations - their practices, knowledges, care and resistance - around forest fires in Spain, Sweden and Chile. The three territories are characterized by having undergone major environmental and territorial transformations and dispossessions based on the implementation of pine and eucalyptus forest plantations. Based on the material analyzed - press documents, interviews, participant observation, etc. - we argue that the presence of women around forest fires is repeatedly structured in roles that we synthesize as follows: "the strong", "the victim ", “the caretaker”, “the wise” and “the witch”. The analysis of these archetypes helps to consider the diversity of women's roles in relation to forest fires, so that the possibilities of just socio-ecological transformations are considered beyond the invisibility or the caricature of the role of women in contexts of extraction and environmental disaster.

Gender differentiated energy use choice in rural households: Evidence from the giant panda nature reserves in China

S5.5 Integration of gender and diversity perspectives in knowledge production

Yijing Zhang[1]
Jinyu Shen[1], Wei Zhou[1], Wei Duan[1]
[1] South China Agricultural University, College of Economics & Management, Guangzhou, China

Abstract: China's economic development faces tremendous pressure from energy constraints, energy conservation and emission reduction. Since rural energy consumption accounts for more than 30% of the total energy consumption and the strict implementation of the ecological-priority principle in nature reserves, focusing on energy use choices in rural China is crucial. Using field investigation of 943 samples in 17 giant panda nature reserves in Sichuan and Shaanxi provinces, this study uses the exogenous switching treatment effect regression to explore the behavioral difference in energy use among the gender of rural households. Results showed that household income and off-farm income ratio directly impact the energy use choices among all household types. Education level only affects energy use decisions in MHHs (male-headed households) and De facto FHHs (i.e., a household where the husband is away). Forest size and distance from home to forest significantly impact dirty energy use in De jure FHHs (i.e., a household run by a single, widowed, or divorced woman). By comparing the energy use choice among MHHs, De facto FHHs and De jure FHHs, it showed that De jure FHHs would have the highest probability of choosing dirty energy, and De facto FHHs would have the lowest. The significant treatment effects indicating that the energy use differences between MHHs, De facto FHHs and De jure FHHs could be explained by resource endowment and return differences of these household types. However, the unobserved institutional and structural challenges different household types face have less explanatory power. Hence, policy supports on skills training and daily life subsidies are expected especially for De jure FHHs to decrease their reliance on forest natural resources. In addition, improving environmental protection awareness and self-health recognition are still needed to increase the life quality of rural households in nature reserves.

The integration of gender dimension at research of environmental legal sources

S5.5 Integration of gender and diversity perspectives in knowledge production

Clara Maria Minaverry[1, 2]
Analia Scarselletta[1, 2]
[1] Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET) - INEDES, Universidad Nacional de Luján
[2] Departamento de Ciencias Sociales, Universidad Nacional de Luján

Abstract: Most qualified public policies related with Environmental Law were elaborated from the contributions made by expert researchers, from the public and private sector, and the whole community, by combining their scientific knowledge and their social institutional expertise to face the complexity of socio-ecological and legal systems. The discipline of Law has limited quantity of methodological tools, so it is important to implement and adapt other which are provided by Social Sciences to obtain solid scientific results. This will be applied at the analysis of legal sources such as regulations, jurisprudence, and doctrine. The methodological strategy of this proposal includes the gender dimension because legal and environmental issues tend to be designed with the assumption that a community is homogenous and has shared interests. Also, some studies about gendered nature of ecosystem services should be considered because they state that they are important for the elaboration and application of public policies and future legal sources. Some authors as K. Bartlett state that without prior consideration of the gender dimension, this can generate unintended trade-offs across sub-groups of individuals that hold variable preferences, opportunities, and constraints. Because of gendered roles, responsibilities and asymmetrical power relations in the household and community, interventions that alter access can differentially affect women. In this regard, it is relevant to consider the epistemological implications of feminist legal methods by examining the nature of the assertions they generate considering the following techniques: rational empiricism, epistemology and postmodernism, and the positioning. The methodological approach of our research projects should include a gender approach which have a relevant role in connection with the analysis and proposal of legal guidelines for future regulations and public policies, to assure that there will be an equal management and protection of forests performed by all citizens and that these legal texts make these aspects visible. In this regard, it is necessary to apply and adapt different feminists' theories which were designed for its application to Law and work jointly with specialists and combine it with other social techniques.

What is the evidence that gender affects access to and use of forest assets for food security? A tool for decision-making.

S5.5 Integration of gender and diversity perspectives in knowledge production

[5] School of Archaeology, University of Oxford

Abstract: A systematic evidence evaluation was undertaken to test the hypothesis that there are wide gender disparities in access to and use of forests, and that better food security outcomes can be achieved for individuals and households when women have equal access to forests in communities that depend on forests for their livelihoods. Ten bibliographic databases and 22 websites of international development and conservation organisations were searched using keywords suggested by stakeholders. Other articles were found by emailing authors and organisations to send potentially relevant publications. 19,500 articles were retrieved from bibliographic databases and 1281 from other sources. After iterative screening, 77 studies were included: 41 focussed on Africa, 22 on Asia, 12 on Latin America, 2 were global. Most indicators of food security measured access to food, measured by total consumption, expenditure, or income. Studies showed that there was strong gender specialisation in roles associated with use of forests. Commercial access and utilisation of forests and forest products were dominated by men, whereas access for subsistence and household consumption was almost exclusively the task of women. The systematic evidence evaluation revealed critical gaps in the evidence base, including geographical representation in primary research and a range of study designs for evaluation of the review topics. Results of the systematic evidence evalaution were used to create an interactive evidence map, which can be used as a tool for decision-making and to focus further research.

“You’re not a “forester” – marginalized voices and unequal relations in professional forestry practice.

S5.5 Integration of gender and diversity perspectives in knowledge production

John Boakye-Danquah[1, 2]
Effah Antwi[2]
[1] University of Saskatchewan, School of Environment and Sustainability
[2] Canadian Forestry Service

Abstract: In Canada, the responsibility for professional forestry practice lies with professional foresters, who offer services related to the development, management, conservation, and sustainability of forested land. These services require extensive knowledge, training, and experience and thus to become a professional forester, individuals must follow a standardized career development process that combines education and practical experience. Professional foresters primarily work in government, industry, conservation authorities, or as private consultants in various roles in the field, management, or policy settings, both in rural and urban contexts. However, their gender and length of work in the field, specific location of their work, the roles they perform, and the values they prioritize can influence how they are perceived, welcomed, and accepted by their peers within the profession, as well as how their knowledge is valued. For instance, what happens when a forester's values regarding forest management conflict with the dominant approaches in the field? This research examines how the decisions of professional foresters to pursue different pathways within the forestry occupation impact their acceptance within the profession, the value placed on their knowledge, and impact on their overall health and well-being. The findings of this study suggest that efforts to promote and attract diverse individuals to the field of forestry should consider alternative practices of knowledge production, different values on forest management and the diversity of roles in the profession.

S5.6 Transforming and restoring forests for more resilient landscapes and societies

A sustainable forest future in the tropics means considering secondary forests as an alternative source for timber production

S5.6 Transforming and restoring forests for more resilient landscapes and societies

Marie Ange Ngo Bieng[1, 2]

[6] CATIE, Centro Agronómico Tropical de Investigación y Enseñanza, Turrialba 30501, Costa Rica

Abstract: Tropical forests are recognized for their exceptional biodiversity related to the provision of vital ecosystem services. They are also highly vulnerable and threatened, primarily by agricultural development. Tropical forests are disappearing at huge rates and old-growth forests now only account for 25% of all existing tropical forests.

In some tropical landscapes, growing deforestation and degradation of old-growth forests is paralleled by the increasing extent of secondary forest (SFs) that regenerates naturally on large areas of abandoned farmland. They represent a hope for sustainable forest future.

However, within tropical landscapes SFs are themselves extremely vulnerable to land use changes, but also natural and human-induced catastrophic events, such as fires. SFs have lost their capacity to provide a high level of goods and services, and are located in highly dynamic and human-pressured landscapes, where they interact with competitive productive landscapes.

Without appropriate silvicultural management to increase their economic value and restore their ecological functions, they often become degraded and are cleared for more short-term economically productive activities.

We hypothesize that the nowadays context of the increasing demand for tropical timber is an opportunity for SF conservation, through active and productive restoration for timber production in tropical SFs.

Promoting sustainable and diverse timber production -associated with other environmental services- in SFs is also a way to reduce logging pressure on the remaining intact primary tropical forests : this may be the most important reason to enhance active and productive restoration in tropical SFs.

In the suggested flash talk, based on results and knowledge of different studies gathered in the special issue "Active restoration of timber production and other ecosystem services in secondary and degraded forests" (Forest Ecology and Management), we show that timber species actually represent an unknown and important proportion of tree diversity and AGB within studied SFs plots in Central America and West Africa.

Future studies may address this key “global south” challenges of sustainable future for wood production in the tropics, working on active and productive restoration for timber production in SFs, but also on other coherent factors as appropriate logistical investment, local policies and incentives that enhance secondary forest regeneration.

Building a pathway for high quality FLR implementation across the globe: WWF´s regional initiatives.

S5.6 Transforming and restoring forests for more resilient landscapes and societies

Anita Diederichsen[1]
Severin Kalonga[1], Trevor Walter[1], James Bampton[1], Laura D´Arcy[1], Daniel Vallauri[1], Inna Bilshchuk[1], Mark Aldrich[1], Diana Colomina[1], Valerie Passardi[1], Susanne Winter[1], Pablo Pacheco[1]
[1] WWF

Abstract: Promoting the implementation of high-quality Forest Landscape Restoration (FLR), accelerating implementation and upscaling it globally has been set as priority for WWF Forest Practice and its globally acting FLR community. The GPFLR, defines FLR as "a process that aims to regain ecological functionality and enhance human well-being in deforested or degraded landscapes" and has adopted six principles to guide implementation; complementary the UN Decade on Ecosystem Restoration has established 10 principles. Achieving high quality FLR requires a strong consideration and adherence to those principles, associated with well-designed strategies, careful implementation, effective monitoring and transparency, under and adaptive management approach. By adopting the Conservation Standards for the Practice of Conservation, WWF developed theory of changes under the adaptive management approach and trough a participatory process. Regional initiatives in Africa, Latin America and Southeast Asia are now structured in a coherent framework set under tree pillars: 1) enabling policy, governance and institutional frameworks; 2) promoting markets and finance mechanisms and 3) delivering Bonn challenges commitments on the ground at scale. The goals and objectives for each country and landscapes were them set under landscapes approaches process considering the local contexts and voices. The FLR in Africa Initiative engages 9 countries and is empowering and enabling national and regional governments to deliver their AFR100 commitments in a just way that promotes sustainable livelihoods for local people and biodiversity conservation. The Transformational Initiative on Forest and Landscape Restoration in Latin America is kickstarting the restoration of over 7 million hectares of degraded and deforested landscapes across 12 countries as a contribution to the Initiative 20x20. Along with the regional work in the Mekong region, WWF is being able to promote cross learning and exchange among the network and partners. For transparency WWF is building landscape collections in Restor. With partners WWF is promoting enabling conditions to accelerate implementation. The Trillion Tree gives us the opportunity to protect and restore, based on science and proven impact. With SER we are developing standards for restoration projects certification. And with IUCN, WRI, with the support from IKI we are launching the FLR Implementation Hub.

Citizen Science as a tool to promote mental well-being and connection with nature in a Brazilian Park

S5.6 Transforming and restoring forests for more resilient landscapes and societies

Gabrielle Abreu Nunes[1]
Danielle Machado Duarte[2], **Teresa Cristina Magro Lindenkamp**[1]
[1] University of Sao Paulo, Brazil
[2] University of the State of Rio de Janeiro, Brazil

Abstract: Participatory approaches have proven essential in natural resource management worldwide, as they can reduce inequalities in decision-making and encourage public engagement in environmental issues. Citizen Science, a relatively unexplored avenue in protected areas, holds great potential for balancing priorities such as education, research, and social development. This exploratory study evaluated the impact of cultural ecosystem services on self-perceived mental well-being, connection to nature, and pro-environmental behaviors among volunteers participating in an environmental monitoring project in the Serra dos Órgãos National Park, Rio de Janeiro, Brazil. We employed a questionnaire with validated psychometric scales, including the Positive and Negative Affect Schedule (1988), Vitality Scale (1997), Nature Relatedness Scale (21-items, 2009), and Inclusion of Nature in Self (2001). The participant profile consisted of low-income undergraduate students and public servants from different age groups, with some people visiting a protected area for the first time. The results were promising, revealing differences in self-perceived well-being before and after participants engaged in observing nature. All scales exhibited positive variations in the median and mean between pre- and post-participation, however only the Negative Affect (PANAS), Nature Relatedness, and Inclusion of Nature in Self resulted in significant differences, with p-values below 0.05 in the Wilcoxon signed-rank test for small paired samples. While further research is needed to explore other aspects of human well-being in citizen science projects, this study provides valuable insights into the influence of this cultural ecosystem service and can guide future public policies and research endeavors.

Conserving grasslands for regenerating degraded forests in a semi-arid region

S5.6 Transforming and restoring forests for more resilient landscapes and societies

SHARAYU GANGURDE[1]

[1] Department of Landscape Design, School of Planning and Architecture, Bhopal, Madhya Pradesh, India

Abstract: An experimental project on conserving and nurturing grasses in the Indian Savannah region is being undertaken in Gajraha, a small hamlet located 100 metres away from the buffer zone of Bandhavgarh Tiger Reserve in Madhya Pradesh. Prakruti Prerana Foundation, a non-profit organisation is working on conservation of forests and grasslands in a 30 acre non-arable area acquired from local villagers. An extensive survey of grasslands was conducted to identify and document a mix of 25 different species of grasses within a forest habit populated with Madhuca *longifolia,* Shorea *robusta,* Diospyros *melanoxylon,* Ficus *benghalensis,* Butea *monosperma,*and Syzygium *cumini* on the premises.

The method used for identification was collection of grass species and its subsequent cross checking with a report published by the state biodiversity board. This study tries to understand the impact of grasslands in helping forests regenerate without any human intervention as both native and invasive species of plants and grasses are present on site. Since the study on grasses is conducted on an experimental forest land, it revealed information on two major species- Aristida *adscensionis* and Cenchrus *ciliaris*. Their widespread distribution throughout the site indicates presence of sandy loamy soil. Typically, this soil has low level of micro nutrients which arrests the growth of plants and fosters grasslands. Out of the above two species, Aristida *adscensionis* thrives in sunlight and extreme heat since temperatures in the tropics reach close to 50 degree celsius in daytime. The other species, Cenchrus *ciliaris* grows in shade, being a pioneer species in this forest helps retain moisture content in soil. It is drought tolerant and extremely beneficial under irrigation in a semi-arid region.

The study revealed the potential commercial use of these grasses as good fodder value, as well as their role in creating grazelands. These grasses have helped restore the soil nutrition balance in the current site. Both species are used in re-vegetation of degraded lands and controlling soil erosion on slopes as well as in ethno-pharmacological studies.

Keywords: Indian Savannah grasslands, Aristida adscensionis, Cenchrus ciliaris, pioneer species, forest regeneration, semi- arid region

Decision making factors influencing land use transformation and its implication on forest landscape restoration in Ethiopia

S5.6 Transforming and restoring forests for more resilient landscapes and societies

Shibire Bekele Eshetu[1, 2]
Stefan Sieber[1, 2], Marcos Lana[3], Katharina Löhr[1, 4]
[1] Leibniz Centre for Agricultural Landscape Research (ZALF), 15374 Müncheberg, Germany
[2] Department of Resource Economics, Albrecht Daniel Thaer-Institute of Agricultural and Horticultural Sciences, Humboldt-Universität zu Berlin, 10115 Berlin, Germany

[4] Division Urban Plant Ecophysiology, Humboldt University of Berlin, 14195 Berlin, Germany

Abstract: Macro level patterns are often a result of a strong influence of human decisions and behaviour at the micro level. To improve our understanding and the process of land use transformation, the abilities, objectives, and motivation of land use decision makers should be explicitly addressed. This research investigates the decision factors of Ethiopian smallholder farmers to transform their land use in the process of implementing Forest Landscape Restoration (FLR). A combination of systematic and random sampling was employed to select 228 households for a household survey. The decision to transform a landscape from one use to another is significantly associated with economic, environmental, social, and institutional decision factors. Economic, soil fertility, and policy are the main drivers of land use transformation occurring in the landscape. Most smallholder farmers changed their land use from cropland to woodlot intending higher economic profit whereby, few have reversed from Woodlot to cropland due to longer waiting period to harvest. The study reveals that crop and grazing have very high significance variation within the group of survivalist, subsistence oriented and market oriented smallholder farmers as compared to land allocation for woodlot and agroforestry. There is a high tendency of subsistence oriented farmers to convert from cropland to agroforestry and woodlot in pursuit of profit. Implementation of FLR in the study area and in similar landscapes where smallholder farmers are targeted to be involved should consider promoting economically rewarding tree species.

Deforestation, Forest Degradation, and Climate Change in Ethiopia: A Physical Recovery and Climate Change Mitigation and Adaptation Strategy

S5.6 Transforming and restoring forests for more resilient landscapes and societies

Zelalem Gebew[1]
Teshome Sormessa[2]
[1] 1Ethiopian Forest Development, Bahir Dar Center, P.O.Box:2128
[2] 2Addis Ababa University

Abstract: Deforestation and forest degradation have been rampant in Ethiopia, posing major challenges to forests and the livelihoods of those who rely on them. The main causes are agricultural expansion; rising demand for construction materials, industrial use, fuel wood, and charcoal; a lack of forest protection and conservation policy; a weak forest administration system incapable of arresting the rapidly increasing rate of deforestation; a lack of effort to ensure community participation in forest protection and conservation and benefit-sharing; and failure to clearly delineate and enforce the boundaries of natural forest reserves. There are currently efforts being made by the government and local communities. Attempts to safeguard forests in the country include the establishment of protected and forest priority areas, as well as the protection of sacred forest sites and the introduction of new energy-efficient stoves. Another conservation initiative being implemented by the government is forest rehabilitation by afforestation, replanting, and area enclosures with participatory forest management methods. Long-term fluctuations in temperature, precipitation, wind, and other characteristics of the Earth's climate system are referred to as climate change. Climate change can be caused by natural or human-made events. Climate change is mostly caused by human activity such as the combustion of fossil fuels and the removal of forests. High-income countries are mostly responsible for greenhouse gas emissions, whereas low-income countries bear the brunt of climate change's harmful consequences. Because of their poverty and significant reliance on the environment for survival, developing countries are less capable of mitigating or adapting to changes. Climate change has a wide range of consequences for the environment, socioeconomic sectors, and linked industries, including water resources, agriculture and food security, human health, terrestrial ecosystems, and biodiversity. The Ethiopian government has previously implemented a number of policies, strategies, and programs aimed at improving adaptability and reducing climatic fluctuation and change. As a result, the goal of this review study is to look at deforestation and forest degradation in Ethiopia, as well as climate change and its mitigation and adaptation initiatives.

Exploring the Sustainable Development Solution of the 2019 Beijing International Horticultural Exposition that Will Never End

S5.6 Transforming and restoring forests for more resilient landscapes and societies

Hongming Peng[1, 2, 3]
Biao Huang[1, 2], Yufei Meng[1, 2], Yayun Deng[1, 2], Zehui Jiang[1, 2, 3]
[1] International Centre for Bamboo and Rattan, Beijing, China
[2] Key Laboratory of Nationaiaol Forestry and Grassland Administration/Beijing for Bamboo & Rattan Science and Technology, Beijing, China
[3] China Flower Association, Beijing, China

Abstract: Sustainable development is promoting and assisting urban sustainable development from the perspective of environment and resources. Due to the large size of the venue for the World Horticultural Exposition, the transformation and development model after the event has become an important issue of concern for domestic venues hosting the expo. On the one hand, due to the large area of the venue during the event, the current post event operation methods adopted by domestic expo include retaining and transforming it into a theme park, conducting secondary development and construction, and serving as urban park green space. The actual operation is almost a combination of multiple modes. On the other hand, unreasonable post event utilization cannot fully utilize the brand effect and potential value created by the expo, It is particularly important to achieve sustainable development after the World Horticultural Exposition.

Taking the following programmatic planning for sustainable use of the 2019 Beijing World Horticultural Exposition as an example, this paper expounds the solution of the 2019 Beijing World Horticultural Exposition, and positions the Beijing World Horticultural Garden Park as a ecotype park based on local adaptive plants to create a near natural landscape and achieve sustainable development. Always embodying the important idea of ecological civilization, we aim to create a professional and experiential plant garden complex that serves the public, and to build a new and vibrant horticultural theme center with a sense of social responsibility that integrates tourism, cultural and creative activities, science and education, and art. To achieve the sustainability of the mission and cultural vision, as well as the sustainability of the operational economy, in order to become a model for post exhibition operations.

Forest Adaptation and Restoraration under Global Change - status and perspectives

S5.6 Transforming and restoring forests for more resilient landscapes and societies

Andreas Bolte[1]
John Stanturf[2], Stephanie Mansourian[3], Mercy Derkyi[4], Palle Madsen[5], Michael Kleine[6]
[1] Thünen Institute of Forest Ecosystems, Eberswalde, Germany
[2] Estonian University of Life Sciences, Tartu, Estonia
[3] University of Geneva, Crassier, Switzerland
[4] University of Energy and Natural Resources, Sunyani, Ghana
[5] InnovaSilva, Vejle, Denmark
[6] International Union of Forest Research Organizations, Vienna, Austria

Abstract: Forests and forest landscapes fulfil multiple essential ecosystem services (ES). These include (i) provisioning services such as the provision of food, raw materials, freshwater and medicinal resources; (ii) regulating services such as carbon sequestration and storage for climate protection, regulation of the landscape water cycling and climate, moderation of extreme events and natural hazards; (iii) cultural services for recreation, mental and physical health, tourism, and aesthetic, cultural and spiritual experiences, as well as (iv) supporting services for preserving biodiversity. For rural populations, forests are often the basis for their social identity, livelihoods, and the local economy. Forest landscapes are social-ecological systems shaped by multiple influences and they play an outstanding role, contributing to all 17 Sustainable Development Goals (SDG). However, forest landscapes are under pressure with the loss of forest areas by conversion to other land uses and degradation of existing forests, and reduced biodiversity. An estimated 10 million hectares of forest area have been lost between 2015 and 2020 and an even larger amount is estimated to be degraded. Environmental and climate changes are rapidly altering the growth, survival, and regeneration conditions for forest ecosystems with direct and dramatic impacts on 3.2 billion people, in particular the most vulnerable. Tropical forests, for example, are home to over two-thirds of the Earth's terrestrial biodiversity and they are facing significant threats from human activities as well as climate change. With this, forests and forest landscapes may lose their characteristic structural and ecological features, and societies worldwide face diminishing levels of ecosystem services provided by forest landscapes. Thus, along with the preservation of intact forest landscapes, forest adaptation and restoration are needed to prevent the continued global loss of ecosystem services and biodiversity, so that forest landscapes can meet the ecological, economic, and societal challenges due to global change. In this presentation we provide an overview about the status of global activities on forest adaptation and restoration based on an online survey and other sources, and discuss the future perspectives of Forest Landscape Restoration (FLR) for various ES like climate protection, water cycling, biodiversity, and the provision of food and raw materials.

Impacts of Establishing Pilot National Parks on Local Residents' Sustainable Livelihoods and Their Coping Strategies in China

S5.6 Transforming and restoring forests for more resilient landscapes and societies

Menghan Zhao
Hongge Zhu[1]
[1] Northeast Forestry University, Agricultural and forestry economic management, China

Abstract: National Parks are a category of protected areas that emphasizes the sustainable use of park resources. In 2013, the Chinese administrative authorities announced the establishment of its own national park system to better protect the country's natural heritage and the integrity of its large ecosystems. Since 2015, ten pilot national parks have been designated to explore a pathway to implement the national park system better. Local communities are among the most critical stakeholders in establishing and managing a national park. Park management wouldn't be successful without the local residents' support and active involvement. Since national parks are positioned in China as protected areas with the highest priority to nature protection, their impacts on the local people, either inhabiting the park or living nearby, are unprecedented in the country. The park-people relationship is not a new topic in national park research; however, in the context of China's social, economic, and political framework, very little is known about the sustainable livelihood impacts of establishing a national park on the local residents and what strategies those residents should adapt to cope. In this study, the authors attempt to reveal the livelihood impacts of the national park creation in China on the local residents and their adaptation approaches by taking Northeast Tiger and Leopard National Park (NTLNP) as a case through a propensity score matching difference-in-differences model (PSM-DID model). The study results indicate that the establishment of NTLNP and its policies have significantly impacted the sustainable livelihoods of the local residents. The weakening effect of the establishment of the NTLNP on the sustainable livelihood of the local residents has a certain lag. The reason may lie in: (1)The local community has a weak self-development ability and has a high dependence on natural resources. (2) The Northeast Tiger and Leopard National Park is a comparatively dense area of wildlife population distribution. The overlapping of human and wildlife activities and the competition for resource utilization also directly or indirectly cause losses to the production and livelihood of the community residents inside and outside the protected areas.

Land Use and Land Cover Change along River Lumi Riparian Ecosystem in Kenya: Implications on forest ecosystems and Local Livelihoods

S5.6 Transforming and restoring forests for more resilient landscapes and societies

Leila Ndalilo[1]
Elias Maranga[2], Bernard Kirui[2]
[1] Kenya Forestry Research Institute
[2] Egerton University

Abstract: Riparian forests minimize impacts of land degradation on stream ecosystems and provide direct and indirect benefits to people. However, these ecosystems are threatened by degradation and deforestation attributed to land use changes. River Lumi riparian ecosystem in Taita- Taveta County in Kenya has experienced rapid and extensive land use changes over the past three decades in response to economic, institutional and demographic factors. There is growing concern of riparian degradation attributed to land use change with far reaching implications on local livelihoods. A study was conducted to examine the patternsof land use and land cover change along River Lumi riparian ecosystem between 1987 and 2019. The aim of the study was to ascertain the impactsof land use and land cover change on the riparian forest and local livelihoods. Landsat images were used to assess land use and land cover change while socio-economic data was collected from 353 households in Njukini, Chala and Mboghoni located in the upper, middle and lower sections of River Lumi ecosystem respectively. Research evidence authenticated that the area under farmlands, settlement and water body increased by 20.5%, 112.1% and 2.3% respectively between 1987 and 2019 while area under forest patches, grazing land and riverine vegetation decreased by 52.7%, 3.0%, and 36.6% respectively. The increase in population in surrounding areas coupled with encroachment of the riparian areas for crop farming and livestock grazing resulted to loss of riparian forest patches/vegetation and associated biodiversity with negative implications on household livelihoods. The implication of these results is the need for land use regulations and management interventions at the County government level to arrest further encroachment of River Lumi riparian ecosystem and consequent loss of biodiversity and livelihoods.

PERFORMANCE OF BAMBOO TREES ALONG RIVER TANA FOR FLOOD RISK MITIGATION AND SOIL AND WATER CONSERVATION WITHIN GARISSA AND TANA RIVER COUNTIES IN KENYA

S5.6 Transforming and restoring forests for more resilient landscapes and societies

AMINA MAALIM[1]
JOSEPHINE MUSYOKI[2], JULIUS HUHO[3], NELLIE ODUOR, JAMES NDUFA, PHILIP LOONIYO, ABDILADIF HARET, MOHAMED OSMAN
[1] KENYA FORESTRY RESEARCH INSTITUTE, AGROFORESTRY, KENYA
[2] KENYA FORESTRY RESEARCH INSTITUTE, DRYLAND FORESTRY, KENYA
[3] GARISSA UNIVERSITY, GEOGRAPHY/CLIMATE CHANGE, KENYA

Abstract: Riparian lands provide suitable environment for human activities and livelihood sources. They support thousands of households by ensuring supplies of food and income through irrigation activities. However, with the ballooning human population and the negative impact of climate change, riparian lands have attracted more people resulting in over-exploitation of resources therein. In addition to the destruction of riparian vegetation, anthropogenic activities in these lands have led land degradation through river bank erosion and consequently flooding and pollution of water sources along the rivers. River Tana in Kenya has faced similar consequences with increased clearing of riparian vegetation for more agricultural land and charcoal burning, and obtaining building poles. As a result, the magnitude of the floods and the associated impacts have been increasing over the years. The recurrent flooding in River Tana has not only destabilized/deformed its banks but has also led to the loss of both human and livestock lives, loss of livelihood, destruction of property and infrastructure, water contamination, and disease outbreak in Garissa and Tana River Counties. In an attempt to mitigate flood risk as well as conserve soil and water, this project planted bamboo trees at erosion hotspots and areas of high, medium, and low flood risks along River Tana bank.

Basing on the flood risk hazard maps by Kenya Red Cross Society and National Drought Management Authority 3 experimental sites with high, medium, and low flood risk were selected in each of the counties. About 1500 bamboo seedlings were planted on 12 farms. A survival rate of 88% was recorded but with differentiated growth rate. The minimum and maximum height recorded in the first year were 0.2 and 4.9 meters respectively while number of shoots per tree between 1 and 12. The challenges encountered included lack of water for watering due to slight changes in the river course, destruction by livestock, *Prosopis juliflora invasion* as well as poor management by farmers. The project observed that the potential for controlling floods and bank erosion through the use of bamboo trees is feasible considering their survival and growth rate and positive attitude toward bamboo trees by farmers.

Socioecological Innovations in Landscape Restoration: Exploring Examples within the Brazilian Context

S5.6 Transforming and restoring forests for more resilient landscapes and societies

[6] Instituto Coruputuba de Desenvolvimento Sociocultural, Educação e Preservação do Meio Ambiente.

Abstract: Forest and Landscape Restoration (FLR) is a transformative process that reshapes land use dynamics to improve ecosystem services and overall well-being by influencing values, behaviours, and social relationships. It involves preserving and expanding areas that provide essential services such as water resource protection, biodiversity conservation, and sustainable agriculture. However, the success of FLR is influenced by complex power dynamics among competing land use interests, where institutions mediate access to resources, decision-making authority, and capital. This can lead to varying outcomes, potentially exacerbating social inequalities and environmental degradation. To address these challenges, participatory and adaptive management approaches led or supported by local communities are crucial and can foster Social Innovations (SI). SI represents the sharing of ideas, knowledge, and collective actions to address common challenges, with Socioecological Innovation (SEI) being the term used when these innovations also benefit nature. This paper examines three SEI cases within the framework of "Socially Innovative Forest and Landscape Restoration" (SIFLR): "Sawing Agroforestry" in Minas Gerais, "Sawing Sustainability," and "Actors of Forest Restoration in the Paraiba Valley" in São Paulo, Brazil. These initiatives, characterized by participatory and adaptive processes driven or supported by local communities, aim to address restoration challenges. Through collective actions, communities bring about tangible changes socially and ecologically by sharing ideas and knowledge. The study uses the SIFLR framework to explore how these initiatives have promoted social and ecological innovation. The framework acknowledges social, political, economic, and ecological interdependence in successful restoration and emphasizes collaboration among diverse stakeholders. The examples demonstrate that SEIs effectively promote sustainable restoration, benefiting local communities and the environment. These initiatives encourage stakeholder participation, enabling knowledge-sharing and consensus-building to address the complex challenges associated with FLR. Given the global urgency to prioritize landscape restoration, it is essential to promote the implementation of such initiatives to ensure social inclusion, equity, and environmental sustainability. Based on the findings, scaling up and supporting these innovative approaches is recommended, as they have the potential to play a vital role in building a resilient and healthy future.

Transitional forestry in New Zealand: re-evaluating the design and management of forest systems through the lens of forest purpose

S5.6 Transforming and restoring forests for more resilient landscapes and societies

Alan G. Jones[1]
Andrew Cridge[1], Stuart Fraser[1], Lania Holt[1], Sebastian Klinger[1], Kirsty F. McGregor[1], Thomas Paul[1], Tim Payn[1], Matthew B. Scott[1], Richard T. Yao[1], Yvette Dickinson[1]
[1] Scion (New Zealand Forest Research Institute), Titokorangi Drive, Private Bag 3020, Rotorua, 3046 New Zealand

Abstract: Forestry management worldwide has become increasingly effective at obtaining high timber yields from plantation forests. In New Zealand, focus on improving an increasingly successful and largely *Pinus radiata* plantation forestry model over the last 150 years has enabled the most productive timber forests in the temperate zone. In contrast to this success, the full range of forested landscapes across New Zealand, including native forests, are degraded by growing pressures from introduced pests, diseases, and a changing climate, placing considerable biological, social and economic value at risk. Government policies further incentivise reforestation and afforestation, but the social acceptability of some newly planted forests is now being challenged.

We present 'transitional forestry' as a solution. This new model design and management paradigm is appropriate to a range of forest types, including non-commercial forests. In our framework, all forest types are optimised as nature-based solutions and forest purpose is placed at the heart of decision making. We use New Zealand as a case study region, describing how a purpose-led transitional forestry model can deliver benefits across a range of forest types; from industrialised forest plantations to dedicated conservation forest reserves and a range of multiple-purpose, mixed-species forests in between. Transitional forestry is an ongoing multi-decade process of change from current 'business-as-usual' forest management to multiple future systems of forest management, embedded across a continuum of forest types. This incorporates ecological thinking to enhance efficiencies of timber production, improve overall forest landscape resilience, and reduce potential negative environmental impacts of commercial plantation forestry. The cultural acceptability and biodiversity value of both commercial and non-commercial forests is maximised.

Transitional forestry addresses emerging tensions between meeting forest climate mitigation and biodiversity targets, alongside accelerating demands for forest biomass feedstocks to meet near-term bioenergy and bioeconomy goals. As ambitious international policies set targets for global programmes of reforestation and afforestation using both native and exotic species, there is an increasing opportunity to make these forest transitions *via* integrated thinking that optimises the values of all forest types, while embracing the diversity of ways in which such targets can be reached.

Why restoring boreal forest landscapes for indigenous Sámi reindeer herding is important to fight effects of climate change on open alpine heathland

S5.6 Transforming and restoring forests for more resilient landscapes and societies

Åsa Granberg[1]
Marja Skum[2]
[1] County Administration Board of Västerbotten
[2] Gran Reindeer Herding community

Abstract: Treeless, alpine areas (and associated species) are in many regions threatened by warming climate as shrubs and trees are moving to higher elevations and latitudes, leading to continuous decrease of alpine habitat. This is also true for the Scandinavian mountains. However, it has been shown that grazing from reindeers can hamper "schrubification" and delay the advance of the treeline.

In northern Sweden there are about 250.000 semi-domesticated reindeers, owned and cared for by the indigenous Sámi people. Reindeer husbandry has a long tradition in Scandinavia but today the herders use modern technology to herd and guard the animals as they roam freely in the search for grazing areas and resting places. The reindeer herding communities (RHC) have exclusive right to use approximately half of the Swedish territory for reindeer grazing, irrespectively of land ownership. Reindeers are migratory and most reindeers in Scandinavia stays in the alpine mountains during summer and in the forested inland and coast during winter. During summer the reindeers eat mainly grass, herbs, and leaves and in the winter, they mainly eat lichens. The winter is the most critical period for the reindeers and thus the amount and access to lichens in the forests during winter is one major factor limiting the number reindeers that will graze the alpine areas in the summer. However, in the last 50 years the amount of ground lichens in the forests has decreased by as much as 70 %, primary due to intensive forestry, and the connectivity between good grazing areas and along the migration routes are continuously being more and more disrupted.

To strengthen the landscape connectivity for reindeers and to halt the loss/enhance (re)-growth of ground lichens, and in the long run protect the alpine habitats, the forests within the reindeer grazing areas need to be restored.

In Vindelälven-Juhttátahkka Unesco Biosphere reserve in northern Sweden, the RHC Ran and Gran are collaborating with both the Horizon 2020-project SUPERB and Rewilding Sweden to map and describe restoration needs, and to perform restoration actions. In this presentation we will talk about the proceeding of this initiative and the results so far.

S5.7 Leadership for Sustainability - Overcoming Challenges in Forest Research

S5.8 Power of youth in scaling multisectoral collaboration: The role of forests in achieving the vision for 2050

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Antifungal Activity of Culture Filtrate from Endophytic Fungus Nectria balsamea E282 and Its Fractions against Raffaelea quercus-mongolicae

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Manh Ha Nguyen[1, 2]
Jong Kyu Lee[1]
[1] Tree Pathology and Mycology Laboratory, College of Forest and Environmental Sciences, Kangwon National University, Chuncheon 24341, Korea
[2] Forest Protection Research Center, Vietnamese Academy of Forest Sciences, Hanoi 11910, Vietnam

Abstract: Since 2004, oak wilt disease caused by *Raffaelea quercus-mongolicae* has been a threat to *Quercus mongolica* in Korea. Our previous study indicated that three endophytic fungal isolates from pine and oak trees, E089 *(Daldinia childiae)*, E282 *(Nectria balsamea)* and E409 *(Colletotrichum acutatum)* had antifungal activities against *R. quercus-mongolicae.* The objectives of this study were to optimize antifungal efficiency of these endophytic fungi and to assess antifungal activities of fractions isolated from culture filtrate. Mycelial growth of *R. quercus-mongolicae* on PDA medium containing culture filtrates was significantly affected by culture periods of endophytic fungi. Culture filtrates of E089, E282, and E409 obtained after three weeks' cultivation had higher mycelial growth inhibitions compared to those of 2 weeks' with inhibition rates of 82.2%, 100%, and 85.0%, respectively. Culture filtrates of these isolates also showed higher sporulation inhibitions on PDA medium containing 3-week culture filtrates with rates of 93.3%, 100%, and 92.1%, respectively. For spore germination of oak wilt fungus, only E409 had a lower inhibition rate on 3-week culture filtrate compared to that of 2 weeks' while the opposite occurred for E089 with an inhibition rate of 100% on 3-week culture filtrate. Especially, spore germination inhibition rates of E282 reached 100% in both culture period conditions. These results showed that E282 (*N. balsamea*) completely inhibited mycelial growth, sporulation, and spore germination of oak wilt fungus. The antifungal activities of its fractions against oak wilt fungus were significantly different. Of which, diethyl ether (Et_2O) fraction completely inhibited mycelial growth, sporulation of oak wilt fungus and had the strongest activity in inhibiting spore germination. Thus, this endophytic fungus could be developed as a potential biocontrol agent against *R. quercus-mongolicae*, the wilt pathogen of *Q. mongolica.*

Assesment of different methods for tolerance testing of Fraxinus excelsior genotypes towards Hymenoscyphus fraxineus

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Elisabeth Britt[1]

[1] Swiss Federal Institute for Forest, Snow and Landscape Research WSL

Abstract: The ash dieback pathogen (*Hymenoscyphus fraxineus*) was first observed in Poland in 1992 and from then it developed to a severe threat for living ash trees in Europe. In many countries as Germany, Austria, France, England or Denmark research-programs were initiated to find common ash (Fraxinus excelsior) genotypes resistant to the ash dieback pathogen. Several methods for testing pathogen resistance of the ash genotypes were used. Here we investigated three different methods and compared them to field observations (crown defoliation). Stem infections, leaf infections (rachis infections) and germination rates of *H. fraxineus* spores on leaf malt agar were tested using 12 ash genotypes. Replicates were achieved by graftings. Stem infections provided the best correlation to the field observations. However, this method needs a long preparation time, and the duration of the experiment takes at least 3 months. The easiest and fastest method was that of the leaf (rachis) infections. It lasts one month and implies almost no preparation time. Although this method correlates less strongly to the field observations it correlates well with the stem infections. The spore germination on ash leaf agar method would be also fast, but the time synchronization between sporulation and leaf malt agar preparation makes the method very difficult to apply. Moreover, we observed no correlation to the stem infections. To get accurate results of the resistance of ash genotypes against ash dieback, stem infections seem to be still the best way.

Chestnut defense genes against the invasive gall maker Dryocosmus kuriphilus

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Abstract: Several chestnut (*Castanea* sp.) genotypes resistant to the Asian gall maker *Dryocosmus kuriphilus* have been described. Studies of the defensive mechanism involved in this process revealed that the immune response of the resistant genotypes is mainly based on a hypersensitivity reaction (HR) to eggs or neonate larvae inside the tree buds, as well as on the early and precise abscission of the nascent galls from the expanding leaves. HR is an induced resistance response that appears in the area immediately adjacent to the egg mass within the tree bud visible as a necrotic lesion that prevents gall formation. HR is triggered by specific molecules responsible for activation of the defensive response and involves several steps: insect recognition, development of the oxidative burst, activation of defense genes and cell death. Abscission consists of a process of cell separation by which plants can shed some of their organs. Abscission of infested leaves, fruit or seeds is common and is considered especially effective against insects with poor motility such as gall makers. In the present work we identified defensive genes involved in this process by massive gene expression analysis. We performed RNAseq on different phenotypes and experimental conditions for highly sensitive and accurate evaluation. This technology allowed us to identify differentially expressed genes and enriched pathways related to the defensive response involving immune-related genes between sensitive and resistant plants. Candidate genes are being validated by qPCR on new plants according to their resistance status. The goal of this research is to improve the understanding of the mechanisms underlying the immune response in plants that may have practical implications for the improvement of tree resistance breeding for chestnut production.

Climate, host and geography are of similar importance in shaping insect and fungal communities of trees on a global scale

Abstract: Non-native pests, climate change, and their interactions are expected to disrupt the relationships between trees and the organisms associated with them, thereby impacting forest health. In order to comprehend and anticipate these changes, it is crucial to identify the factors that shape tree-associated communities. We collected and analysed insects and fungi obtained from dormant twigs of 155 tree species across 51 botanical gardens or arboreta in 32 countries on six continents.

Fungi were characterized by high-throughput sequencing. Insects were first reared and then sorted into taxonomic orders and feeding guilds. Herbivorous insects were then grouped into morphospecies and were identified using molecular and morphological approaches. By employing generalized dissimilarity models, we assessed the relative significance of various climatic, host-related, and geographic factors in driving dissimilarities among tree-associated communities. This dataset reveals the diversity of tree-associated taxa, as it contains 12,721 amplicon sequence variants and 208 herbivorous insect morphospecies, sampled across broad geographic and climatic gradients and for many tree species. Mean annual temperature, the phylogenetic distance between hosts, and the geographic distance between locations were the primary determinants of dissimilarities. The increasing influence of high temperatures on community differences suggests that climate change could directly and indirectly impact tree-associated organisms through shifts in host ranges. Furthermore, insect and fungal communities exhibited greater similarity among closely related hosts compared to distantly related hosts, implying that expansion of host ranges could facilitate the emergence of new pests. Additionally, dissimilarities among tree-associated communities increased with geographic distance, suggesting that human-mediated transportation could lead to the introduction of new pests. These study results underscore the importance of limiting the introduction and establishment of tree pests and enhancing the resilience of forest ecosystems in response to climate change.

Commodity imports and climatic filtering drive compositional variation in non-native insect establishments

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Abstract: Invasions of non-native insects can have substantial impacts on agriculture, forestry, human health and biodiversity with considerable economic and environmental consequences. To better understand the causes of this process, it is important to quantify the relative importance of main drivers such as commodity imports vs climatic requirements. To evaluate the relative contributions of these factors in explaining global variation in numbers of non-native insect establishments in different world regions, we conducted direct ordination analyses considering temporal changes in family-level composition and changes in native range composition of established non-native species from 1881 to 2020, focusing on the six most data-rich world regions, North America, Chile, Europe, Australia, New Zealand, and Japan.

At the family level, there were overall temporal changes in the composition of non-native species assemblages, however, were dominated by scale insects prior to 1900 but then shifted to a more diverse set of species while North America exhibited relatively small compositional changes over the entire 140-year period. Changes in the composition of established species were partially driven both by imports and climatic factors, each explaining 8.4% and 5.0% of total variation, respectively. The analysis of native ranges of non-native species indicated that there was no conspicuous temporal variation. Established species in New Zealand were predominantly native to Australasia, and species in North America and Chile were mainly from Europe. Non-native assemblages in Europe, Japan and Australia mainly originated from the Nearctic, Indomalayan, Afrotropic, and Asian regions. Imports had the primary effect (27.0%) on the total variation in the native range composition, although climatic factors in the destination regions also had substantial effects (21.3%). Based on these results, we conclude that both commodity imports and climatic filtering act together as drivers of establishment success for non-native insects in all six regions.

Cross-scale drivers of Sirex noctilio outbreaks in its native and invasive ranges

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

[3] USDA Forest Service Northern Research Station, Morgantown, WV 26505, USA
[4] Departamento de Producción Vegetal, Universidad de Santiago, 27002 Lugo, Spain

Abstract: *Sirex noctilio* is a woodwasp native to Europe that has been inadvertently introduced across the world and is a highly destructive pest in southern hemisphere pine plantations. *Sirex noctilio* was also detected in the northeastern USA in 2004 where it has become established but is not currently a major pest to native or plantation forests. However, concern exists over its potential expansion into the vast pine forests of the western and southern USA creating a need to understand how tree- to landscape-scale factors affect Sirex outbreaks to inform risk projections for pine species in the USA. A variety of demographic forces affect local, stand-level Sirex dynamics (e.g.,parasitism, reproduction) but across its intercontinental range, stand- to landscape-scale abundance of *S. noctilio* is consistently linked to the availability of suppressed trees – a consequence of high stocking levels linked to stand management objectives and market value of pine products and to abiotic conditions that affect tree growth and mortality. In this project we will evaluate multi-scale models describing interactions between *S. noctilio* and forests, from individual trees to forest stands to landscapes, to assess key determinants of *S. noctilio* outbreaks and tree mortality in northern versus southern hemispheres. This research will help support management of pine stands affected by *Sirex* and provide updated risk projections for key pine resources in the USA

Detection of a Rhizoctonia Fungus Associated with Vascular Streak Dieback of Ornamental Woody Plant Species in the United States.

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Sarah Boggess[1]
Katherine Kilbourne[1, 2], Robert Trigiano[1], Matthew Huff[1], Marcin Nowicki[1], John Bonkowski[3], Michael Munster[4], Fulya Baysal-Gurel[5], Jean Williams-Woodward[6], Marc Cubeta[4], Denita Hadziabdic[1]

[5] Tennessee State University, Otis L. Floyd Nursery Research Center, Department of Agriculture and Environmental Sciences, McMinnville, TN
[6] University of Georgia, Plant Pathology, Athens, GA

Abstract: Ornamental nursery production in the United States is currently being challenged by a recently discovered dieback and vascular streaking disorder observed on at least 21 tree and shrub species across California, Florida, Indiana, North Carolina, Oklahoma, Tennessee, and Virginia. The host list includes several economically important North American native tree species including, but not limited to Eastern redbud (*Cercis canadensis*), red maple (*Acer rubrum*), and flowering dogwood *(Cornus florida*). This emerging disorder, named Vascular Streak Dieback (VSD), presents symptoms as plant decline, twig/limb dieback, and vascular system streaking that vary with host plant species. While pathogenicity testing is in progress to confirm the causal agent of VSD, an association with a *Rhizoctonia* fungus tentatively identified as *Ceratobasidium theobromae* sensu lato (syn. *Rhizoctonia theobromae*) has been proposed. The associated VSD fungus is challenging to isolate and grow in culture which complicates identification and assessment of plant pathogenicity. We plan to implement previously developed microsatellite-based methodology used for molecular detection of thousand cankers disease in walnuts, laurel wilt in avocado and sassafras, and oak wilt in oak trees. Our goal is to decrease confirmation time while providing a reliable and rapid detection method for VSD. DNA sequence analysis of a *Rhizoctonia* like isolate sampled from *C. canadensis* in Tennessee identified 985 candidate microsatellite markers and 570 primers were developed for 384, 91, and 95 di-, tri-, and tetra-nucleotide motifs, respectively. Microsatellite genetic markers will be developed and examined for allelic diversity and polymorphism within *C. theobromae* sensu lato and compared to closely and distantly related groups of *Rhizoctonia* fungi. The development of a TaqMan-based probe assay for identifying and detecting *C. theobromae* sensu lato from plant tissue that deploys improved microsatellite and specialized blue wavelength technology to increase cost effectiveness and fungal specificity will be discussed.

Developing an Integrated Pest Management system for the invasive insect, oystershell scale, in Populous tremuloides

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

[7] USDA Forest Service Kaibab National Forest

Abstract: Oystershell scale (OSS; *Lepidosaphes ulmi*) is a regionally important and rapidly emerging invasive insect pest affecting aspen (*Populus tremuloides*) in the interior western United States. Aspen is considered a foundation species with disproportionately high ecological value in this region. Rapid climate change has likely facilitated the emergence of OSS as an agent of aspen mortality and a threat to aspen sustainability in the region. We are developing an Integrated Pest Management (IPM) system for OSS in aspen ecosystems using silviculture, insecticide, and prescribed fire. We will evaluate the efficacy of these treatments using a before-after-control-intervention experimental design, which includes pre- and post-treatment monitoring of treated units and untreated controls. Silvicultural treatments, which include clearfelling and sanitation thinning units, were first implemented in 2019, with additional units treated annually. Limited experimental use of the insecticide dinotefuran will occur in spring 2024, and prescribed fire will be included as resources and opportunities allow. We are also evaluating OSS life cycle timing, voltinism, and survival across elevational and latitudinal gradients. Through continued monitoring of permanent plots, OSS biology, natural enemies, insecticide movement, and non-target arthropods monitoring, we will develop the initial IPM system, which will be refined as new data are collected and interpreted and new sites are added. Through a formal outreach plan, we will develop products for land managers, forest health professionals, and other interested parties about OSS and the status of IPM development. This presentation will present results from our collaboration to date, including OSS geographic distribution, OSS-caused aspen mortality estimates, early results from the silvicultural treatments, and status of IPM system development.

DISTRIBUTION AND POPULATION DYNAMICS OF INVASIVE PESTS OF EUCALYPTS IN CENTRAL KENYA HIGHLANDS

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Eston Mutitu[1]
Miriam Gathogo[1, 2]
[1] 1. Kenya Forestry Research Institute, P.O Box 20412-00200, Nairobi, Kenya
[2] 2. University of Nairobi, P.O. Box 30197, GPO, Nairobi, Kenya

Abstract: Eucalypts are native to Australia and are grown in many areas as exotics in the world. There is increasing understanding of spread and distribution of the invasive pests of Eucalyptus in Kenya's forestry systems, however there is paucity of information on their natural enemies, despite the economic loss they cause. A survey was carried out from 2018 to 2023 to determine the trends in population, distribution and parasitoids of invasive insect-pests of Eucalyptus, to implement biocontrol program. A transect cutting through counties in Central Highlands of Kenya was identified and eighty plots inform of woodlots, plantations and on-farm trees assessed for occurrence and infestation severity. In each plot, 50 trees of *E. grandis, E. camaldulensis, E. maculata, E. panculata* and clonal hybrids were individually assessed. Plant materials were collected from sample plots, reared in the KEFRI quarantine facility and parasitoid emergence monitored. Altitude and geographical coordinates were obtained for all plots using a mobile application or GPS apparatus and the readings used to generate distribution maps. Host damage was assessed by assigning different damage category levels as follows: Cat. 1: No canopy damage, Cat. 2: less than 25% canopy damage, Cat.3: between 25%-50% canopy damage, Cat. 4: more than 50% canopy damage. Results indicated that Red Gum Lerp Psyllid was the most prevalent at 47.4% during the dry and wet seasons followed by Eucalyptus Snout beetle 23.2%, Bronze bug 18.9% while Blue gum chalcid was reported at 10.5%. According to the year 2019/2020 results, majority of the trees assessed irrespective of species were 25% attacked (45.11%), followed by those not attacked (30.49%). In 2023, new pests; *Spondyliaspis sp* and *O. maskelli* were identified on Eucalypts. *Eucalyptus camadulensis* had the highest frequency of attack by all invasive insect pests followed by clonal hybrids. Hot spot areas were marked as possible permanent sample plots to be used for monitoring and assessment of parasitoids for implementation of classical biological control program which will enable management of the target insect pests.

Key words: Eucalypts, invasive insect pests, *Thaumastocoris peregrines, Leptocybe invasa, Glycaspis brimblecombei* and *Gonipterus scutellatus,* Central Highlands of Kenya

Diversity of polyphagous Phytophthora species in international retail chains poses a serious phytosanitary risk

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Markéta Hrabětová[1]
Marcela Mrázková[1], Dita Šetinová[1], Štěpán Pecka[1], Karel Černý[1]
[1] Silva Tarouca Research Institute for Landcape and Ornamental Gardening, Pruhonice, Czech Rep.

Abstract: It has long been known that oomycetes belong among the most dangerous invasive plant pathogens spreading via international trade. Emphasis on the health and safety of traded material is one of priorities of national and international phytosanitary institutions. Given that this issue has been known for a long time, we decided to verify to what extent the relevant measures and control mechanisms were reflected in the quality of the material distributed in the networks of European retail chains.

During 2021 and 2022, 525 samples of 100+ taxa of ornamental conifers (*Cupressus*, *Chamaecyparis*, *Juniperus*, *Pinus*, *Taxus*, *Thuja*) and some other taxa imported from different countries and sold in stores of four of the largest international retail chains were analyzed. The strains were acquired via baiting method and direct isolation and determined by ITS sequencing, cox1 etc.

A total of 71% of samples were found to be positive. A total of 42 oomycete taxa were determined, including at least 25 *Phytophthora* species. Both known and already common in Europe species such as *P. pseudocryptogea*, *P. plurivora*, *P. cinnamomi* and *P. pini* as well as number of less common and lesser-known taxa on these hosts (e.g. *P. chlamydospora xamnicola*, *P.* cf. *multibullata, P. nemorosa, P. nicotianae, P. niederhauseri*, *P. occultans, P.* cf. *ornamentata, P. palmivora, P. xstagnum*) were found; some of them were first detected in Europe. Quite clearly, the environment of big retail chains (network size and operational characteristics – storage, rapid turnover of goods, excessive irrigation, temperature etc.) is very suitable in terms of spread, transition to other hosts and hybridization of these pathogens. In addition, a number of visibly unthriving and infested plants (e.g. by *P. ramorum*) were ruthlessly offered at large discounts and gladly bought by small growers. The distribution of ornamental plants in international retail chains is still one of the significant and insufficiently treated phytosanitary risks.

Early detection tool for Agrilus anxius (Bronze Birch Borer): laboratory and field validation of a LAMP molecular assay

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Abstract: *Agrilus anxius* (Bronze birch borer, BBB), a buprestid pest from North America that in its native range attacks weakened or injured birch (*Betula* spp.) trees. However, like other secondary buprestid pests, they can cause significant damage to evolutionary naïve hosts due a lack of co-evolutionary defences. In garden studies, BBB has been shown to cause a significant mortality in the evolutionary naïve European birch trees.

Birch is the third most common species in Sweden and in Finland, and represents up to 13% and 16% of the total timber supply, respectively. It is one of the dominant species in Latvia, constituting 28% of standing forests. In the Nordic-Baltic region, birch is increasingly being planted and promoted in admixtures with other conifers with the aim to diversify and increase resilience in forests against climate change. However, introduction of alien species like BBB could be devastating for the forest sector that is increasing its reliance on broadleaved tree species like birch for the future.

Early detection tools play a critical role to prevent non-native pests and pathogens from being introduced into new areas. Loop-mediated isothermal amplification (LAMP) is a valuable tool that can detect target species with rapid results using environmental DNA in the field. We present work in which a newly developed LAMP assay for BBB is tested both under laboratory and field conditions. Environmental DNA from birch collected from within the infestation areas of BBB in western Canada were tested using a portable Genie II to validate the use of the assay in practice. The results demonstrate the ease of use and ability to readily detect BBB with an efficient, molecular tool to be used for biosecurity tool for European plant protection agencies.

Keywords: early detection, bronze birch borer, LAMP, *Agrilus anxius*, environmental DNA

Ecological and socioeconomic drivers of the biogeographic patterns of global insect invasions

Abstract: Biological invasions are largely an unintended consequence of globalization. With increasing mobility, humans have accidentally transported organisms around the world, breaking the geographical boundaries that separated species ranges that persisted for millions of years of evolution. Among animals, insects are the most numerous group of species, with thousands of insect species having been established outside of their native ranges and many of these species causing immense impacts on agriculture, human health and conservation of native ecosystems. Here, we report on an analysis of historical insect invasions in 11 world regions. We use these data to compare frequencies of invasions among different insect orders and among different insect families. Certain groups, such as the Hemiptera, Formicidae and the Staphylinidae are generally over-represented in non-native insect assemblages, while other taxa are under-represented. These patterns generally reflect characteristics of these insects that cause them to enter important invasion pathways and biological characteristics that facilitate invasions. These results ultimately can be of use when conducting invasive pest risk analysis. We also investigated environmental drivers that explain geographical variation in numbers of species in various insect taxa. Results indicate a strong species-area relationship for both native and non-native insects. However, we found that this appears to be driven by an indirect effect of land area affecting plant diversity and that the strongest drivers of insect species richness are native and non-native plant species richness. The substantial effect of non-native plant richness on non-native insect richness suggests that plant invasions create new ecological niches that promote insect invasions.

Effects of Psyllaephagus bliteus on spread of Glycaspis brimblecombei in Western and Eastern, Kenya

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Miriam Gathogo[1]
Eston Mutitu
[1] 1.Kenya Forestry Research Institute, P.O Box 20412-00200, Nairobi, Kenya

Abstract: *Glycaspis brimblecombei* is known to cause 20-30% defoliation, crown thinning and death of eucalypts. The main natural enemy of the pest from Australia is the parasitoid *Psyllaephagus bliteus*, which has been proved to manage *G. brimblecombei.* The current study was designed to evaluate the distribution of *G. brimblecombei* and *P. bliteus* in Western and Eastern, Kenya after National Forestry Resources Research Institute (NaFORRI) released *P. bliteus* in their *Eucalyptus camaldulensis* plantations bordering Western Kenya. Eucalyptus plantations in Western Kenya (Busia, Bungoma and Siaya counties) and Eastern Kenya (Ndufa and Kiamuringa Kenya Tea Development factory plantations in Embu County) were assessed. Ten *E. camaldulensis* trees were randomly selected from each plantation. The Global Positioning System (GPS) Coordinates of the sampled plantations was recorded. Damage categories by *G. brimblecombei* were assigned to sample trees through visual observation. Adult population of *P. bliteus* was assessed by placing two yellow sticky traps on each sample tree. Three assessments were carried out in three different months. Data analysis was carried out using R statistical tool. Distribution maps were drawn using ArcGis to indicate the intensity of spread of the pest and parasitoid in the regions of study. Results showed that Embu County (Eastern Kenya) had the highest *G. brimblecombei* populations 40.67 ± 1.58, recorded in the month of February with damage ranging between 50 – 75%. Tree infestation by *G. brimblecombei* were highly varied across the four counties ($F = 7.44$, $df = 3, 1492$, $p < 0.001$) and time of assessment ($F = 91.91$, $df = 2, 1492$, $p < 0.001$). There were significant variations in the number of exit holes among the counties ($F = 72.72$, $df = 3, 994$, $p<0.0001$) and time of assessment ($F = 5.76$, $df = 2, 994$, $p = 0.0032$). The highest number of lerps with exit holes was highest in both December (1.81±0.21) and June (1.59±0.34) in Bungoma County, indicating that the parasitoid, *P. bliteus* found its way into Kenya. This study will enable initiation of implementation of Bio-control program for sustainable management of *G. brimblecombei* in Kenya.

Key words: *Psyllaephagus bliteus, Glycaspis brimblecombei, Eucalyptus camaldulensis,* distribution, Western and Eastern Kenya

First report and characterization of Fusarium circinatum, the causal agent of pitch canker on Pinus merkusii in Indonesia

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Sri Rahayu[1]
Pujo Sumantoro[1], Ananto Triyogo[1], Siti Muslimah Widyastuti[1], Fiqry Ardiansyah[1]
[1] Universitas Gadjah Mada

Abstract: *Pinus merkusii* is the only pine that occurs naturally in the South of the Equator particularly in the archipelago of Indonesia. Up to 2019, there was no report on disease problems except damping-off. However, In March 2020, dieback symptoms (basal needle dieback, wilting, and dieback of terminal shoot) were first observed on pine planted at the more than 1200 above sea level area. We also found that some bark beetles including *Tomicus* spp were associated with the symptomatic trees. In order to identify and ascertain the characteristics of the pathogen and the diseases, 120 *P. merkusii* trees (with and without symptoms) were collected. Small pieces (1 cm long; two from the roots, stem at the soil level, and the aerial part, also from the leaf, totalling eight pieces) of 20 symptomatic trees were sterilized with 3% sodium hypochlorite, and isolations were performed on potato dextrose agar (PDA). A species of Fusarium was isolated from all infected tissues and pure cultures were obtained by single hyphal tip transfers on PDA, incubated at 25°C for 10 days with a 12-h photoperiod. (1). The species was identified as *Fusarium circinatum* Nirenberg & O'Donnell on the basis of morphological and cultural characteristics (2). They produced white, aerial mycelia, violet pigment, typically three-septate macroconidia with slightly curved walls, single-celled microconidia, and characteristic sterile, coiled hyphae. Microconidia were ovoid or allantoid and born in false heads on aerial polyphialides. (3). Pathogenicity tests were performed by inoculating 5-month-old *P. merkusii* seedlings. Small strips of bark (10 × 1 mm) were cut from the stems and similar-sized pieces of PDA colonized by four isolates of *F. circinatum* were placed in contact with the open wounds and covered with Parafilm. In Total 80 seedlings were provided for pathogenicity tests. First symptoms, basal needle and shoot dieback, were observed at 15 days after inoculation. Between 6 weeks later, all seedlings tested were dead. No symptoms were observed on control seedlings. *F. circinatum* was reisolated from symptomatic seedlings tested. To our knowledge, this is the first report of *F. circinatum* on *P. merkusii* in Indonesia.

First report of Ophelimus maskelli (Ashmead, 1900) (Hymenoptera: Eulophidae) in Uruguay.

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Carolina Jorge[1]
Lucio Arbiza[1], Lucía Pérez[1]
[1] Laboratorio de Manejo integrado de insectos forestales. PDU Instituto Superior de Estudios Forestales. Sede Tacuarembó, CENUR Noreste, Universidad de la República. Tacuarembó, Uruguay.

Abstract: Forest plantations in Uruguay has become one of the higher productive activities for the country, where *Eucalyptus* spp. represents more than the 80% of the commercial plantations. In the last decades the reports of forest pests were exponentially increased. The gall forming insects have caused important injuries in forest plantations worldwide. *Leptocybe invasa* and *Ophelimus maskelli* (Hymenoptera: Eulophidae) are the main gall wasp species in this insect guild. *L. invasa* was found in the year 2011 being the latest *Eucalyptus* insect pest reported for our country. In the summer of the year 2020 we found Eucalyptus camaldulensis leaves with unknown galls in the Tacuarembó city. We collected branches with these galls and the emerged adults were sexed and identified. We observed two species that were determined as a *Ophelimus maskelli* and their parasitoid *Closterocerus Chamalaeon* (Hymenoptera: Eulophide). In this sense, the aim of this work was reported for the first time the presence of Ophelimus and their parasitoid in Uruguay and assess their distribution. In order to evaluate the distribution of *O. maskelli* we realized field trips in *Eucalyptus* plantations and windbreaks in ten departments of Uruguay during February of 2020 to May 2023. When found Ophelimus galls we collected Eucalyptus branches and place in ziplock bags. The samples were kept in a climatic room at 23 °C with photoperiod (12:12) and adult emergences were daily checked. The emerged exemplars were identified, sexed and placed in tubes with 70% alcohol. We found *O. maskelli* galls in six of ten departments sampled. The parasitoid emergences were variable, but in the most of collected sites was higher than 75%. Future prospects will be focus in the study of the impact of this insect pest in the Uruguayan forest plantations and evaluate the parasitism level.

Forest insect biosecurity: what's working, what's not – and what else can we do?

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Helen Nahrung[1]
Andrew Liebhold[2], **Eckehard Brockerhoff**[3], Davide Rassati[4]
[1] Forest Research Institute, University of the Sunshine Coast, Australia
[2] US Forest Service Norther Research Station, West Virginia, USA
[3] Swiss Federal Research Institute WSL, Switzerland
[4] Department of Agronomy, Food, Natural Resources, Animals and the Environment, University of Padova, Italy

Abstract: Considerable effort globally goes into safeguarding against invasions by non-native forest insect species because of their significant environmental, economic, and social impacts. Here, we describe pre-border, border and post-border biosecurity measures that are used to mitigate the arrival, establishment, spread and impact of forest insects, and discuss their successes and limitations using relevant key examples. Some countries (e.g., Australia, New Zealand, USA) have maintained a relatively constant accumulation rate of non-native forest species, despite virtually exponential increases in trade and travel over the last ~150 years, suggesting biosecurity efforts in these regions have had an impact on arrival and establishment. Nevertheless, risk profiles change constantly through globalisation opening new trade pathways and species source pools, and through increased movement of goods and people, and differences in biosecurity strengths between countries. We illustrate the mutual advantages of programs that increase capacity in under-resourced nations to (i) protect their resources and trade, (ii) reduce the flow-on effects of "invasion begetting invasion", and (iii) provide "intelligence" on potential risks.

Risk assessments and pest predictions can be foiled by insects that defy traditional "red flag" metrics and aren't pests in their country of origin, aren't invasive elsewhere, or aren't even known to science until they become invasive. Mitigating these "known unknowns" is challenging; we discuss the utility of border interception data in identifying emerging threats and pathways. There are further dangers posed by pathways beyond our direct control, such as smuggling or the wilful introduction of exotic insects or their hosts, fraudulent practice, ineffective treatment, or deliberate circumvention of biosecurity protocols. We describe post-border surveillance frameworks, including the increasingly important role of citizen science and public awareness in reporting forest pest detections and spread, and reiterate the principle that biosecurity is a shared responsibility that benefits countries, governments, industries, and individuals.

Forest Phytophthora - ecology, diversity and management

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

[3] Department of Plant Protection Biology, Swedish University of Agricultural Sciences, Alnarp, Sweden
[4] Forestry and Wood Technology, Linnaeus University, Växjö, Sweden

Abstract: Damage to trees in forests and urban environments caused by *Phytophthora* species are an increasing threat to the vitality and productivity of these ecosystems in many parts of the world, including Sweden. *Phytophthora*, which seriously damages the fine roots of trees and several other woody plants, is efficiently introduced to new environments through imported plant material (mainly non-native plants through the nursery trade). A study was conducted in Southern Sweden aimed to characterise the differences in soil microbial diversity and taxonomic composition between dieback asymptomatic and symptomatic *Quercus robur* trees. The idea is to explore how network community may change across vitalities, and adaptations when there is the presence of oomycetes species and their potential influence on the microbiome. To uncover ecological interactions, the microflora present in soil samples were quantified using a new approach combining high-throughput qPCR Biomark Fluidigm chip technology optimised for oomycete analysis and Next Generation Sequencing. The fungal communities in the soils included a wide range of pathogens and ectomycorrhizal taxa. Amongst the most abundant oomycetes, *Phytophthora plurivora, Phytophthora cactorum* and *Phytophthora gonapodyides* were identified. A specific taxon in the genus *Trichoderma* was strongly correlated with scarcity of pathogenic *Phytophthora* spp. The meta-analysis of the soil microbiome represents an excellent tool supporting the development of biocontrol strategies for the management of diseases caused by *Phytophthora* spp.

From historical cultures to genomic exploration: An investigation of the enigmatic conifer root pathogen Rhizina undulata

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

[2] Forestry and Agricultural Biotechnology Institute, Department of Plant and Soil Sciences, University of Pretoria

Abstract: In the 1970s and 1980s, a number of *Pinus* plantations in South Africa experienced patch death. The causal agent was originally thought to be *Phytophthora cinnamomi*, but the mysterious disease was later attributed to *Leptographium serpens*. However, there was a long-standing debate regarding the ability of *Leptographium* species to act as primary pathogens. This raised doubt regarding the role of this fungus as the cause of the patch deaths. At the time of studying this disease, the available research tools precluded further investigation. In the present study, we revived cultures originally isolated from the dying trees and used DNA sequencing to identify them. *Rhizina undulata* was thus identified as the primary pathogen associated with the disease, some 40 years after it was first studied. Also known as "the coffee fire fungus" because it requires exposure to high temperatures for germination, *R. undulata* is a well-known conifer pathogen, particularly relevant to forestry in Europe and Asia, but surprisingly poorly studied. The availability of cultures arising from the recent reassessment of the patch death problem in South Africa provided the opportunity to further investigate the thermotolerant nature of this enigmatic fungus using modern comparative genomics techniques. The sequenced genome of *R. undulata* was similar to the genomes of other Pezizales species in terms of size and gene content, but it exhibited significant expansions in the heat shock protein 20 (HSP20) and glutathione S-transferase (GST) gene families. Both HSPs and GSTs are known to be involved in heat shock defense in fungi, suggesting that these expanded gene families may contribute to the thermotolerance displayed by *R. undulata*. These findings highlight the importance of preserving cultures for future studies and emphasize the utility of advanced genetics tools in forest pathology.

Genomic biosurveillance of invasive alien tree pests

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Richard Hamelin[1]
[1] Faculty of Forestry, Department of Forest & Conservation Sciences, The University of British Columbia, Vancouver, Canada

Abstract: Biological invasions by invasive alien tree pests have caused irreversible changes to forest ecosystems worldwide. Early detection for rapid response is key to preventing new invasions or to limit or contain newly established ones. Genomics has provided a new toolbox that is already making a difference in our ability for early detection and rapid response. Rapid and accurate PCR assays are robust and can be used with a variety of host tissues or life stages of insects, fungi and oomycetes. They are used operationally in surveys or inspection activities for the detection of many pathogens, such as the *Phytophthora*, from tree foliage, stems, roots and soil samples. PCR is also widely used to differentiate insect subspecies with different regulatory requirements, such as the Asian and European *Lymantria* subspecies. While PCR targets a few genome regions and is useful for detection, genome sequencing can provide a much fuller picture that can help reveal the genomic signature of the invasion history. The process of invasion, colonization and spread leaves a genomic signature in the invader's genome. This signature can be used to identify populations, assign intercepted samples to putative sources or identify potential pathways. Increasingly, these tools are used routinely in diagnostic labs. By comparing the genomic profile of intercepted samples to global sequence databases, it is possible to assign these unknowns to source populations with high accuracy. Genome reduction approaches, such as target-enrichment genome sequencing, can generate genome profiles at low cost and they can be analyzed rapidly to provide highly accurate results. The capacity to perform DNA-based analyses in the field is causing a shift in paradigm, where samples can be processed rapidly and accurately on-site. Portable PCR assays that can be used on-site are now available and allow rapid and accurate detection and identifications. On-site target-enrichment approaches that can generate genomic data of targeted regions are promising because they can provide taxonomic as well as phenotypic information that will become an essential part of pest-management decision-making.

Genomic insights into the movement of Fusarium circinatum and virulence on the co-evolved host Pinus elliottii

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

[4] United States Forest Service, Gainesville, Florida, United States
[5] Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, South Africa

Abstract: Pine pitch canker is a serious disease of *Pinus* spp. that is caused by the fungus *Fusarium circinatum*. Endemic in Central and North America and invasive elsewhere, *F. circinatum* is considered one of the greatest threats to pine forests globally. While genomic resources are increasingly available to facilitate the study of this pathogen, little is understood about the interactions between the pathogen and co-evolved pines within its endemic range. Moreover, accurate prediction of host resistance to pine pitch canker is not yet possible. We analyzed *F. circinatum* populations from throughout the southeast United States to investigate relatedness among isolates, identify genetic markers of both pathogen virulence and host resistance, and incorporate the markers into genomic selection models to ultimately improve the resources available to guide the breeding of pitch canker resistant pines. To achieve these goals, disease severity, as caused by 50 different *F. circinatum* isolates on multiple lines of clonally propagated *Pinus elliottii,* is being quantified. Fungal isolates were collected from symptomatic pines throughout the pathogen's endemic range in the southeast United States. Inoculation trials using *P. elliottii* clones provided by the Cooperative Forest Genetics Research Program are being utilized. Whole genome sequences of all isolates have been obtained to analyze relatedness among the populations of the pathogen and to identify genomic regions associated with virulence. Future work will include the comparison of southeast US isolates to those from México and Central America to pinpoint the geographic origin of *F. circinatum*, and sequencing and characterization of resistance genes of the slash pine clones. Genomic selection models will be developed to predict pitch canker resistance more accurately, based on co-associating host resistance and pathogen virulence markers. Examining diverse lines of a co-evolved host and a wide array of isolates will enable investigation of the genomic architecture of resistance, resistance generality to multiple fungal isolates, reveal virulence factors, and identify resistant lines. Better prediction of pitch canker resistance and a stronger understanding of the genetic factors that underpin virulence and host defense are critical for preparing land managers for this emerging invasive threat.

Integrated Pest Management of fungal pathogens in forestry

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

René Eschen[1]
Michelle Cleary[2], Maarten De Groot[3], Alberto Santini[4]
[1] CABI, Delémont, Switzerland
[2] Southern Swedish Forest Research Centre, Swedish University of Agricultural Sciences, Alnarp, Sweden
[3] Slovenian Forestry Institute, Ljubljana, Slovenia
[4] Institute for Sustainable Plant Protection (IPSP), National Research Council C.N.R., Sesto Fiorentino, Italy

Abstract: Climate change and human activities increase the occurrence, abundance and impacts of fungal pathogens in forests, and these factors increasingly threaten forest productivity and biodiversity. A number of factors currently limit the successful management of pathogens in forests, including the long rotation of forest plantations (compared to agriculture), the limited use, or prohibition of pesticide use in many countries, and uniform stands in plantation forests. More limitations apply to natural forests or protected areas. Integrated pest management (IPM) is an effective and environmentally sensitive approach to pest management that aims to prevent, detect and control pathogens to maintain forest vitality and productivity while reducing negative environmental impacts, but it is currently not widely practiced. Implementation of IPM in forestry would require a switch of traditional, reactive management of forest pathogens to proactive management. However, the problem is complex, as indicated by the diversity of potential pathogens, as well as insect pests, their pathways of introduction and spread, as well as the multitude of factors that affect outbreak dynamics. Thus, promoting healthy and resilient forests by using a holistic approach for IPM should consider multiple risk factors, novel tools and strategies in conjunction with mitigation practices and forest management practices that simultaneously target different pathogens and pests, as well as hosts. In this talk, we provide an overview of ongoing IPM approaches that specifically address pathogens in forestry, identify gaps and propose approaches and needs for effective future management of forest pathogens.

Interactions between invasive pests and pathogens in native chestnut forest

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Maria J. Lombardero[1]
Maria Flora Romay-Rio[1]
[1] Unit for Sustainable Forest and Environmental Management, Universidad de Santiago de Compostela

Abstract: The number of invasive pathogens and insect pests in forest ecosystems has increased dramatically in the last century. These introductions often have negative economic and ecological consequences for forest ecosystems and can lead to novel interactions, with unpredictable consequences. Chestnut blight (*Cryphonectria parasitica*) has been present in southern Europe since the mid-20th century and remains a threat to the European chestnut. *Dryocosmus kuriphilus* arrived in southern Europe at the beginning of the 21st century, causing significant losses in chestnut production. Both species can colonize the same trees. To assess the potential interactions between them, we conducted a study in Galicia (NW of the Iberian Peninsula), one of the most important areas for chestnut production in southern Europe. We studied five plots that contained both organisms; in each plot we sampled 10 trees affected only by the insects and 10 affected by both the insect and the fungus. We estimated the level of attack of each tree and analyzed the nutritional quality, water content, and secondary metabolism compounds of five leaves without galls and five leaves with galls from the study trees. We evaluated the effects of these parameters on insect fecundity and larval growth. We also conducted a greenhouse study to evaluate insect preference when offered 20 trees with chestnut blight and 20 healthy trees. In the field, insect attack levels were significantly higher on trees with chestnut blight, especially in plots with a longer attack; however, in the greenhouse, insects displayed no preference for either healthy or infected trees. Chemical analyses revealed no differences in foliar nitrogen or water content of trees affected or not by the fungi. Similarly, the mass of larvae was no different between trees that were healthy or infected. However, the number of eggs per female was significantly higher in trees affected by chestnut blight. There were no differences in the composition of terpenes or phenols between trees. However, the tannin concentration was significantly higher in trees also affected by chestnut blight. Higher tannins induced by chestnut blight may directly or indirectly benefit the gall wasps.

Invasive gall-forming wasps of the genus Ophelimus threaten eucalyptus plantations in Argentina, South America.

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Carmen Marcela Hernández[1]
Rocío Buyatti[1], Andrea Andorno[1], Sergio Ramos[2], Edgar Eskiviski[3], Silvia López[1]
[1] Instituto Nacional de Tecnología Agropecuaria (INTA). Instituto de Microbiología y Zoología Agrícola (Argentina)
[2] Instituto Nacional de Tecnología Agropecuaria (INTA). Estación Experimental Agropecuaria Concordia. (Argentina)
[3] Instituto Nacional de Tecnología Agropecuaria (INTA). Estación Experimental Agropecuaria Montecarlo. (Argentina)

Abstract: Numerous pests native to Australia and associated with eucalyptus invaded other countries. The genus *Ophelimus* has several gall wasps that are continually expanding and causing damage to the eucalyptus plantation. Two species of *Ophelimus* were detected in Argentina: *O. maskelli* reported in 2013 with its parasitoid, *Closterocerus chamaeleon*, and an unidentified species, *Ophelimus* sp., in 2017. A field survey was carried out in eucalyptus plantations to assess the distribution of *Ophelimus* spp. and *C. chamaeleon*. Twenty-one eucalyptus plantations were sampled from 2017 to 2022, covering four provinces in an extensive productive area. Branches (50-60 cm) with leaves containing developed galls were collected in each plantation. The external morphological aspect of galls was characterized. Adults were identified after emergence according to their morphological characteristics and counted in the laboratory. *Ophelimus maskelli* develops in a single-cell gall and expands to both sides of the leaf blade; galls are round, green, or red and have a smooth texture. Galls induced by *Ophelimus* sp. are also nearly round, smaller, and expand only to one leaf surface; they have a brown-grey color and a rough appearance. *O. maskelli* is present in all provinces sampled in plantations of *E. tereticornis*, *E. camaldulensis*, *E. grandis*, and some hybrids (*E. grandis* x *E. camaldulensis* and *E. grandis* x *E. urophylla*). Besides, *C. chamaeleon* was found at all sample sites. About 14.000 adults (gall wasp + parasitoids) were collected and parasitism ranged from 60 to 100 %. *Ophelimus* sp. was present in Buenos Aires province in *E. viminalis* and *E. cinerea*. Adults of *C. chamaeleon* emerged from galls but in low numbers (parasitism ≤ 0.6 %). In conclusion, *O. maskelli* has a wide distribution and is always associated with *C. chamaeleon*, which seems to contribute to the mortality of the population pest. The spread of *Ophelimus* sp. may represent a threat to eucalyptus plantations in the region. Further molecular studies are needed to identify the pest at the species level. The host range and life cycle of *Ophelimus* sp. and the role of *C. chamaeleon* as a biological control agent of this pest also need to be studied.

Abstract: The outbreak of alien invasive plant pathogens, such as *Phytophthora* adversely impact natural and semi-natural forest ecosystems. Rising temperatures and extreme climatic events are amplifying the impact of *Phytophthora* diseases on evergreen oak and chestnut forests thought the Mediterranean basin. Limited public awareness, sensible human impact on forest areas and the current EU fertilizer regulations restricting the use of the most effective and eco-friendly disease mitigation compound, K-phosphonate, further heighten the risk of disease epidemics. Challenged forest ecosystems need improved tools and strategies to enhance their adaptation to the outlined issue, finally ensuring their preservation as important natural carbon sinks. The project LIFE FAGESOS, started in September 2022, aims to propose and apply new integrated pest management protocols, that can be tailored to specific traits of the target ecosystem implemented by an extensive multi-actor network. The consortium comprises 13 multi-actor partners, including research institutions, enterprises, local authorities and growers and several stakeholders in Italy, Portugal and Spain. Over the first year mesocosm trials, which include new biostimulant and antagonistic microorganisms as well as products already available in the market, have been undertaken to evaluate their potential use, in alternative to K-phosphonate, along with hygiene measures to prevent disease spread. A disease risk model to identify the areas at risk of introduction of the disease and a remote sensing-based monitoring system have been implemented. These tools will support informed decision-making for policymakers and forest managers. Finally, FAGESOS will encourage cooperation among entities involved in forest management and conservation, ensuring a holistic and integrated approach to address the outbreak of plant athogens and enhance forest resilience.

Molecular Characterization and Phylogeny of Foliar Pathogens in Select Native Forest Tree Species in the Philippines

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Romana Alyssa Mastrili[1]
Cristienne Alfred Ramos[1], Karl Angelo Yap[1], **Jessa Ata**[1]
[1] Department of Forest Biological Sciences, University of the Philippines Los Baños, College, Laguna 4031 Philippines

Abstract: Foliage diseases have been projected to become more prevalent as sporulation and infection of many foliar fungal pathogens intensify with frequent warm rain events. More intermittent outbreaks of foliar diseases could likely occur in the Philippines during warm and wet seasons, although seasonal drought may slow down foliar disease impact. However, the lack of basic molecular information on many foliar fungal forest pathogens in the Philippines limits fungal identification and understanding of fungal pathogen lifestyles, which further impedes efficient disease management and appropriate phytosanitary measures. This study characterized the morphological and molecular features and elucidated the phylogenetic relationships of foliar fungal pathogens on Philippine native trees and palms. Examinations from pure cultures and DNA of fungal pathogens isolated from symptomatic tissues of native species such as *Pterocarpus*, *Litsea*, *Pongamia* and *Areca* revealed common and unique tropical foliar pathogens including one that is potentially causing new disease on native palm species. While information from this study contributes to the global fungal identification system for pathogen surveillance and plant quarantine, further investigations are needed to fully understand the impact of fungal foliar pathogens on forest ecosystems and industries.

Morphological and Molecular Identification of Pine Bark Beetles Infesting Pinus kesiya in the Philippines: Insights for Pest Management

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Redentor Reyes Jr.[1]
Sheryl Yap[1], Karen Alviar[1], Romnick Latina[1]
[1] Institute of Weed Science, Entomology and Plant Pathology, College of Agriculture and Food Science, University of the Philippines Los Baños

Abstract: Pine bark beetles are considered to be one of the most destructive pests of Pinaceae in North America and Central America where most species are found to be native. Outside their native host range, pine bark beetles can cause widespread mortality in novel and more susceptible host trees. In the Philippines, *Ips calligraphus* (Germar) is known to infest Benguet pine, *Pinus kesiya* Royle ex Gordon, since 1966 and is now widespread in Northern Luzon. In a recent study, species of *Ips* DeGeer and *Dendroctonus* Erichson were found to infest *P. kesiya* in Benguet, but no morphological evidence was provided. This study aimed to identify pine bark beetle specimens collected from Benguet and Pangasinan, Philippines, based on morphological characteristics and molecular analysis using the mitochondrial *cytochrome c oxidase subunit I* (*COI*) gene. PCR amplification of the *COI* fragments was carried out using the barcoding primers LCO1490/HCO2198 and validated through agarose gel electrophoresis before being subjected to bidirectional Sanger sequencing. Results revealed that pine bark beetles collected from Baguio were species of *Xyleborus* Eichhoff based on a combination of antennal, pronotal, and elytral characters. On the other hand, specimens from Pangasinan were identified as *I. calligraphus* based on their elytral declivity features, confirming previous reports. Molecular analysis supported this finding, with *I. calligraphus* sharing 99.7% identity with an *I. calligraphus* accession in GenBank. However, for the *Xyleborus* sp. specimen, the best hits, *X. dryographus* (Ratzeburg) and *X. vulcanus* Perkins, only shared 87.4% and 86.8% identity, respectively. Further study on the diversity and distribution of pine bark beetles in the Philippines is needed in order to establish a more accurate basis for morphological and molecular identification, and ultimately contribute to the ongoing pest management program in the country.

Natural regeneration of beech on Phytophthora-infested soils

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Carmen Romeralo[1]
Johanna Witzell[2]
[1] Institute of Forest Sciences, INIA-CSIC, Madrid, Spain
[2] Forestry and Wood Technology, Linnaeus University, Växjö, Sweden

Abstract: Fungal-like, oomycetes of the genus *Phytophthora* are increasingly found in European beech forests where they damage the roots of the trees, weaken the trees and make them susceptible to other disturbances. The infection in the soil cannot be eradicated and therefore new plants may also be affected by the pathogen. The *Phytophthora* spp. can be spread with nursery plants, and natural regeneration could therefore be a better alternative to regenerating forests. However, there is very little information on how naturally regenerated plants are affected by the pathogens already present in the soil. The study explored whether the natural regeneration and seeds were already infected by the pathogen at an early stage of development. We had a unique opportunity to study this issue in a protected area where the *Phytophthora* infection was found in a 120-year-old beech forest where natural regeneration started without grazing damage. Small beech seedlings (2-3 years old) and seeds were collected to study, by means of microscopy, cultivation tests and molecular methods, whether the plants and seeds were already infected by the same *Phytophthora* species found in previous studies in the large trees and in the soil. The results of the study showed that *Phytophthora* was not widespread in the plant material since it was found in only one seedling out of the ninety sampled, and in any of the seeds collected. The research was carried out as a collaboration between SLU Alnarp and Söderåsens National Park (County Administrative Board of Skåne) with the aim that results could be translated into practical advice to stakeholders regarding regeneration strategies. This study is one of the first studies that examines the practical possibilities to adapt to *Phytophthora* damage in forest environments.

New fungi associated with sentinel plants from North America in Italy

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

[3] The Ohio State University, USA

Abstract: Sentinel plants are used to detect potentially harmful organisms before they are introduced to new countries. Through the project, "A global, reciprocal sentinel gardens approach to assess risk of invasion by alien pathogens and insect pests of important woody plant species", led by Pierluigi (Enrico) Bonello at Ohio State University, *ex patria* sentinel plantings were established in Florence, Italy, in 2019 using seven North American tree species. Monitoring led to the detection of leaf lesions on the plants. Subsequent isolations and Sanger sequencing for multiple genes were performed. Sixty-seven different strains were obtained, of which: 25 were known to be pathogenic on these hosts; 7 are considered new species or subspecies; 10 have not yet been determined to species level; 13 were not known to occur in Europe; 5 are widely distributed but not known to occur on these hosts; and 7 are considered to occur in Europe but not on these hosts. For 10 selected strains, pathogenicity tests were conducted in plants and on detached leaves in the laboratory, using both spore suspensions and mycelium slurries for inoculation. Results of the study are forthcoming and will be discussed at the meeting.

New insights on the Ophiostoma novo-ulmi – Geosmithia associations

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Alessia Lucia Pepori[1]
Francesco Pecori[1], Nicola Luchi[1], Alberto Santini[1]
[1] National Research Council, Institute for Sustainable Plant Protection (IPSP), Via Madonna del Piano, 10 50019 Sesto fiorentino (FI) - ITALY

Abstract: In Europe as in North America, elms are devastated by Dutch elm disease (DED), caused by the alien ascomycete *Ophiostoma novo-ulmi*. Pathogen dispersal and transmission are ensured by local species of bark beetles, which established a novel association with the fungus. Elm bark beetles also transport fungi of the genus *Geosmithia* that are also found in scolytids' galleries colonized by O. *novo-ulmi*. Widespread horizontal gene transfer between *O. novo-ulmi* and *Geosmithia* was recently observed.

The relation between these two fungi in the DED pathosystem, i.e., *O. novo-ulmi* and *Geosmithia* species from elm, including a *G pumila* GFP-tagged strain, were grown in dual culture, and mycelial interactions were observed by light and fluorescence microscopy. Growth and sporulation of *O. novo-ulmi* in the absence or presence of *Geosmithia* were compared. The phenotypes of the two fungi were also characterised individually and in dual culture using phenotypic microarray (PM) techniques. The impact of *Geosmithia* on DED severity was tested in vivo by co- inoculating *Geosmithia* and *O. novo-ulmi* in elms. A duplex qPCR molecular technique was also developed to identify the presence of both fungi within elm plants and on the body of elm bark beetles.

The results of the numerous tests show a close and stable relation between the two fungi, and that some *Geosmithia* strains exhibits aggressiveness (*in vitro*) towards *O. novo-ulmi*, and we observed hyperparasitic behaviour of *Geosmithia*. These results prove the existence of a new component in the complex of organisms involved in DED, which might be capable of reducing the disease impact on elm trees.

Overcoming the invasion paradox: Population genomics and phenotyping provide clues to the repeated emegence of P. ramorum in the US and Europe

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Jared LeBoldus[1, 2]
Nicholas Cauldron[1, 3], Adam Carson[2], Hazel Daniels[1], Niklaus Grünwald[3]

[2] The Forest Enginering, Resources and Management Department, Oregon State University, Corvallis Oregon, USA.
[3] Horticultural Crops Research Laboratory, USDA Agricultural Research Service, Corvallis, Oregon, USA.

Abstract: Oomycete pathogens threaten food, fiber, and forests around the world. *Phytophthora ramorum*, the causal agent of sudden oak death has repeatedly emerged in both the Western USA and Europe. Divergent lineages of *P. ramorum* have survived millions of years reproducing primarily clonally. A phenomenon, known as Muller's ratchet, predicts that asexual populations experience a high genetic load increasing their risk of extinction. However, most outbreaks of introduced exotic plant pathogens are the result of clonal expansion from a single introduction. The separate outbreaks of EU1 and NA1 in forests of the western United States, replicated natural experiments, can be used to understand this invasion paradox. Populations of the EU1 (n =160) and NA1 (n =135) were sequenced and phenotyped to examine how mutation impacts epidemic development. These samples were collected during the first 5 years of each epidemic. Re-sequenced populations yielded 106,070 high-quality SNPs in genic regions; 55,913 were polymorphic within NA1 and 22,700 within EU1. Low diversity in the EU1 population is contrasted with higher cryptic diversity in the NA1 population. These differences are mostly attributed to losses of heterozygosity (LOH), a chromosomal aberration resulting in the spontaneous loss of one allele or chromosomal regions in the diploid genomes. LOH is correlated with reduced aggressiveness, sporulation, and growth rates in most NA1 isolates. However, there are rare examples of increased aggressiveness. LOH is much less prevalent and less severe in the EU1 population. This implies that there may be a system regulating LOH, or that there is a reproductive mechanism that is more dysfunctional in the NA1 population.

Pathogen evolution in the era of globalism: case study with invasive Cronartium ribicola and native Cronartium comandrae hybrids in North America

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Olga Kozhar[1]
Kelly S. Burns[2], Anna W. Schoettle[3], **Jane E. Stewart**[1]
[1] Colorado State University, Fort Collins, CO, USA
[2] USDA Forest Service, Forest Health Protection, Lakewood, CO, USA
[3] USDA Forest Service, Rocky Mountain Research Station, Fort Collins, CO, USA

Abstract: Invasive pathogenic fungi increasingly threaten tree species resulting in possible fundamental ecosystems changes around the globe. Besides being more aggressive towards new hosts, non-native fungal species carry additional risks for the health of forest ecosystems via interactions with native species. Interspecific hybridization plays a key role in the evolution and emergence of novel fungal pathogens, and when it occurs between native and invasive species, can lead to unforeseen and potentially serious consequences. Early detection of hybrids, before they become prevalent in ecosystems, can help resource managers develop timely risk-assessment strategies. The objective of this study was to determine whether hybrids (CrxCc) of two rust species, non-native invasive to North America *Cronartium ribicola* (Cr) and native *C. comandrae* (Cc), previously detected in Canada, were present in forest ecosystems of Wyoming and Colorado, USA. In total, 726 and 1452 individual aecia from 178 lodgepole (*Pinus contorta* ssp. *latifolia*) and 357 limber (*P. flexilis*) pines were collected from 25 sites in 5 national forests from 2019-2021. Using morphological and molecular analyses, 71 aecia collected from 25 *P. flexilis* trees had intermediate morphology and contained heterozygous SNPs in the Dcon10 and Dcon35 genomic regions. Population analyses revealed the presence of 4 and 9 CrxCc hybrid genotypes in Dcon10 and Dcon35, respectively. The distribution of these genotypes varied by geography and year. Different CrxCc aecial genotypes were frequently sampled from the same cankers in the same year, indicating multiple independent hybridizations and perennial presence of CrxCc. Aeciospores from 2 CrxCc aecia were capable of infecting the alternate host *Ribes nigrum* and produced urediniospores on *R.nigrum*leaves in a growth chamber. Overall, these results suggest that, even though low in frequency, CrxCc is persistent in the studied region, and has pathogenic potential. Hybrid expansion into the large range of susceptible pines could have cascading impacts on forest ecosystem health.

Pathogenicity of Oomicetes Isolated from Declined Alders in Spain

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Eduardo Pastor Durántez[1]
Raquel del Campo Calvo[1], Alba Díez Galán[1], Julio Javier Diez Casero[1]
[1] Sustainable Forest Management Research Institute UVa-INIA. E.T.S.II.AA.

Abstract: Alder decline is caused by different oomycetes, such as *Phytophthora alni* species complex and *P. plurivora*. This disease affects alder, one of the most ecologically important riparian tree species. The pathogens mainly affect the root and the lower parts of the trunk, producing bleeding cankers, as well as crown dieback and yellowish leaves. Solla et al. (2010) detected *P. alni* complex species in Spain for the first time, where a decrease in alder population has been detected in recent decades. As a response to this problem, we are performing a research program on alder protection and restoration against the oomycetes causing the alder dieback. The aim of this work was to evaluate the pathogenicity of the oomycete species involved in the alder decline. To this end, we have identified different oomycetes on the wood and soil of affected alder trees coming from different places of Spain to perform pathogenicity tests. The pathogenicity of the different oomycete species was tested on alder seedling through different inoculation methods: by flooding, by watering and by bleeds, using mycelia and zoospores. Differences in pathogenicity among oomycetes was detected and discussed in the context of the alder decline.

Keywords: Oomycetes, Phytophthora spp.*, alder, alder decline, pathogenicity*

Patterns and drivers of Scolytinae invasions in the Southern Hemisphere

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Maria Victoria Lantschner[1]
Gimena Vilardo[1], Juan Corley[1, 2]
[1] Instituto de Investigaciones Forestales y Agropecuarias Bariloche, INTA Bariloche – CONICET, Argentina
[2] Centro Regional Universitario Bariloche, Universidad Nacional del Comahue

Abstract: Non-native insect invasions are increasing globally and can have significant negative effects on forest ecosystems. While forest insect invasions have been mainly studied in the Northern Hemisphere, there is a significant knowledge gap regarding the Southern Hemisphere. By filling this gap, we can gain a more comprehensive understanding of global invasion patterns and dynamics, allowing us to better predict and respond to future invasions. Scolytinae (Coleoptera: Curculionidae) are a diverse group of forest insects known for their successful invasion abilities and role in tree mortality. We explored geographic invasion patterns of Scolytinae in countries of the Southern Hemisphere and evaluated the importance of potential invasion drivers, including trade volume, climatic similarity and heterogeneity, and forest heterogeneity. Analyses were conducted separately for main feeding guilds: ambrosia beetles, bark beetles, and seed and twig feeders. We identified a total of 75 non-native Scolytinae species in the Southern Hemisphere, with Brazil having the highest number of established species (31), followed by South Africa (21) and Australia (19). We found a positive relationship between species host breath (number of plant families) and the number of colonized countries. We observed contrasting patterns and drivers explaining the number and origin of non-native species among feeding guilds. Non-native ambrosia beetles were predominantly native to the Indo-Malay region (55%), and climatic similarity between the donor region and the recipient country was the factor that best explained this pattern. Most established bark beetles were native to the Palearctic region (65%), and the variable that best explained this pattern was the trade volume between the donor region and the recipient country. The origin of seed and twig feeders was dominantly tropical: Afrotropic (32%), Neotropic (23%), and Indo-Malay (23%), and this pattern was related to forest and precipitation heterogeneity and import volume. Overall, our results suggests that difference in biological traits of each feeding guild influences their invasion process in the Southern Hemisphere. It highlights the importance of international trade on bark beetle invasions, while climatic conditions appear to be the key factor for ambrosia beetle invasions, and a combination of several drivers affects the invasion of seed and twig feeders.

Peekers and Streakers: Voyeurism into genomics of a Vascular Streak Disorder isolate

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Marcin Nowicki[1]
Sarah Boggess[1], Robert Trigiano[1], Margaret Staton[1], Matthew Huff[1], John Bonkowski[2], John McVay[3], Denita Hadziabdic[1]
[1] University of Tennessee, Entomology and Plant Pathology Department, Knoxville, TN
[2] Plant and Pest Diagnostic Laboratory, Purdue University, West Lafayette IN
[3] Florida Department of Agriculture and Consumer Services, Tallahassee, FL

Abstract: Recent emergence of dieback and vascular streaking disorder (VSD) has been reported in several states in the eastern USA and recovered from more than 20 different tree and shrub species. The affected plant species include ecologically important native plants and economically valuable ornamental crops that are grown and sold for use in managed landscapes, parks, and restoration projects. VSD manifests in infected host plants with symptoms such as dieback, general plant decline, and streaking in stems. Despite ongoing pathogenicity testing, the exact cause of this disorder remains elusive. Our preliminary evidence suggests an association with a *Rhizoctonia*-like fungus tentatively identified as *Ceratobasidium theobromae* (syn. *Rhizoctonia theobromae*). As we address the challenges associated with isolating and maintaining the cultures in laboratory conditions, there is a notable knowledge gap in the genomics of the fungus suspected to cause VSD. Whole-genome Illumina sequencing of a local isolate from VSD-symptomatic *Cercis canadensis* in Tennessee has yielded valuable insights into its genomics. Assembly of the approximately 9kbp nuclear rDNA region from the Tennessee isolate is serving as a reference for mapping the available reads from 82 Ceratobasidiaceae isolates, including *Ceratobasidium* (n = 14), *Rhizoctonia* (n = 50), and *Thanatephorus* (n = 18) generic representatives. Variant analysis revealed that the Tennessee isolate is clustered with other *Thanatephorus* isolates, suggesting a separation between *Ceratobasidium* and *Rhizoctonia* clades that have been collected from different host species. Successful mitochondrial assemblies have not yet been obtained, however, when the *R. solani* mitochondrial genome is used as a reference, only 10 of the 88 Ceratobasidiaceae isolates and yielded sequence variants. No differences were observed between the Tennessee isolate and the reference *R. solani* mitochondrial genome. This evidence supports rDNA mapping results, in which the Tennessee isolate was grouped within isolates representing the perfect stage of *Rhizoctonia* - *Thanatephorus*. To facilitate the assembly of a high-contiguity nuclear genome for the suspected VSD causal agent, and to allow classification of the Tennessee isolate within the Ceratobasidiaceae family, an analysis of long-molecule DNA sequences is ongoing.

Performance of emerald ash borer (Agrilus planipennis) on three European Fraxinus species

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Donnie Lee Peterson[1]
Beatrice Tolio[1, 2], Patrick Sherwood[1], Mateusz Liziniewicz[2], Michelle Cleary[1]
[1] Southern Swedish Forest Research Centre, Swedish University of Agricultural Sciences, Alnarp, Sweden
[2] Skogforsk - The Forestry Research Institute of Sweden, Svalöv, Sweden

Abstract: Emerald ash borer (EAB - *Agrilus planipennis*) is a wood-boring beetle native from East Asia that following its accidental introduction into North America in the early 1990s, caused widespread mortality of millions of ash (*Fraxinus* spp.) trees. In Europe, EAB was first detected in Moscow in 2003 and shown to have the potential to kill native European ash (*F. excelsior*). Since then, the beetle has spread westward and in 2019 it was confirmed in Ukraine. EAB is expected to further spread across Europe due to both natural dispersal and anthropogenic activities. Meanwhile, in the last few decades, large-scale decline and mortality of European ash has resulted because of the invasive fungal pathogen *Hymenoscyphus fraxineus*. The combined effect of these two threats could prove to be highly destructive, posing a serious risk of extinction for European ash. Additionally, other European *Fraxinus* species are affected by ash dieback, including *F. angustifolia* and *F. ornus* to a lesser degree, but may be severely impacted by EAB.

In this study, we aimed to: i) investigate the volatile profiles of the three native European *Fraxinus* spp. to explore potential host selection cues for EAB and how it influences EAB performance, and ii) characterize host tree defences involved in the interaction of EAB and in trees with dual stressors *H. fraxineus* and EAB. The study utilizes saplings of three European ash species: *F. excelsior*, *F. angustifolia* and *F. ornus*. For each species, 10 replicate trees were subjected to one of three treatments i) healthy controls, ii) *H. fraxineus* inoculated, and iii) trees infested with EAB and inoculated with *H. fraxineus*. Volatile organic compound emission will be analysed using gas chromatography-mass spectrometry to examine quantitative and qualitative variation among host volatile profiles in relation to larval survival and development. To look for interspecific differences in host chemical defences, phenolic metabolite extracts from phloem tissue will be analyzed using liquid chromatography–mass spectrometry. The results of this study provide insight into the performance of EAB on European native *Fraxinus* species and the phytochemical traits involved in the interaction between EAB and *H. fraxineus.*

Pests and diseases of Cinnamomum cassia in Vietnam

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Nhu Quynh Dang
Van Binh Le[1], Jen McComb[2], Treena Burgess[2], Simon Lawson[3], Giles Hardy[2]
[1] Vietnamese Academy of Forest Sciences, 46 Duc Thang, Bac Tu Liem, Hanoi, Vietnam
[2] Murdoch University, 90 South Street, Murdoch Western Australia 6150 Australia
[3] University of the Sunshine Coast, 90 Sippy Downs Drive, Sippy Downs Qld 4556 Australia

Abstract: Cinnamon (*Cinnamomum cassia* Blum) is a valuable multi-use tree in Vietnam. It is extensively utilized in the food, medical, pharmaceutical, and animal husbandry industries and play a significant role in the economy of highland regions, alleviating poverty particularly among ethnic minorities there. It is prioritized as a non-timber forest product in Vietnam's afforestation programs, and some 200,000 hectares have been established across several provinces. However, damage from bark and leaf pests, as well as shoot and root pathogens reduce the quality of these trees and are a challenge to sustainable cultivation. Comprehensive surveys have been undertaken to accurately identify the full range of pests and diseases present so that more targeted control measures can be implemented.

A total of 50 species of pathogenic fungi, oomycetes, and algae were identified, including 37 new records specific to cinnamon in Vietnam. Additionally, three potentially new species were discovered. Pathogenicity testing using excised cinnamon branches revealed that out of the 78 tested isolates, 15 caused very severe lesions, 18 caused severe lesions, 13 caused moderate lesions, 21 caused small lesions, and 11 were non-pathogenic. The most frequently isolated pathogen was *Phytophthora cinnamomi*, as well as *P. heveae, P. multibullata, P. × vanyenensis*, and an undescribed *Podosphaera* species which cause root rot,wilting and powdery mildew. Other frequently observed diseases were witches' broom (Phytoplasma), leaf spot (*Collectotrichum* spp.), and stem canker (*Diaporthe* spp).

Eighteen pest species from 16 families and 5 orders were recorded to affect cinnamon in nurseries. White-striped flower thrips (*Echinothrips americanus*) emerged as a severe pest of cinnamon in both Yen Bai and Quang Nam nurseries. Of these 65 species were causing harm in Yen Bai and 45 species in Quang Nam. Dominant pest species in forest plantations included the Vietnamese oak silkworm (*Cricula vietnama*), the nine-spotted moth (*Biston suppressaria*), the grayish-brown moth (*Krananda semihyalina*), and the bark borer (*Aetherastis grandisalba*).

These surveys have provided valuable information for growers and managers, enabling them to promptly identify and address potential threats with appropriate treatments. Addressing these challenges is crucial for enhancing productivity, ensuring sustainable cinnamon cultivation, and fostering environmental protection in Vietnam.

Pests and diseases of Macadamia in Vietnam

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Van Binh Le[1]
Viet Thang Tran[1], **Nhu Quynh Dang**
[1] Vietnamese Academy of Forest Sciences, 46 Duc Thang, Bac Tu Liem, Ha Noi, Vietnam

Abstract: The macadamia tree has been successfully introduced and cultivated in Vietnam for its highly valuable nuts. Its economic significance, coupled with adaptability to various climatic and soil conditions, in areas of the highland regions of the Northwest, Central Highlands, Northeast and North Central Coast, have led to widespread plantings which in 2022 totalled ~ 30,000 hectares; ~10,000 hectares dedicated to pure cultivation and 20,000 of mixed species (Vietnam Macadamia Association).

However currently the health of Macadamia trees in Vietnam is being negatively impacted by a range of pests and diseases damaging leaves, flowers, fruits, and branches. This research summarises comprehensive surveys of the pests and diseases of Macadamia trees in nurseries and cultivated plantations in the Northwest (Lai Chau, Dien Bien, and Son La) and Central Highlands (Dak Lak and Gia Lai) regions. A total of 12 harmful insect species, belonging to 8 families and 5 orders have been identified in nurseries. Among them, the most significant is the Red-Banded Thrip (*Selenothrips rubrocinctus*). Five fungal species from three families and three orders have been identified, with *Colletotrichum fructicola* recognized as the most damaging fungal pathogen pathogen in macadamia nurseries. In cultivated plantations, a total of 19 harmful insect species belonging to 13 families and 5 orders have been identified, with the Black Citrus Aphid (*Toxoptera aurantii*) causing the most damage. Sixteen fungal pathogens from 8 families and 7 orders have been identified. The most notable is *Phytophthora cinnamomi*, an oomycete responsible for gummosis on trunks and branches, and *Eremothecium coryli* which causes yeast spot the macadamia nuts.

This information from this comprehensive investigation provides invaluable insights which will assist managers and macadamia growers to select appropriate management strategies, particularly organic approaches. By doing so, they will mitigate the potential threats of future outbreaks and enhance the productivity and quality of macadamia nuts from Vietnam.

Phytophthora species associated with alder declined forest in Spain

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Raquel Del-Campo Calvo[1]
Eduardo Pastor-Durántez[1], Alba Diez-Galán[1], **Julio Javier Diez**[1]
[1] Sustainable Forest Management Research Institute. UVa-INIA. E.T.S.II.AA. Palencia, Spain

Abstract: The riparian forest ecosystems have an especial importance for the maintenance of the balance with the hydric sources in our country. Alder (*Alnus lusitanica*), one of the most important trees that conform this ecosystem, is affected by the alder decline, caused by pathogenic oomycetes including in the *Phytophthora* genus. *Phytophthora alni* complex includes *Phytophthora xalni*, *Phytophthora uniformis* and *Phytophthora xmultiformis* as the principal oomycetes described. The objectives of the work were to identify the *Phytophthora* species associated to alder decline in Spain. For this purpose, multiple unexplored river ecosystems in the Northern and Western Spain were sampled in areas were the disease has been described. Oomycetes identification was performed by extracting DNA from the alder wood and mycelium of isolated oomycetes and analyzing by conventional PCR, and qPCR, with specific primers to amplify the ITS region. Preliminary results show that in addition to *Phytophthora* species, many oomycetes could be involved in the disease. We have isolated other oomycetes like *Globisporangium* sps. and *Phytophytium* sps. that were found in other plant trees described as pathogens. This study will help to know more about *Phytophthora alni* complex and also for the management of this decline via biocontrol treatments.

Key words: Oomycetes, *Phytophthora alni* species complex, alder, alder decline.

Predicting the European Invasion of the Oak Lace Bug: A Species Distribution Modelling Perspective

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Abstract: Biological invasions pose significant threats to ecological and economic stability worldwide. The oak lace bug (*Corythucha arcuata*), a North American species, has rapidly spread across 24 European countries in just two decades, signalling its potential establishment as a major pest for European oak communities. This invasive species has the potential to negatively impact oak growth, vitality, and reproductive success in both the short and long term. To effectively understand and manage its environmental impact, it is crucial to conduct a comprehensive assessment of its distribution and identify risk areas for further spread within Europe.

In this study, we gathered presence data from 19 countries using various sources, including expert observations, citizen science reports, and GBIF data, which were meticulously verified by national experts. By employing advanced machine learning techniques, we developed a species distribution model that incorporates both current and future climate conditions, with the distribution of host species acting as a covariate. Additionally, we conducted environmental systematic sampling to account for the non-equilibrium of the invasive species with the environment and removed geographically distant absences that were environmentally close to the presence data.

Our findings highlight the dual role of climate and host species in driving the distribution of the oak lace bug in Europe, with the potential distribution of sessile oak and Turkey oak emerging as important predictors. Currently, the species is mainly confined to the southern regions of Europe. However, considering the distribution capacity of the species, climate change dynamics, and potential host distribution, it is likely to expand its range into new territories in Central and North-eastern Europe.

This study provides a comprehensive dataset of the oak lace bug's current presence as well as its potential distribution under different climate change scenarios. This dataset serves as a valuable tool for forestry and environmental science professionals, facilitating the development of integrated monitoring and pest management strategies that protect forest ecosystems and human health.

RELATING FARM AND LANDSCAPE TREE STRUCTURAL PROPERTIES TO FALL ARMYWORM (Spodoptera frugiperda J. E. Smith) MANAGEMENT IN AFRICA: EVIDENCE FROM ZAMBIA

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Clement Sullibie Saagulo Naabeh[1, 2, 3]
Rhett D. Harrison[4], Eefke Mollee[1], Tim Pagella[1]

[2] University of Copenhagen
[3] Forestry Commission of Ghana
[4] CIFOR-ICRAF

Abstract: Fall armyworm (FAW) is a serious agricultural pest threatening food and livelihood security in the continent of Africa. This pest is challenging to control due to its resistance to pesticides and genetically modified cultivars, and high pesticide costs. To find environmentally friendly and cheap options for managing this pest, agroecological options are being considered as a priority research area globally. This study aimed to understand the influence of farm and landscape-level tree characteristics on FAW damage and incidence, natural enemies, and maize yield in Zambia. The study established 90 circular tree survey plots across the three major agroecological zones during the 2019/2020 crop season. Farm tree data included species identification and diameter at breast height, while landscape tree cover was estimated using remotely sensed data in QGIS and R. Data on maize yield, natural enemies, FAW incidence, and damage were made available by the NORAD Project team. Multiple linear regression and Kruskal Wallis test with Dunn multiple pairwise comparison tests were used to model the effect of each predictor variable.

The results indicate that FAW incidence and damage declined with increasing farm-level tree diversity and landscape-level tree cover, but landscape-level tree cover was only marginally significant. Farm-level tree basal area was not significantly associated with FAW incidence or damage. The abundance of natural enemies did not significantly associate with landscape tree cover, but farm-level tree diversity and tree basal area were negatively associated with natural enemy abundance. However, none of the tree cover variables were significantly associated with maize grain yield, due to the overall low FAW incidence and FAW damage in this study.

Overall, the study concludes that tree diversity and landscape tree cover have a positive effect on controlling FAW abundance and damage, which should be considered when designing tree-based agroecological options for FAW management. The findings have important policy implications for natural resource management and the design and deployment of sustainable integrated pest management (IPM) technologies for managing FAW in Africa and other invaded regions.

Risk of oak wilt further north: exploring linkages between potential vectors and springtime oak phenology in North America

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Tara L. Bal[1]
Sharon Reed[2], Kathleen Bershing[1], Violet Butterwort[2], Simeon Wright[3], Jon Sweeney[4], Cory Hughes[4]

[3] Michigan Department of Natural Resources
[4] Natural Resources Canada

Abstract: Oak wilt, caused by the invasive pathogen *Bretziella fagacearum,* is currently confirmed in 24 states in the U.S., including Michigan. Canada, where the DNA of the pathogen has been detected on beetles known to transmit the disease, is at risk of oak wilt becoming established. The disease has been present throughout the Lower Peninsula of Michigan and just near the Wisconsin border in the Upper Peninsula of Michigan for decades with no apparent expansion across the Upper Peninsula. In a cooperative international effort, vector activity, climate variables, and spring bud phenology were monitored at sites across the Upper Peninsula, Michigan (including one control site with oak wilt), and partner sites across Canada (including Ontario and New Brunswick). Our objectives are to evaluate timing and relationships between host phenology, nitidulid beetle vectors, and environmental factors potentially limiting oak wilt progression north. As these factors are impacted by human movement of materials and climate change, a better understanding of northern expansion risk is critical for oak wilt prevention.

Since 2021, each partner site has used three methods of trapping beetles: artificial wounding of oak trees and windvane and Lindgren traps baited with nitidulid pheromone and fermenting bread dough. At least eleven species of nitidulids have been collected from artificial wounds in Michigan and in Canada, including known oak wilt vector species at sites without the disease. Additional nitidulid species have been collected in traps including new records. In the 2021-2022 spring field seasons, nitidulids were observed in traps well before being collected in wounds, suggesting attractiveness to wounds may be delayed compared to flight traps, potentially not until leaves were expanded. Bud phenology was included in 2023-2024 field protocols, allowing the exploration of relationships between vectors and host phenology. We anticipate models incorporating vector flight and degree days with observable tree phenology may allow managers to refine the high-risk prevention period. This may allow improved predictions of when the disease will expand beyond its current northern range increasing preparedness.

Science to underpin international standards for the international movement of forest products

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Meghan Noseworthy[1]
Eric Allen[2], Esme John[1], Tyranna Souque[1], Josie Roberts[3], **Jeremy Allison**[1]
[1] Natural Resources Canada, Canadian Forest Service
[2] Natural Resources Canada, Canadian Forest Service retired
[3] Canadian Food Inspection Agency

Abstract: Global forests are integral for regulating water cycles, contributing to carbon sequestration, and providing habitat that supports biological diversity while also playing an important role in supporting the economy through sustainable harvesting for forest product trade. However, global trade of forest products presents a potential pathway for pests to enter novel forests. To reduce the risk of pest movement associated with traded products, phytosanitary measures such as treatments to eradicate pests are fundamental. Applying pest-risk reduction measures prior to moving forest products provides a safeguard that reduces the risk of post-entry incursions, and the reliance on resource-intense surveillance, quarantine and eradication programs.

Gathering efficacy data on treatments that reduce pest risks underpin the development of standards for phytosanitary measures. Guidelines for the implementation of phytosanitary measures are outlined and described in regional and international standards for phytosanitary measures. Creation of these standards requires science to ensure practical, environmentally and economically feasible recommendations. Standards are subject to review and updating as more data becomes available.

A current example of science supporting regional and international standards for phytosanitary measures is the use of a carefully calibrated heat treatment apparatus to determine the specific lethal dose (time and temperature) for forest product pests. Current research findings will be presented.

Sentinel plantations in China – early warning for threats to economically important European and North American tree species

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

[5] Institute for Sustainable Plant Protection - C.N.R, Sesto Fiorentino, Italy

Abstract: Non-native Invasive tree pathogens and insect pests have caused significant damage to global forest ecosystems and industries. The increasing frequency of invasions is attributed to economic globalization, changing land use, and environmental change. Sentinel gardens are a versatile method that uses host trees planted in a non-native range (ex-patria planting) to document potentially new damaging agents to the country/continent of origin of those planted trees. At least in principle, this method can effectively detect non-native invasive pathogens and insect pests in advance of their potential intercontinental movement. Through an international collaborative project, we established twin plantations of North American and European tree species in Nanjing, China in 2021. Equivalent plantations, using identical planting schemes, were established in Alnarp, Sweden, and Florence, Italy, with Asian and North American species, and in Columbus, Ohio, and Portsmouth, New Hampshire, in North America with European and Chinese species. We then monitored the trees for signs and symptoms of pathogen attack for two years, followed by fungal pathogen isolation and identification through morphological and molecular methods. The aim of this sub-project is to proactively identify potentially invasive and damaging pathogens present in China that may threaten trees in North America and Europe if they ever reached those shores.

Spatially implicit models to explore the utility of Wolbachia infection to control forest diseases vectored by insect pests

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Yuko Numajiri[1]
Daisuke Kageyama[1], **Takehiko Yamanaka**[2]
[1] NARO, Institute of Agrobiological Sciences (IAS), Japan
[2] NARO, Research Center for Agricultural Information Technology (RCAIT), Japan

Abstract: Many forest diseases are transmitted by insect vectors, and manipulation of the contagious properties of the vector population plays a key role in suppressing disease spread. *Wolbachia* is a symbiotic intracellular bacterium that is harboured by many species of invertebrates, including insects. Recently, it has been reported that some *Wolbachia* can suppress the propagation of plant pathogens in insect vectors and reduce vector competence. In addition, *Wolbachia* has a desirable property to spread autonomously among vector populations via cytoplasmic incompatibility, which confers a fitness advantage to *Wolbachia*-carrying insects over non-carrying ones. If we can find conditions under which artificially established *Wolbachia*-carrying vectors can spread within wild populations, then the release of such vectors may effectively control the spread of forest diseases over large areas.

In our study, spatially implicit models that account for the mating behaviour of both sexes are used to explore the desirable conditions in which *Wolbachia*-carrying insects can propagate in the early stages of release. We conduct simulations with the model parameterized to represent two types of insects: coleopteran-like insects, which are long-lived and capable of multiple mating but have low daily reproductive rates, and lepidopteran-like insects, which are capable of mating only once per generation, have an ephemeral reproductive stage, and have high reproductive rates. We change key parameters related to the degree of cytoplasmic incompatibility, the vertical (transovarial) transmission rate, and the reduction rate of vector competence. Specifically, Allee effects (the positive relationship between population size and per capita growth rate) caused by mate-location failure in the very low-density situations are incorporated into the models. We will discuss which type of insects and what condition and how many inoculations are required for successful *Wolbachia* applications in practical forest disease management.

Specific isothermal DNA amplification assays for biotypes of the Myrtle rust disease pathogen Austropuccinia psidii

[11] Universidad de la República, Uruguay

Abstract: *Austropuccinia psidii* is a fungal rust pathogen causing myrtle rust disease to trees in the Myrtaceae around the world. At least four different biotypes have been described and are distributed in distinct geographic regions: the pandemic biotype largely at Hawaii and within regions of Oceania and Southeast Asian, Central America, the Caribbean and Colombia; the South African biotype in South Africa; and the guava and eucalypt/rose apple biotypes in South America regions. Potential introductions of biotypes to other regions are a cause of great concern as bioclimatic modeling has identified suitable conditions for their movement into new geographic areas. For example, the eucalypt/rose biotype poses a threat to Hawaii, Australia, and New Zealand, while the pandemic biotype threatens regions in Brazil and Uruguay. To distinguish *A. psidii* biotypes and monitor their potential movement, we designed specific and sensitive isothermal DNA amplification assays for the four characterized biotypes. These assays have been tested using purified DNA as well as crude-extracted DNA from *A. psidii* spores collected in the field, with ongoing testing by collaborators around the world. These assays are also currently being used to monitor sentinel plantings in Hawaii. Preliminary results show that the developed assays can be used with little technical expertise and inexpensive equipment, making it useful for field monitoring. The assays will help in the development of regulatory protocols for preventing spread into new areas and improve management strategies for minimizing the damage caused by *A. psidii*.

STRENGTHENING PHYTOSANITARY RESEARCH PROGRAMMING AND COLLABORATION: FROM EUROPEAN TO GLOBAL PHYTOSANITARY RESEARCH COORDINATION

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

[4] Norwegian Institute of Bioeconomy Research, P.O. Box 115, NO-1431 Ås, Norway

Abstract: In a world of increasing global trade and movement of people, the risks to trees from the introduction and/or outbreaks of pests have increased significantly in recent decades.These challenges are truly global in nature and require significant capacities, resources and sophisticated infrastructure that cannot be found within the limits of a single country. The Euphresco network for phytosanitary research coordination and funding started in 2006 to support phytosanitary research programme owners and programme managers to develop and take advantage of synergies amongst national research programmes and activities in Europe. The success of Euphresco as a primarily European network for phytosanitary research coordination has set the ground for discussions on the development of initiative(s) to address the needs of other regions of the world and on global phytosanitary research coordination.

The EUPHRESCO III project aims to enhance national and regional phytosanitary research coordination and to set the foundations for global phytosanitary research coordination. The project will focus on i) the development of a global strategic research agenda, ii) the organization of joint transnational calls on shared research priorities and iii) the shaping of governance, structures and operations of a global network for phytosanitary research coordination. These activities will be shaped through bottom-up alignment actions that involve research stakeholders and top-down alignment actions that involve research funding organizations.

During the project, capillary consultations of stakeholders (i.e. policy makers, research funders, scientists, industry, farmers and foresters, civil society) that operate in plant health at national and regional level will be organized under the leadership of selected organizations that will lead discussions of stakeholders within a geographic region or of experts on a specific research topic.

The presentation will provide an opportunity to explain the work on forest/tree health and to consult the IUFRO international community.

The emerging threat of Ganoderma root rot in Eucalyptus plantations in Indonesia

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Ariska van der Nest[1]
Samuel A Santos[2], Irene Barnes[1], Marthin Tarigan[2], Alvaro Duran[2], Michael J Wingfield[1]
[1] Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria 0083, South Africa
[2] Research and Development, Asia Pacific Resources International Limited (APRIL), 28300 Pangkalan Kerinci, Riau, Indonesia

Abstract: Ganoderma root rot is a disease that affects the roots of various tree species worldwide. In Indonesia, this disease has particularly affected *Acacia mangium* plantations in the past. Although several *Ganoderma* species are present in the country, *Ganoderma philippii* is the primary pathogen causing disease in Indonesian *Acacia mangium* plantations. To mitigate the damage due to Ganoderma root rot, various other *Acacia* and *Eucalyptus* species as well as their hybrids have been planted in areas where the disease is present. Since 2021, outbreaks of Ganoderma root rot have emerged in *Eucalyptus* plantations throughout Sumatra, Indonesia. Disease symptoms include characteristic red rhizomorphs on the bark surface of infected roots with light yellow to white mycelia present under the root bark. Within the roots, characteristic red streaks are commonly observed. Above ground symptoms include yellowing of leaves and subsequently rapid wilt and death of trees. Stumps left in the soil after felling appear to be an inoculum source for new disease outbreaks, as field observations suggest that the disease spreads via root-to-root contact. The aim of this study was to determine which *Ganoderma* species is the causal agent of Ganoderma root rot in the affected *Eucalyptus* plantations and to determine whether stumps from previous rotations might be a source of inoculum for the current disease outbreaks. A total of 167 isolates were collected in six locations in Sumatra from newly infected trees, and 194 old stumps were excavated in two locations where Ganoderma root rot was sporadically observed. All 167 isolates were identified as *Ganoderma philippii* based on DNA sequence data. Of the 194 stumps that were excavated, 100% had typical symptoms of Ganoderma root rot in the remaining roots. Root-to-root contact was observed between these infected stumps and dying trees adjacent to these stumps. The results confirmed that *G. philippii* is the primary cause of the emerging root rot problem in *Eucalyptus* plantations. Furthermore, that the pathogen is spreading actively via root-to-root contact. However, further investigations to determine whether freshly cut stumps are infected after felling is planned to fully understand the dispersal of the pathogen to implement effective management strategies.

The Pine Pandemic Preparedness Plan (P4): A proactive approach to responding to high-impact invasive pests and diseases

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Kamal Gandhi[1]
Kier Klepzig[2]
[1] University of Georgia
[2] Jones Center at Ichauway

Abstract: Southern U.S. forests are considered the wood-basket of the world, and provide major economic and ecological benefits regionally and nationally. Most of the economic benefits are from native planted pines (*Pinus taeda* and *P. elliottii*) that are grown as single species and are intensively managed. Longleaf (*P. palustris*) and other pine species also provide many ecosystem services. While these forests have not, as of yet, experienced major mortality from non-native pests and pathogens, their sustainability could be at risk from novel biotic threats. In response, a diverse group of personnel from diverse disciplines and agencies developed the Pine Pandemic Preparedness Plan (P4) to provide guidelines for stakeholders to respond rapidly, efficiently, and effectively to any new incursion in southern U.S. forests. The P4 is a proactive approach, usable by anyone, flexible, and exportable across regions. The four central components of the P4 are: 1) Communication; 2) Detection and diagnosis; 3) Delimitation and assessment; and 4) Response. These components are actionable, strategic, sequentially linked with each other, and provide additional support to current state and federal emergency responses. We present details of the P4 components, discuss ways to engage in the plan, and solicit input from the larger forest health and forestry community in the plan.

The regulatory context of international trade of forest products

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Thomas Schröder[1]
Christopher Howard[2]
[1] Federal Ministry for Food and Agriculture, Division 714 Plant Health and phytosanitary aspects in export, Messeweg 11-12, 53123 Bonn, Germany
[2] Department of Agriculture, Fisheries and Forestry 70 Northbourne Avenue, Canberra ACT 2601 Australia PO Box 858 Canberra ACT 2601 Australia

Abstract: Wood, wood products and other forest products may contain pests (insects, nematodes, fungi, bacteria) if they have not undergone phytosanitary treatment. Live plants and wood, especially wood packaging, are internationally regarded as the main source for the introduction and spread of these pests. Demand for trade in forest products is constant and often changing, e.g. increases in trade of round wood and the current movement towards climate-neutral energy leading to an increased demand for international trade of wood chips.

To counteract the phytosanitary risk of international trade of plants and plant products, the International Plant Protection Convention (IPPC) was developed in 1952. The IPPC is an intergovernmental treaty of 184 signatory countries, which aims to protect the world's plant resources from the spread and introduction of pests and to promote safe trade. The IPPC established numerous International Standards for Phytosanitary Measures (ISPMs) as the main tools that govern the activities performed by National Plant Protection Organisations to achieve the Convention's objectives.

A number of ISPMs directly influence the trade of forest products including: wood packaging (ISPM 15); phytosanitary treatments (ISPM 28), and the international movement of seeds (ISPM 38) and wood (ISPM 39). Other ISPMs protect forest health in other ways by influencing trade in forest products by governing: plants for planting; the movement of used vehicles; pest status; phytosanitary certification system etc.

Arguably the best known ISPM, ISPM 15 'Regulation of wood packaging material in international trade', describes agreed phytosanitary requirements for solid wood packaging (e.g. pallets, boxes, dunnage) used in international trade. Since publication in 2002, it has been revised several times to refine the requirements or introduce new phytosanitary treatments based on best practice and scientific knowledge generated largely by international scientific collaboration led by the International Forestry Quarantine Research Group. Implementation of ISPM 15 is a global regulatory success story; the movement and spread of forest pests has been reduced while allowing greater facilitation of market access for some countries.

Unveiling a hidden menace: Less known but increasingly emerging in the Southern Hemisphere

T1.1 Biology, ecology and management of pest and pathogen invasions in forests: a global perspective

Treena Burgess[1, 2]
Michael Wingfield[1]
[1] Forestry and Agriculture Biotechnology Institute, University of Pretoria, South Africa
[2] Harry Butler Institute, Murdoch University, Australia

Abstract: The first recognized disease and insect (pest) pandemics affecting natural forest ecosystems were recorded around the start of the 20th Century in the northern hemisphere (NH). Notable examples include Dutch Elm Disease, Chestnut Blight, as well as infestations by the spongy moth and pine wood nematode. Since then, new pandemic diseases have continued to emerge in the NH, with increasingly shorter intervals between outbreaks. It is believed that the relatedness between tree genera (congeners) across Asia, Europe, and North America play a significant role in facilitating these pandemics. In contrast, the southern hemisphere (SH) has experienced fewer recorded pandemics. These can be attributed to factors such as limited human and product movement between SH continents, which reduces opportunities for pathogen introductions. Additionally, the greater diversity of tree genera in the SH may contribute to this disparity. However, the SH is now witnessing the emergence of new and severe tree disease pandemics caused by host-specific pathogens. Examples include myrtle rust caused by *Austropuccinia psidii* and the polyphagus shot-hole borer, *Euwallacea fornicatus*. Moreover, numerous pests with the potential to spread between countries in the SH have been discovered, posing significant disease risks. Unlike in the NH, plantation forestry in the SH predominantly utilises non-native tree species, which serve as "bridges" for pests to invade natural forest environments. To better understand this growing threat to the future of tree health, valuable insights can be gained from research on tree pest pandemics in the NH, which must also emphasize the need for a robust global approach.

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

A 'Get-Save- Return' process continuum runs on phosphorus economy among subtropical tree species

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Lei Jiang[1]
Huimin Wang[1], Shenggong Li[1], Xiaoqin Dai[1], Shengwang Meng[1], Xiaoli Fu[1], Han Yan[1], Jiajia Zheng[1], Ning Ma[1], **Liang Kou**[1]
[1] Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, China

Abstract: Plants allocate nutrients to new leaves via making a cost–benefit trade-off between root nutrient absorption ('get') and leaf nutrient resorption ('save'). This active trade-off in nutrient acquisition pathways may cause a passive trade-off between resorption and decomposition ('return'). However, whether these nutrient-associated processes are linked and form a 'get-save-return' (GSR) continuum,
and its linkages with the above-ground leaf economics spectrum (LES) and the below-ground mycorrhizal association remain unclear. Here, we present the first empirical evidence of a direct link among multiple nutrient-associated processes and tested this continuum hypothesis by synchronously integrating root nutrient absorption, leaf nutrient resorption and leaf litter decomposition of 15 co-occurring tree species hosting either arbuscular mycorrhizal or ectomycorrhizal fungi in subtropical forests of China. Across species, there was an active trade-off between phosphorus (P) absorption and resorption, which further caused a passive trade-off between P resorption and leaf litter decomposition, indicating that the GSR continuum exists and runs on P economy. However, these processes associated with nitrogen economy were not well linked. Interestingly, the loading scores of species on the LES were positively correlated with root P absorption, negatively with leaf P resorption and positively with leaf litter decomposition. These linkages indicate that species running in the 'fast lane' had greater root P absorption, lower leaf P resorption and faster leaf litter decomposition than species running in the 'slow lane', and that the process-based GSR continuum follows the trait-based 'fast-slow' LES. Furthermore, the continuum on P economy emerged evidently in the ectomycorrhizal tree species rather than in the arbuscular mycorrhizal tree species, indicating critical control of mycorrhizal association over the continuum. Overall, these results demonstrate the existence of the GSR continuum on tree P economy, which conforms to the economics spectrum theory but varies with mycorrhizal association type. Our findings provide a process-based framework for mechanistic understanding of the whole plant nutrient economy and ecosystem nutrient cycling, and facilitate improved predictions of biogeochemical models.

Above and belowground phenology of four tree species with contrasting root and leaf traits

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Qiwen Guo[1]

[2] Mendel University in Brno, Department of Forest Protection and Wildlife Management, Faculty of Forestry and Wood Technology, Czech Republic
[3] Vienna Scientific Instruments, Research & Development, Austria

Abstract: The turnover of fine roots and mycorrhizal hyphae is a major source of necromass for soil organic matter formation. Although much is known about leaf phenology, little is known about root phenology and the factors that control it, or how aboveground and belowground phenology interacts. Knowledge of the length of the growing season below ground and the longevity of fine roots is crucial for estimating necromass inputs to soils.

In this study, we access the leaf and root phenology and the development of mycorrhizal hyphae of four tree species (*Acer platanoides, Carpinus betulus, Tilia cordata, and Quercus robur*) growing in either monocultures or mixtures at the B-tree experimental site in Austria. Root growth is monitored using 96 minirhizotron tubes installed at the site to 40 cm depth in late 2021. Measurements were carried out from January 2023. To estimate the growth of mycorrhizal hyphae, ingrowth bags were buried at the beginning of March 2023. Initial data indicates the start of root growth in 2023 in February for *Tilia cordata* and *Acer platanoides*, in early March for *Carpinus betulus* and in late March for *Quercus robur*. In parallel with the belowground measurements, a leaf phenological study is being carried out to record the progression of leaf growth and senescence. On non-rainy days, images were taken every 7 days with the camera of an iPhone 13 smartphone placed approximately 10 cm above the ground, oriented horizontally and aimed at the canopy above the rhizotron tubes. The images were then processed using CAN-EYE V6.495 software to quantify the number of green pixels. Bud break in 2023 occurred around the end of March for Carpinus betulus and *Acer platanoides*, mid-April for *Quercus robur* and late April for *Tilia cordata*. Our data thus indicate a generally earlier onset of the root growing season, and large differences between the synchronicity of above- and below-ground growing seasons within species.

Belowground carbon dynamics in various urban green spaces

Abstract: Urbanization is an increasingly prevalent global phenomenon, leading to significant modifications in land use and the transformation of natural environments into urban landscapes. Cities are urgently seeking solutions to reach carbon (C) neutrality due to climate change. For this purpose, quantifying soil and vegetation C storage is needed in urban green areas. Fine roots are playing a vital role as they often form the only tree litter input into the soil due to heavy management in urban green spaces. Fine roots are also key players in the formation of most stable soil carbon and in the biogeochemical cycle of many green ecosystems. The urban green areas do not have much competition in the canopy layer, but the root growth could be hindered by limiting belowground soil space in addition to other complications such as soil compaction, pollution and low water content. In this study, we followed tree growth and longevity in three urban green spaces (Garden, Forest and Street) in Helsinki, southern Finland. We aim to figure out how fine root growth dynamics and morphological traits are affected by urban site types, and by extreme weather events such as summer droughts. Moreover, the study allows to link the root growth phenology to whole-tree organs' growth *in situ*. The gained results on the belowground litter C input in urban soils provide crucial information on carbon dynamics in urban green areas which will be further implemented in land-surface models.

Continuous-cover forestry affects the stabilization of soil C through continuous root litter inputs and root exudates

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Abstract: Trees fix and store atmospheric carbon (C), about half of which they transport belowground. This C enters the soil organic carbon (SOC) pool as root exudates and root litter and feeds soil microbiota. Microbial necromass and microbial exudates in turn contribute to the SOC pool and simultaneously stabilize C in the soil. Root derived tannins furthermore contribute to SOC stabilization in interaction with fungal residue. Recent studies suggest that clear-cut harvesting disturbs the belowground food web in forests. Retaining a certain number of living tress and living roots to sustain the belowground ecosystem may mitigate post-harvest losses of SOC. Continuous cover forestry has been suggested as a way to protect the SOC storage.

We studied how continuous-cover forestry (CCF) affects SOC stocks and stability in boreal forests through its effects on living roots, compared to clear-cut based rotation forest management (RFM). We hypothesized that (1) more effective use of rooting space leads to higher amounts of living tree roots and root derived tannins in uneven-aged CCF plots than in even-aged RFM plots and in clear-cut plots without trees and (2) the undisturbed soil in CCF holds higher amounts of mineral-associated organic matter (MAOM) and higher shares of chemically stable organic matter. We carried out measurements in Norway spruce (*Picea Abies* Karst.) dominated experimental forest plots of the Natural Resources Institute Finland in central Finland. We sampled (1) clear-cuts, (2) even-aged forests (both representing RFM), (3) uneven-aged forests (representing CCF) and (4) uncut control forests.

We determined living tree root and fine root biomass, understorey and dead roots and calculated annual belowground litter inputs. We measured soil C content and calculated soil C stocks. We analysed the amount of root-derived condensed tannins. To evaluate the effects on C stabilization we separated particulate organic matter (POM) and MAOM and we distinguished the different soil organic matter fractions within the POM fraction with chemical extraction. We analysed amino sugars, and used glucosamine and muramic acid as indicators of fungal and bacterial necromass.

We will discuss potential effects of the forest management system on the long-term SOC storage based on our results.

Contribution of Root Dynamics to Carbon Balance of Agroforestry Coffee Plantations - a Case Study in Costa Rica

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Abstract: Accurate carbon budgets are important when estimating the potential benefits of reforestation programmes for climate change mitigation. Including crop specific data makes estimates more accurate. Coffee is an important crop, often grown in agroforestry systems considered to sequester carbon. However, little is understood about contributions of plant roots to the system carbon balance.

Results will be presented from a study on soil carbon dynamics in agroforestry coffee plantations, in a long term experiment in Costa Rica. The experiment was set up in 2000, to compare organic and conventional coffee production systems under various types of shade. The current study focuses on the effect of shade trees on belowground carbon. The three treatments used were i) coffee, full sun ii) coffee+*Erythrina poeppigiana*; *and iii) coffee+Terminalia amazonia,* all with moderate conventional fertilization.

Carbon stocks have previously been estimated at the site, but without including root biomass and turnover. Those results showed that large aboveground biomass alone cannot explain changes in soil carbon storage in these agroforestry systems.

The aim of this study was to study belowground biomass and production, and how that correlates with soil carbon stocks and aboveground biomass. Fine root turnover was estimated using sequential coring in combination with root litter decomposition. Root biomass data was collected from August 2022 to July 2023. The results from this study will be used to calculate carbon budgets for these coffee plantations, incorporating fine root dynamics.

Decomposition of fine-roots of different species in a cool-temperate forest zone in South Korea

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

[2] Institute of Agricultural Science, Chungnam National University

Abstract: Plant litter decomposition in terrestrial ecosystems constitutes one of the largest annual fluxes of global carbon (C) and nutrient cycling. Especially fine-roots are great components of net primary production and their decomposition is crucial for plants to return C and nutrients to the soil. Fine-root decomposition is affected by several factors as climate, litter quality, soil chemical properties, and soil microorganism activity. The decomposition rate also differs among different root diameters, since tissue chemistry varies with the diameter. Therefore, this study aims to analyze the decomposition of fine-roots of different species in Gariwang Mountain, Pyeongchang, South Korea. Four different sites were selected, each one dominated by a different species: *Quercus mongolica, Pinus koraiensis, Pinus densiflora*, and *Larix kaempferi*. Then, the sites were subdivided into 3 plots of 20x20 m. The climate is classified as cool-temperate and the altitude in the sites varies between 933 m and 1.065 m. Soil chemical properties and microorganism activity will be analyzed at each site. To estimate the decomposition rate, litterbags of 10x10 cm size with 115 µ mesh size will be used. Samples of each species were collected, divided into 4 diameters, and placed in the litterbags. The amount of samples in the litterbags differ by diameter: 0 – 0.5 mm (0.08 - 0.1 g), 0.5 – 1 mm (0.16 - 0.2 g), 1 - 2 mm (0.3 g), and 2 – 5 mm (0.5 g). In December 2022, 768 litterbags (4 species x 4 diameters x 4 replicates x 3 plots x 4 collection times) were buried. In 2023, the litterbags are planned to be seasonally retrieved after 4, 6, 9, and 12 months. After collection, the samples will be oven-dried and weighed to determine the biomass loss. The initial root quality (C, N, P, K, Ca, Mg, cellulose, hemicellulose, and lignin) and morphological traits (specific root length and area) will also be determined. It is expected that the decomposition rate will increase exponentially with the temperature and the lowest decomposition rate will be observed in the winter. Also, the decomposition of very fine-roots will be higher compared to bigger root diameters.

Early Overyielding in Mixed Plantations is driven by Above- and Belowground Species-Specific Adaptation

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Abstract: Forests face significant challenges in the context of climate change, and mixed forest plantations have been proposed as a promising approach to enhance ecosystem stability and productivity. While mixed forest plantations are known to exhibit higher ecosystem productivity compared to single-species plantations, there is a research gap in understanding the interplay between above- and belowground productivity, specifically regarding how aboveground productivity patterns relate to belowground dynamics. To address this critical aspect, we conducted a comprehensive forest inventory of a young mixed forest plantation, where four tree species were planted in four different mixture variants (monoculture, acquisitive two-species mixture, conservative two-species mixture, four-species mixture). We used linear mixed effect models to quantify belowground productivity and distribution and its relationship to aboveground parameters such as growth rates, crown characteristics, and biomass.

Our findings revealed that initial effects of tree species mixtures on aboveground growth could be observed as early as six years after planting even before light competition occurred. Biomass allocation patterns were found to be strongly influenced by species composition after nine years. The most diverse and intermediate diverse stands, particularly those with acquisitive tree species, exhibited high aboveground biomass accumulation, surpassing monoculture yields by 1.5 to 1.9 times. In addition, belowground biomass showed a similar trend, with the most diverse stands achieving significant overyielding in fine root biomass. Intermediate diverse stands, however, exhibited species-specific patterns, with acquisitive species achieving clear overyields and conservative species producing lower yields. These differences in biomass accumulation at various diversity levels may be explained by functional trait-specific differences in above- and belowground biomass allocation.

By shedding light on the dynamics of tree diversity and its impact on niche construction, our study provides valuable insights into enhancing above- and belowground ecosystem productivity in mixed forest plantations. The findings underscore the significance of managing forest ecosystems with a diverse species portfolio to promote both stability and productivity.

Effects of environmental factors on daily root growth phenology in southern boreal forests

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Abstract: Boreal forest soil carbon storage is largely attributed to roots and root symbionts. Fine root growth and turnover significantly affect belowground carbon cycling. Climate change, including temperature increases and precipitation shifts, directly impacts fine root growth and overall the tree growth. However, compared to the detailed observation of aboveground components, there is limited knowledge about the growth of roots, especially regarding their growth patterns. To address this knowledge gap, we conducted a study in a mature Scots pine stand in southern Finland in 2018, a year marked by an unexpected summer drought. We used flat-bed scanners to scan and capture daily images of the belowground organs. Specifically, we categorized the roots into two types based on their morphology: pioneer roots and fibrous roots. The growth phenology of aboveground organs, including shoots, needles, buds, and secondary xylem, was estimated using a validated process-based model describing the carbon balance of a tree (CASSIA).

Our results revealed a positive correlation between soil temperature and root growth. However, the growth patterns of the two root types exhibited significant differences. The relationship between root growth and soil moisture varied across the different scanners due to the spatial heterogeneity of soil moisture distribution. We found that pioneer roots showed greater resilience to harsh environmental conditions compared to fibrous roots. Pioneer roots emerged and ceased growth at temperatures 2°C lower than fibrous roots. Interestingly, the drought had no significant impact on pioneer root growth, while fibrous roots immediately halted their growth in response to limited soil moisture. Additionally, the growth of roots displayed a delayed start, peak, and cessation compared to aboveground organs.

We recommend that future carbon allocation models for boreal forests should incorporate separate consideration of the growth phenology for belowground and aboveground organs. Moreover, distinguishing between different root types is crucial, as their growth responses to environmental factors differ. By integrating these factors, we can enhance the accuracy of carbon allocation models and gain a comprehensive understanding of root growth dynamics in boreal forest ecosystems.

Fertilization fosters positive tree mixture effects on soil respiration, largely independently of changes in community root trait structure

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Abstract:

1. Eutrophication is expected to change functional structure of plant communities. However, it remains unclear how the shift in community functional trait structure impacts soil respiration (Rs) in forests, which is one of the most important pathways of the carbon cycle.
2. Here, using a young tree diversity × fertilization (nitrogen and phosphorus) experiment with six European species, we test our hypothesis that fertilization amplifies positive tree mixing effects on Rs indirectly through changes in community-level root traits linked with the root economics space and belowground ecosystem functioning. Specifically, we expected that fertilization enhances positive tree mixing effects on (1) root length density of metabolically active absorptive roots (aRLD), (2) fine-root nitrogen content (fRN) and (3) biomass ratios of absorptive to transport fine roots (ATR), leading to positive tree mixing effects on Rs.
3. Soil respiration was marginally higher in species mixtures than could be expected from monocultures under fertilization, while Rs was unaffected by species mixing in unfertilized plots. When each community-level root trait was analyzed separately, species mixing tended to shift community root trait structure toward one that is resource acquisitive and metabolically active (high aRLD, fRN and ATR), with the trend reinforced by fertilization. A subsequent multivariate analysis with a piecewise structural equation model showed that tree species mixing effects on fRN and ATR increased with fertilization, while the responses of community root trait structure to fertilization did not mediate the observed marginally positive effects of fertilization on Rs in mixtures relative to monocultures.
4. Our study provides novel experimental evidence that fertilization tends to positively amplify species mixing effects on Rs in young tree communities, but largely independently of changes in root traits typically used to quantify root metabolism and root interactions with soils. This suggests that other biotic (e.g., soil microbiota) and/or abiotic factors (e.g., water availability) may be essential to understand the tree diversity-soil respiration relationships. Nevertheless, our study highlights that tree diversity effects on CO_2 emissions should be addressed to assess co-benefits for forest-based climate change mitigation and biodiversity conservation.

Fine root biomass and production in European forests

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Timo Domisch[1]

[1] Natural Resources Institute Finland (Luke)
[2] University of Copenhagen, Denmark

Abstract: The allocation of photosynthates to fine roots represent a major carbon flux from trees into the soil. Assessing fine root dynamics is thus of great importance for a better understanding of belowground C, in the context of biodiversity as well as of climate change. This study was carried out at the six FunDivEUROPE field sites (www.fundiveurope.eu), established in the main European forest types for assessing the effect of tree species diversity on ecosystem functioning. Root biomass was assessed in all 209 plots of the network, whereas a subset of 65 plots was used for estimating root production. Plots were established in Finland (boreal), Poland (hemiboreal), Germany (temperate beech), Romania (mountain beech), Italy (thermophilous deciduous) and Spain (Mediterranean mixed). The tree species richness gradient ranged from 1–3 species in Finland to 1–5 species in Poland and Italy. Root biomass was estimated with the soil coring method and root production with the ingrowth core method within the forest floor and 0–20 cm layer of the mineral soil. We assessed the significance of various variables related to stand, soil and climate, and how they affected tree fine root biomass and production. We observed a positive but nonsignificant effect of tree species richness for both root biomass and production. The most significant factors explaining root biomass and production were soil stoniness and clay content. Soil clay content, when included in the models, overruled all other factors. Tree root biomass peaked at a clay content of 15–20%, whereas biomass and production decreased with increasing soil clay and stoniness in the whole dataset. Root biomass increased whereas production decreased with increasing mean annual temperature. Consequently, this resulted in a higher root turnover in colder climates. Similarly, we also observed a decreasing trend in soil C with higher mean annual temperatures.

Fine root production and turnover rates across different land-use types in suburban area of Central South Korea

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Abstract: Roots play a vital role in ecosystem functioning, contributing to biomass production, nutrient cycling and carbon sequestration. However, little is known about fine (0-2mm) and small (2-5mm) roots dynamics of different land-use types and their processes. Here, this study aimed to investigate seasonal root mass, root production and turnover rates in different land-use types including grassland (ZJ), apple orchard (MP), temperate coniferous forest (PD) and temperate deciduous forest (QA) to gain insights into root functioning and how root dynamics vary across different land-use types. Sequential coring was used to study the vertical distribution and dynamics of the root system and roots were characterized into two root diameter size classes (0–2 and 2-5mm) sampled at depth up to 30cm. Root annual production was analyzed and quantified using Simplified Decision Matrix. The overall root mass (0-5 mm diameter up to 0–30 cm soil depth) was in order: ZJ>QA>PD>MP. The vertical distribution revealed that more than 60% of the fine and small roots mass were allocated in the uppermost soil layer (0-10cm) and decreased significantly with depths in ZJ, PD, QA, while in MP, the biomass was more uniformly distributed across soil depth. Although these land-use types situated in similar climatic condition, soil characteristics were significantly different, which influenced trends in seasonal root biomass, necromass, production and root turnover rate. The mean turnover rates of small roots (2-5mm) were about 1.1 to 2.1 times higher than that of fine roots (0-2mm) in ZJ, PD and MP. Understanding root dynamics in different land-use types can provide insights into their contribution to ecosystem processes, the adaptive strategies of plants, and, which can be useful for improving suitable management practices for each ecosystem.

Key words: fine root; biomass; necromass; production; turnover rate; grassland; apple orchard; temperate coniferous forest; temperate deciduous forest.

Fine-root related carbon fluxes in forests under changing environment: from root research methods to root-rhizobiome functioning

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Abstract: Root studies are increasingly prominent, and an extensively increasing number of root datasets has great potential to improve our understanding of ecosystem functioning and sustainability in the context of rapid global changes. We address two topics in root research, both of which are related to the impact of environmental changes on fine root growth and dynamics and which affect future projections of the soil organic carbon cycle.

Yet, root research is still time-consuming, and we lack comparisons of the estimates of fine root biomass, production, and turnover measured with different research methods at the same forests. Here we analyzed fine root production (FRP) and turnover from 13 boreal-hemiboreal coniferous forests with three methods: ingrowth cores, ingrowth meshes, and minirhizotrons. In hemiboreal forests, FRP was measured twice, with a 4-6-year interval. Total FRP (trees+understory) and understory root production didn't depend on the method it was measured, while the mean FRP of conifers was significantly higher as measured by ingrowth core compared to ingrowth mesh method. The estimate of FRP and turnover seems to be stable for at least the next 5-years if any major disturbance does not happen. We found that ingrowth dynamic of roots differed along the north-south gradient, which should be taken into account in modeling root litter dynamics and soil C input.

Another fast-evolving research field is related to root-rhizobiome functioning. Root-rhizobiome contains a large number of interactive and potential drivers – roots, mycorrhiza, bacteria, archaea etc that has an essential impact on ecosystem sustainability and functioning. We will envisage a role of multilateral relations between the fine roots, colonizing EcM fungi and rhizosphere and bulk soil bacterial community structure along different environmental gradients (water, temperature) and discuss how the qualitative changes in fine root functional structure affect biomass allocation pattern and qualitative change in SOM formation.

Investigating fine root dynamics and phenology in temperate forests: a comparative analysis

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Abstract: Forests play a critical role in the global carbon cycle by acting as substantial carbon sinks. While much attention has been paid to aboveground carbon sequestration, recent research has highlighted the significant contribution of forest soils, particularly through fine root dynamics. Fine roots play a key role in belowground net primary productivity, facilitating carbon and nutrient cycling in forest ecosystems. However, a comprehensive understanding of fine root dynamics and functions remains elusive due to methodological limitations. This study aims to compare the effectiveness of methods for estimating fine root production, to investigate fine root dynamics and phenology, and to explore the intricate interactions between below- and above-ground ecosystems in temperate broadleaved and coniferous forests. Preliminary findings revealed notable discrepancies in fine root production estimates among three direct methods—sequential soil coring, ingrowth coring, and the root scanner method—in the same forest types. Annual fine root production accounted for 10-44% of net primary production, with more productive forests displaying higher belowground carbon allocation. The phenology of fine roots exhibited differences between pine and oak-dominated forests, with elevated fine root mortality coinciding with aboveground bud burst. This research sheds light on the intricacies of fine root dynamics and belowground phenology, providing valuable insights into the essential role of fine roots in carbon and nutrient cycling. The findings will have implications for forest management and ecosystem restoration efforts aimed at enhancing carbon sinks. This study deepens our understanding of carbon sinks in forest soils, enabling us to effectively manage forest ecosystems in the face of ongoing environmental challenges. This research not only advances our knowledge of belowground carbon giants but also supports efforts to develop sustainable practices that optimize carbon sequestration in forests.

Litterfall production and fine root dynamics in a Pinus koraiensis plantation for 10 years following thinning intensities

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Byung Bae Park[1, 2]
Si Ho Han[1], Ji Young An[1, 2], Jonathan Ogayon Hernandez[3], Woobin Youn[1], **Hyunju Lee**[1]
[1] Department of Environment and Forest Resources, College of Agriculture and Life Science, Chungnam National University, Republic of Korea
[2] Institute of Agricultural Science, Chungnam National University, Republic of Korea

Abstract: Thinning must be done in a sustainable and ecologically responsible manner since aggressive thinning negatively impacts forest ecosystem health and function by modifying soil physicochemical characteristics, fine root dynamics, and litterfall production. Here, we investigated the long-term changes in fine root biomass and necromass, litterfall production, and soil physicochemical properties in a 50-year-old *Pinus koraiensis* plantation for ten years in different thinning intensities (based on diameter at breast height, DBH). Three thinning treatments were used: control (CON), low thinning (LT) or double thinning in 1975 (15%) and 2007 (38%), and high thinning (HT) or triple thinning in 1975 (15%), 2000 (25%), and 2007 (66%). The soil physicochemical characteristics in the plantation were compared between soil depths. Fine roots of *P. koraiensis* and understory vegetation were analyzed by diameter class and soil depth. Leaf, twig, and miscellaneous litter in 2007 and needle, understory leaves, twig, and miscellaneous litter in 2018 were also analyzed. In 2018, soil pH, OM content, and total N were the highest at HT and lowest at LT treatment. Available P2O5, CEC, K+, Ca2+, Mg2+, and EC were significantly higher at CON and/or HT than LT. Fine root biomass were the highest at CON, intermediate at HT, and the lowest at LT in 2018. While the fine root biomass decreased by 59% (149.7 g m-2) in 2018 compared to that of 2007, the necromass increased by about four times (108.1 g m-2) in the 0-20 cm soil depth. Fine root biomass (83%) and necromass (78%) were mostly distributed in the 0-20 cm soil depth. Litterfall decreased with thinning intensity, i.e., CON (7,000 kg ha-1) > LT (5,998 kg ha-1) > HT (5,238 kg ha-1). Overall, *P. koraiensis* plantation showed significant changes in soil physicochemical characteristics, fine root biomass and necromass, and litterfall production over time, and the magnitude of the effects varied depending on thinning intensity. Results reported herein provide the threshold at which sustainable and ecologically responsible thinning should be performed for *P. koraiensis* plantation to help maximize the climate change mitigation potential of thinning.

Microdialysis for measuring the root exudates in the rhizosphere

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Aliya Sultonova[1]
Ivika Ostonen[1]
[1] Department of Geography, Institute of Ecology and Earth Sciences, University of Tartu

Abstract: A significant portion (20%) of the carbon (C) assimilated through photosynthesis by plants is subsequently released by their roots into the soil in the form of exudates in the rhizosphere. Changes in plant root exudation profiles during extreme climate conditions and their species-specific metabolic components need more attention. Moreover, for a comprehensive understanding of the belowground microworld, it is essential to explore non-destructive assessment techniques for native soil areas. The aim of this work is to measure plant root exudates in the rhizosphere to understand their role in C cycling and plant response to climate change using microdialysis as a minimally invasive technique that can be used to simulate, measure and quantify the root exudate content.

In the current study, 36 three-years-old Norway spruce (*Picea abies)* seedlings were grown in growth chambers (Percival Scientific Inc, USA) at a constant light intensity. Drought simulation was undergone by manipulation with several parameters: air humidity (RH was decreased to 10% compared to control), air temperature (was increased by + 6°C), and soil moisture (the threshold for watering was decreased to 45% and 60%). Overall, there was three microdialysis (CMA Microdialysis AB) collection sessions of root exudates: (i) before the drought simulation (control); (ii) the period after the simulation, and (iii) the recovery period. After the final microdialysis campaign root carbon exudates were collected following the culture-based cuvette method. Analysis of root exudate samples was performed by Vario TOC analyser for total organic carbon and by high-performance liquid chromatography-mass spectrometry (HPLC-MS) to determine the profile of plant secondary metabolites.

For understanding the effect of drought on the root exudation profile we analyzed metabolic profile of root exudates and the TOC. In addition, we compared the amount of TOC that was collected using the new microdialysis technique and the well-known cuvette method. According to the literature review and experimental comparison of the two methods, the pros and cons of the microdialysis technique were analyzed. The perspectives of microdialysis for plant root exudate studies will be discussed during the presentation.

Soil carbon pool may become vulnerable by waterlogging in forested peatlands

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

[2] Natural Resources Institute Finland (Luke), Natural Resources, Helsinki, Finland

Abstract: Forested peatlands are a globally significant carbon pool. Decomposition rate in forested peatlands is largely controlled by soil water-table level, but also roots, their chemistry, and microorganisms play roles in the stabilization of soil organic carbon (SOC). Weather extremes including waterlogging will become more common with climate change, but so far, drought has obtained much more research interest than waterlogging that potentially affects SOC pool. Our hypothesis was that soil waterlogging decreases stable SOC formation through the decreased amounts of fine roots, tannins, and root-associated microbial necromass compared to non-waterlogged soil. We studied the effects of waterlogging on carbon pools, soil enzyme activities, soil and root chemistry, and biomass, necromass and community composition of soil fungi. *Pinus sylvestris* rhizosphere was investigated in a controlled-environment experiment with and without waterlogging and in a wetter and a drier forested peatland site. Generally, stable SOC content and its share of total SOC content, tannin content, enzyme activities, and live fungal biomass were lower in the experiment in waterlogging than control treatment, and lower in the wetter than the drier forested peatland site. Ectomycorrhizal fungi were more abundant in the fungal community of the drier than the wetter site in the deepest studied soil layer. In the wetter site, stable SOC content and the communal proportion of ericoid mycorrhizal fungi were highest in topsoil containing more roots than the layers deeper in soil. To conclude, specific root-related SOC stabilization mechanisms are present in forested peatlands where waterlogging consequently can make their SOC more vulnerable due to lowered C stabilization via root-microbial interactions and decreased root growth.

Soil Compaction Effects on the Abundance, Dynamics and Characteristics of Fine Roots and Mycorrhizal Associations in Forest Soils

Abstract: Logging-induced soil compaction poses a significant threat to soil habitat functions, particularly to root systems and their symbiotic relationships with mycorrhizae. Understanding the consequences of soil compaction is essential for sustainable forest management, as intact forest ecosystems play a critical role in climate change resilience and mitigation efforts. Remaining knowledge gaps highlight the need for comparative studies of different harvesting methods, fine-scale analysis to understand the spatial heterogeneity of compaction effects, and the interactions between soil compaction, root growth and mycorrhizal associations.

To gain a detailed insight into these complex relationships, we conducted an empirical Before-After Control-Impact study in a beech-dominated forest in Lower Austria. Different harvesting methods (harvester-forwarder with/without tracks and cable-yarding with motor-manual-felling), were applied in the winter 2022/23, taking into account previous harvests (18 years earlier). Our study used a transect approach to determine spatially explicit effects on standing root biomass and growth rates by using soil cores and in-growth cores, respectively. Transects were placed transversely across the tracks, covering areas directly (tracks, cable-yarding corridor) or indirectly (between the wheel tracks, marginal areas) affected by the logging activities. Comprehensive assessments of root biomass (distribution), nutrient content, anatomy and morphology were undertaken. In addition, logging effects on mycorrhizal morphotypes, mycorrhization rates of root tips, and hyphae growth (in-growth bags) were analysed.

Preliminary data show a significant influence of both recent and historical timber harvesting on the standing root biomass, indicating altered patterns of root growth and distribution, with significant

differences between and within transects. Our results indicate that different harvesting methods cause widely varying degrees and patterns of soil compaction – with contrasting effects on fine root dynamics.

The long-lasting consequences of soil compaction, hindering root system establishment and mycorrhizal symbionts, underlines the importance of maintaining soil as an intact habitat. The implications of this research are relevant for sustainable forestry practices, emphasising the need for appropriate soil management strategies to mitigate the negative effects of logging related soil compaction to ensure the long-term functionality of the soil as a habitat for roots and mycorrhizae.

Stand age-induced tree diversity and size inequality control aboveground biomass and soil organic carbon with abiotic drivers in South Korean forests

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Abstract: Forest biomass and soil organic carbon (SOC) are crucial for the terrestrial carbon cycle. However, the mechanisms underlying the interaction between trees and site properties (e.g., stand age, climate, soil) that drive the SOC remain unclear. We assumed that tree diversity, functional trait identity, and stand structural attributes regulate aboveground biomass (AGB) and SOC. Vegetation data from 125 plots dominated by 11 major tree species in South Korea were used to investigate these relationships. We analyzed the effects of tree diversity, community-weighted mean, stand structural attributes, and abiotic drivers such as stand age and topography, climate, and soil variables on AGB and SOC. We also tested the effect of AGB on SOC's biotic and abiotic drivers. We performed multimodel inference test with model averaging approach and piecewise structural equation modeling to compare and quantify the effects of the predictors on AGB and SOC. Stand age, species richness, and stand the standard deviation of diameter at breast height significantly affected AGB, but their effect on AGB varied depending on the dominant tree species. For SOC, elevation-related climatic drivers (i.e., mean annual precipitation, mean annual temperature and aridity), soil pH, species richness, and AGB directly regulate SOC. Dominant tree species also modulated the SOC. Our results show that the interactions of biotic and abiotic determinants with dominant tree species are important in both AGB and SOC despite the differences in the direction and magnitude of their effects. Therefore, our study suggests that understanding the interactions of biotic drivers with site-specific conditions, which determine the forest ecosystem's carbon cycle, is crucial in expecting the global carbon cycle.

Temporal variations in tree root dynamics and its implications on carbon balance in Peninsular Malaysia

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Jeyanny Vijayanathan[1]

[1] Soil Management Branch, Forestry Biotechnology Division, Forest Research Institute Malaysia, 52109 Kepong, Selangor, Malaysia

Abstract: Different components of net primary production (NPP) control the balance of tropical forests particularly, in terms of being a net carbon sink or source. Fine roots with a diameter ≤ 2 mm are essential for plant growth and the global carbon cycle but they are often neglected in NPP estimations. Approximately 10% to 60% of total NPP in tropical forests are contributed by fine roots production and 0.33 of the annual global NPP is used to produce fine roots. Fine root production (FrP) is influenced by root decompositions (Frd), necromass (FrN), turnover (FrT), biomass (FrB), standing litterfall (Lf), soil respiration (Rs), and climate. Our objective was to determine how fine root dynamics (Frb, FrN, Frd, FrP & FrT) vary with time with regards to the factors controlling it. Sequential soil core sampling and the root bag technique were used in a tropical forest at 120 days interval for two years at Jengka, Pahang, Peninsular Malaysia. Continuous inflow method was used to estimate FrP, FrN, and Frd. The litter and fine roots stocks were 3.34 and 0.98 Mg C ha^{-1}, respectively. The annual decomposition decay constant *k* was -0.6168 $year^{-1}$. Frb, FrN, and Frd correlated with mean air temperature whereas Lf correlated with Rs, Frb, and Frd. Total FrP, FrN, Frd, and FrT ranged as 627.80 –791.05 g m^{-2} yr^{-1}; 854.10 – 704.80 g m^{-2} yr^{-1}; 585.22 – 511.89 g m^{-2} yr^{-1}; 0.71 t $year^{-1}$, respectively. Inter-annual variations were prominent in our site whereby higher fine root biomass and litterfall were recorded during higher precipitation but drier periods restricted root decomposition, resulting in higher fine root necromass, affecting NPP. This study confirms the need to estimate temporal variations of belowground carbon allocation of roots and the necessity of including fine root dynamics and soil respiration in NPP ecosystem modeling for tropical forests.

The above- and belowground phenology of Picea abies in response to different drought episodes

T1.2 Carbon sinks in forest soils as controlled by fine-root dynamics

Marili Sell[1]
Gristin Rohula-Okunev[1], Priit Kupper[1], Ivika Ostonen[1]
[1] University of Tartu, Tartu, Estonia

Abstract: The air temperature in Estonia is projected to increase, affecting the growth of economically and ecologically significant tree species, especially young *Picea abies* seedlings used for regenerating forests. There is a close relationship between the aboveground parts and the development of the root system. We estimated the effects of increased temperature, decreased air humidity, and soil moisture on the shoot and root growth dynamics in *Picea abies*. We analysed the senescence dynamic within fine roots by separately measuring young and older root growth. Additionally, we studied the effect of potential asynchrony between above and belowground phenology caused by these changing climate factors.

Three-year-old Norway Spruce (*Picea abies*) seedlings were grown separately in transparent boxes in growth chambers. We conducted two separate experiments where drought episodes were simulated by decreasing relative air humidity and soil moisture and increasing air temperature in short and long-term scales. Images of fine root growth were taken with a smartphone, and images were analysed by the deep learning method-based program RootPainter. From that, we have data on the total fine root projection area and the area of young white root tips. Shoot growth was measured manually throughout the experiment.

The shoot phenology followed a well-known pattern; the length of shoots increased fast at the beginning of the growing season and stabilised after seven weeks of growing. At the same time, the fine root growth proliferated. High temperatures with lower relative air humidity showed longer needle growth, and the fine root senescence was also more pronounced than in the high-temperature treatment without the change in relative air humidity. The relative growth rate of young fine root tips was almost twice as high as the relative growth rate of older brown roots. In the second experiment, the spruce saplings showed continuous root growth even though they experienced strong drought without watering. After experiencing three weeks of harsh drought, the spruce seedlings showed clear recovery underground, especially in immense pioneer root growth. The asynchrony of above and belowground phenology in Picea abies caused by drought episodes along different time scales will be discussed.

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

A Study on Stand Growth of Larix kaempferi by Thinning Intensity over 9 years

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

[1] Department of Forest Management, Kangwon National University, Chuncheon 24341, Republic of Korea
[2] Institute of Forest Science, Kangwon National University, Chuncheon 24341, Republic of Korea
[3] Natural Resources Institute Finland (Luke), Latokartanonkaari 9, 00790 Helsinki, Finland

Abstract: This study was carried out to understand the change of stand growth of Japanese larch (*Larix kaempferi*), which is one of the major plantation species in Korea. The permanent plots in 45 sites were established in 2013. Each site consists of three plots by thinning intensity: unthinned, light thinning and heavy thinning. The thinning was carried out based on the basal area in the year of plot establishments, and the thinning intensity was 20% for the light thinning plot and 40% for heavy thinning plot in each site. The measurement was repeated every 3 years, and it was performed three times for 9 years. According to the last measurement, the stand age in all sites, and the unthinned plots were, on average, 24.5 cm in diameter at breast height (DBH), 23.1 m in height, and 835 trees/ha in stand density. On the other hand, in the light and heavy thinning plots, DBH and height were higher; 27.5–29.1 cm in DBH and 23.6–24.3 m in height while the stand densities were lower; 412–601 trees/ha. Additionally, the growth changes of DBH, height, basal area, volume and carbon sequestration by thinning intensity were analyzed to examine the thinning effects. The DBH growth was highest in heavy thinning plots, followed by light thinning plots and the unthinned plots. As the stand age increased, the differences between thinning intensities decreased in each site. The height growth was not significantly different by thinning intensity. The stand basal area growth was high in a descending order of control, light thinning, and heavy thinning plots due to the differences in the number of residual trees after thinning. The stand volume growth and carbon sequestration rate were the highest in control plots. This study can offer fundamental information about the thinning effects on the sawtimber production and carbon sequestration rate of Japanese larch and its potential for enhancing sustainable forest management.

A supra-regional field trial in Thuringia/Germany to test different management options for the reforestation of disturbed spruce areas

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Ingolf Profft[1]

[7] Friedrich Schiller University Jena, Institute of Geography
[8] TU Dresden, Institute of Forest Growth and Forest Computer Sciences

Abstract: The impact of extreme weather events such as droughts, heat waves, storms and the associated intensification of bark beetle outbreaks in spruce forests in recent years, has lead to a vast loss of spruce trees in Thuringia and other regions in Germany. There are various options for the management of disturbed areas, but their pros and cons are not clearly resolved. The ResEt-Fi consortium implemented a supra-regional field trial to test how specific practices for deadwood management affect the ecological conditions and subsequent reforestation dynamics of natural regeneration and planted trees. It aims at generating climate-stable mixed forests by an ecological valuable transition offering socio-economic benefits. For stakeholders and forest practitioners, it is planned to create guidelines and showcase scenarios for facilitating the selection of management procedures that fit optimally to the regional conditions and goals for mid- and long-term development.

The investigations focus on disturbed areas in three particularly affected model regions distributed across Thuringia, each characterized by specific ecological site conditions: 1. Southern Harz Mountains ('Südharz'), 2. Western Thuringian Forest ('Marksuhl'), and 3. Thuringian Slate Mountains ('Neuhaus'). A nested experimental design integrates different silvicultural strategies for dealing with disturbed areas, comprising (a) clearing, (b) high stumbs and (c) dead wood patches, which are compared with undisturbed sites as control (d). Furthermore, subplots with artificial regeneration and deliberately spread deadwood are additionally included in the investigations. Local climatic conditions of the treatments are recorded intensively, as are the comprehensive aspects of soil ecology, succession of vegetation, and effects on fungal communities, birds and wood-dwelling beetles. Taking all this information into account, predictions of the dynamics of various scenarios are derived by process-based simulations.

Changes in aboveground and belowground biomass partitioning of trees planted in the Desert Region of Mongolia in different irrigation regimes

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Batkhuu Nyam-Osor[1]
Ser-Oddamba Byambadorj[1], Enkhchimeg Tsedensodnom[1, 2]
[1] Laboratory of Forest Genetics and Ecophysiology, National University of Mongolia, Ulaanbaatar, Mongolia
[2] Institute of Geography and Geoecology, Mongolian Academy of Sciences, Ulaanbaatar, Mongolia

Abstract: Increasing land degradation and desertification remain serious issues in Mongolia, a country with a low density of the natural forest, limited precipitation, a large number of livestock, and, most importantly, an arid environment. Planting more trees that are adapted to the specific environment is an obvious strategy to tackle this recurring issue. Thus, our research is focused on irrigation on afforestation sites of *Ulmus pumila* L., *Tamarix ramosissima* Ldb., *Elaeagnus moorcroftii* Wall. ex Schlecht tree species for a over decade using four different irrigation regimes. Aboveground (leaf, stem branch) and belowground (fine roots, small, medium, large, very large, tap root) biomass and carbon contents of trees were determined. The biomass of all species was increased under 12 L h^{-1} irrigation regimes and the lowest biomass was found under 4 L h^{-1} irrigation regimes, except *T. ramosissima*. Furthermore, *U. pumila* showed the highest biomass than the other species. As expected, tree carbon and CO_2 sequestration were higher in *U. pumila* and *E. moorcroftii*. Overall, we concluded that these planted tree species exhibited similar responsed and were effective under irrigation.

Changes in tree seedlings and understory plants following soil scarification and amendments in a northern hardwood forest

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Fidèle Bognounou[1]
David Paré[1], Jérôme Laganière[1]
[1] Laurentian Forestry Centre, Natural Resources Canada, 1055 du PEPS, P.O. Box 10380, Sainte-Foy Stn., Québec, QC G1V 4C7, Canada

Abstract: A combination of global changes (e.g., soil acidification, invasive species, forest management, climate) impacts the regeneration dynamics of sugar maple-dominated stands in northeastern North America. More specifically, there are concerns about the regeneration of sugar maple and other high-value species due to the expansion of American beech and its bark disease, killing mature trees, compromising fiber supply and other ecosystem services. Here, we set up a field trial to study the effect of soil scarification, amendments (nitrogen fertilization, liming, and wood ash), and their interactions, on tree species establishment following understory vegetation removal in a beech-invaded sugar maple stand to promote the establishment of high-value species (i.e. sugar maple and yellow birch), to control beech regeneration, and help reduce the impacts of beech bark disease on stand development. Collateral effects of these treatments on understory vascular plant communities were also monitored. After four years of monitoring, we found that maple-beech stands with well-drained soils were promising sites for the success of sugar maple and yellow birch establishment. Soil scarification had a limited effect on sugar maple and beech establishment while it enhanced that of yellow birch, pin cherry and red maple. The combination of soil scarification and amendments was more effective in promoting the recovery of yellow birch and pin cherry and controlling the recovery of beech and red maple than their separated effects. Lime amendment promoted sugar maple establishment without favouring competitors such as yellow birch, pin cherry and red maple, and limited beech establishment. Scarification reduced species richness and functional diversity of understory plants and was further amplified by soil amendments. Overall, our results suggest that combining soil scarification and amendments on targeted site types could help fine-tune tree establishment conditions in northern hardwood forests but may impact the resilience of non-targeted understory plants.

Comparative study of forest structural diversity, birds and plant species diversity between mature oak forest and Plantations in Basque Country

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Jaime Uria Diez[1]
Nahia Gartzia Bengoetxea[1], Ander Arias Gonzalez[1], Mikel Anza Hortalá[1], Jabier Zabala Albizua[2]

[2] Department of Zoology and Animal Cell Biology, Basque Country Univeristy, Farmacy Faculty. Paseo de la Universidad, 7, 01006 Vitoria, Spain.

Abstract: Biodiversity has declined rapidly over the last 50 years, with severe implications for human health and well-being, societal resilience, and sustainable development. The main direct cause of biodiversity loss is land use change which drives an estimated 30% of biodiversity decline. Forests, when sustainably managed, play a crucial role in regulating climate, providing renewable materials or halting biodiversity loss. However, the spread of intensively managed monospecific even-aged forest plantations raises the question of how this land use can affect biological diversity at local level. Moreover, most of these forest plantations include exotic species that may not be suitable as habitat for many local species. Sixty percent of Atlantic side of the Basque Country (north of Spain) is covered by forest systems, but monospecific even aged exotic plantations cover as much as 68% of forest area, while English oak forests, the main potential forest system in the region, only cover 5,1% of this area.

Our hypothesis is that this simplification of the forest system reduces resources and shelters for native species, negatively affecting their survival and reproductive capacity.

The objective of this study is to determine differences in forest structure, the amount of deadwood, and small scale biodiversity (plant and bird species) among four forest types: semi-natural oak forest, eucalyptus, Japanese larch and radiata pine plantations. All four types of forest are located at similar altitudes and climatic conditions. We stablished three plots of 18m radius in each forest type.

Based on preliminary results, plant and bird diversity tend to be higher in oak semi-natural forest and lower in plantations (lower in eucalyptus than in conifers). Forest structure is different among all type of forest related to its own natural development and management. Oak semi-natural forest is more uneven-aged and random distributed, having a higher presence of deadwood. Plant diversity tend to be higher in oak seminatural forest and lower in plantations (lowest in eucalyptus). However, there is a higher presence of shrubland species in eucalyptus plantations. The same pattern is observed in avian diversity although differences between conifers and oak seminatural forest are smaller due to similar age characteristics.

Continuous cover forestry will not benefit biodiversity without improved environmental considerations

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Therese Löfroth[1]
Adam Ekholm[1], Jörgen Sjögren[1]
[1] Swedish University of Agricultural Sciences

Abstract: Continous cover forestry (CCF) is often considered a better option than rotation forestry for biodiversity conservation and pest insect management. However, for species depending on old growth structures like old trees and dead wood CCF induce the same basic problems as rotation forestry in terms habitat loss.

In this project we evaluate the effects of one type of CCF, selective felling, on the beetle community in a field experiment including nine locations in central Sweden. At each location there are two treatments and a control: one even-aged stand that is managed by traditional rotational forestry, as well as two un-even aged stands that have either become selectively cut or left untouched as a control. By putting out two different kinds of insect traps, flight intercept traps and malaise traps, which together catch a large part of all flying insect species, we examined how the beetle assemblage responded to the different management methods. We examined species richness, assemblage composition, and occurrence of beetles of conservation concern, and pest bark beetles and their enemies. We found that the beetle assemblage in the clearcut stand was different from those in the selectively cut and the control stands. Selective harvesting did not substantially change assemblage composition or the abundance of species of conservation concern of pest bark beetles. However, selective felling reduced the amount of deadwood and large trees compared with the control. Thus, CCF can potentially benefit species that thrive in continuous forest but measures must be taken to ensure habitat availability in selectively cut stands.

Contrasting mitigation and adaptation forest management strategies: unraveling the effects on biodiversity and ecosystem services

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Anna Repo[1]
Katharina Albrich[1], Juha Aalto[2], Ilari Lehtonen[2], Juha Honkaniemi[1]
[1] Natural Resources Institute Finland (Luke), P.O. Box 2, 00791 Helsinki Finland
[2] Finnish Meteorological Institute, P.O. Box 503, FI-00101 Helsinki, Finland

Abstract: Boreal forests play an important role in climate change mitigation, biodiversity conservation and the provision of vital ecosystem services. Changing climate is likely to increase the frequency and the severity of forests disturbances. Hence, increasing disturbances may offset the past and ongoing efforts to increase carbon sequestration in forests and halt biodiversity loss. While forest disturbance risk prevention measures i.e., adaptation management, offer solutions to safeguard future timber yields, the effects of adaptation management on biodiversity, climate change mitigation potential of forests and other ecosystem services has received little attention. In this study we contrast the effects of mitigation versus adaptation forest management on the resilience of boreal forest ecosystems in a changing climate. We address the following questions: 1) How does adaptation management affect the carbon sequestration and storage potential and other ecosystem services of boreal forests in a short and long term in a changing climate? and 2) What are the synergies and trade-offs of mitigation and adaptation management on selected biodiversity indicators? To address these questions, we used a process-based forest landscape and disturbance model iLand that models interactions with climate change and disturbances dynamically. We simulated combinations of seven forest management scenarios and three climate scenarios in two different forest landscapes with ten replicate runs for 80 years. The forest management scenarios included business as usual scenarios and mitigation and adaptation scenarios with changes in rotation lengths and in the shares of deciduous trees in regeneration. Our findings highlight the complex interactions between disturbance risk prevention, biodiversity, carbon storage and sequestration and other ecosystem services. The results help to guide forest managers and policymakers in planning conservation and mitigation efforts, maximizing multiple benefits and enhancing forest resilience under a changing climate.

Dynamics of biomass evaluated with remote sensing in Pinus pinaster in Portugal

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Ana Cristina Gonçalves[1]
Adélia M. O. Sousa[2]
[1] MED – Mediterranean Institute for Agriculture, Environment and Development & CHANGE – Global Change and Sustainability Institute, Departamento de Engenharia Rural, Escola de Ciências e Tecnologia, Universidade de Évora, Pólo da Mitra, Ap. 94, 7002-554 Évora, Portugal
[2] MED – Mediterranean Institute for Agriculture, Environment and Development & CHANGE – Global Change and Sustainability Institute, Laboratório de Deteção Remota – EaRSLab, Departamento de Engenharia Rural, Escola de Ciências e Tecnologia, Universidade de Évora, Pólo da Mitra, Ap. 94, 7002-554 Évora, Portugal

Abstract: Above ground biomass was estimated with an allometric functions with crown projection area on a per area basis, for *Pinus pinaster* stands in Portugal. The allometric function is a linear function with crown projection area as explanatory variable derived from the vegetation mask of high spatial resolution satellite images. It was attained with contrast split segmentation over normalized different vegetation index. The above ground biomass was calculated on a per square grid of 500 m^2, for high spatial resolution satellite images of 2004, 2007 and 2011 and its dynamics evaluated. During the period under analysis two types of disturbance occurred forest fires and salvage cuttings (to control the pinewood nematode). The results indicated a trend towards the decrease of above ground biomass from 2004 to 2007, due mainly to forest fires and salvage cuts and an increase in *circa* half of the area from 2007 to 2011. The increase in above ground biomass was due to growth as well as natural regeneration mainly in the burned areas. Overall, the advantages of monitoring biomass with remote sensing data are the monitoring of the entire area (without conversion or extrapolation methods), it is a simple method, especially indicated for stands and/or forests where disturbances and natural regeneration occur, and its implementation in a geographical information system is straightforward being a useful tool to forest management and planning. Moreover, the monitoring of above ground biomass can be done at several temporal and/or spatial scales enabling increasing the flexibility in monitoring above ground biomass and carbon.

Effects of thinning intensity on growth, species diversity of understory vegetation and forest productivity of Korean pine plantation

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Peng Zhang[1]
Hailong Shen[1], Haibo Wu[1], Yuanqin Hao[1]
[1] Northeast Forestry University

Abstract: In the context of sustainable forest management, the cultivation goal of artificial forests should not only meet the demand for wood production, but also consider ecological service functions such as carbon sequestration, biodiversity protection, and forest productivity maintenance. Density regulation is one of the important measures for silviculture. In the past, the stage adjustment of artificial forest density was mainly aimed at increasing wood production. Under the premise of considering wood production and main ecological service functions, further research is needed to determine the reasonable density of artificial forests at different stages. This paper takes the 71 year old Korean pine plantation in Caohekou Town, Benxi City, Liaoning Province, China as the research object, to explore the impact of different intensity (extreme intensity, intensity, moderate intensity, weak intensity and control) thinning modes on the growth of Korean pine plantation, timber volume, understory vegetation species diversity and soil physical and chemical properties, and comprehensively evaluate the forest growth, timber yield, understory vegetation species diversity and forest productivity through Entropy-Topsis method. The results showed that there were significant differences in growth status, wood yield, species diversity of undergrowth vegetation, and soil physical and chemical properties under different thinning intensity models. If the management goal is to increase the large diameter timber output of Korean pine plantation or protect the species diversity of understory vegetation, it is recommended to adopt the moderate thinning mode; if the goal is to maintain forest productivity, it is recommended to adopt extreme intensity thinning mode; If you want to simultaneously consider the above three aspects, it is recommended to prioritize the moderate thinning mode, followed by the extremely intensive thinning mode.

European forest potential for carbon sequestration and biodiversity conservation under different silvicultural regimes

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Abstract: Climate change mitigation and biodiversity conservation are deeply connected and must be considered jointly. Forests are of primary relevance for both these major environmental challenges. Our study aimed to assess the synergies and trade-offs between thesechallenges in European forests. We used forest structural and biodiversity data from 2,282 sampling units across 12 European countries merged and harmonized in the framework of the COST Action "BOTTOMS-UP" (CA18207). We calculated living trees and deadwood carbon stocks, according to IPCC guidelines, and species richness for six taxonomic groups (Birds, Epiphytic Bryophytes and Lichens, Saproxylic Beetles and Wood inhabiting Fungi, Vascular plants). The species richness of each taxonomic group in each sampling unit was standardized through rarefaction and extrapolation curves. We used boosted regression trees to estimate the relationship between the scaled species richness of different taxonomic groups in relation to carbon stocks and other covariates, including forest type, silvicultural regime and sampling protocol. Since biodiversity conservation should focus not only on the number of species, but also on their identities, we used species-only distribution models (MaxEnt) with GBIF occurrences to assess the climatic suitability for each species in the dataset at the continental level. Obtained climate suitability was extracted for each “BOTTOMS-UP” sampling unit and modeled against presence/absence data in the platform through GLMMs by taking into account the silvicultural regime among the fixed effects.

Species richness response to carbon stock was generally positive for saproxylic and epixylic groups, but it varied greatly across taxonomic groups and carbon pools, with a diverse impact of and silvicultural regimes across taxonomic groups. Forest multifunctionality for carbon sequestration and biodiversity conservation may be achieved only by accounting for different responses when planning silvicultural strategies. Indeed, by analyzing the responses of a wide range of forest species, we were able to assess the effects of different silvicultural regimes on biodiversity in European forests.

Forest management and climate change – forest management trends in the forest offset market in the United States

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Dr. Lilli Kaarakka[1]
Dr. Meredith Cornett[2], Julia Rothey[3], Dr. Laura Dee[3]

[3] University of Colorado Boulder, Department of Ecology and Evolutionary Biology

Abstract: Land management interventions such as forest management have gained significant traction in the last few years as instruments in increasing carbon (C) sequestration in working lands of the United States. Indeed, storing C in forests have been identified as a key nature-based solution pathway. While the importance of forest management in maintaining and potentially enhancing the terrestrial C sinks has been well established, C as a management objective in the practical context of silviculture and forest management is a relatively new concept. Yet a new emissions trading market, the Voluntary C Offset Market in California, has been dominated by offsets originating from managed forests. Furthermore, almost two hundred million forest C offsets have been issued through the California Cap-and-Trade-Program and Voluntary Offset Market yet little information is available on the practical forest management applied in these projects.

Improved forest management (IFM) has been identified as one of the forestry-related land management pathways with significant climate change mitigation potential. Currently, IFM is loosely defined and how it translates into practical forestry and connects to sustainable forest management (i.e., best management practices) as a whole, has not been identified in detail. **Here, we assess IFM, evidence for the potential for different IFM practices to sequester C, and gaps in IFM and the incentives for their adoption.** We offer specificity to IFM through reviewing existing best management practices and additional silvicultural practices.

Growth and biomass production of major tree species in Korean forests: Implications for forest management and climate change mitigation

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

[3] Institute of Agricultural Science, Chungnam National University, Republic of Korea

Abstract: The role of forests as a major carbon sink is becoming increasingly important in mitigating climate change and achieving carbon neutrality. In particular, Korea's forests were established as a reforestation and greening project after the Korean War and have reached a harvest age of 40-50 years, so there is increasing interest in managing forests before and after harvesting. It is necessary to develop a forest management plan for each tree species in order to improve the carbon sequestration capacity of the forests.

This study was conducted to evaluate the growth and biomass production characteristics of *Larix kaempfi* (LK), *Pinus densiflora* (PD), *Pinus koraiensis* (PK), and *Quercus mongolica* (QM), and to investigate the effects of past forest management practices and climatic factors on the growth of each tree species in Mt. Gariwang, Pyeongchang, Gangwon-do, Korea.

The study stands were located at an elevation of 900-1000 m and on the same southeastern slope. Mean tree height, DBH, and stand density were 10.34-18.54m, 21.04-35.54cm, and 267-758 trees ha-1 across all stands.

For the growth characteristics, aboveground biomass was measured by tree inventory and stem coring. Belowground fine root biomass was measured by soil coring. For the productivity survey, aboveground litterfall was measured with a litterfall trap, and belowground fine roots were measured with ingrowth cores. To obtain data on the site environment, soil characteristics, understory vegetation, and historical climate characteristics were also investigated. Net primary production (NPP) was estimated as the sum of woody biomass, litterfall and fine root production.

Preliminary results of this study showed that most of the fine roots were distributed in the 0-20 cm soil depth and leaf litter accounted for 70% of the total litterfall. NPP follows the order QM > PK > LK > PD. Tree growth seems to be more influenced by annual precipitation than by annual temperature change.

The results of this study will be able to provide basic data for establishing species-specific forest management plans in response to future climate change.

Influence of silvicultural scenarios on potential forest use, carbon storage and biodiversity in tropical forest landscapes

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Daniel Kübler[1]
Sven Günter[1]
[1] Thünen-Institute of Forestry, Hamburg, Germany

Abstract: Human-modified forest landscapes are widespread in tropical regions. They are important for climate change mitigation and biodiversity conservation, but also for food security and wood production. The multitude of initiatives aiming to protect and restore forests in these landscapes often faces the challenge of trade-offs between different objectives. On the level of forest stands, there is robust knowledge on trade-offs associated with different wood production systems. However, there is a lack of understanding about their landscape-wide impacts. Studying these impacts is challenging because land use in tropical regions is highly complex and empirical data on the landscape-level are scarce. Additionally, deforestation for agriculture has a huge influence on landscape-level outcomes. It is thus important to account for interactions between wood production and deforestation risks.

We extended the land sharing vs sparing framework to wood production in old-growth and restored forests and developed silvicultural scenarios of meeting wood demands in human-modified tropical forest landscapes with either high-intensity or low-intensity wood production systems. We then quantified impacts on carbon storage and biodiversity in different stylized virtual landscapes in Ecuador, Zambia and the Philippines for each scenario using a modelling approach. Our probabilistic and spatially implicit model simulates a time frame of 30 years and includes the following main components: 1) landscape-wide fuelwood and timber demands based on estimations of per capita demand and population; 2) biomass growth and wood production estimated using simple and robust growth equations; 3) different wood production systems with distinct deforestation risks estimated based on remote sensing data, and 4) changes in species richness due to loss or degradation of natural habitat estimated using a species-area relationship model. For each silvicultural scenario and landscape, we run 1000 iterations and present results from a sensitivity analysis that estimates the contribution of input parameters to the overall output uncertainty.

Preliminary results of our exploratory model suggest that it is more favourable for landscape-wide carbon storage and biodiversity to meet wood demands using low-intensity wood production systems. Our model shows the importance of considering landscape-level outcomes when comparing wood production systems in the tropics.

Long-term effects of (slow-release) liming in Norway spruce stands reveal soil restoration boosting tree productivity, and herb layer biodiversity

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

[4] Forest Research Institute Baden-Württemberg department of Soil and Environment, Freiburg, DE
[5] KU Leuven division of Soil and Water Management, Leuven, BE

Abstract: Norway spruce (*Picea abies* L.), a fast-growing conifer, has been managed to meet the growing demand for wood as it boasts a high revenue while having the ability to cope with acid soils. However, because of climate change, this tree species is currently experiencing severe beetle-induced diebacks. Furthermore, multiple (fast) rotations and ongoing atmospheric deposition have exacerbated the nutrient deficiencies of K, Ca, and Mg leading to poor tree vitality and low productivity.

A multitude of field experiments were deployed in the 90s to alleviate these nutrient imbalances in the soil. They encompassed additions consisting of (mixtures of) rock powders, dolomite or wood ash (Ca, Mg and K), and other mineral fertilizers (P and S). However, an important knowledge gap remains because the long-term effects on belowground restoration, aboveground productivity, and herb layer biodiversity are paramount to assess the future feasibility and sustainability. To this goal, we resampled experiments (28-35 years after application) in 2022 and cored 250 trees.

In 1987, three experiments with broadcast fertilization (±5 Mg/ha, plots 1 ha) were set up in mountainous Vorarlberg (AT) forests ($pH_{topsoil}$-$CaCl_2$ = 3.0, tree age_{1987} = 110-185 yo) with sites varying from crystalline stony podzols to albic luvic stagnosols (von Mersi et al., 1992). Furthermore in 1995, in Baden-Württemberg (DE) on a gleyic luvisol ($pH_{topsoil}$-$CaCl_2$ = 3.0, tree age_{1995} = 56 yo) a broadcast comparison (1-10 Mg/ha, plots 2500 m^2) of phonolite rock dust, dolomite, K_2SO_4 and wood ash was laid out (von Wilpert & Lukes, 2002).

Belowground, soil pH and base saturation increased while carbon stocks changed and yielded more carbon in deeper horizons. Aboveground, the BAI (ranging from 1000-4000 mm^2/year), increased up to 50% for K-deficient stands in Baden-Württemberg while more subtle increases (+10-20%) were found due to lower N deposition, smaller amendment dose, and higher tree age in Vorarlberg. Total ecosystem carbon increment generally increased (+10-40 Mg C/ha) after amendments, and herb layer biodiversity was increased. In conclusion, soil ameliorative treatments are promising to boost Norway spruce productivity but the gain is highly site-specific and care must be taken to preserve climate resilience.

Partial harvesting for climate mitigation in forests of northwestern British Columbia

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Flora Krivak-Tetley[1]
Caren Dymond[2], Erica Lilles[3], Bianca Eskelson[1]
[1] Department of Forest Resources Management, University of British Columbia, Vancouver, BC, Canada
[2] Forest Carbon and Climate Services Branch, Government of British Columbia, Victoria, BC, Canada
[3] Ministry of Forests, Government of British Columbia, Smithers, BC, Canada

Abstract: Canada is one of the world's largest producers and exporters of timber products, with almost half of the country's wood coming from clear-cut harvesting in British Columbia. Implementation of partial harvesting can increase carbon retention and has the potential to offer a transformative and sustainable alternative that promotes regional and global climate mitigation goals. Additionally, increased structural complexity and the maintenance of biodiversity and other ecosystem services promote adaptation in partially harvested landscapes. However, it is unknown how clearcutting versus partial harvesting affects carbon dynamics and other ecosystem services at a landscape scale, particularly if a larger area is harvested in order to meet the demand for wood. We used the landscape model LANDIS-II to simulate forest stand growth and mortality, disturbance, and harvest in northwestern British Columbia's interior cedar-hemlock zone. We implemented three harvesting intensities (30%, 60%, and clearcutting) across a range of realistic harvest rates in mature and old-growth forested landscapes, then compared carbon storage and sequestration. We also assessed the impact of harvest waste residue burning and harvested wood product storage on carbon dynamics and analyzed changing road density and forest structure. Empirical data from inventory plots and long-term partial harvesting trials and the stand-level model SORTIE were used to parameterize and validate LANDIS-II. Our results highlight tradeoffs between carbon storage and wood production: as expected, we found that reducing harvest intensity increased carbon storage and decreased wood production. Harvest volume targets could be maintained by increasing the area harvested, but differences in carbon dynamics across forest ages and partial harvesting approaches were strongly mediated by overall harvest rate. Due to their high carbon storage and sequestration rates and lower merchantable volume, old growth forests represent a promising carbon mitigation tool in northwestern British Columbia. Decision support tools developed using our results will support Provincial and First Nations land managers in British Columbia who are working to balance complex harvest, carbon mitigation, and ecosystem services goals.

POTENTIAL OF DIPTEROCARPS AS FOREST PLANTATION SPECIES AND FOR CARBON SEQUESTRATION IN MARGINAL AREAS

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Wai Mun Ho[1]
Mohamad Fakhri Ishak[1], Faridah Ahmad Azam[1], Amir Saaiffudin Kassim[1], Rosdi Koter[1], Mohd Zaki Abdullah[1]
[1] Forestry Biotechnology Division, Forest Research Institute Malaysia (FRIM), 52109 Kepong, Selangor, Malaysia

Abstract: *Anthoshorea roxburghii* and *Hopea odorata*, both from the Dipterocarpaceae family, are native to the mixed dipterocarp forest of Malaysia and are classified as 'Vulnerable' in the IUCN Red List of Threatened Species. Both species have been promoted not only as plantation species but also suitable to be planted in open area of degraded sites including ex-mining and logged over areas in Malaysia. This paper aims to 1) determine the growth, biomass and carbon accumulation in *A. roxburghii* and *H. odorata*, 2) determine suitable sites as plantation species and 3) explore the possibility of the two species for rehabilitation of degraded or problematic sites. Results show the growth performance of both species in marginal or degraded areas besides ability to sequester carbon. Eleven years old *A. roxburghii* can grow with mean annual increment in diameter at breast height (MAID) of 1.73 ± 0.65 cm with an estimated aboveground biomass (AGB) of 126 Mg/ha. Meanwhile, seven years old *H. odorata* recorded average MAID of 1.80 ± 0.53 cm and AGB of 33 Mg/ha. FIndings from this study thus indicated that *A. roxburghii* has higher potential in terms of biomass as well as carbon accumulation on degraded sites.

Restoration of Introduced Species Plantations through Native Shade-Tolerant Species: The Case of Abies holophylla in South Korea

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Kwanghyun Nam[1]
Hyunjoong Sung[1], Jongwoo Kim[1], Pil Sun Park[1]
[1] Seoul National University

Abstract: As biodiversity loss becomes a growing concern, biodiversity conservation and forest restoration have emerged as critical topics. Restoring severely damaged areas by immediately reintroducing native shade-tolerant species presents challenges. In such cases, plantation with introduced species is often initiated to gradually improve the damaged environment over time. This approach encourages the natural invasion of native species from adjacent natural forests, facilitating the recovery of species composition and biodiversity. Korea has predominantly implemented plantations using introduced species like *Pinus rigida*, *Robinia pseudoacacia*, and *Larix kaempferi* for soil stabilization or timber production, whereas the establishment of plantations with native species remains limited. This study aims to propose a silvicultural practice that achieves the forest restoration through natural regeneration or underplanting of *Abies holophylla*, a native shade-tolerant species, with the goal of biodiversity conservation. We examined changes in the stand structure of two types of *Larix kaempferi* plantations in the central region of the Korean Peninsula to understand native species invasion and restoration processes. *Larix kaempferi* plantations were grouped as (1) plantations with remaining *Abies holophylla* individuals as mother trees and (2) plantations located adjacent to natural stands of *Abies holophylla*. After 40-60 years of plantation establishment, the importance value of *Abies holophylla* exceeded that of the planted species. Active natural regeneration of *Abies holophylla* in the understory was observed, suggesting the potential of stand development into *Abies holophylla* stands. Furthermore, we assessed the survival rate and growth of underplanted *Abies holophylla* seedlings in closed-canopy stands after 20 years of planting. The survival rate and growth of these seedlings demonstrated the feasibility of underplanting as a means of advancing native species establishment. The results suggest silvicultural practices such as natural regeneration or underplanting of native shade-tolerant species could be tried in forest restoration efforts aiming at biodiversity conservation.

Short-term Study of Abies kawakamii and Tsuga chinensis var. formosana in Central Taiwan's Forests

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Wei-Chun Chao[1]
Huan-Yu Lin[2], Chieh-Yu Liao[3], Wen-Ling Shen[1]
[1] Department of Forestry and Natural Resources, National Chiayi University, Taiwan
[2] Department of Forestry and Natural Resources, National Ilan University, Taiwan
[3] Ph.D. Program of Agriculture Science, National Chiayi University, Taiwan

Abstract: *Abies kawakamii* and *Tsuga chinensis* var. *formosana* are the major species found in the high mountain forests of Central Taiwan. These forests are particularly vulnerable to the impacts of climate change due to their specific bio-climatic and topographical requirements. In this study, we conducted tree-by-tree censuses in the 6-ha Hehuan-Mountain forest dynamic plot, located in the upper part of the Tsuga forest zone and the lower part of the Abies zone. All free-standing trees with a diameter at breast height (DBH) ≥ 1 cm were identified, measured, and mapped in 2008 and 2022.

During these two surveys, a total of 14 species were recorded in the plot. The most abundant species was *A. kawakamii*, accounting for approximately 58.65-58.72% of the total number of individuals, followed by *T. chinensis* var. *formosana* as the second most abundant species (17.52-17.22% of total stem density). Both *A. kawakamii* and *T. chinensis* var. *formosana* exhibited a decrease in stem density over the 14-year interval. Despite the substantial decline in stem density, the basal area of *A. kawakamii* increased from 30.32 to 34.78 m^2 ha^{-1}. However, the basal area of *T. chinensis* var. *formosana* decreased from 11.10 to 9.02 m^2 ha^{-1} due to the falling of numerous large trees (DBH ≥ 150 cm) and limited recruitment of new individuals. Using biomass calculations and bootstrap simulation based on Chave et al. (2015), the biomass in this plot was estimated to be 789.69 Mg ha^{-1} in 2008 and 808.74 Mg ha^{-1} in 2012, indicating a significant increase in biomass. Our 14-year field investigation yielded contrasting results to the predicted population decline and limited upward migration of *A. kawakamii* based on species distribution models (SDMs). Our research suggests that *A. kawakamii*, a tree species found above 3,000 m in Taiwan, maintains a stable population with individual and biomass increment. Conversely, *Tsuga chinensis* var. *formosana*, occurring at elevations of 2,500-3,100 m adjacent to A. kawakamii, exhibits negative population growth without an upward range shift.

Trade-off between woody diversity and millet yield in agroforest parklands in central southwestern Niger

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Mamane Bawa Sakina[1]
Moussa Massaoudou[2], Lawanou Mahamne[1]
[1] University Abdou Moumouni of Niamey (UAM)
[2] University Dan Dicko Dankoulodo of Maradi (UDDM)

Abstract: The ever-increasing rate of population growth in Niger combined with the demand for food, sometimes results in the scarcity of agricultural land. This leads to the abusive cutting or even disappearance of trees in the fields in order to have space available for agricultural production. This use of land to the detriment of trees can be a competition for the woody diversity present in the fields. The present study, carried out in two agro-ecological zones (Sahelian zone in the department of Kollo and the Sudanian zone in the department of Gaya) of Niger, aims to find a balance between these two situations. The main objective is to study the trade-off between agricultural production and woody diversity in agroforestry parks in southwestern central Niger. The work was based on an inventory of the woody stratum in two (2) villages of each department, i.e. forty (40) plots of 50 m x 50 m in each village and the establishment of forty (40) yield squares of 5 m x 5 m in each village. Weighing was done on ear weight and stem weight in each yield square. The results showed that the woody flora of the Sahelian zone and the Sudanian zone is 37 and 17 species respectively. The results of dendrometric parameters such as cover, basal area, Shannon diversity index and regeneration density were significantly higher in the Sudanian zone, but there was a slight difference in the density of trees per hectare. The bell-shaped structural analysis reveals a renewal or good functioning of the woody stands. The results of the trade-off analysis reveal a slight difference between zones. The trade-off between trees cover and seed yield of millet was 638 ± 125 kg/ha in the Sahelian zone and 679 ± 374 kg/ha in the Sudanian zone; and between ear yield of millet was 2025 ± 578 kg/ha in the Sahelian zone and 1819 ± 1206 kg/ha in the Sudanian zone. Thus, a trade-off model emerged from this study in two agro-ecological zones of Niger.

Key words: trade-off, woody diversity, agricultural production, agroforestry parks, central southwest, Niger

Use of introduced species to facilitate native species establishment in forest restoration

T1.3 Challenges for silviculture to meet demands from carbon sequestration to biodiversity conservation to forest restoration

Pil Sun Park[1]
Kwanghyun Nam[1], Jongwoo Kim[1], Hyunjoong Sung[1], Ju-in Ko[2], Jihye Kim[2]
[1] Seoul National University
[2] Research and Development Team 1, KOMIR

Abstract: Many parts of world forests are suffering from exploitation, degradation or land conversion. Forests are a major carbon sink that helps to mitigate climate change and provide habitats for majority of terrestrial organisms. Efforts to restore forests are put into action in many areas. One of primary consideration for forest restoration is the selection of tree species that would be introduced to damaged areas. Severely damaged areas need forest restoration efforts; however, their environment is often too damaged to conduct restoration practices with native species that require better environment such as mature forest condition. In this case, step by step approach in a long-time scale may be needed. Korea was heavily deforested in early- and mid-20th century. National reforestation project launched and planted about 2.9 billion trees from 1973 to 1978. Major species used for reforestation during that period was *Pinus rigida*, *Robinia pseudoacacia*, and *Alnus* spp. that were introduced pioneer species. As soil condition improved, native species came back whereas introduced pioneer species became senescent without further regeneration. The introduced pioneer species acted as intermediaries in forest restoration to native forests. The application of exotic species in forestation has advantage of less natural enemies especially insect pest and diseases, whereas there is a risk that the exotic species would thrive, continue to regenerate and even expand to occupy habitats for native species. Selection of right tree species is a key factor in forest restoration. Introduced species that could facilitate native species restoration may be used in severely damaged area where even native species could not stay. Introduced species plantation would be an intermediate stage toward mature forest of native tree species in restoration process following forest stand development.

[4] Department of Forest Work Science and Engineering, Georg-August-Universität Goettingen, Goettingen, Germany

Abstract: According to ICCP projections for Central Europe and other regions of the world, heavy rainfall events will increase in frequency and especially in intensity, often resulting in severe damage or even destruction of forest infrastructure such as roads, culverts and bridges. Soil erosion, siltation of waterways, landslides and downstream flooding are often negative consequences for both the forest and the public. In addition, instead of infiltration and recharge, forest water tables and water sources are at risk of drying up as early as spring. Water runs off at the surface and is "lost" to supply vegetation, leading to drought risks and calamities later on.

Hydrological modelling combined with high-resolution GIS-based surface models makes it possible to predict rainfall events of varying intensity and to model the associated surface runoff. Based on this, the design of roads and the capacity of water control infrastructure can be critically evaluated in detail with the aim of minimising damage and reducing water run-off from the forest. A set of technical measures necessary and viable to achieve these objectives is proposed. Comparative cost/benefit calculations for the implementation of these preventive measures versus "business as usual" with the risk of damages support appropriate management decisions.

The concept is presented as an example for a case study in the southern Black Forest, Germany. It can be applied generally if the necessary data are available: High resolution DGM and related information on soil and vegetation cover combined with actual and predicted climate data are available.

Advancing Climate Smart Forestry Adoption through Improved Forest Carbon Measurement Tools and Resources

T1.4 Climate Smart Forestry

Lara Murray[1]
Christopher Woodall[1]
[1] United States Department of Agriculture, Forest Service Research & Development

Abstract: In the United States, it is estimated that forests offset 10-15 percent of annual economy wide greenhouse gas emissions. Emerging research is indicating a trend toward a weakening forest carbon sink across some regions due to the increasing severity, frequency, and size of forest disturbances. Efforts to expand the adoption of forest management practices to improve forest health and resilience and enhance carbon sequestration have been introduced through both public and private sector mechanisms at many scales. This has increased the demand for user-friendly guidance and tools to quantify the impact of climate-smart forestry; better definitions of what constitutes climate-smart forestry given the continuum of management intensities and ecosystem types; as well as research to identify and improve models for projecting stand dynamics in a changing climate. This oral and/or poster session will introduce some of the latest national-scale efforts to improve and deliver consistent science-based measurement, monitoring, and reporting resources for climate-smart forestry practices. Among these is the Forest Management chapter in the United States Department of Agriculture 2023 publication "Quantifying Greenhouse Gas Fluxes in Agriculture and Forestry: Methods for Entity-Scale Inventory" which provides guidance and standards for greenhouse gas estimation for private landowners, but also applicable on public lands. This work connects ecosystem accounting for silvicultural practices with an approach for estimating the greenhouse gas flux in wood products, as well as lifecycle quantified potential substitution benefits of using wood products and bioenergy. Application of this consistent, tool-supported quantification approach can also enable national scale reporting toward climate goals, including Nationally Determined Contributions as part of the Paris Agreement.

An economic approach to carbon offsetting and GHG reduction potential through woodland expansion on areas used for livestock grazing

T1.4 Climate Smart Forestry

[4] Institute of Economics, Geography and Demography, The Spanish National Research Council (CSIC), Spain
[5] Forestry Commission UK

Abstract: Voluntary carbon markets involving forestry carbon sinks are experiencing rapid growth. Offsetting greenhouse gas (GHG) emissions through forest-based investment is a source of debate, however, due to allegations of carbon over-crediting and lack of permanence. Improving the credibility of the carbon offsetting process calls for a critical analysis of the potential and feasibility of forest-based investments to generate carbon units that are truly additional and long-lasting.

In this paper we analyse the economic potential of using woodland expansion to offset carbon in areas currently used for livestock grazing using high resolution data for a case study area (Scotland). Our study accounts for spatial variability in timber yield classes for six different types of tree species, including climate effects on timber yield, as well as, soil carbon stock, land cover and livestock stoking rates for main livestock enterprises in the country.

Carbon additionally from planting woodlands, particularly in upland areas of Scotland used mostly for livestock farming, has been questioned by a few recent studies, especially when organic soils and intensive ground preparation practices are concerned (loss of carbon). The latter has important economic implications, as planting trees is expensive and low carbon sequestration rates on poorer quality lands may make woodland expansion an unattractive investment. Furthermore, changing the use of land conveys opportunity costs in terms of livestock farming benefits forgone for landowners and/or land tenants, but also loss of flexibility when land is converted to forest which can result in short–term devaluation of afforested land.

This paper develops an optimal land use change and forest management economic model, that accounts for timber and carbon net benefits, woodland expansion implementation costs at different management intensities, and land opportunity costs from livestock farming, and GHG mitigation potential from reducing stocking rates. The model analyses the cost-effectiveness of land use change and tree species selection decisions under different carbon payment levels, and addresses a hypothetical scenario where there are financial penalties from livestock carbon emissions. We further explore the cost-effectiveness of woodland expansion and the role of spatial heterogeneity in forest productivity, soil attributes, livestock stocking rates and land use typologies.

An exploration of Climate-Smart Forestry to reduce risk, enhance opportunity, and seek alignment across landscapes

T1.4 Climate Smart Forestry

Lauren Cooper[1]
David MacFarlane[1]
[1] Michigan State University

Abstract: Climate change is presenting a global challenge to society and ecosystems and, in doing so, is changing long-standing human valuation of forests. This shift is encompassing their role in climate mitigation and adaptation alongside traditional forest products and services. Because of their framing as a Natural Climate Solution (NCS) or Nature-Based Solution (NBS), forests have become increasingly important in climate change dialogues, including and well beyond international climate negotiations. In turn, the term "Climate-Smart Forestry" (CSF) has recently entered the vernacular in myriad disciplines and decision-making circles espousing the linkage between forests and climate.

Our analysis shows this new emphasis on climate change in forestry has a wide range of interpretations and applications and finds that CSF remains loosely defined and inconsistently applied across professions and landscapes. Adding to this confusion, it remains unclear how existing guidance on sustainable forest management (SFM) is relevant or might be enhanced to include CSF principles, including those that strive for demonstrable carbon benefits in terms of sequestration and storage. Identifying a science-practice gap, this work explores potential gaps and risks under a current framing of CSF and explores opportunities to increase scale and benefits of CSF principles. Methods include a literature review, qualitative assessment of documents, and statistical analysis of datasets from related studies. Identified risks including overly simplified relationships between carbon sequestration and forest management, 'carbonization' of forest values generally, unintended social effects and unequal access to benefits, and overlooked efficiency gains and economic misalignments. Identified opportunities include social inclusion and equitable benefit distribution, addressing the co-occurring biodiversity crisis, cross-sector and -landscape communication, and supporting a climate-aligned economic transformation.

This presentation will cover (1) current definitions and framing of CSF, (2) CSF risks and opportunities, (3) a broadened CSF definition that includes additional intervention types for multiple scales of decision-makers, and (4) sources of evidence of CSF. This final section will include an overview of key indicators, as well as tools and metrics to safeguard against potential harm.

An Innovative Modelling Framework to Simulate and Optimize the Climate Change Mitigation Potential of the Forest Sector in British Columbia, Canada

T1.4 Climate Smart Forestry

Walter Yan[1]
Gregory Paradis[1], Qingshi Tu[1], Céline Boisvenue[1, 2]
[1] The University of British Columbia
[2] Natural Resources Canada

Abstract: Canada's current strategic forest management planning processes rely heavily on forest management modelling for wood supply simulation and optimization. However, these forest management models typically do not include carbon stock, sequestration and flux indicators. To promote the climate change mitigation potential of the forest sector in British Columbia (BC), Canada, this study aims to build an innovative methodology framework with pure Python to add carbon indicators for both the forest ecosystem and harvested wood products into forest management models for mathematical simulation and optimization. The research area is in the interior of BC. Firstly, a forest management model was built to simulate and optimize forest resources management, and a forest carbon budget model was constructed to quantify the ecosystem carbon dynamics. An improved approach was applied to link the forest management model with the forest carbon budget model to enable setting forest ecosystem carbon as management goals and constraints. A wood product carbon module was then built and linked to the forest management model to track the carbon dynamics and calculate the substitution benefits of harvested wood products. The final modelling framework was run under four scenarios: baseline, maximizing total carbon stock, maximizing total carbon sequestration, and minimizing total net carbon emission. Given current modelling assumptions, I would find which target can optimize the climate benefits of the BC forest sector and provide suggestions for future modelling work. I would also quantify the impact of forest management activities on the carbon dynamics of the whole forest sector in BC.

This research can contribute to including forest carbon in current BC strategic forest management planning processes. The modelling framework is the core of a large forest carbon research project in the UBC FRESH lab. It could be applied in any forest carbon management projects elsewhere in Canada. It can also be further improved and expanded to find optimal long-term management plans to maximize the climate change mitigation potential of the BC and Canada forest sectors. All the data, models, and results in my research will be published online for the public, increasing my research's transparency, repeatability, and credibility.

Application of the Carbon Budget Model to assess the contribution of climate-smart forestry for climate change mitigation in Alpine forests.

T1.4 Climate Smart Forestry

Sebastian Brocco[1]
Roberta Berretti[2], Renzo Motta[2], Matteo Vizzarri[1], Giorgio Vacchiano[1]
[1] Department of Agricultural and Environmental Sciences DISAA, University of Milan, Italy
[2] Department of Agricultural, Forestry and Food Sciences DISAFA, University of Turin, Italy

Abstract: Climate-smart forestry (CSF) aims to tackle complex challenges related to climate change impacts on forests, such as increased mortality from natural disturbances, reduced forest productivity, and implications on social and economic sustainability. However, few studies on CSF have addressed the combined impact of management, climate change and altered disturbance regimes on the real mitigation potential of forests, especially at scales larger than the management unit.

We used the Carbon Budget Model (CBM) of the Canadian Forest Service to simulate the mitigation potential of forests located in Valtellina and Valcamonica on the Italian Alps, according to three management scenarios (from 2020 to 2050). The investigated scenarios are i) business as usual, ii) adaptative silviculture (focused on fire prevention and fire vulnerability reduction) and iii) mitigation based on wood substitution effects (with an increase in producing wood adequate for buildings and other long-term uses).

To overcome lack of climate sensitivity in growth and disturbance modules of CBM, we coupled it with a process based model (3PG), to modify growth curves depending on future climate scenarios (i.e. trends in temperature and precipitations). Moreover, we updated the wildfire regimes by statistically modelling the link between burnt-area and drought indices using historical data, and extrapolated this relationship to expected future drought occurrence. Both climatic variables and change in the wildfire regime were modelled for climate change scenarios RCP4.5 and RCP8.5.

Results show that broadleaves' growth will increase more than conifers', and thus their carbon sink. Nevertheless, simulated frequency of drought in the future results into higher C losses because of increased vulnerability of forests to wildfires. We argue that fire-prevention interventions in combination with CSF might support forest resilience under climate change. Concerning productive management, harvested wood products should be used for long life-span products since this can help to mitigate greenhouse gasses emissions from hard-to-abate sectors like buildings.

Our findings can be helpful in orienting landscape planning towards ensuring forest-based mitigation potential, especially in areas where the combination of various climate-driven forces might limit both the resilience and adaptation capacity of forest ecosystems.

Carbon sequestration in forest soils. How it will change after the extreme bark beetle outbreak and expected change in forest management strategy?

T1.4 Climate Smart Forestry

Vít Šrámek[1]

[3] Dpt. of Forest Botany, Dendrology and Geobiocoenology

Abstract: In temperate and boreal forests C sequestration in soil is usually higher than its stock in aboveground biomass. Although soil carbon is not influenced by forest management directly, its change resulting from ongoing changes and forest management strategies should not be underestimated. Central Europe was recently exposed to extreme bark beetle outbreak leading to extreme spread of clear-cuts and temporary loss of forest cover in range of hundred thousands of ha. Such a rapid change may have considerable effect also on soil properties mainly due to processes in the upper organic (humus) layer. Changes in carbon stock as well as in other chemical properties are expected. Further expected change is connected with the ongoing shift in long-term forest management strategy which should lead towards more diverse forest composition, increased representation of broadleaved species and closer-to-nature silviculture. To describe the current situation and future development in the Czech Republic, we have compiled a large national "Aggregated soil chemical properties database" combining harmonized results from several surveys during the period 2000-2020. These data are compared with dozens soil samplings on large clear-cuts resulting from bark beetle infestation and newly established young stands. Moreover the carbon storage was assessed in relation to different forest management procedures – e.g. tree species composition, stand age and age structure, methods of tending as well as with examples of native old-growth forests. Recent results comparing soil analysis on clear-cuts, however, are rather hazy. On one hand accelerated humus decomposition leads to loss of carbon from the upper organic soil layer on open plots, on the other hand the same layer is often enriched by logging residues biomass which may results even in enhanced carbon stock. Further changes may be expected as a consequence of planned increase of broadleaved stands. Such development can result in lower C stock in the organic layer of forest soils. More stable carbon pool in deeper mineral soil, however, will probably increase. There are also other beneficial effect for several qualities of forest soils – e.g. for carbon sequestration, soil biodiversity or hydrological features due to more complex rooting in deeper soil layers.

Climate and biodiversity-smart forestry and forest restoration across Europe; who does it, why, and how it could develop?

T1.4 Climate Smart Forestry

Abstract: Climate and biodiversity smart forestry (CBS) and forest restoration emphasize the integration of biodiversity conservation to climate change mitigation and adaptation approaches that synergistically realize multiple ecosystem services. These approaches purport spatially integrating multiple forest management objectives by selecting the "smartest" management practices for enabling synergies within the forest region in question. When it comes to examining the current state of CBS and forest restoration practices across Europe, little can be said, as there is limited country specific information about the different types of CBS and forestry restoration practices implemented by European forestry practitioners. At the same time, there is limited knowledge about the barriers and drivers impacting the implementation of these practices. To tackle these shortcomings, this research examines primary data from (i) inductively analyzed interviews with forestry practitioners in nine countries across Europe (i.e., Finland, Hungary, Italy, Latvia, Netherlands, Portugal, Romania, Switzerland, and the United Kingdom), and (ii) a Europe-wide questionnaire distributed through both a representative general-population survey and through top-down umbrella organizations representing various forestry practitioners. The interviews function to elicit country-specific CBS and forest restoration management practices alongside their respective barriers and drivers to implementation. The survey operationalizes these salient findings and asks respondents to identify their current forest management objectives, the CBS and forest restoration practices they implement, and relevant drivers and barriers to implementation. This data is used to descriptively quantify which CBS and forest restoration practices occur across different countries in Europe and statistically analyzing the extent to which different drivers and barriers shape the implementation of these practices. Aside from providing a concrete overview of CBS and forest restoration practices, the study inductively builds a European-level typology of forestry practitioners based on forest owner objectives. This typology is useful for designing future CBS forest policy scenarios and large-scale agent-based modelling.

Climate-smart forest management in Europe: Beyond carbon dioxide

Abstract: Forests are a key plank of European policies to mitigate and adapt to climate change and to promote biodiversity. These policies are starting to become more nuanced with respect to the account of their impacts on carbon storage, considering the effect of long-lived wood products and value of conserving old-growth forests, along with indirect land-use change impacts. However, a CO_2-focused perspective means that many processes are still omitted for the quantification of the true extent of climate effects. Emissions of the greenhouse gases nitrous oxide and methane, short-lived climate forcers and effects from albedo changes and heat fluxes are also relevant. These processes are interconnected and influence the climate mitigation of forests in a complex way and need to be considered.

The CLImate Mitigation and Bioeconomy pathways for sustainable FORESTry (CLIMB-FOREST) Horizon Europe project that runs until 2027 uses a holistic approach to estimate the climate impacts of various management alternatives. The foundation of CLIMB-FOREST is the use of European-wide empirical data, as well as an advanced coupled vegetation and earth-system modelling framework that includes biodiversity indicators and the interaction of forestry stakeholders in a global trade system. This framework is used to model management, forest tree species and climate on short- to long-term in Europe.

We present first results of the climate effects and ecosystem functioning for a range of management alternatives in boreal, temperate, and Mediterranean forests. For example, introducing broadleaved trees in a coniferous forest promotes resilience and increased cooling from higher solar light scattering and latent heat flux of broadleaved trees. On the other hand, higher evapotranspiration might lead to an accelerated soil moisture depletion and reduced monoterpene emissions. The latter would have a warming effect because terpenes produce atmospheric particles, which are effective cooling agents through their involvement in cloud formation. Consequently, understanding these complex climate effects is key for appropriate climate-smart-forestry policies and approaches.

The main outcomes and impacts of CLIMB-FOREST are to suggest alternative pathways for the forest sector to mitigate climate change in entire Europe, create attitude change in the policymaking process and influence foresters to adopt to new forest management strategies.

Climate-smart forest management may decrease vulnerability of forest carbon to disturbances

T1.4 Climate Smart Forestry

Giorgio Vacchiano[1]
Edoardo Nevola[2], Natalie Piazza[1]

[2] World Wildlife Fund for Nature - Italy, via Po 25C, 00198 Rome, Italy

Abstract: Natural disturbances like windthrows or forest fires have an effect on the provision of ecosystem services like timber production, protection from natural hazards or carbon sequestration. After a disturbance, forests release large amounts of carbon and therefore change their status from carbon sinks to carbon source. However, forest management may improve the forest capacity to absorb carbon by decreasing the vulnerability to disturbances. In this study we used simulation tools ForestGALES (windthrow) and FlamMap (forest fire) to model the vulnerability to the two disturbances. We analysed forest stands prone to windthrow and forest fire and proposed forest management in the most vulnerable forest stands, increasing their resistance to the respective disturbance. We simulated the future carbon stock and sink under two scenarios: (1) business-as-usual management, and (2) forest improved using climate-smart forest management to decrease the vulnerability to disturbances. Forest under business-as-usual management led to a decrease in total carbon. Using climate-smart management compared to business-as-usual resulted to an increase of carbon stocks and sink (with additional increase in case of no disturbance). We showed that using disturbance simulation tools may help in decision making process to analyse the most vulnerable forest stands. In combination with simulations of future scenarios of carbon we may be able to direct the climate-smart forestry.

Climate-Smart Forestry and forest restoration: an overview of experimental trials across Europe

[5] Natural Resources Institute Finland (LUKE)

Abstract: Climate change and other environmental stressors, such as air pollution and natural disturbances, are putting growing pressure on forest ecosystems and their biodiversity. To date, we still have limited knowledge on the effectiveness of various mitigation and adaptation measures to guide forest management decision making. Climate-Smart Forestry and restoration-oriented management are viewed as promising management approaches in order to preserve and restore biodiversity, ensure the provision of ecosystem services, and to support forest adaptation to climate change.

Across Europe, many forest management and restoration experiments and field trials already exist, but a systematic overview of all experiments and trials is still missing. Based on an extensive, systematic review of existing experiments and trials, we developed a public and spatial database of Climate-Smart Forestry and restoration pilots from international and national networks, projects and other initiatives. For each experiment, the geographical location, the experimental design or treatments, the initial state of the forest stands, the year of establishment, and the obtained findings were explored. Trials and experiments were clustered according to the management measures, objectives, geographical regions, and European forest types to highlight the knowledge gaps on Climate-Smart Forestry and restoration. Outcomes can facilitate the implementation of Climate-Smart Forestry and restoration practices across European forest ecosystems. The overview can guide the allocation of public funds to support the establishment of new trials in those European forest types, geographical regions, and management systems that are currently missing.

Climate-smart forestry in Europe under uncertain future climate and other constraints

T1.4 Climate Smart Forestry

[3] Department of Forestry and Renewable Forest Resources, Biotechnical Faculty, University of Ljubljana, Slovenia

Abstract: Climate-smart forestry aims at combining sustainable forest management with climate change mitigation, adaptation, and the provision of ecosystem services. This is an immensely challenging task which is further complicated by the fact that the future climate and the extent of its consequences such as more frequent forest disturbances are highly uncertain. Nevertheless, despite this uncertainty, forest management strategies need to be made already today. In addition, the demand for wood products is increasing on the one hand while on the other hand, the importance of strictly protected forests is becoming increasingly recognized and is now also included in new legislation in Europe.

Here, we propose a methodology to address this, based on the dynamic vegetation model LPJ-GUESS and robust multi-criteria optimization. Our approach creates forest management portfolios that are viable for a broad range of climate scenarios and offer an optimally balanced provision of multiple ecosystem services such as climate change mitigation, timber provision, local climate regulation, and the provision of various habitats.
Our approach indicates that a shift towards more broad-leaved species and more unmanaged forests is essential to achieve multi-functional, climate-resilient forests in Europe. This, however, entails a strong decrease in harvests, especially those for long-lived products. This conflicts with increasing wood demands, including the use of wood products as a means of climate change mitigation and indicates that trade-offs between ecosystem services need to be made.

Including strict constraints on keeping harvest levels at present-day values further reduces the options for portfolios offering multiple ecosystem services. We thus conclude that climate-smart forestry in Europe can only go together with other measures that alleviate the pressure on Europe’s forests. Such measures could be increasing the forest area, improving the longevity of products and their recycling, and decreasing the currently large share of woody bioenergy in the EU’s energy provision.

Climate-smart forests at the lower tree line: a long-term experiment to evaluate adaptation options under pannonic, summerdry climate conditions

T1.4 Climate Smart Forestry

Silvio Schueler[1]
Anita Zolles[1], Viktoria Valenta[1], Kerstin Michel[1], Magdalena Langmaier[1]
[1] Austrian Research Centre for Forests BFW

Abstract: About 50% of Austria is covered by forests which include a wide range of forest types and climate conditions. Besides productive montane and subalpine forests, regions with lower elevations in eastern Austria are characterized by low forest shares and continental climate conditions. Yet, the remaining forests have a high cultural and recreational value and are important resources for water supply given the low precipitation and intensive agricultural production. These forests are close to the lower timberline and under increasing temperature conditions they might transform into steppe ecosystems. It is therefore of high importance to maintain the forested sites and the ecosystem services they provide.

After severe forest dieback of various native tree species due to extreme drought conditions and pest infections, we established an experimental plantation with 40 different tree and shrub species. The selection of tree species included native and non-native tree species as well as non-local seed provenances to test for various assisted migration schemes. In addition, a control plot for the monitoring of natural regeneration and regrowth was included in the experimental setup. The long-term experiment is aimed to address the following questions: 1) to characterize and compare the survival and growth of various tree species and seed provenances; 2) to analyse the development of above and belowground carbon stocks at the lower timberline; 3) to evaluate the effects of species composition on soil water contents; 4) to monitor the local climate conditions and the change of site climate with increasing forest development; and 5) to monitor the putative long-term side-effects of non-native trees on forest biodiversity.

Here, we report the first results of seedling survival and growth under the enduring drought conditions of the first years after establishment as well as the initial soil carbon assessment on 80 inventory points which were undertaken after forest dieback and prior to planting.

Commercial forestry of Northern Europe will benefit from wider use of silver birch due to its high plasticity of mechanical stability

T1.4 Climate Smart Forestry

Abstract: In forests of Northern Europe, wind is the most prominent natural disturbance, causing more than a half of all losses of biomass. The severity of wind damages is amplified through the synergy with other disturbances leading to water and temperature stress. This emphasizes the need for climate-smart forest management to link the ecological needs of tree species with their adaptation to wind loading. Silver birch (*Betula pendula* Roth.) has a wide ecological plasticity, and thus a potential to meet requirements of productivity and wind resistance. However, the information on mechanical stability of birch so far has been insufficient; therefore, static tree-pulling test data were obtained in a wider range of growing conditions (140 trees in total). Stronger soil root anchorage was apparent for birch on less stable and more saturated soils, such as periodically waterlogged mineral and drained deep peat soils, as indicated by the increased loading resistance and higher frequency of stem breakage. This implies high capabilities of birch in adjusting mechanical stability. Moreover, under frozen soil conditions, a higher increase in loading resistance was observed for birch on well drained mineral soils, implying suitability of birch for soils with substantially higher wind damage risk. Accordingly, such ability in adjusting mechanical stability on less stable soils decreases the risk of the synergic effects of intensifying natural disturbances on birch. This suggests a potential for wider application of birch in Northern Europe, supporting the approach of climate-smart forestry by coupling ecological plasticity and mechanical stability with regard to the intensifying risks of wind damage.

Enhancing forest models by incorporating forest managers' behavior

T1.4 Climate Smart Forestry

[3] European Forest Institute, Platz d. Vereinten Nationen 7, 53113 Bonn, Germany

Abstract: For centuries humans have managed forests for the provisioning of desired products and services to society. Quantitative forest models are frequently used to deal with complexity under uncertain conditions. Many of these models rely on a theoretical concept of how forest management is done. These models also ignore that forest management decisions are shaped by socio-economic factors, such as individual preferences, societal pressure, market aspects, policies and regulations, resulting in different forest owners and managers behavioral responses. Considering this, our study aims to improve the representation of the behavior of forest owners and managers in forest models to provide better decision support systems. By employing agent-based modeling principles, a preliminary framework was developed to define forest management prescriptions that would better reflect real-world conditions. This framework takes into account the impact of socio-economic factors on forest management incorporating the perspectives of multiple forest agents. EFISCEN-space was used as a base model to simulate forest development, as it allows a comprehensive understanding of forest dynamics, while considering multiple environmental objectives and management strategies. In order to assess forest management behavior, a dataset derived from a survey with forest managers and forest owners in two regions of Germany (Baden-Württemberg and North Rhine-Westphalia) was used. The collected data were employed to formulate alternative management scenarios, which were implemented in a practical exercise. During this exercise, forest managers simulated their management decisions in permanent sample plots, providing valuable insights into the motivation behind their actions. Follow-up in-depth interviews were conducted to further enhance the understanding of their decision-making process. Subsequently, we applied the improved tool to explore the impacts of a set of climate-smart forestry practices to provide decision support on maintaining and restoring forest biodiversity, as well as climate change mitigation and adaptation. Finally, we discuss how forest models could be further improved by including forest management behavior and behavioral responses.

Enhancing resilience - a key strategy to support Climate Smart Forestry

T1.4 Climate Smart Forestry

Marcus Lindner[1]
Sara Uzquiano[1], Laura Nikinmaa[2], RESONATE Team[3]
[1] European Forest Institute
[2] Tapio, Finland
[3] RESONATE project partners

Abstract: Climate change and enhanced disturbance risks are strongly affecting the social-ecological forest systems and their resilience. Forest owners and managers need concrete guidance on forest management when it comes to climate change adaptation and enhancing biodiversity while ensuring the resilience of forests to disturbances. Similarly, forest value chain decision makers should aim to make their business more resilient to climate change, changed societal demands and increased disturbance risks, affecting the production potentials and climate change mitigation effects of wood products. Climate Smart Forestry (CSF) needs to consider both, forest and value chain resilience. Forest resilience may vary depending on forest typ. Therefore, it is crucial to understand how forest resilience can be increased through management decisions to safeguard sustainable forest ecosystem provisioning and mitigate undesirable impacts. Value chain resilience, on the other hand strongly depends on technology and timber resourcing choices, and finally, the broader societal resilience depends on the societal context, demand and substitution possibilities.

We present results from the Horizon 2020 research project RESONATE, which investigates resilience enhancing measures in nine regional case studies across Europe. Using criteria and indicators derived from model projections with consistent climate scenarios we demonstrate that enhancing resilience is a balancing act: increasing resilience in one part of the social-ecological system may lead to trade-offs in another part of the system. For example, increasing share of broadleaved species and enhancing tree species diversity are crucial climate change adaptation and CSF strategies, which on the other hand may limit climate change mitigation potentials of long-lived harvested wood products made of coniferous wood. By analysing such examples from diverse regional cases we aim to synthesize practice-relevant recommendations for Climate Smart Forestry.

EU climate-smart forestry : which is the best strategy to enhance forest and HWP mitigation potential

T1.4 Climate Smart Forestry

Abstract: Climate change impacts, adaptation, and mitigation are pressing concerns for global forests and forest management. Climate-Smart Forestry (CSF) is a key approach that combines mitigation and adaptation measures to enhance the resilience of the forest sector and addresses the challenges posed by climate change. Even though accounting for regional features of the forest sector is one of the core aspects of the CSF approach, there is scarcity of studies that comprehensively analyses its effects with detailed spatial and temporal resolutions. In this research, we aim to identify and test a CSF strategy that may enhance the mitigation of the EU forest sector. In order to accomplish this, we used the EFISCEN_space model, which offers a spatially explicit distribution of wood resources at national forest inventory plot level (300,000 NFI plots), including details about the species and diameter per individual tree. For the demand side, we compiled the European Forest Industry Database (EUFID), which encompasses the location and capacity of 6,000 forest industry facilities, distinguishing three value-chains: sawmills, pulp and paper, and bioenergy. The simulations consider various forest management approaches, natural forest dynamics, and the regional industrial pull. For three national case studies (Germany, Norway, and Czech Republic) three scenarios were tested: business as usual, CSF+, and PORT. The CSF+ scenario represents the most ambitious strategy, incorporating a maximum sustainable harvest rate, utilization of residues for bioenergy, and increased use of long-lived wood products. The PORTfolio (PORT) scenario includes specific policy targets of the respective analyzed country. The study indicates which scenario may significantly enhance the forest sector's mitigation potential, including the forest sink, carbon in harvested wood products (HWP), and material and energy substitution. Furthermore, this analysis provides projections of future wood assortment availability under different types of disturbances of the resources. The results emphasize the significance of CSF practices, tailored to local circumstances, in promoting sustainable and resilient forest ecosystems, and may guide policy-makers and stakeholders in taking informed decisions to optimize the forest sector contribution to climate change mitigation.

Abstract: Climate change impacts, adaptation and mitigation are undoubtedly in the centre of attention for global forests, and forest management, demanding immediate attention. Climate-Smart Forestry (CSF) is designed as a prominent way to address these challenges and is urgently needed to connect mitigation with adaptation measures, enhancing the resilience of forest resources and to meet the needs of a growing population. A critical element of CSF lies in carefully regarding the local circumstances, ensuring the measures are planned accordingly.

We will present an excerpt of the knowledge gathered by the European Network on Climate-Smart Forestry, with representatives from 15 European countries. This network connects researchers working on CSF, stimulating and facilitating the exchange of information and capacity building.

Examples of fundamental and applied research projects will be presented, from e.g. research on tree responses to drought periods to afforestation and forest restoration initiatives. The time for concrete action is now, so we will also discuss possibilities for implementation and upscaling of CSF measures.

Exploring the Versatility of Resilience Components: Applications and Insights in Forest Ecological Research

Abstract: The concept of resilience plays a crucial role in ecological research, offering insights into the dynamics and adaptive capacity of ecosystems facing various disturbances. This contribution explores the different uses of resilience components (i.e., resistance, resilience, and recovery indices) in forest ecological studies and highlights their importance in understanding ecosystem dynamics. We discuss how these indices have been employed and improved over time, showcasing their versatility and applicability across diverse research topics and environmental settings. Additionally, we present three examples of the application of these indices to different research contexts.

Firstly, we examine the use of resistance, resilience, and recovery indices in assessing the impact of drought on Mediterranean forest plantations. By quantifying the ability of different pine provenances to withstand and persist in the face of drought, these indices provide valuable information for assessing forest stability and vulnerability, guiding adaptation strategies to climate change impacts.

Secondly, we explore the application of these indices in studying the response of mixed oak-fir forests (Turkey oak and silver fir) vs. pure stands of the same species in a Mediterranean mountain context (Apennine). Here, we relate the variation in resilience components between monospecific and mixed stands with admixture type, tree species, and site aridity, and tree growth.

Lastly, we validate the application of resilience components in investigating the vulnerability of Norway spruce trees to bark beetle infestations in mountain forests in the Swiss Alps. By quantifying the resilience of forest ecosystems to disturbance-driven alterations, these indices help identify vulnerable areas and prioritize interventions to ensure the sustainable provision of ecosystem services.

Through these applications, we showcase the versatility and significance of resistance, resilience, and recovery indices in advancing ecological research and implementing climate-smart forestry. These methods offer valuable tools for assessing ecosystem health, informing conservation practices, and guiding decision-making processes in the face of global change. By integrating these indices into future research endeavours, we can deepen our understanding of ecological dynamics and foster effective strategies for adapting and restoring resilient ecosystems.

Integrating biodiversity protection into Climate Smart Forestry

Abstract: European Forests are threatened by climate change, increasing disturbance regimes, and continuous biodiversity decline. For this reason, over the last decade, Climate Smart Forestry (CSF) arose as a conceptual solution for jointly addressing climate change mitigation and adaptation activities alongside biodiversity and ecosystem service provisioning. However, the preservation and enhancement of biodiversity were not given equal importance as climate change mitigation and adaptation, even though they are closely interlinked; biodiversity loss reduces global carbon sinks due to productivity loss, while climate change mitigation can help prevent biodiversity decline and species extinction. To provide more comprehensive management guidance based on criteria and indicators, we propose extending the CSF concept to prominently address biodiversity. Here, we present Climate and Biodiversity-Smart Forestry (CBS) as a wider concept integrating climate change mitigation, adaptation, and biodiversity conservation, to promote resilient forest ecosystems under climate change and disturbances, benefiting society and the environment. CBS is developed and operationalized within the Horizon European ForestPaths project, aiming at holistically co-designing, quantifying, and evaluating forest-based policy pathways. Based on a comprehensive review of scientific and grey literature, we provide a broad definition of CBS and a collection of successful practical examples that highlight existing and potential new CBS measures. A holistic guide for adopting the concept to different European regions and management regimes is offered to support forest stakeholders in identifying and adopting CBS management measures. The guide considers both the good maintenance of European forests and the sustainable provision of their ecosystem services. With a clear definition and specification of regionally relevant requirements, criteria, and indicators, CBS management options can be evaluated to facilitate operational use of this new concept.

Intensive monitoring in different woodlands

T1.4 Climate Smart Forestry

Bence Bolla[1]
Miklós Manninger[1], Tamás Molnár[1], András Szabó[1], Bálint Horváth[1]
[1] University of Sopron Forest Research Institute Department of Ecology and Silviculture

Abstract: Forest Protection Measuring and Monitoring System is one of the most acknowledged monitoring systems in Hungary which has cooperated with the ICP Forest organisation since 1996. The monitoring system itself has existed since 1988. Intensive monitoring is one of the main parts of Forest Protection Measuring and Monitoring System in Hungary. We currently have seven monitoring sites in different parts of the country. There are two old common beech and two sessile oak, a Black locust, a Scots pine and a Turkey oak forest stands. There are seven open-field areas as control points near each forest site. The meteorological parameters (precipitation, temperature, humidity, wind speed, wind direction) were measured in each open-field area by HWI weather stations near the forest monitoring sites. The throughfall was determined by twelve funnels which were arranged in a regular system. We also used five bucket and one measuring tub in each forest monitoring site to evaluate the yearly interception of the foliage. For the calculation of stem-flow, stem collars (connected with collecting barrels) were settled for each tree. Five stem collars were installed to calculate stem-flow with regard to the distribution of the diameters of the trees in each forest site. Temperature and humidity data were measured with Testostor logger in English thermometer in the wood stocks. The biomass was measured using five 1x1 meter nets in every month in the seven forest sites. We concluded that the dry periods have affected the forests more severely in the central and eastern part of the country in 2021, 2022. The amount of precipitation was extremely low in the vegetation period. Based on our meteorological measurements at the forested sample areas, the average temperature is constantly increasing. The number of heat days (T_{max}≥30°C) and the number of hot days (T_{max}≥35°C) also showed an increase. The canopy loss was significant in our monitoring sites in July and in August. The annual growth of the forest stands also was less than in previous years because of the extreme dry weather conditions. Our data sets proved the positive, temperature-tempering effect of forests in all monitoring sites.

Interactive tree breeding and silviculture in sparse plantations can be climate-smart forestry of Norway spruce

T1.4 Climate Smart Forestry

Āris Jansons[1]
Pauls Zeltiņš[1], Roberts Matisons[1], Raitis Rieksts-Riekstiņš[1], Kristaps Ozoliņš[1]
[1] Latvian State Forest Research Institute Silava

Abstract: Forests of Northern Europe are and will remain the main local source of raw material for developing a fossil-free economy (bioeconomy) in the whole European Union. Climate-change-induced alteration of natural disturbances particularly affects one of the main commercial tree species – Norway spruce – triggering discussions on the potential changes of its management. The resulting recommendations often include reduced species area, and applying low-intensity, selective management. We aim to explore different alternative for climate-smart management of Norway spruce – low-density plantations of selected genotypes. Sample trees for destructive analysis were collected and sample plots were placed in such clonal plantations, that have reached dimensions for the final harvest.

The realized genetic gain in DBH reached +24.0%, leading to nearly double mean DBH and similar yield compared to 30-35 years older conventionally managed stands. A distinct relationship between DBH and wood density was not found at a tree or clonal level. Highly heritable branching traits demonstrated the potential for the selection of suitable clones for sparse plantations. Visual strength grading of the sawn material (standards BS4978 and INSTA142) demonstrated a notable variation between clones and the potential to maintain a quality similar to that obtained in conventional management.

Due to improved light conditions, indices of ground vegetation diversity were similar to those in old-growth Norway spruce stands in Latvia. A lack of deadwood, however, was not different than in conventionally managed stands and needs to be addressed at a forest landscape level.

The long-term weather sensitivity of inter-annual height increment indicated higher tolerance and resistance to weather fluctuations for productive clones, hence potential to maintain productivity also in the uncertain future climate. The accelerated growth in the sparse plantation, leading to a shorter rotation period, can also mitigate risks such as drought or wind damage. In addition, the stem cracking caused by prolonged summer droughts exhibited variation between clones, yet no clone-specific relation with growth, hence the potential for selection without increasing risks of this defect.

In summary, the study highlights various benefits of combining tree breeding and silviculture in highly productive sparse clonal plantations, serving as a climate-smart forestry solution for the region.

Is establishment of drainage systems a long-term climate smart forestry measure in hemiboreal Scots pine forests on deep organic soils?

T1.4 Climate Smart Forestry

Valters Samariks[1]
Kristaps Ozoliņš[1], Āris Jansons[1]
[1] Latvian State Forest Research Institute "Silava"

Abstract: Forest ecosystems comprise important carbon pools, notably in the trees and soils, with the organic soils being particularly significant. To achieve the climate neutrality goals set by the European Union, it is vital to implement forest management practices that improve carbon storage and reduce greenhouse gas (GHG) emissions. In hemiboreal region forest drainage is the most significant forest management tool with positive long-lasting large-scale influence on tree growth. Moreover, a substantial proportion of Scots pine (*Pinus sylvestris* L.) forests in the hemiboreal region are growing on organic soils and have undergone drainage (in the 1960s). Although recent studies have focused on several aspects of forest carbon storage and GHG emissions from mineral soils, there is a lack of information on the long-term effects of drainage system establishment or maintenance as a climate smart forestry measure on tree carbon stock and soil GHG fluxes from old-growth forests on organic soils.

The aim of the study is to evaluate differences of tree carbon stock and the intra-annual dynamics of soil carbon dioxide (CO_2) and methane (CH_4) fluxes in hemiboreal old-growth Scots pine stands growing on organic soils with contrasting groundwater levels. Six Scots pine-dominated old-growth forests (130 to 180 years old) on deep organic (peat) soils with diverse soil moisture regimes and conditions, were selected and tree carbon stock and seasonal CO_2, CH_4 fluxes (once per three weeks in frost-free period) were measured.

Organic soil drainage has long-term positive (statistically significant) impact on aboveground tree carbon stock, and no effect on soil carbon stock. Old-growth forests with contrasting groundwater levels did not result in notable differences in soil CO_2 emissions, since the CO_2 flux was primarily influenced by soil temperature. Old-growth Scots pine forests, which were previously drained, showed CH_4 uptake throughout the entire growing season. In contrast, in sites with high groundwater levels (undrained), soil CH_4 uptake or release depended on the time of season and was influenced by the groundwater level. Overall, organic soil drainage system establishment and maintenance can be a climate smart forestry measure with a long-term positive effect on tree aboveground carbon storage and soil CH_4 uptake.

Model Based Comparison of Forest Carbon Uptake and CO2 Release Due to Forest Operations for Case Studies in Europe and South Africa

T1.4 Climate Smart Forestry

Peter Biber[1]
Stefano Grigolato[2], Julia Schmucker[1], Enno Uhl[1], Miren del Río[3], Hans Pretzsch[1]

[2] University of Padova, Department of Land, Environment, Agriculture and Forestry
[3] Forest Research Centre, INIA, Madrid, Department of Silviculture and Management of Forest Systems

Abstract: While carbon sequestration in forests has been studied in high detail, there is less information available about the CO_2 release caused by forest operations in relation to the actual forest growth and status. In order to allow for such comparisons under a broad range of frame conditions, we developed a generic phase-area model. For any silvicultural concept to assess, it requires a set of growth and yield characteristics, including area loss risk estimates, broken down to the main phases of stand development. We kept the set of required information as small as possible in order not to overstrain data availability in practice. The information can come from a broad range of sources; often it is condensed from observational plot data or from runs with detailed stand-level simulation simulation models.

The model allows to populate a given large area with user-defined initial area shares of the different stand development phases; therefore, it can cover all initial situations between an afforestation, and an established normal-forest like equilibrium. From there, the dynamic development of the stand-phase wise areas can be simulated for arbitrary time spans. Damage events are simulated stochastically according to user-scalable scenarios. Growth and yield related simulation results on the whole area are obtained by upscaling the known phase-wise variables to the whole area. As the model provides information for calculating the fuel consumption by harvest, the annual CO_2 release due to forest operations on the whole area can be calculated and put into relation with growth and yield variables related to C fixation. This procedure was used for evaluating silvicultural concepts from case studies in several European countries and South Africa. Our first results suggest a high importance of the initial situation and the disturbance regime for the potential to optimize climate-smart management.

At the time of presentation, the model will be freely available as an R package. The study was supported by the European Union H2020 project CARE4C.

Nature-based Climate Solutions Partnership: Forest Carbon Modeling Research and Development Priorities

T1.4 Climate Smart Forestry

Holly L. Munro[1]
Christopher W. Woodall[2], Stephen P. Prisley[1], Lara T. Murray[2]
[1] National Council for Air and Stream Improvement (NCASI), Inc.
[2] Inventory, Monitoring, and Assessment Research, United States Department of Agriculture, Forest Service

Abstract: Accelerated emphasis on increasing climate mitigation and adaptation measures throughout the forestry sector is evident across local, state, and national policy spheres in the United States (U.S.). Within the past year, a range of national legislation and policy developments have increased funding and institutional support for public and private sector actors to conserve land sector carbon sinks and enhance carbon sequestration and storage (e.g., Bipartisan Infrastructure Law, Inflation Reduction Act, and U.S. Department of Agriculture Secretary's Memorandum). Refining biometrical methodologies to simulate forest vegetation response to various management actions within the 'Natural Climate Solutions' (NCS) framework has emerged as a major knowledge gap. In response to these national priorities, a partnership was created between the U.S. Forest Service Research and Development and the National Council for Air and Stream Improvement, Inc. (NCASI) to coordinate and advance biometrical research by creating the Forest Carbon Modeling Group (FCMG). Consisting of over 100 experts in academia, government, industry, and NGOs, the FCMG collectively evaluated the relevant science and identified pressing NCS knowledge gaps. Future research priorities identified include: (1) improving consistency in reporting of forest carbon stocks and fluxes following well-defined mensuration practices with uncertainty standardization; (2) enhancing belowground (e.g., coarse root) and soil carbon models; (3) incorporating disturbance (e.g., fire) models in forest carbon projection systems; (4) advancing small area estimation (SAE) techniques to help reduce costs of forest carbon monitoring and assessment; and (5) building the workforce for the future. Refining biometrical approaches to assess forest carbon response to various management actions is a core necessity to inform the implementation and measurement, monitoring, and evaluation of the effect of NCS policies and regulations.

Potential benefits for spruce – beech mixture vs. spruce monoculture from the belowground view

T1.4 Climate Smart Forestry

Fabian Weikl[1]
Thorsten Grams[1], **Karin Pritsch**[1, 2]
[1] AG Ecophysiology of Plants, Professorship for Land Surface-Atmosphere Interactions, Technical University of Munich, Germany
[2] Research Unit Environmental Simulation, Helmholtz Munich, Germany

Abstract: Growth of *Picea abies* has been shown to profit from growth with *Fagus sylvatica* compared to monoculture, particularly under unfavourable (drought) conditions. In the project HoliSoils, we study soil biodiversity as below-ground factor that may contribute to this beneficial interaction. In addition, the effects of tree mixture on greenhouse gas (GHG) emissions will be used to estimate the potential of climate smart forestry by spruce-beech mixtures and thus attenuating losses of spruce trees during projected increasing hotter and drier episodes.

We have established 3 sites along a precipitation gradient each comprising a paired monospecific and mixed stand. In each stand, soil CO_2 efflux is regularly recorded with or without roots excluded. Representative soil samples were taken for biodiversity analyses.

Preliminary data indicate generally lower soil CO_2 efflux in root free soil (Rh) compared to total soil (Rs), and generally lower emission profiles on the dry site. Rh and Rs both peaked in late spring, but Rs dropped almost to Rh levels during hot and dry summer months. Only for Rs, a secondary peak followed during autumn which got more prominent on wetter sites for spruce. While mixed stands overall had similar emissions, their Rs profiles were marked by having two equal annual peaks in late spring and autumn.

Soil biodiversity in mixture is strongly influenced by the presence of tree species, and its composition differs between monospecific and mixed spruce stands. Fungal community composition differed also between the moist and the dry site.

Product and Carbon Traceability Throughout the Wood Products Supply Chain

T1.4 Climate Smart Forestry

Raju Pokharel[1]
Kathryn Maloney[1]
[1] Department of Forestry, Michigan State University

Abstract: ForesTrust, LLC was introduced by the U.S. Endowment for Forestry and Communities (the Endowment) as the newest venture to take advantage of Blockchain technology. ForesTrust creates traceability in the supply chain, offering the ability to accurately and efficiently track wood and wood fiber from the forest to the consumer and consolidate and ease the financial and administrative burden of forest certification. Forest Carbon and Climate Program at MSU, which will conduct a feasibility analysis and communications effort not only to advance blockchain technology in forest product tracking but also to include the unique, timely, and high-demand emphasis on carbon tracking for credits and climate accountability. As the project explores how blockchain technology can be leveraged as a mechanism for various actors (including private sector companies, timber producers, already those in procurement), this component will focus on how the blockchain system can track carbon stored in Harvested Wood Products (HWPs), embodied carbon emissions, and carbon through the chain of custody. The aim is to support transparency and traceability to overcome both known (illegal timber laundering) and emerging (climate change mitigation) challenges in the forestry sector. This will provide a platform for the forestry sector to improve traceability and present cost and time savings with certification and chain of custody administration. We will identify meaningful carbon tracking mechanisms to include in the platform and present findings. The technology and capabilities created for carbon tracking will expand the market penetration of U.S. domestic wood products.

Restoring climate-resilient hardwood forests for climate-smart ecosystem services in the Lower Mississippi Alluvial Valley

T1.4 Climate Smart Forestry

Jianbang Gan[1]
Nana Tian[2]
[1] Department of Ecology and Conservation Biology, Texas A&M University, College Station, TX 88743, USA
[2] Arkansas Forest Resources Center, College of Forestry, Agriculture, and Natural Resources, University of Arkansas at Monticello, Monticello, AR 71655, USA

Abstract: Bottomland hardwood forests (BHFs) offer a variety of ecosystem services that generate ecological, economic, and social benefits to the local communities and beyond. Yet over two-thirds of BHFs in the southern United States have disappeared over the last century due to land-use change especially agricultural expansion and other drivers. We assess the climate resilience of red oak restoration plantations in the Lower Mississippi Alluvial Valley and the potential of the forests for providing climate-smart ecosystem services including timber, carbon, and wildlife. Our tree ring data analysis reveals that Cherry bark oak (*Quercus pagoda*), Shumard oak (*Quercus shumardii*), and Nuttall oak (*Quercus texana*) are resilient to climate change even under the high greenhouse gas emissions scenario (RCP 8.5) although the maximum temperature from January to August and total precipitation from April to July are negatively associated with tree growth. Restoration of BHFs on working agricultural land can enhance carbon sequestration and wildlife habitat while woody materials and wildlife yielded from the forests promote bioeconomic development in the region.

Spatial and economic robust optimization of selected forest ecosystem services under climate change, considering biodiversity conservation

T1.4 Climate Smart Forestry

Victor Jorquera Olave[1]
Emma Hart[2], Marc Hanewinkel[1]
[1] University of Freiburg, Chair of Forestry Economics and Forest Planning, Germany
[2] Edinburgh Napier University, School of Computing Engineering and the Built Environment, Scotland

Abstract: We are working under the project Pathfinder of the European Union, and we will perform a spatial and economic optimization of the ecosystem services of timber production and climate regulation, using the proxy of carbon sequestration, plus incorporating a metric for biodiversity conservation (amount of deadwood). The forest growth will be modeled with the European Forestry Dynamics Model (EFDM). This is an area-based matrix model that requires the pair data of consecutive national inventories to obtain activity (no management, thinning, and felling) and transition probabilities (forest development). The model will work with cells of 1 km^2 each, that we will aggregate into sub-regional levels that share similar characteristics, such as, species, type of soil, and region.

Different policy alternatives translated into management strategies will be run within the EFDM, including: a minimum forest conservation (no management), business as usual (BAU), intensified forest wood harvest, and decreased forest wood harvest. We will introduce a variation of the activity probabilities of each of these management options in the model, to generate an array of different outputs needed for the robust optimization. Likewise, different climate change scenarios will be integrated (representative concentration pathways 2.6 and 4.5), by using the process- and data-based hybrid ecosystem model Formit-M, that generate a change in the transition probabilities of the EFDM. These different management strategies will be evaluated and optimized using a multi-objective approach. We will define performance goals and/or constraints, to achieve the diverse objectives considered in our study. Likewise, we will consider multiple and deep uncertainties, such as the different climate change scenarios, and economic parameters, e.g., interest rate, wood prices, harvest costs, carbon costs. Furthermore, a sensitivity analysis will be conducted to identify the uncertainty parameters that affect most strongly the performance and robustness of the optimization.

We expect to show the optimal distribution of management options in Europe, in a spatially-explicit fashion. Plus, identifying the trade-offs between timber production, carbon sequestration and conservation of biodiversity under different climate scenarios and discount rates. At the moment, we are working on the study's framework and expect to have our results by next Winter.

Testing a framework for the assessment and implementation of Climate-Smart Forestry in Mediterranean forests

T1.4 Climate Smart Forestry

Diana Alfieri[1]
Roberto Tognetti[2], Hans Pretzsch[3], Giovanni Santopuoli[2]
[1] Department of Biosciences and Territory, University of Molise, C.da Fonte Lappone snc 86090 - Pesche (IS)
[2] Department of Agriculture, Environment and Food, University of Molise, Via Francesco De Sanctis I - 86100 Campobasso (CB)
[3] Chair of Forest Growth and Yield Science, Department of Life Science Systems, TUM School of Life Sciences, Technical University of Munich, Hans-Carl-Von-Carlowitz Platz 2, 85354 Freising, Germany

Abstract: Climate-Smart forestry (CSF) aims to balance climate change mitigation and adaptation strategies into sustainable forest management practices, while facilitating the provision of many ecosystem services. Although the attention around CSF has grown in recent years, further efforts are necessary to translate the concept of CSF into social-ecological resilience practices.

This research aims to facilitate CSF assessment and monitoring through a straightforward and user-friendly method, based on the development of a composite smartness indicator set. This method was tested on Mediterranean forests based on data from the Italian National Forest Inventory, namely INFC 2005 and INFC 2015.

The methodology includes: (i) selection; (ii) normalization; (iii) weighting, and (iv) aggregation of CSF indicators. A systematic literature review was carried out to select the indicators, which are frequently used to evaluate adaptation and mitigation over time. The keywords used to implement the literature review were: “climate smart forestry”; “forest management”; “indicator”; “mitigat*”; “adapt*”, using Elsevier’s Scopus® database. A total of 39 indicators were obtained from 78 examined scientific papers. Some of the most frequently cited indicators (e.g., carbon stock, diameter distribution, tree species composition) were used to assess the smartness of the main Italian forest categories.

To compare the indicators with each other, they were normalized through distance to the target, or min-max normalization. Moreover, an online survey (https://forms.gle/BRPDARHH3oaHppmR6) was developed and shared with experts of the forestry sector across Europe to collect opinions about the importance of each indicator facing CSF assessment. These findings were used to rank the indicators through the Analytic Hierarchy Process.

Preliminary results showed an increment of smartness in all forest categories from 2005 to 2015. This increase over time was more pronounced for some forest categories (e.g., silver fir, Norway spruce).

Feedbacks from forest managers are discussed in terms of gaps, uncertainties, and perspectives for improving the assessment and implementation of CSF practices. This study represents a starting

point for the design and application of decision support tools to evaluate and monitor the evolution of CSF, and guide forest managers in their decisions.

The alleviation potential of tree-cutting interventions on drought stress and growth of pedunculate oak and beech in temperate forest

T1.4 Climate Smart Forestry

Sanne Verdonck[1, 2]
Anneleen Geussens[1], Koenraad Van Meerbeek[1], Arno Thomaes[2], Bart Muys[1]
[1] Department of Earth and Environmental Sciences, KU Leuven, Belgium
[2] Forest Ecology and Management, Research Institute for Nature and Forest, Belgium

Abstract: Climate change threatens forest functioning through hotter droughts, leading to increases in tree mortality and decreasing growth trends in European forests. To maintain the provisioning of ecosystem services, climate-smart forest management has been proposed as a drought alleviation strategy, with stand tending as one of its suggested tools. Thinning, particularly, is expected to reduce competition for nutrients, light, and water, of which the latter is crucial during drought events. However, no scientific consensus exists on the relationship between thinning and tree drought stress, with forest management being reported to reduce, increase or not affect drought stress. Additionally, research highlights the importance of local stand conditions. Therefore, this study aims to investigate the effects of thinning on the drought response in pedunculate oak (*Quercus robur* L.) and beech (*Fagus sylvatica* L.) dominated forests in the Brabantse Wouden, Belgium. We hypothesize that thinning initially reduces drought stress for both pedunculate oak and beech, but may increase drought stress once a certain threshold of management intensity is reached. The threshold is expected to occur at a lower intensity for beech than pedunculate oak. To analyze this research question, tree ring data (yearly time steps) and point dendrometer data (hourly time steps) were collected, providing information on trees' past and present drought responses at distinct time scales. The drought responses are then linked to weather data and the recent history of forest management practices, which was reconstructed using wood sale records dating back to 1975 (tree ring data) and characterized by the competition intensity as experienced by the studied tree (point dendrometer data). Combining these techniques results in a thorough understanding of short-term drought stress and long-term growth trends. Preliminary results based on dendrometer data suggest that beech experiences more stress than pedunculate oak, and this drought response is aggravated by higher management intensities. In contrast, pedunculate oak endures more stress in dense stands, indicating a preference for open canopy structures. Overall, this study provides insights into the complex relationship between forest management practice and drought response of beech and pedunculate oak in temperate forest ecosystems, which can support informed climate-smart forest management strategies.

T1.5 Climate-smart pine forest management

Adaptation Strategies for Scots pine forests at the SW edge of its distribution

T1.5 Climate-smart pine forest management

[3] iuFOR, Instituto universitario de investigación en gestión forestal sostenible, Universidad de Valladolid, Spain
[4] Unidad Asociada I+D+i al CSIC Gestión Forestal Sostenible, Spain

Abstract: Global change is modifying Scots pine (*Pinus sylvestris* L.) forests dynamics and triggering new climate-driven threats. Negative impacts are particularly dangerous in its Southern range-edge, where adaptation strategies might be urgently necessary. In this presentation we focus on the South-West distribution area of Scots pine, showing the main impacts observed and proposing adaptation measures based on current scientific knowledge.

Higher temperatures and more extreme and frequent droughts are causing lower growth rates and some decay processes at lower altitudes and more xeric sites, which are often exacerbated by some biotic agents, like mistletoe or pine processionary moth. Moreover, they are the main limiting factors of the Scots pine natural regeneration, inducing changes in the optimum altitudinal range of regeneration that might affect species competitiveness and potential replacements in near future. Under new climate change scenarios, more biotic and abiotic disturbances are expected, including forest fires and storms, which can influence forest functioning and associated ecosystem services.

We reviewed scientific studies on Scots pine in the study area, which address forest dynamics and management under climate change, and describe different adaptation silvicultural measures grouped in seven strategies: 1) Promotion of natural regeneration; 2) Promotion of adaptive evolution; 3) Promotion tree species diversity; 4) Facilitation of natural species substitution at lower altitudes; 5) Reduction of water stress; 6) Promotion of stability against wind; and 7) Pest and disease control. The adaptation measures will be explained and discussed for each strategy, including some examples from our own experiments. Finally, the synergies and possible trade-offs between different measures will be discussed.

Admixtures of broadleaves to Scots pine stands: stabilization or additional stress?

T1.5 Climate-smart pine forest management

Jens Schroeder[1]
Michael Koerner[2]
[1] Eberswalde University of Sustainable Development
[2] Public Enterprise Sachsenforst, Competence Centre for Woodlands and Forestry

Abstract: Large-scale conversion of pure, even-aged stands of Scots pine (Pinus sylvestris) in Central European lowlands in the past decades has led to large forest areas with European beech (Fagus sylvatica) in a second layer below the conifer canopy. The respective efforts aimed at enhancing ecological stability and habitat diversity, increasing contributions tot he groundwater table, and reducing biotic risks associated with pure Scots-pine stands.

Drastic shortages in rainfall in spring in the recent past (especially 2018-2020) accompanied by high temperatures have caused widespread losses in vitality and frequent individual mortality in many forests in Northeastern Germany, including pine-dominated stands. Relating to these previously unknown decline symptoms, a discussion has evolved about the possibly detrimental influence of deciduous understorey layers on water supply and successive survival of the Scots pine overstorey. During severe drought periods, the additional beech layer is suspected of increasing interspecific competition for water. The positive effects of admixtures would in these cases be countered by negative consequences for the water supply during extreme shortages.

The prove this hypothesis, we carried out comparative analyses of radial increment time series for representative samples of Scots pines from pure and from mixed stands under similar site conditions. Investigations included tree-ring width series and tree-ring index chronologies from various regions. A wide array of derived dendro-ecological parameters were applied to characterize variablility, sensitivity, and responses to monthly and seasonal climate. Additionally, we quantified resilience indicators after particularly conspicuous drought years. Preliminary results show no significant differences in the behavior of trees with understorey to that of trees from pure stands. Further tests based on a larger data set shall provide forest management with reliable information on the competion an/or facilitation relations that could be included into more flexible guidelines for future conversion activities.

Assessing Resilience Components in Maritime Pine Provenances Grown in Common Gardens

T1.5 Climate-smart pine forest management

Concetta Lisella[1]
Serena Antonucci[2], Giovanni Santopuoli[2], Marco Marchetti[1], Roberto Tognetti[2]
[1] Dipartimento di Bioscienze e Territorio, Università degli Studi del Molise, Contrada Fonte Lappone, 86090, Pesche, Italy
[2] Dipartimento di Agricoltura, Ambiente e Alimenti, Università degli Studi del Molise, Via Francesco de Sanctis, 86100, Campobasso, Italy

Abstract: Maritime pine is a widespread conifer native to the western Mediterranean basin with economic importance in southwestern Europe. Climate change is predicted to increase episodes of drought-induced decline and mortality in Mediterranean forests. Understanding the responses of different maritime pine provenances to drought is, therefore, important to tackle the climate crisis and to guide climate-smart forestry.

This study aims to assess resilience components (i.e., resistance, recovery, and resilience) to drought in five different provenances of maritime pine (Corsica, Tuscany, Portugal, Telti and Limbara), and the relationships with climate variables. Four common gardens were implemented in Sardinia, in the early ’80, to compare these provenances. At each site, all provenances were planted within five 25-tree square plots, and the arrangement of plots were randomized within five (Montarbu, Montes and Usinavà) or three (Uatzo) blocks. In each site 8-10 trees per provenance were selected from which two wood cores were taken. From SPEI analysis, it was found the 2003 as drought year in all sites and, based on this year, the resilience components were calculated. For each index, GLMs were built to predict the possible response of them to climate variables.

Provenances showed differences in growth rates. Tuscany was the least productive, while Limbara showed good growth rates in drier sites. The resilience and resistance had a similar pattern, while the recovery showed an opposite trend, suggesting a trade-off among these indices. Models highlight a noticeable adaptation of maritime pine to the harsh environment conditions of Sardinia.

This common garden study increases our knowledge on the responses of maritime pine provenances in the Mediterranean area, at the boundary of the species range, for which reports are limited. We stress the importance of the analysis of tree rings and resilience components, as well as the establishment of long-term experiments, to determine the response of maritime pine to disturbance-induced growth decline and to support adaptation strategies to climate change for this species, such as assisted migration.

Can silvicultural thinning be used to regulate water utilization in dryland pine forest ecosystems?

T1.5 Climate-smart pine forest management

Yagil Osem[1]
Moshe Vladislav Dubinin[2], Dan Yakir[3], Tarin Paz-Kagan[2]
[1] Institute of Plant Sciences, Agricultural Research Organization, Volcani Center, Rishon LeZion, Israel
[2] The institute for Desert Research, Ben-Gurion University of the Negev, Sde Boqer, Israel
[3] Earth and Planetary Sciences Department, Weizmann Institute, Rehovot, Israel

Abstract: Evapotranspiration ratio (ER=evapotranspiration/precipitation) and water use efficiency (WUE=gross primary productivity/evapotranspiration), are key functional attributes of dryland ecosystems that reflect water utilization. While the importance of ER and WUE is recognized, understanding the factors that control them remains a challenge. Moreover, hardly any information exists on the ways by which these attributes can be regulated through silvicultural practices. We studied the variation in ER and WUE as affected by silvicultural thinning in dryland forest ecosystems along an aridity gradient. Estimates of Leaf area index (LAI), gross primary productivity (GPP) and evapotranspiration (ET) were based on empirical models relating spectral indexes from high-resolution satellite-sentinel-2A and climatic data from weather stations to flux records from eddy covariance towers. We monitored LAI, ET and GPP during 2018-2022 in two long-term research sites (LTER) of pine forests (*Pinus halepensis*) in Israel – Semiarid Yatir forest and dry-subhumid Kedoshim forest (annual precipitation ~280 and 550 mm, respectively), both have undergone thinning treatments (i.e., control, 300, 200 and 100 tree ha^{-1}) in 2009 as part of a long-term experiment. In the non-thinned (control) plots of Yatir (~320 tree ha^{-1}), LAI, GPP and ET (1.5 m^{2}m^{-2}, 450 gCm^{-2}year^{-1} and 400 mm year^{-1}, respectively) were lower than in those of Kedoshim (~550 tree ha^{-1}, 2.6 m^{2}m^{-2}, 640 gCm^{-2}year^{-1} and 700 mm year^{-1}, respectively). In Yatir, 9-13 years after thinning, LAI, GPP and ET were lower than the non-thinned control by up to ~53%, 40% and 68%, respectively, while in Kedoshim, they were lower by up to ~32%, 30% and 80%, respectively. WUE of non-thinned plots was significantly higher in the semiarid than in the dry-subhumid forest (1.5 vs. 0.93 gC kgH_2O^{-1}, respectively). Moreover, WUE was significantly higher in thinned plots in both forests by up to 37% and 23%, respectively. Finally, in non-thinned plots of Yatir and Kedoshim, ER was ~0.95 and was lower in thinned plots by up to 57% and 64%, respectively. While the thinning effect on ER was attributed to LAI reduction, its impact on WUE was explained by higher leaf exposure to sunlight. Our results demonstrate long-term regulation of dryland forests' ecohydrology through silvicultural practice.

Climate change on pinewoods in inner Spain: observed impacts and proposals for adaptive management

T1.5 Climate-smart pine forest management

Rafael Calama[1]
Javier Gordo[2], Guillermo Madrigal[1], Miren Del Río[1], Sven Mutke[1], Gregorio Montero[3], Alfonso González[2], Marta Pardos[1]
[1] ICIFOR - Forest Research Institute. INIA_CSIC. Madrid, Spain
[2] S.T. Medio Ambiente de Valladolid. Junta de Castilla y León. Valladolid, Spain
[3] SECF. Spanish Society for Forest Science. Madrid, Spain

Abstract: The Spanish Northern Plateau conforms a flat land extension occupying the whole river Duero Basin. The inner part of this territory (approx. 2.10^6 ha) is located at 800 m a.s.l, and is characterized by a Continental Mediterranean climate, with very low annual rainfall (< 400 mm), extreme summer drought, and soils with a high content of sand and low water retention ability. This territory, largely depopulated, is mainly occupied by rainfed crops, with fragmented patches of pinewoods covering about 20% of the area. The two main species are the Mediterranean pines *Pinus pinea* and *Pinus pinaster*, whose forests have been traditionally managed to promote the coproduction of nonwood forest products (cone and resin), together with timber and other relevant ecosystem services, as protection against soil erosion.

The Mediterranean pinewoods in the inner part of Spain have been considered as hotspots for climate change. In the recent decades we observed in the territory a significant increment on the mean temperatures, more irregular precipitations, and more frequent and intense heatwaves and extreme drought events. This have resulted in recent impacts as the increment in processed of tree decay and dieback, failure of natural regeneration, reduction in timber and non-timber products yields, shifts of vegetation, and higher frequency and virulence of biotic (native and exotic pests) and abiotic (fire) perturbations.

Facing these impacts, during the last 25 years INIA-CSIC and the Forest Service of Castilla y León have been collaborating in a program for adapting Northern Plateau pinewoods to changing conditions, combining research and practical management applications. Among the tested proposals, we can mention the implementation of more gradual regeneration cuttings, application of early and more intense thinnings, facilitation of species substitution, promotion of structural and specific heterogeneity of the pinewoods, and the development of different climate sensitive models to support forest management decision under current and future scenarios. This program is accompanied by a continuous process of transfer knowledge, feedback and information sharing between researchers and forest practitioners. In the current presentation, we will summarise the main results and outputs of this program, and will show ongoing and future lines of collaboration.

Climate-adapted silvicultural strategies for harvest cuts of Scots pine (Pinus sylvestris L.) stands in Northern Germany

T1.5 Climate-smart pine forest management

Hergen Christian Knocke[1, 2]
Jan Hansen[1], Ralf-Volker Nagel[1], Matthias Albert[1]
[1] Northwest German Forest Research Institute, Department of Forest Growth, Göttingen, Germany
[2] Ministry for Climate Protection, Agriculture, Rural Areas and the Environment Mecklenburg-Vorpommern, Department of Climate Protection, Nature Conservation and Forests, Schwerin, Germany

Abstract: Pine stands dominate the landscape in Northern Germany. They are subject to forest conversion towards mixed stands, because of increasing risk resulting from often insufficient mixture and structure. In the six northern federal states the silvicultural guidelines are expert-based adapted towards climate change and schedule pine cultivation even on poorest and driest sites. However, evidence-based studies indicate pines' increasing vulnerability especially in warm-dry weather. The unbalanced age class structure and increasing proportions of strong dimensioned wood also pose challenges for harvest cuts and associated climate adaptation. We question how cultivation area, standing and harvested volume and increment of pine develops by climate-sensitive simulations.

To analyze stand development, the plots of the third German NFI are simulated until the year 2062 using the single-tree growth simulator WaldPlaner. We account for climate change effects using climate projections of the moderate global model EC-EARTH12 in combination with the regional model RACMO and the extreme global model HadGEM2 with the regional model WettReg2013 under RCP8.5. For current stands site index shifts are predicted applying site-sensitive height-age curves. For future stands species suitability strongly depends on site water supply, which is dynamized considering the climate projections.

The simulation further considers two target diameters for pruned and unpruned pine stands. The silvicultural concepts of the investigated federal states are implemented in the growth simulations using targeted basal areas and crop tree numbers. Besides the projection of current stands, two contrasting scenarios concerning the next forest generation are simulated. Based on the catalog of suitable tree species derived from the site water budget corresponding to the respective climate projection, the first scenario maximizes the proportion of future pine by selecting light-demanding species from the said catalog. The second scenario minimizes the proportion of pine by preferring shade-tolerant species. This requires different harvest courses of the current stands by means of shelterwood cutting.

Afterwards, the simulation results are evaluated looking at abiotic and biotic risks. Within the guardrails outlined in this variant study, pine area consolidates after decades of decline, whereas the uneven age-class structure leads to bugwave effects regarding timber usage.

Differing effects of mortality agents on snag persistence in mountain ponderosa pine forests

T1.5 Climate-smart pine forest management

Joy Mast[1]
Carol Chambers[2]
[1] Carthage College, Department of Geospatial Science, USA
[2] Northern Arizona University, School of Forestry, USA

Abstract: Understanding how snags respond following high-severity crown fires or outbreaks of bark beetles in mountain forests can help resource managers maintain habitat for wildlife. Our study compares these two key mortality agents to predict the persistence and characteristics of snags. The primary tree species in these mountain forests are ponderosa pine (*Pinus ponderosa* Laws.), one of the most widely distributed pines in western North America occurring across 15 million ha from Mexico to southern Canada and from the Pacific Coast to the Great Plains. In the southwestern United States, ponderosa pine covers 3.2 million ha, supporting more than 75 species of birds, mammals, reptiles, and amphibians. The thick bark and sapwood of ponderosa pine snags are valuable to cavity-nesting birds and bark insectivores for nest excavation and foraging. Mortality agents are crucial for modeling snag dynamics, given that the cause of death determines much of the functional pathway as wood deteriorates. Our objectives were to (a) conduct a longevity analysis to predict the lifespans of ponderosa pine snags comparing large-scale mortality events and (b) determine falling hazard based on characteristics of snags that remain standing by agents of mortality. We documented snag dynamics following two high-severity wildfires (burned 1996 and 2000) and 4 bark beetle outbreaks (2002-2005). After repeat sampling 2490 snags for 1 to 13 years post-mortality, we determined that the time to failure (snag fall) was 7.6 (±0.05) years. Mortality agent was the strongest predictor of how long a snag stood, with the hazard of a snag falling 2.5 times greater for beetle-killed than fire-killed snags. We found snags more likely to fall are beetle-killed, with intact tops, greater lean, and a smaller diameter. Inversely, snags more likely to remain standing are fire-killed, with broken tops, larger diameters, and straighter. Our long-term study provides a model for resource managers working with snags immediately following a high-severity fire or beetle outbreak and in predictions of future snag densities. Understanding the longevity of snags helps managers of mountain forests model future risks associated with massive mortality events and track attributes such as snags to the delivery of future ecosystem services.

Effect of site and Tuber borchii inoculation on Pinus pinea growth through the analysis of three consecutive years of plant establishment

T1.5 Climate-smart pine forest management

Claudia Delard[1]
Veronica Loewe-Muñoz[1, 2], Rodrigo del Rio[2], Mónica Balzarini[3]

Abstract: Stone pine (*Pinus pinea* L.) is a Mediterranean species that produces one of the most important nuts worldwide. In Chile, it shows vigorous growth and high fruiting, and it is considered as an interesting emerging crop. *Tuber borchii*, called Bianchetto truffle, is a mycorrhizal Ascomycete that produces edible truffles, increasingly renowned on the market. Due to its adaptability to different environmental conditions, its cropping can expand to non-native areas. This mycorrhizal fungus has symbiotic root association with various trees, being stone pine its favorite. Considering that stone pine is impacted by climate, we analyzed the impact of inoculation, interaction of the inoculation with environmental effects related to spatial variability, and inter-annual variability on stone pine growth. A multi-environment trial involving three sites was established in Chile. To separate permanent effects (soil) from the random effects (climate), the trial was repeated in three consecutive years, and it was annually monitored for growth, vigor, health, and mycorrhization level. Significant differences were found for height, collar diameter, crown diameter and vigor in relation to the plantation site and year, inoculation and their interactions. Chacaico established in 2019 showed higher height than Pirque and Cabrero for all plantation years, but without differences between inoculated and non-inoculated plants. Pirque for all plantation years, and Chacaico established in 2020 showed the lowest percentage of vigorous trees, without differences among inoculated and non-inoculated plants. Regarding plant survival, it was observed an environmental effect, but not an effect of inoculation nor interactions over this variable. The biplot of the principal components showed that Chacaico site was positively correlated to growth variables. We found a significant negative correlation between growth and maximum temperature, spring hydric deficit and potential evapotranspiration. Root mycorrhization with *T. borchii* was high in all sites and in all plantation years, without statistical differences. *T. borchii* quantity was positively correlated with mean temperature. We conclude that in Chile it is feasible the co-production of Bianchetto truffle and pine nuts in different environments showing both species high plasticity.

Effects of intensive thinnings on wood production and carbon sequestration in boreal Scots pine stands

T1.5 Climate-smart pine forest management

Saija Huuskonen[1]
[1] Natural Resources Institute Finland

Abstract: Forest management plays a crucial role in the climate impact of forests by influencing tree growth and carbon storage. Key factors affecting tree growth include decisions during the regeneration phase (such as tree species selection, seed origin, and regeneration method), thinnings (including intensity, number, method), and rotation length. In practice, diversified thinning types and intensive thinnings have become more common due to societal and operational changes. Intensive thinnings aim to achieve immediate and profitable cutting incomes, promote diverse forest structures, transition to continuous cover forest management, or rehabilitate partially damaged stands. These practices involve higher thinning intensities than previous norms.

Empirical experiments have shown that intensive thinning reduces the yield of commercial wood, particularly after thinning and throughout the rotation, with Scots pine being more affected than Norway spruce, especially in young stands. However, most studies employed relatively low thinning intensities compared to those used in today's commercial forests. To address this gap, a new intensive thinning trial was established in Finland nearly two decades ago to examine the effects of extremely heavy thinning intensities and different thinning types on the growth and carbon sequestration of mature pine stands.

Based on this trial, we investigated the effects of thinning intensity on growth and carbon capture and conducted simulations using Motti software to predict future development. Our findings revealed that, across thinned plots, moderate thinnings resulted in higher total volume increment and carbon accumulation compared to more intensive thinning practices, both in observations after 15 years and simulations at final felling. In conclusion, intensive thinnings may offer early higher wood production at the expense of later stages and lower overall total timber production and annual carbon accumulation.

Effects of thinning on short-term transpiration in Scots pine stands in Sweden

T1.5 Climate-smart pine forest management

[2] Department of Forest Ecology and Management, Swedish University of Agricultural Sciences, Umeå, Sweden
[3] Unit for Field-based Forest Research, Siljansfors Experimental Forest, Swedish University of Agricultural Sciences, Mora, Sweden

Abstract: Scots pine (*Pinus sylvestris*) is the most widely distributed pine species in the world. In Swedish forests, it represents about 40% of the total standing volume. Due to recent and forecasted changes in temperature and precipitation patterns, it is important to understand how this species responds to various management practices, particularly water uptake and growth dynamics. Thinning is one of the key practices in forest management commonly applied on Scots pine forests, and which has significant implications for mortality, growth, aboveground biomass allocation, biodiversity and resistance to extreme climate events e.g. drought. Within this context, our study aimed at evaluating the effects of common thinning practices: unthinned, thinning from below, from above and heavy thinning from below, on individual tree and stand transpiration. We hypothesized that individual trees in the heavily thinned treatment will transpire more and exhibit enhanced growth rates due to a higher resource availability, while cumulative stand transpiration will be lower in this treatment. The study sites are located in central and southern Sweden (Siljansfors and Hallarp, respectively). Tree transpiration was estimated using heat pulse sap flow sensors on selected trees covering the entire diameter distribution per site. Sensors were installed in two blocks (32 sensors in Siljanfors and 40 sensors in Hallarp). Our study is one of the first in describing with high temporal and spatial resolution, the short-term and seasonal transpiration patterns, resulting from various thinning treatments in one of the most economically-relevant species in Sweden and around the world.

Forest thinning as a climate-smart forest strategy to promote early-stage regeneration of maritime pine

T1.5 Climate-smart pine forest management

Abstract: Evidence of forest regeneration failure under a changing climate and disturbance regime is urging the development of management and adaptation strategies that promote regeneration. Thinning has been shown to reduce the vulnerability of forests to several stressors such as drought, but the alteration of site conditions could negatively influence regeneration due to the narrower range of environmental conditions tolerated by early plant stages (especially under climate change). Therefore, studies evaluating the effect of this silvicultural practice and the interactions with climatic conditions are needed. In this research, we examine the effect of thinning on the regeneration of maritime pine (*Pinus pinaster*) stands in the western Mediterranean as well as how climatic, edaphic and topographic factors influence the effectiveness of this practice. This was achieved by comparing early-stage regeneration dynamics in13 pairs of thinned and control plots along a thinning intensity gradient (23–69 % basal area removal) in the northeastern Iberian Peninsula for 5 consecutive years. Thinning had a strong positive effect on the establishment, density and survival of seedlings, as well as a weak positive effect on primary and secondary growth. Not only was the number of seedlings and survival in thinned plots considerably higher than in control plots (10-fold and 30-fold, respectively) but both increased with increasing thinning intensity. Overall, the positive effect of thinning was greater under drier and warmer conditions, indicating that it is particularly beneficial in alleviating competition in water-limited forest ecosystems. Since water-stress is predicted to increase in the Mediterranean region under climate change, our results suggest that thinning may become an increasingly important management and adaptation strategy to promote the regeneration of pine stands.

Group selection system cuttings as a strategy to diversify Pinus pinaster plantations

T1.5 Climate-smart pine forest management

Abstract: Adaptation to global change has become a main topic in forest research nowadays, as die-back processes, pest infestations and regeneration failures due to climatic issues are currently affecting forests throughout the world. Silvicultural treatments, especially those oriented to enhance the individual tree resistance to stress conditions and to promote species and structural diversification of the stands, have been highlighted as a solution to adapt stands of different species. Group selection system cuttings are among a group of promising silvicultural treatments, as they are able to promote the creation of uneven-aged and mixed stands in presence of favorable conditions. However, its application is typically limited to shade/mid-shade tolerant species in boreal or temperate conditions, with less examples in shade-intolerant species under Mediterranean conditions, the habitat of maritime pine (*Pinus pinaster* Ait.). Small gap sizes represent also a challenge to regenerate a light demanding species as maritime pine, but have less erosion hazard and landscape impacts than bigger sizes, potential issues in stands with soil protection and social recreation as objectives. This work presents the results from two experimental trials located in 50-70 year old maritime pine plantations in Central Spain, cut in 2017 using gaps with diameters from 1.5 to 3.5 times the dominant height of the stand. Both sites were monitored annually for five years using over 900 one-meter radius subplots distributed within the gaps, looking at maritime pine and other species regeneration while recording ecological parameters that potentially drive the regeneration process. Several models were developed to explain different processes of maritime pine regeneration, such as seed germination and first establishment, seedling survival, growth and root development. Our results were very site dependent. The northern site presented maritime pine regeneration well established (in terms of survival and growth) and distributed within the gaps, with inter-species competition (scrub and herbs), position within the gap and weather conditions as the main drivers of the different processes. Nevertheless, in the southern site, herbaceous competition and browsing were hampering pine seedling establishment. Species diversification was very limited in both sites due to the absence of other species seed trees and browsing respectively.

Implementation of a long-term pine-forest real world laboratory

T1.5 Climate-smart pine forest management
Ferréol Berendt[1]
Tobias Cremer[1]
[1] Eberswalde University for Sustainable Development, Department of Forest Utilization and Timber Markets

Abstract: In Brandenburg, in Northeastern Germany, the share of pine (*Pinus sylvestris*) dominated forests is above 70 %. Nowadays, these forests are particularly at risk from climate change and the extreme weather conditions of the last decades. Moreover, for climate protection reasons, there is a real need to bind carbon as long as possible by increasing and prolonging the material use of wood.

To make German forests more resilient and resistant against the challenges mentioned above, forest management aims at increasing the fraction of broadleaved tree species. However and because of the simultaneously increased demand for timber (and especially timber from coniferous tree species), a close interlocking of adaptive forest management and efficient timber use is of enormous importance.

Within the ADAPT-Wald-Holz project, a research group of young scientists develops an adaptive forest-wood management system with a focus on an integrative, efficient and regional value chain. The heart of the project is the forest real world laboratory (or forest living lab). Within that real world laboratory, the effects of pine forest management scenarios on several ecosystem services such as wood production (utilization), C-binding (climate protection), groundwater and drinking water supply (water balance) and microhabitats (biodiversity) are analyzed. Moreover, the effects of both changing climatic conditions and different management scenarios on the mechanical properties of pine wood are analyzed in order to develop standards for timber construction with pine. The results help to customize the regional wood supply chain through timber allocation.

Relevant parts of the research are done forest stands close to Eberswalde, where in each stand three management scenarios and a reference scenario are implemented. These stands constitute the forest real world laboratory. Besides the place for experimental plots, the forest real world laboratory is a transdisciplinary place for scientists, practitioners, society and students. Thus, research needs are identified together with practitioners, results are communicated to the public and student projects raise new ideas.

Integrating Resin Tapping in Maritime Pine Forest Management for Climate-Smart Silviculture: Insights from the RN21 Project

Abstract: Resin extraction can bring multifaceted benefits in the context of adaptive forest management, such as enhanced income for forest managers and local communities, as well as increased human presence and vigilance in the forest, thereby deterring and detecting potential fire hazards more effectively, contributing to mitigating climate change effects on fire recurrence and severity.

This communication presents results achieved under the Integrated Natural Resin 21 project (RN21, supported by the PRR-Recovery and Resilience Plan and the European NextGeneration EU Funds). The project focuses on revitalising the resin sector extracted from maritime pine to strengthen the national bioeconomy. One of the project's main components is to make resin tapping an engaging activity for forest owners so they adhere to its use. The inclusion of resin tapping as a complementary practice in maritime pine forests' management needs to align with appropriate silviculture models that allow for operation profitability and do not conflict with or impede the usual density management practices, namely intermediate thinning. Moreover, resin tapping system, to death (trees are tapped in the four years immediately preceding their cut, by thinning or final cut) or to life (wounds made over several years) with constraints on tree size (minimum tree diameter breast height =20 cm) in the latter, have to be decided and adequately considered in the life span of the forest.

To assess the economic feasibility of integrating resin tapping into maritime pine forest management, the authors defined two initial scenarios, one corresponding to planted forests and another corresponding to naturally regenerated stands (from clear-cutting or after a fire disturbance). The design of suitable silvicultural models that could accomplish the objectives was performed with the ModisPinaster growth simulator.

The identified silvicultural itineraries offer management guidelines for sustainable practices of

density regulation and resin extraction, ensuring appropriate stand development and forest health. Integrating resin tapping in maritime pine management can strengthen bioeconomy while fostering resilience, biodiversity conservation, and cultural heritage. The findings provide valuable insights for policymakers, forest managers, and researchers interested in sustainable forest management practices and the potential of resin tapping as a climate-smart solution.

Ips acuminatus – Diplodia sapinea complex increases mortality of drought-stressed pines (Pinus sylvestris) in boreal forests

T1.5 Climate-smart pine forest management

Tiina Ylioja[1]
Eeva Terhonen[1], Markus Melin[1], Juha Siitonen[1]
[1] Natural Resources Institute Finland

Abstract: Bark beetles (Coleoptera: Curculionidae, Scolytinae) have increased in their abundance over wide geographic area in Europe due to several warm and dry summers. Outbreaks of spruce bark beetle (*Ips typographus*) have regularly been in the headlines, but sudden deaths of Scots pine (*Pinus sylvestris*) have also started to attract attention in boreal forests.

Mortality of pines caused by *Ips acuminatus* was noticed for the first time in Finland in 2013. In 2021, sudden deaths of mature *P. sylvestris* in multiple locations in coastal Finland were observed, and *I. acuminatus* had obviously killed the pines.

In addition to *I. acuminatus* galleries and heavily blue-stained wood, trees were tested positive for Diplodia tip blight-disease caused by *Diplodia sapinea*. Other pathogens, such as root rot fungus (*Heterobasidion annosum*) was also observed and it likely contributed to the drought stress of pine trees.

D. sapinea is spreading unnoticed due to its asymptomatic endophytic life stage and is currently emerging as a pathogen in its northern limits. We present results on the distribution of *D. sapinea* expanding northwards in Finland combined with increasing numbers of infestation spots of *I. acuminatus*.

Currently 90 percent of the studied *I. acuminatus* infestations have been positive for *D. sapinea*. Bark beetles that are attracted by host volatiles may sense also compounds released by fungi in host trees. Therefore, we aim to investigate whether there is causality in the interrelation or whether the two species are both attracted to drought and/or heat stressed pine individuals.

Information presented calls for further studies and can be used in both risk assessment and management guidelines to support adaptation to climate change.

Learning from an unprecedented mortality event induced by extreme hot-drought in planted pines in Argentina to support climate-smart practice

T1.5 Climate-smart pine forest management

Gabriel Gatica[1]
Javier Gyenge[1, 2], Nardia Bulfe[3], Norberto Pahr[3], **María Elena Fernández**[1, 2]
[1] UEDD Instituto de Innovación para la Producción Agropecuaria y el Desarrollo Sostenible (IPADS Balcarce, INTA CONICET). Grupo de Ecología Forestal, EEA Balcarce, AER Tandil, Argentina.
[2] International Associated Laboratory FORESTIA, INRAE France-INTA Argentina
[3] Instituto Nacional de Tecnología Agropecuaria (INTA). Grupo Forestal, EEA Montecarlo

Abstract: In contrast to studies focused on natural forests, little evidence exists on the impact of "hotter-drought" events on commercial forestry species planted outside their native range. Here, we report an unexpected and regionally-distributed tree mortality event that occurred recently in commercial pine species across the Mesopotamian region of Argentina, South America. The event was associated with a hotter-drought period during the 2021-2022 warm season preceded by three years of drought and was spatially heterogeneous at regional and local scales. We aimed to elucidate the mortality timing, rate, and magnitude associated with environmental and stand characteristics at local scale to determine which conditions make these productive systems more vulnerable to extreme climatic events. We used high-resolution (10 m) maps based on Sentinel-2 multispectral images to estimate canopy mortality from November 2021 (corresponding to the first field mortality observations) to October 2022, in *Pinus* spp plantations (~25,000 ha) installed in grassland areas. Most (90%) of the stands belong to *P. taeda*, which was also the most affected species at regional level. We found that spatio-temporal heterogeneity in canopy mortality was mainly associated with spatial variation in site quality, but not in stand age and size. Higher maximum accumulated, earlier, and advancing faster canopy mortality was observed in shallow soils (with a rocky impediment at about 50 cm) where soil water availability would probably be scarce and low-lasting. In contrast, the lowest accumulated canopy mortality (near zero during the study period) occurred in stands located on depressed and waterlogged landscape units. Intermediate levels, delayed and slowed canopy mortality were observed in deep soils (>1 m), but within them, higher accumulated mortality was observed in those associated with a shallow water table, where trees developed a shallow rooting system. We here provide evidence showing that at the landscape level, those sites allowing a deeper rooting development and/or where soil water availability is expected to be higher and long-lasting could represent the areas more suitable for climate-smart pine management.

Natural regeneration of Scots pine under varying shelterwood densities in the context of climate change

T1.5 Climate-smart pine forest management

Matej Domevscik[1], Mikael Andersson[2], Karin Hjelm[1], Ulf Johansson[3], Kristina Wallertz[2], Urban Nilsson[1]
[1] Swedish University of Agricultural Sciences, Southern Swedish Forest Research Centre, Sweden
[2] Swedish University of Agricultural Sciences, Asa Experimental Forest and Research Station, Sweden
[3] Swedish University of Agricultural Sciences, Unit for Field-based Forest Research, Sweden

Abstract: During the last few decades, regeneration of Scots pine (*Pinus sylvestris L.*) in southern Sweden has decreased in favour of planting Norway spruce (*Picea abies*). Majority of the area regenerated with Scots pine is planted, whereas natural regeneration and direct seeding are uncommon. However, in line with the increased need for site adaptation, some of these alternative regeneration methods may still be of interest, especially in the context of climate change. Therefore, the objective of this study was to evaluate the effects of mechanical site preparation and shelterwood density (0, 100 and 200 stems/ha) on establishment of naturally regenerated Scots pine. The study was based on empirical data from two adjacent sites located in southern Sweden (57.06°N, 14.39°E), both of which were fenced. On site I., a total of 1286 seedlings were mapped and monitored annually over a period of 4 years (2017-2020). Results from the last inventory showed that the total seedling density was positively affected by mechanical site preparation and shelterwood density. Additionally, we observed the effect of 2018 drought year, where rich seedfall did not result in abundant germination in the same year. Instead, most of the germination was delayed until 2019, likely due to the unfavourable growing conditions caused by the severe drought. On site II., 667 seedlings were followed for 3 years (2020-2022), where, similarly to site I, mechanical site preparation had a significantly positive effect on recruitment of Scots pine seedlings. The effect of shelterwood density was however less pronounced than in site I. Overall, we show that natural regeneration of Scots pine is possible in southern Sweden, however the method is sensitive to site conditions and environmental variables, especially drought.

Stand structure and growth change according to the long-term repeated investigation of Korean white pine plantations in South Korea

T1.5 Climate-smart pine forest management

Sang Hyun Jung[1]
Yeongwan Seo[2], Heejun Jin[1], Daesung Lee[3], Jungkee Choi[1]
[1] Department of Forest Management, Kangwon National University, Chuncheon 24341, Republic of Korea
[2] Institute of Forest Science, Kangwon National University, Chuncheon 24341, Republic of Korea
[3] Natural Resources Institute Finland (Luke), Latokartanonkaari 9, 00790 Helsinki, Finland

Abstract: This study was conducted to compare the growth change patterns and find out the stand structure of Korean white pine (*Pinus koraiensis*) in South Korea using long-term repeated monitoring. The data were collected from three permanent plots in the Korean white pine plantations located in the North Central region of South Korea (Gangwon Province) for a period of 41 years (1981~2021) with 9 measurements by plot. The target plots were established between 1981 and 1984; average stand age of 49 years according to 2023. The climate in the study area is temperate characterized by hot and humid in summer and low temperatures in winter. Thinning treatments were conducted based on qualitative and quantitative considerations, with initial thinning performed to promote stand development and subsequent thinning aimed at pest prevention and forest tending. The size of the plots is 0.05 hectares (50 m × 50 m), and The growth factors such as diameter at breast height (DBH), height, crown width, crown class, as well as site factors including aspect and slope, were collected to figure out the growth change of the trees. Total increment (TI), mean annual increment (MAI), and periodic annual increment (PAI) of DBH, height, basal area, and volume were calculated for each plot, and then the growth patterns and allometry were analyzed. The results showed a consistent increase in TI with increasing stand age for DBH, height, basal area, and volume. MAI of DBH and height was increased, while the PAI showed a decreasing trend after the specific point, resulting in a crossover pattern. Although the monitoring period for growth analysis might be relatively shorter compared to other countries, this study holds significance in analyzing the long-term growth changes of Korean white pine considering the average stand age in South Korea. Furthermore, as the age class of plantations in South Korea is gradually distributed more at the stage of mature forests, the results of this study can offer fundamental information for future research on the growth of older stands in South Korea and the development of silvicultural manuals.

Stone pine shows no trade-offs between growth and survival over its distribution range

T1.5 Climate-smart pine forest management

[2] Univ. Bordeaux, INRAE, BIOGECO, F-33610 Cestas, France

Abstract: In the current context of rapid climate change, understanding adaptation mechanisms and tolerance thresholds to climate in forest tree species is essential for the management of forest genetic resources. The distribution of forest tree species may reflect a trade-off between the populations' growth potential and survival in harsh environments or under limited resources such as at climatic margins.

To test this hypothesis, we focused on stone pine, a Mediterranean conifer largely used for restorative afforestation and landscaping, thanks to its capacity to thrive in full sunlight and its resilience to drought and heat, providing a significant potential for increase the climatic resilience of Mediterranean woodlands. Despite its sparse populations scattered over the Mediterranean area from the Atlantic coast in Portugal to the shores of the Black Sea and Mount Lebanon, the species is characterized by a limited intraspecific genetic variability and high phenotypic plasticity. We used data from an international network of 10 common gardens established in France, Spain, and Tunisia in the 1990s, testing 56 provenances (16,545 tree individuals) covering the species distribution range.

We tested single trait models for height growth and mortality, and a multi-trait model for height growth with mortality as a covariate. Results showed a marginal effect of the provenance on single trait models that is consistent with previous studies. The multi-trait model revealed that growth decreased in sites with increased mortality for all populations, disregarding hence a clear trade-off at least at the studied trial sites. The lack of adaptive differentiation observed among provenances is valuable for the management of ecosystem services this species provides and for the conservation and use of its genetic resources.

Surviving volcanoes and fires and perishing from drought. Effect of climate change and lack of management on pine plantations

Abstract: Episodes of drought-induced forest dieback in conifer forests have been observed in the last decades worldwide, and are likely to become more frequent in the future as a consequence of increasing aridity. Pinus canariensis is an endemic pine to the Canary Islands, able to resprout after severe injury as shown by surviving trees after the eruption in La Palma in 2021. However, during the last decade, a generalized decline of the species in plantations located in the island of Tenerife at altitudes between 1800 and 2200 m has been observed. These reforestations were carried out between 1946 and 1950 and maintain densities ca. 800 trees ha^{-1}. To understand the causes and identify the possible physiological mechanisms involved in the decay, we classified the pine stands according to the degree of affection following an altitudinal gradient, establishing plots at 1,850, 1,950 and 2,050 m on the windward and leeward sides of increasing level of decay. In addition, a plot was established at 1,750 m without signs of decay. Radial stem growth was measured continuously using point dendrometers and physiological measurements were made on healthy and decayed pines.

Trees in the control plot maintained higher values of water potential in summer, while the most stressed trees, with the highest rates of electronic transport, were found in the highest plots, where decay was more intense. We found no significant differences between vigorous and decayed trees in water potential or gas exchange, suggesting that the photosynthetic capacity of remaining needles in decayed (heavily defoliated) trees is not related to tree vigor. However, we observed higher radial growth in vigorous (low defoliated) trees than in decayed trees. We found that daily and annual changes in growth are good indicators of forest decline. Moreover, the generalized lack of cones and regeneration across the altitudinal gradient can compromise the future of pine forests at high elevation in the island. To increase the availability of water and nutrients, two types of thinning intensity were suggested, 50% and 70% of basal area, with and without enrichment of native understory species to study whether more diverse forest are more resilient.

Wildfire, Management and Heatwaves: Conifer Tree Regeneration in a Changing Climate

T1.5 Climate-smart pine forest management

Theresa S. Ibáñez[1]

[6] Uppsala University, Department of Ecology and Genetics, Sweden

Abstract: Wildfires have a pivotal role in boreal forests by sustaining forest regeneration and ecosystem dynamics. However, the warming climate has escalated the fire regimes in the boreal forest over the past decade. Consequently, the warming occurring after a fire can create new environmental conditions that pose challenges to the growth and survival of tree seedlings. Implementing management interventions that mitigate these effects holds the potential to counterbalance the impacts of fire severity and warming.

To gain novel insights into how conifer tree regeneration responds to multiple environmental drivers, we performed a field mesocosm experiment. The experiment was conducted within a post-wildfire area located in Västmanland, Sweden, where a severe wildfire took place in 2014. We focused on investigating the interactive effects of fire severity, salvage logging, experimental warming and the presence of understory shrubs on different provenances of planted *Pinus sylvestris* and *Picea abies* seedlings. We found that low fire severity, when combined with non-logging operations, resulted in suboptimal aboveground growth of conifers. Meanwhile, in areas characterized by high fire severity, the practice of salvage logging showed no apparent impact. Further, experimental warming and the removal of ericaceous shrubs increased aboveground seedling biomass, irrespective of fire severity or management treatment. This implies that augmented light accessibility and reduced resource competition from the understory vegetation perform vital functions in promoting conifer seedling growth. The diminished impact of logging in stands with high fire severity can be attributed to factors such as high tree mortality and the open canopy resulting from intense wildfires. Additionally, our study indicates that post-fire warming may expedite the recovery rate of conifer seedlings, regardless of the severity. This study endeavors to enhance our ability to predict the underlying mechanisms driving post-fire conifer regeneration, which are influenced by a multitude of factors such as fire severity, logging activities and the impacts of global warming. By unraveling the complex interactions among these variables, we provide valuable insights that can guide the development of post-fire plantation strategies. These strategies hold significant promise in fostering sustainable regeneration practices, thereby mitigating the risks associated with regeneration shortcomings in an ever-evolving future.

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Adapting Mangroves to Sea-Level Rise: A Framework Based on Species Traits and Vulnerabilities

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Michael Jenke[1]
Aor Pranchai[1]
[1] Department of Silviculture, Faculty of Forestry, Kasetsart University, Thailand

Abstract: Sea-level rise (SLR) presents an emerging threat to mangrove ecosystems and other coastal forests worldwide. These ecosystems provide numerous ecosystem services to support local livelihoods, biodiversity, and climate change mitigation. Recognizing this vulnerability, adaptation strategies have begun to emerge. However, strategies should consider the varying vulnerability levels among mangrove species given their unique environmental tolerances, regeneration and growth potential, and other functional traits. In this conceptual study, we developed an adaptation framework that integrates (1) the functional traits of mangroves, (2) their vulnerability to SLR as a function of exposure, sensitivity, and adaptive capacity, and (3) the effectiveness of adaptive measures.

Our findings underscore that resistance-oriented adaptive measures may shield mangroves from SLR-induced alterations by promoting sediment accretion, reducing erosion, and fostering forest health. Meanwhile, resilience-oriented adaptive measures aim to facilitate the recovery from SLR-induced disturbances and assist in the landward migration of mangrove species through interventions such as gap thinning. Transformation-oriented adaptive measures encourage substantial alterations in the socio-ecological system, embracing natural colonization processes and proactively introducing mangroves beyond their current range. Thus, a multifaceted adaptive approach is instrumental in preserving the species composition, forest structure, and, consequently, the ecosystem services provided by mangroves, including their potential to act as carbon sinks. Our analysis revealed that the long-term effectiveness of these measures differs according to SLR rates and is further modulated by the functional traits of mangrove species and the local site conditions. Thus, site- and species-specific measures should be prioritized in coastal management plans over generalized solutions. Otherwise, less-adaptive species might be lost in favor of more adaptive mangrove species. Furthermore, a keen eye is needed for potential maladaptive measures, such as focusing on the establishment of monoculture plantations.

By considering a range of adaptive measures, managers of mangrove ecosystems can respond to SLR and help to ensure the long-term health and productivity of mangroves. Although this trait-specific approach derived from our conceptual study is promising, further empirical research and monitoring are required to assess its effectiveness in specific locations. Such research could also enable the application of this approach in similar coastal forest ecosystems threatened by SLR.

Analysis of the development of new governance approaches for the provision of mangrove forest ecosystem services. Five case studies in Colombia

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Stefan Sorge[1, 2]
[1] Humboldt University Berlin, Natural Resource Management, Germany
[2] Corporation Center of Excellence in Marine Sciences (CEMarin)

Abstract: Little is known about the emergence and development of novel governance approaches for mangrove forest ecosystem services (MFES) provision and their conservation, what drives them, and how they can be fostered to serve as nature-climate solutions. Existing frameworks often deal with single aspects of resource management and thus fail to assess processes, multi-level influences, and interacting dimensions and factors in a system-based understanding. I will present the conceptual foundation and empirical application of an adapted Social-Ecological System framework with additional elements that builds on the idea of complex and interlinked social-ecological-technical-forestry-innovation systems (SETFIS) that allows for the identification of key factors for revealing MFES dynamics to understand the emergence and development of such governance innovations Colombia. The development of the framework was applied previously to many case studies in diverse biogeographical regions for knowledge co-creation as alternative governance and business approaches to current timber-based models. Results out of its application served to further develop the framework and its holistic applicability. The application of the SETFIS framework in five Colombian cases, such as Vida Manglar, a community mangrove reforestation compensation and biodiversity conservation scheme, and Playa Viva, a community managed mangrove forest focusing on conservation and tourism, proofed and validated previous methodological and content-related results of this holistic applicability in the context of coastal blue forests in Colombia. While we observed common patterns in the influencing factors that seem to play a key role in all the cases analysed, we were also able to identify particular conditions for the design and work of governance. These relate to their individual historical development, disruptive events, local context, knowledge sharing, policies and incentives. The key impact lies in assisting the management of mangrove governance innovations, shedding light on their emergence and potential for future development.

Arthropod Diversity and Functional Composition Across Mangrove Areas of del Carmen, Siargao Island, Philippines

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Sheryl Yap[1, 2, 3]
Cristian Lucañas[2, 3]

[3] Biological Sciences Division, National Research Council of the Philippines, Department of Science and Technology, General Santos Avenue, Bicutan, Taguig City, Philippines

Abstract: Mangrove species diversity is well known for larger animals and plant, but little is known about mangrove insects and their significance and yet they perform important roles in the ecology of the habitat. The present study was conducted to determine the diversity of insects associated with mangrove. Eight sites were established based on the geographical location in July 2019 and October 2022. One malaise trap was set up for each site for a total of eight traps per sampling period. A total of 11 insect orders, 3 non-insect hexapod orders, 297 morphospecies, and 1737 individuals were collected and identified. Orders Hymenoptera and Diptera (61 taxa) is the most specious followed by Coleoptera (39), Lepidoptera (34), Hemiptera (16), and Psocodea (12). Phase 1 sampling is observed more diverse than Phase 2 sampling. Phase 2 sampling is more even than the Phase 1 sampling, but Phase 1 sampling is more abundant than the Phase 2 sampling. Viewdeck Phase 1 sampling has the highest diversity. Decomposers, herbivores, pollinators, predators, and parasitoids were observed as arthropod functional guilds in the mangrove ecosystem. This study has shown that the mangroves of Del Carmen have a vast array of insects which will contribute to their biodiversity data and subsequent conservation and management of ecosystem in the Siargao Island.

Blue Forests Unveiled: Mapping, Monitoring, and Reporting the Global Distribution and Anthropogenic Changes of Tidal Freshwater Forests and Mangroves

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Lola Fatoyinbo[1]
[1] Biospheric Sciences Laboratory, NASA's Goddard Space Flight Center

Abstract: The distribution of Blue Forests - Mangroves and other tidally inundated forests- has changed extensively over the past 60 years, mainly due to direct anthropogenic causes such as deforestation, conversion to agriculture and aquaculture, urbanization, draining, and other modifications to the hydrology. Remote Sensing based mapping has been integral in better understanding the distribution and change of forest, Blue Carbon and Tidal ecosystems, with increasing availability of global and regional datasets that can be used for management and policy decisions, as well as scientific analysis.

Mangroves forest distribution has been extensively mapped and studied on local to global scales, starting with publications such as the Global mangrove Atlas (Spalding et al, 2008), the USGS Global Mangrove Distribution Map (Giri, 2011) and now with efforts such as the Global Mangrove Watch (Bunting et al, 2023). Their status as high carbon density Blue Carbon ecosystems has also resulted in extensive scientific research, advocacy and conservation efforts focused on mangroves. While Mangrove loss has been extensive in the past century, with estimates of 50% of original mangrove cover loss, remote sensing studies show that deforestation rates have declined since 2000. The distribution of changes is highly variable across the globe, depending on socioeconomic, political, climate and other environmental drivers. In this talk, we will provide an overview of the drivers of global mangrove extent and carbon distribution, an overview of historic and current change hotspots, and what is driving changes we are seeing now and into the future.

Other tidally inundated forests are challenging to map using Satellite data and have not historically been mapped on a global scale. Here we will highlight the existing datasets, what gaps exist and how we may be able to address these gaps using Remote Sensing. Through an overview of the advances in data analysis, new satellite missions, data and models, we will describe a framework for the development of maps of blue forest.

Carbon Stocks Assessment of Selected Mangrove Plantations in the Philippines

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

LOURDES BREVA[1]
Jose Allan Castillo[1]
[1] Ecosystems Research and Development Bureau

Abstract: Tropical forests play an important role in the climate change as sources and sink of carbon. Thus, mangrove forests have significant role in mitigating the climate change problem. This study was conducted to determine the biomass, carbon stored in the biomass and sediment and carbon sequestration/accumulation rate in selected plantation stands of mangrove in the country. Quadrat Sampling Technique was used with 10m x 10m quadrats established.

Results of the study showed that the mangrove plantation has a mean biomass carbon density of 164.15 tC/ha with ranges from 70.20 tC/ha to 293.03 tC/ha. Aboveground biomass constitutes 73% on the average to the total biomass with belowground biomass 27% of the total. The carbon held in the biomass of the plantation stands which are dominantly *Rhizophora*s in all of the four sites investigated ranges from 32.99 to 137.72 tC/ha or 77.15 tC/ha, on the average. Soil however, accounted to 113.44 tC/ha, on the average and ranges from 57 to 158.15 tC/ha. The combined carbon held by the biomass and upper 30cm depth of sediment in the mangrove plantations studied is on the average 190.59 tC/ha and ranges from 117.56 to 262.45 tC/ha. The total carbon value is equivalent to 699.45 tons of carbon dioxide per hectare that are held and stored in the aboveground biomass, belowground biomass and sediment of the mangrove plantations under study. The yearly rate of carbon accumulation in the biomass of four mangrove plantations studied based on carbon stock and plantation age is 4.01 tC/ha on the average and ranges from 2.75 to 5.15 tC/ha/year.

In conclusion, this study demonstrated the potential of selected mangrove plantations in the Philippines in light of climate change mitigation as a strategy to combat climate change. This implies that mangrove can offer a great potential carbon sink.

Key Words: mangrove, plantation, biomass, carbon density

Climate Change Mitigation Potential of Philippine Mangrove Forests and Carbon emission arising from mangrove deforestation

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Jose Alan Castillo[1]
Sedric Caliwagan[1], Judith Fortus-Castillo[2]
[1] Ecosystems Research and Development Bureau, Department of Environment and Natural Resources, Forestry campus, Los Banos, Laguna, Philippines
[2] Forestry Development Center, College of Forestry and Natural Resources, University of the Philippines, Los Banos, Laguna, Philippines

Abstract: Mangrove forests provide many ecosystem goods and services, and are an important carbon sink in the tropics. However, despite the numerous goods and services they provide, mangroves are being depleted at alarming rates. Carbon stocks in biomass and soil as well as the potential C emissions owing to land use change in mangrove are important parameters to quantify, monitor in the mangrove area, and are vital inputs for assessing the impact of mangrove conversion on the C budget. While the studies are growing on estimating the Ecosystem Carbon Stock of mangroves and C losses arising from their conversion to other land uses, very few reports are available at the country level, including in the Philippines. To address these gaps, this study was conducted in 11 selected coastal areas of the Philippines, spread across the major islands of Luzon, Visayas and Mindanao with the following objectives: 1) to quantify and evaluate the Ecosystem Carbon Stocks of mangrove forest; and 2) to estimate the potential C losses owing to conversion of mangrove forest to other land use. Intensive field assessments combined with laboratory analysis were implemented to achieve the above objectives.

Results of this study revealed that the mean Ecosystem C stocks of mangrove forests based on was 529.7 MgC ha^{-1} (1,944 tCO_2eq ha^{-1}). The potential contribution of our Philippine mangrove to global Climate Change mitigation could translate to about 589.7 M tCO_2eq based on its 2019 total area of 303,381 ha. The mangroves of Palawan had the highest C stock. Potential C losses was 176 MgC ha^{-1} (645.9 tCO_2eq ha^{-1}) or 22% - 25% decline in Ecosystem C stock when mangroves are converted to other land uses.

This study has shown the relatively enormous amount of Carbon stocked and stored in the biomass and soil of Philippine mangroves and suggests the need to protect them from human disturbance. The decrease in C stocks indicates C losses and emissions owing to the conversion of mangrove forests to other land uses. Future research works and other implication of the results will be discussed.

Complementing Natural Regeneration with Active Planting: A New Approach to Mangrove Rehabilitation in the Philippines

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Abstract: Natural regeneration and active planting are two contrasting approaches to mangrove rehabilitation, each with its own advantages and disadvantages. In the Philippines, most of the rehabilitation initiatives are focused on active planting and a harmonized guideline in rehabilitating Abandoned Brackish Water Fishponds (ABFs) is still needed. A total of sixteen (16) ABFs across different climatic types in the Philippines were assessed in terms of initial mangrove establishment. This study was done to determine the environmental conditions suited for natural regeneration and active planting in ABFs. Multiple Regression Analysis shows that natural regeneration is significantly influenced by surface elevation while other factors such as water pH, salinity and distance to mangrove stands also play a role in natural recruitment. The model shows that at elevations of >0.43 masl, sufficient numbers of mangrove recruits are observed, making it conducive for natural regeneration. Lower elevation areas which are less suitable for natural recruits (<0.43 masl) require interventions such as active planting, preferably with *Avicennia marina*. %Survival of planted seedlings was not significantly different between the lower and higher elevation levels. Results further provide empirical evidence of the suitability of ABFs for rehabilitation. By maximizing the benefits of natural regeneration and lesser cost for active planting, the complementation of these approaches provides an ecological and sustainable, yet practical option to mangrove rehabilitation.

Do tree-mediated greenhouse gas emissions offset blue carbon in mangroves?

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Julio A. Salas-Rabaza[1, 2]

[5] Universidad Autónoma Metropolitana (UAM), División de Ciencias Básicas e Ingeniería, México

Abstract: Mangroves ecosystems have a great potential as a blue carbon reservoir, especially in its soils. Conversely, some of that carbon is emitted, mainly as methane (CH_4) and carbon dioxide (CO_2), through the soil-plant-atmosphere continuum. Although many studies have focused on greenhouse gases emitted from soils, emissions could be being underestimated because trees also mediate soil-produced CH_4 and CO_2, especially by their aerial roots that act as snorkels for trees in flooded environments. Moreover, magnitudes, patterns, and drivers of these emissions remain poorly understood. In this regard, we estimated the spatiotemporal variation of CH_4 and CO_2 from tree stems and aerial roots (stilts and pneumatophores) in three mangrove species along different mangrove ecological types during both rainy and dry seasons. We also searched to elucidate the contribution of mangrove trees to local carbon budget in Ría Celestún Biosphere Reserve (Mexico) and the role of tree anatomy in the transport of these gases. Overall, CH_4 and CO_2 emissions were dependent on the species, tissues, exchange interfaces, and seasons. Dwarf *Rhizophora mangle* had the highest CH_4 emission rates from stems and stilt roots. Basin mangrove forest contributed to increased CO_2 fluxes through the stems and pneumatophores of *Avicennia germinans* and *Laguncularia racemosa*. Rainy season limited CO_2 fluxes but enhanced CH_4 emissions. CH_4 and CO_2 were higher in near-ground tissues such as third-order stilt roots in *R. mangle* – which had a higher aerenchyma tissue – both in dwarf and hammock mangrove forests. CH_4 were positively correlated with lenticels number, but negatively with wood density, while CO_2 was dependent of salinity and sediment temperature in pneumatophores. Also, the number of pneumatophores explained more than half the variation for CO_2 fluxes in fringe mangroves at water-air and sediment-air interfaces. To date, stem CH_4 emissions have been studied in eleven mangrove species worldwide. Therefore, we encourage to accurate our local-to-global carbon estimations including trees into our current carbon budgets and models. It is also valuable to remark that mangrove trees act as CH_4 sources or sinks, depending on physicochemical and micro-environment conditions, thus they must be understood from their basis on plant physiology and anatomy.

Effects of watering regimes and soil media content on performance of propagules and seedlings of three mangrove species of the Kenyan coast

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Emmanuel Karisa[1]
Gladys Rutto[1], Henry Komu[1], Stanley Nadir[1], Simeon Mwadiga[1]
[1] Kenya Forestry Research Institute

Abstract: Mangrove restoration should be sustained in Kenya in order to maintain the ecological functions of the ecosystem. Restoration through reforestation or planting faces a myriad of challenges among them; inadequate planting materials which are sometimes of poor quality. Therefore, knowledge on mangrove nursery establishment and management is essential in providing sufficient and quality planting materials for sustainable restoration initiatives especially where natural regeneration is unsuccessful. This study therefore, sought to determine the effects of nursery watering regimes and soil media content on the performance of seedlings and propagules of three key mangrove species at the Kenyan coast: *Rhizophora mucronata, Ceriops tagal* and *Bruguiera gymnorrhiza.* Propagules and Seedlings were planted in three soil media i.e. silt-clays (mud), clay-sands (muddy-loams) and sands (pure sand texture). Both planting materials were tested under different watering regimes i.e. flooded by tidal events and in a floating nursery where propagules and seedlings were watered using sea water. Growth performance was measured by germination of (propagules), height, girth, number of leaves and internodes of seedlings.

From preliminary results; The effect of Nursery type, Mangrove species and Soil media significantly influenced seedling's height, diameter, number of leaves (foliage) and number of internodes developed ($P < 0.05$). *Rhizophora mucronata* recorded the highest shoot height and diameter while *Ceriops tagal* the least. Muddy textured soil media with high content of silt and clays significantly affected growth by producing higher shoot heights, diameter, number of internodes but not number of leaves compared to sandy textured soil media. This trend in performance was also observed in propagules and being statistically significant. Propagule germination occurred within the first month of sowing. Rhizophora mucronata propagules had the highest germination, height, diameter with no difference between *Ceriops tagal* and *Bruguiera gymnorrhiza*. Silt-clay soil media had a higher germination, height compared to sand. In conclusion, the flooded nurseries are recommended with silt-clayey mud being preferred soil media for raising *Rhizophora, Ceriops* and *Bruguiera* sp seedlings for restoration initiatives.

Empowering Coastal Communities for Effective Mangrove Restoration in Fiji

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

HWANOK MA[1]
Sanjana Lal[2], Aporos Ramulo[3]
[1] ITTO
[2] Conservator of Forests, Ministry of Forestry, Fiji
[3] Ministry of Forestry, Fiji

Abstract: Coastal mangrove restoration holds immense potential as a nature-based solution for climate mitigation and adaptation, making it a key contributor to Fiji's economy. Fiji boasts the third-largest area of mangroves in the Pacific, covering approximately 46,600 hectares. The Ministry of Forestry in Fiji has taken significant steps to promote the rehabilitation and sustainable management of coastal and mangrove wetlands. These efforts include establishing demonstration sites, engaging with communities and stakeholders to enhance decision-making processes, developing national guidelines on mangrove use and management, and raising awareness about the importance of sustainable mangrove management. The Community-based Management Guideline for Mangrove Rehabilitation and Restoration in Fiji, prepared based on successful pilot activities by the Ministry of Forestry, aims to empower coastal communities especially women groups, to effectively manage their mangrove resources.

Benefits of Sustainable Mangrove Management: By promoting sustainable use of natural resources, Fiji's Ministry of Forestry recognizes the crucial importance of benefiting both people and the environment, especially in the face of current global climate change challenges. Their collective efforts generate a transformative approach that involves local communities in forest management, leading to their well-being and enabling effective climate change mitigation. This approach has the potential to benefit numerous coastal communities across Fiji. The enhanced version emphasizes empowering coastal communities through good technical guides with the aim of the Community-based Management Guideline. This guideline serves as a "how-to" manual, enabling communities to improve their mangrove resource management. The updated text highlights the transformative approach taken by the Ministry of Forestry, which engages local communities in forest management. This approach not only combats climate change effectively but also has wide-ranging benefits for coastal communities in Fiji. By incorporating these improvements, this provides a more comprehensive and solid overview of coastal community-based mangrove restoration in Fiji.

Establishing tipping point in mangrove ecosystem function

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Gladys Rutto[1]
James Ndufa[1], Chemuku Wekesa[1]
[1] Kenya Forestry Research Institute, P.O. Box 20412 – 00200 Nairobi

Abstract: Mangrove forests in Kenya are not pristine and the area under them is reducing at an alarming rate due to overexploitation, pollution mainly through oil spills and sewage discharge, conversion to agricultural land, siltation, construction of aquaculture ponds and urban development. Development of rehabilitation and restoration technologies is needed to save Kenya's mangroves from further loss. This study sought to establish indicators of degrading mangroves, determine tipping points in mangrove ecosystem where ecosystem functioning is lost irreparably with an aim of developing evidence based restoration approaches peculiar to different sites. The study revealed that sites dominated by *Rhizophora mucronata* and *Ceriops tagal* were most degraded as species are targeted for poles, high seedling density and low microbenthic populations were observed in degraded sites. Oil spillage and siltation affected mangroves leading to degradation and loss of specific mangrove species. Recovery of mangrove forests degraded as a result of oil spillage and siltation was slow and difficult to achieve without human intervention as compared to human-overexploited sites. The results will guide development of appropriate restoration interventions that can be scaled up by stakeholders engaged in the conservation of mangrove resources.

Key words: Degradation, Ecosystem function, Rehabilitation, Restoration

Human-Driven Degradation Impacts on Mangroves in Southern Sierra Leone

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

[4] Njala University Quality Control Laboratory, Soil Science Department, Njala University, Sierra Leone
[5] Department of Natural Sciences, Manchester Metropolitan University, UK
[6] Department of Environment and Geography, Wentworth Way, University of York, UK

Abstract: Mangroves are important stores and sinks of blue carbon, foster biodiversity, and provide ecosystem services supporting local livelihoods and enhancing coastal protection. However, mangroves are declining in extent and experiencing degradation due to human activities. This study investigated how different levels of human-driven degradation affect forest structure, above- and belowground carbon stocks, tree species composition, and the population structures of dominant tree species. We investigated 19 transects of different degradation levels (pristine, moderately degraded, heavily degraded) in various locations (oceanic, riverine, interior) in the Sherbro river estuary in Sierra Leone.

Results showed that pristine mangroves stored 707 Mg ha^{-1} of carbon including soils to 1 m depth, which is higher than values reported from many other regions in Africa. Degradation resulted in declining basal area, decreasing density of large trees (≥ 30 cm diameter) but increasing stem density of small trees (5-10 cm diameter). All carbon pools declined with increasing degradation across all locations. While above- and belowground carbon decreased by 96 %, soil carbon (up to 1 m depth) decreased by 44 %. Heavy degradation resulted in a change in the dominating species from *Rhizophora racemosa* to *Rhizophora mangle* across all locations. Overall, we found major effects of degradation on mangrove characteristics and minor effects of location. We urge conservation of pristine forests, restoration of degraded mangroves, and the establishment of management systems that are ecologically informed and based on a comprehensive understanding of human-driven degradation impacts.

Management and Conservation of Mangrove Species in Pagbilao Mangrove Experimental Forest, Quezon Province, Philippines

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

ANALYN PASAGDAN[1]
Judy Anne Gutierrez[1], Maria Yliese Corpuz[1]
[1] Ecosystems Research and Development Bureau, Department of Environment and Natural Resources, Philippines

Abstract: The decline of mangrove forests is indeed a pressing issue that requires urgent attention. Reforestation efforts are crucial for sustaining the productivity and genetic resources of mangroves. However, the lack of knowledge regarding superior mother trees and the ideal qualities for high-quality mangrove seedlings poses significant challenges in the Philippines. To address this problem, an inventory survey of mangrove Individual Plus Trees (IPTs) was conducted in the Pagbilao Mangrove Experimental Forest in Pagbilao, Quezon, Philippines. A total of 115 IPTs belonging to 10 families and comprising 24 species were identified ,geo-tagged, and monitored regularly. These established IPTs serve as sources of quality germplasm for the respective mangrove species.

The phenotypic qualities and phenology of the potential IPTs were monitored using the assessment method developed by the Department of Environment and Natural Resources. The identified IPTs displayed desirable characteristics such as being free from defects, having no signs of insect infestation or diseases, prolific flowering, and fruiting, vigor, and dominance. Quarterly, 3,000 quality germplasm samples were collected from these IPTs and raised in the nursery to produce high-quality planting stocks. To enhance the collection and utilization of high-quality germplasm, an Information, Education, and Communication (IEC) campaign on the value of germplasm quality should be conducted. This can raise awareness among seedling producers about the importance of superior mother trees and provide them with the necessary knowledge and skills to identify and utilize high-quality germplasm.

The development of an effective germplasm collection and distribution mechanism is necessary to increase the accessibility of high-quality germplasm from a diverse range of mangrove species. The mechanism should ensure that germplasm from superior mother trees is readily available to seedling producers and restoration projects. By implementing these measures, there can be significant progress in the restoration and conservation of mangrove forests in the Philippines, while also ensuring the availability of high-quality planting stocks for future reforestation efforts.

Mapping of the global mangrove forest governance

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Lukas Giessen[1]
Pradip Kumar Sarker[1], Fredy Polo Villanueva[1], Md Faisal Abedin Khan[2]
[1] Chair of Tropical and International Forestry, TUD Dresden, Germany
[2] Georg-August University, Göttingen, Germany

Abstract: The scholars found more than 800 definitions of forest used worldwide due to the nature of diversified goods and services that forest owns and provides for the environment. Mangrove forests then possess beyond human thinking goods and services. As a result, society creates governance mechanisms for protecting and managing those resources sustainably for their societal well-being and to fulfil their self-interests over time. On the other hand, the forest issue areas induce the society to establish the regime or regime complexes not only at the international level but also at the regional, national and local levels. These regimes involve rule makers and rule takers, the former setting and modifying, often in conflict and competition, the rules with which the latter are expected to comply. These regimes are furthered as a regime complex or fragmented global governance due to the heap of agreements and regulations that intersect concerning a particular issue or set of issues and conceptualise how the complexity of rules and institutions can, in and of itself, shape the politics of cooperation.

This paper applies the institutional elements research technique to map the global mangrove forest governance. The core-institution method was used to determine which elements were part of the regime. It analysed their policy goals to identify potential synergistic and conflicting relationships among them. The online-based secondary data sources, e.g., regimes websites, will be used for this research. The result assumes the fragmented nature of identified regimes, which will be synergistic and conflicting interactions between regime elements. A deeper analysis may suggest that it ranges from a positive, affirmative assessment of fragmentation to a rather negative one.

Monitoring greenhouse gas emission in different mangrove management: Lesson from Berau, East Kalimantan, Indonesia

Abstract: Mangrove ecosystems provide essential ecosystem services for climate change mitigation that warrant protection and restoration as they keep a huge amount of carbon. It is particularly critical in Indonesia, home to about a quarter of the world's mangrove ecosystems. A national study indicates that avoiding mangrove degradation and restoring mangroves can reduce greenhouse gas (GHG) emissions by up to 67 $TgCO_2e\ yr^{-1}$.

Unfortunately, vast expanses of these mangroves have been deforested, degraded, or converted for other uses. These anthropogenic activities disturb the ecosystem's stabilization and release GHG emissions into the atmosphere. Thus, accurate prediction of the values of mangrove conservation and restoration requires knowledge of the carbon dynamics of intact and degraded mangroves. Our study aims to measure GHG fluxes from natural and managed mangrove ecosystems as well as aquaculture practices in Berau, East Kalimantan. The natural mangrove is located adjacent to the sea, while the managed mangrove areas comprise controlled mangroves. In aquaculture practices, we established monitoring plots in the pond embankment and shrimp ponds. We measure CO_2 and CH_4 fluxes using an LI-COR portable trace gas analyzer equipped with a smart chamber. We installed trenching to quantify heterotrophic emissions in the natural and managed mangrove areas. Meanwhile, we did not trench in the pond embankment and used floating chambers in the shrimp pond.

We found that total gas emission fluxes were highest in the natural mangrove and the lowest in the aquaculture practice plots. We may assume that the carbon was removed during the aquaculture establishment. More information on carbon stock is crucial to understand better the contribution of aboveground carbon to total emissions. Sustainable aquaculture is essential to bridge the needs of mangrove restoration and the community's well-being.

Recognizing the the of mangrove forest as a nature-based climate solution: Empirical evidence from Sundarbans mangrove forest

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Sharif Mukul[1, 2]
Mohammed Abu Sayed Arfin Khan[3], Sanjeev Srivastava[2]
[1] United International University, Bangladesh
[2] University of the Sunshine Coast, Australia
[3] Shahjalal University of Science and Technology, Bangladesh

Abstract: Mangroves are increasingly regarded as a cost-effective nature-based climate solution for critical ecosystem services they provide, including habitat for terrestrial and aquatic fauna, biodiversity conservation, and protection from cyclones. it has repeatedly been claimed in the literature that mangroves store greater amounts of carbon (C) than any other terrestrial ecosystems. This claim, however, is not supported by enough empirical data, particularly from South Asia. Our study provides a comprehensive scenario of the C storage and sequestration potential of mangroves along a successional gradient in the Sundarbans mangrove forest - the world's largest contagious mangrove forest shared between Bangladesh and India. Carbon stocks and fluxes were monitored along three successional (pioneer, secondary, and climax forest) and salinity gradients (i.e. oligohaline, mesohaline, and polyhalite). We used a stratified random sampling approach, and data were collected both through destructive and non-destructive sampling. Carbon stocks were measured in tree biomass, undergrowth, litter/woody debris, fine root, and soil. Both autotrophic and heterotrophic respiration and litterfall were measured as an indicator of C flux in the forest. Our study suggests the highest C stock in the climax forest and less saline zone dominated by Sundri (Heritiera fomes), while the largest C sequestration potential is in the pioneer forest and newly accreted land dominated by Keora (Sonneratia apitala). Our study would be useful for scientists and policymakers to recognize the potential of Sundrabans forest as a nature-based climate solution.

Soil as a reservoir of blue carbon in mangrove forests - the case of Pemba Bay in Mozambique

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Ezídio Cuamba[1]
Paula Soares[2], Salomão Bandeira[3], Manuel Madeira[2]
[1] Faculty of Natural Sciences, Lúrio University, Mozambique
[2] Forest Research Center, School of Agriculture, University of Lisbon, Portugal
[3] Departamento de Ciências Biológicas, Faculdade de Ciências, Universidade Eduardo Mondlane, Mozambique

Abstract: Climate change mitigation strategies have highlighted the mangrove forest's role in carbon stock and carbon sequestration. In Mozambique, mangroves occur mainly in sheltered shorelines and river estuaries. Rising water levels, storms, and anthropogenic action (resulting in the overexploitation of resources and, in some cases, changes in land use) are some of the threats to which mangroves are subjected. Efforts are being made to preserve the Mozambique mangroves and restore the destroyed areas by introducing policies, and conservation and management strategies. In this work, the mangrove carbon stock in Pemba Bay, on the northeast coast of Mozambique, was estimated. Data were collected on fifteen inventory plots to describe the forest structure and quantify the carbon pools - considering above and belowground biomass, deadwood biomass, forest floor litter, and soil. In the inventory plots, soil samples were collected, which allowed the characterization of the soil profile up to 1.20 m according to salinity, pH, and organic carbon concentration. Six mangrove species were found in Pemba Bay - *Avicennia marina*, *Bruguierra gymnorhiza*, *Ceriops tagal*, *Rhizophora mucronata*, *Sonneratia alba*, and *Xylocarpus granatum*. *Avicennia marina* was the most frequent species. Stand density varied between 477 and 24,172 trees/ha, in the understory layer, and between 299 and 1,156 trees/ha, in the overstory layer. The organic carbon concentration, measured at different depth soil layers, showed a large range with soil depth, with the highest values in the 35-40 cm soil layer. The mangrove carbon stock in Pemba Bay was estimated to be 309 Mg ha^{-1}, with 71% in the soil (up to 1.50 m), 20% in the aboveground biomass, 6.4% in the belowground biomass, 1.6% in the deadwood biomass, and 0.9% in the forest floor layer. Pemba Bay can contribute to fulfilling Mozambique's carbon commitments, such as mangrove restoration strategies, NDC climate commitments linked to mangrove forests, as well as the extension of Mozambique's marine protected areas (MPA). A further recommendation is to align mangrove stocks and mangrove sequestration studies within Pemba Bay and beyond in Mozambique.

Study on Mangrove Vegetation in Coastal areas of Myanmar: Case study in Kyunsu Township, Tanintharyi Region and Ramree Township, Rakhine State

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Zar Chi Hlaing[1]

[1] Assistant Director, Forest Research Institute, Forest Department, Ministry of Natural Resources and Environmental Conservation

Abstract: The vegetative composition of mangrove forests and plantations in two coastal areas of Myanmar: Kyuntsu Township and Ramree Township, was investigated in this study. This study focuses on species diversity, distribution, and regeneration. Data were collected by using the circle shape of the sample plot (0.07 ha), and the distance between the sample plots is 100 m. All vegetation within the sample plot was recorded and measured the diameter at breast height and tree total height, and the regenerations were enumerated within 5 m radius subplots that lay at the center of the main plot. In Kyuntsu, all study plots were located in the natural forest area while both 4 plantations and natural forest areas were included in Ramree. The results demonstrated that Byu Oak Saung (*Bruguiera gymnorhiza*) showed the highest importance value index followed by Byu (pho) (*Rhizophora apiculata*) and Madama (*Ceriops decandra*) in Kyuntsu. In Ramree, the importance value index revealed that Madama dominated plantations and natural forest areas, followed by Byu (pho) in natural forest areas and Yae-khayar (*Aegiceras corniculatum*) in plantations. Kyuntsu had high diversity index of H= 0.83 while Ramree's natural forest site had H= 0.68 and plantation sites had H= 0.47. Totally 19 species were recorded in both study sites and, among them, 7 species were found in both study sites as the common species. Kyutsu had big-sized trees compared with both the natural forest area and plantations of the Ramree site. Significant differences were observed in GBH ($p<0.05$, $F = 57.718$) and Ht ($p<0.05$, $F = 390.030$) among the natural forest sites of both study areas. The vegetation regeneration among the study sites indicated different ($p<0.05$) but not significant. Generally, the mangrove forest in the study sites had different vegetation structural formation and species composition which could be attributed to the different agents of degradation i.e. degree of perturbations that greatly depend on human access to the mangrove area. Therefore, understanding the structure and regeneration patterns of the mangrove is critical for developing site-specific management strategies that enhance and preserves the ecological function of the mangrove ecosystem.

The positive impact of restoration and conservation: A case study of Mangroves in Mida Creek, Kenya

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Stanley Nadir[1]
James Ndufa[1], Linus Wekesa[1], Henry Komu[1], Gladys Rutto[1], Emmanuel Karisa[1], Julius Sila[2], Kenneth Mubea[3]

[2] Community Based Environmental Conservation (COBEC), Kilifi 377-80108, Kenya
[3] Digital Earth Africa, Pretoria 0087, Gauteng, South Africa

Abstract: Mangrove forests cover in Kenya represent approximately 3% of natural forest cover or 1% of national land area. Mida Creek, a tidal inlet in Arabuko-Sokoke Forest, has experienced overexploitation of mangrove forests due to human encroachment and climate change in the past. Significant efforts in rehabilitation and conservation taken place within the Creek for the last 10-15 years; however, the success in restoration has not been well quantified. Therefore, this study aimed at assessing status of mangrove cover, change and degradation in Mida Creek between 1985 to 2022 to ascertain the gains in restoration and conservation initiatives in recent years. GIS and remote sensing techniques were employed for mangrove vegetation analysis. Mangrove degradation, change and recovery over the study period was carried out by analyzing the Normalized Difference Vegetation Index (NDVI) for a period covering 37 years with 1985 as the benchmark. Satellite data for 1985, 2002, 2015, 2017 and 2022 at 30m resolution being processed with remote analysis of water extent and coastal erosion done using Normalized Difference Water Index (NDWI) from satellite imagery. From the results, mangrove cover has been on an increasing trend for the last 37 years (1985-2022). Between 1985 and 2022, mangrove cover increased by 71% from 819ha to 1404ha which translated into a rate of 1.7% per year or 15.81 ha for the last 37 years. On average. There has been an increase in dense (closed) mangrove forest from the year 1985 to 2022 with moderate or regular mangroves decreasing over time with bare lands decreasing too. The area covered by degraded mangroves in Mida Creek was 145ha against the intact or dense mangroves covering of about 1404ha on average as per the year 2022. Flooding and high energy affected Mangroves with time series analysis showing April 2015 and December 2018 recording the highest. In conclusion, there is a positive impact on mangrove restoration efforts in Mida Creek but a few challenges still exist like off-season planting, poor species site marching, pests and diseases, livestock and climate change which derail restoration

Key words: Mangroves, Conservation, Restoration, Degradation, Cover, Mida Creek.

To harvest or not to harvest Mangroves: situation analysis for Kenya

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Gladys Rutto[1]
Chemuku Wekesa[1], James Ndufa[1], Henry Komu[1], Emmanuel Karisa[1]
[1] Kenya Forestry Research Institute, P.O. Box 20412 – 00200 Nairobi

Abstract: Mangrove exploitation support livelihoods for the local people in Coastal Kenya. The government of Kenya permits regulated harvesting of mangrove products in Lamu county under the issuance of licences by the Kenya Forest Service. Exploitation is guided by products demand rather than available stock within these ecosystems. This study assessed stocking rates within management blocks where harvesting is permitted. The assessed stock mainly comprised of dominant mangrove species (*Rhizophora mucronata* and *Ceriops tagal*). The merchantable densities of the dominant species were high for Mazio and Pau utilization classes followed by Nguzo, Boriti and Fito. Pate Island swamps had the highest density of merchantable poles while Southern Swamps had the lowest proportion of merchantable stems per hectare. The results revealed that merchantable stock available in harvestable areas are below annual allowable cut targets in the ecosystem and prompts the need to promote alternative or non – extractive livelihood options such as carbon credit that is gaining prominence globally. The findings will guide the development of harvesting plans to promote sustainable harvesting of mangrove resources and prevent further degradation in areas where mangrove harvesting is being undertaken.

Key words: Allowable off –take level; Resource sustainability and stocking rates

Towards sustainable tourism in protected areas: A carrying capacity study in the Hundred Islands National Park

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Rogelio II Andrada[1]
Nathaniel Bantayan[1], Cristino Jr. Tiburan[1], Pastor Jr. Malabrigo[2], Francis Ian Gonzalvo[3]
[1] Institute of Renewable Natural Resources, College of Forestry and Natural Resources, University of the Philippines Los Banos
[2] Department of Forest Biological Sciences, College of Forestry and Natural Resources, University of the Philippines
[3] School of Environmental Science and Management, University of the Philippines Los Banos

Abstract: The Hundred Islands National Park is both a popular tourism destination and an ecologically important protected area with unique karst forest and aquatic resources. Like all protected areas in the Philippines, the Hundred Islands is mandated to prioritize biodiversity conservation among its main goals. To balance a well-established tourism industry with its novel purpose, the management must put a mechanism in place that aims to realize and maintain this equilibrium. Presently, the Hundred Islands intends to capitalize on the tourism activity that it supports to become a protected area that is financially independent in terms of supporting its conservation initiatives. The study aims to determine the critical parameters concerning environmental and socio-economic aspects that sets the carrying capacity of the area. Also, the study profiled various aspects needed in determining carrying capacity and provided strategies and recommendations in operationalizing the carrying capacity estimates and use it to harmonize tourism and scientific activity. Furthermore, various strategies on visitor management, resource management and tourism management were identified and enumerated. In the aspect of visitor management, strategies that can help in the improvement of tourism activity and at the same time minimize negative impacts of tourists to the forest and aquatic resources as well as to the local community were identified. Among these include operationalization of the carrying capacity estimates, establishment of distinct visitor flows over time and space, and improvement of signage and key information that influence visitor behavior. For resource management, strategies that guarantee a balance and complementarity between biodiversity conservation vis-à-vis economic activities inside the park are recommended.

Trade-offs between Carbon Stock and Tourism Potential in Different Mangrove Forest Types

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Aor Pranchai[1]
Michael Jenke[1]
[1] Department of Silviculture, Faculty of Forestry, Kasetsart University, Thailand

Abstract: Mangrove ecosystems are increasingly recognized for their potential as significant carbon sinks, contributing to global carbon sequestration efforts. However, efforts to maximize one ecosystem service, such as carbon storage, could potentially diminish others resulting in trade-offs. These trade-offs can have repercussions for local communities that rely on a diverse range of services from these ecosystems. In Thailand, mangrove boardwalks have emerged as popular tourist attractions, offering substantial support to the local economy. Nevertheless, the construction and maintenance of these boardwalks is costly, highlighting the need for a balanced approach to providing ecosystem services. This study aimed to examine the interplay of ecosystem services provided by three distinct forest types in a community-managed mangrove forest located in Eastern Thailand: old-growth *Rhizophora* stands, young *Rhizophora* plantations, and species-diverse back mangroves.

In a comparative analysis of these forests, carbon stock was assessed using standard biomass and soil carbon sampling methods, whereas forest attractiveness was evaluated through visitor surveys and analysis of boardwalk usage data.

Our results revealed that *Rhizophora* plantations exhibited high rates of carbon sequestration due to their rapid growth rates, making them a potential source of carbon credits. However, these monoculture plantations were found to be less attractive to tourists compared to old-growth and species-diverse back mangroves. Old-growth *Rhizophora* forests, despite demonstrating lower rates of carbon sequestration, held a high carbon stock and exhibited significant appeal to visitors. Moreover, the species-diverse back mangroves held lower carbon stock but still maintained high attractiveness.

These findings underscore the potential trade-offs in managing mangroves for carbon storage versus other ecosystem services. It suggests that while plantation-style rehabilitation of mangroves can enhance carbon sequestration capacity, it may diminish the tourism potential and affect other ecosystem services. Therefore, an integrated, multi-objective approach to mangrove conservation and rehabilitation is advocated. Such an approach must balance carbon sequestration goals with the need to maintain diverse, healthy mangrove ecosystems that continue to provide a broad spectrum of ecosystem services, including support for local economies through eco-tourism. Moreover, local communities should be involved in mangrove governance and management to strive for multi-functional mangrove management and ensure sustainable development.

Watershed factors contributing to the erosion of sandy coasts where coastal dune vegetation grows in Japan

T1.6 Coastal Blue Forests: Global Significance, Ecology, Management and Conservation

Yasutaka Nakata[1]
[1] Graduate School of Life and Environmental Sciences, Kyoto Prefectural University

Abstract: Sandy coast is one of the most important ecosystems because it has developed a unique ecosystem and has multilateral functions. Many plants adapted to the dynamic environment grow here. In addition, coastal dunes that develop on sandy coasts have attracted attention as protective barriers and buffer zones that prevent seawater from entering inland due to tsunamis and storm surges. Since the late 20th century, increased development and recreational use near the coast have caused ecological destruction and landscape degradation. Furthermore, there is concern that rising sea levels due to climate change will accelerate coastal erosion. Therefore, coastal erosion is an urgent issue for both human society and marine and terrestrial ecosystems.

Most studies of erosion on sandy coasts have used changes in the shoreline as an indicator, and little have targeted changes in the dunes behind the beach. There are also scattered studies that have measured dunes in three dimensions and measured the changing, but none have focused on multiple sandy coasts. Also, there is little study of the relationship between the changes on sandy coasts and watershed factors. This study will overcome the above issues by measuring and utilizing high-definition spatial information from high-accuracy RTK (Real-Time Kinematic) -UAVs (Unmanned Aerial Vehicles) and ALS (Airborne Laser Scanning). In this study, the amount of change (erosion and sedimentation) was calculated from the difference analysis between the DSM (Digital Surface Model) created by RTK-UAV-SfM and ALS to clarify the actual erosion of coastal dunes on the sandy coasts of Hokkaido, Honshu, Shikoku, and Kyushu, Japan. I performed a correlation analysis and generalized linear model to understand the relationship between coastal changes and Watershed variables.

As a result, there is a trend toward many coasts with erosional trends and more erosion of sand dunes. The Honshu trend toward erosion. In Hokkaido, Shikoku, and Kyushu, the amount of erosion is relatively low. Oceanic type and population density in the watershed significantly contributed to dune changes. In the future, I would like to increase the number of target watersheds, and explanatory variables to identify the actual erosion and factors contributing to it in more detail.

Assessing Collaborative Strategies for Boreal Forest Futures: Insights on Carbon, Biodiversity, and Economic Consequences

T1.7 Collaborating for boreal forests futures

Parvez Rana[1]
Artti Juutinen[1], Kyle Eyvindson[1], Anne Tolvanen[1]
[1] Natural Research Institute Finland (Luke)

Abstract: Finland and the European Union aim for carbon neutrality by 2035 and 2050, respectively. Achieving these goals necessitates innovative measures from forests to decrease net greenhouse gas emissions. We examined carbon reduction potential in the forests of Ii municipality, Northern Finland, focusing on carbon storage in living trees, deadwood and soils. The future carbon storage capacity of forests heavily depends on their management. We evaluated several management alternatives, including traditional rotation forestry (BAU) and continuous cover forestry (CCF). We also assessed the impact of these alternatives on carbon storage, biodiversity and net present value (NPV) using available data and models. Using the SIMO simulation, we predicted forest stand characteristics, carbon storage, and biodiversity indicators and NPV for 100 years Our findings suggest that the CCF management regime were more cost-effective i.e., efficiently combines carbon storage, biodiversity, and economic performances compared to BAU management regime. This study also explores how alternative forest management approaches could inform planning and decision-making processes aimed at climate change mitigation.

Carbon residence time in forest ecosystems under climate change

T1.7 Collaborating for boreal forests futures

Virpi Junttila[1]
Francesco Minunno[2], Stefan Fronzek[3], Nina Pirttioja[3], Timothy R. Carter[3], Anu Akujärvi[1], Annikki Mäkelä[2]
[1] Finnish Environment Institute (Syke), Nature solutions, Finland
[2] University of Helsinki, Department of Forest Sciences, Finland
[3] Finnish Environment Institute (Syke), Climate solutions, Finland

Abstract: Carbon residence time in forest ecosystems is an essential determinant of vegetation-atmosphere carbon interactions, reflecting the ability of the forest ecosystems to sequester atmospheric carbon and retain it bound to vegetation and soil biomass. Model predictions of carbon residence time have therefore been of importance and subject to comparisons between models and measurements, especially in relation to the global vegetation models that inform climate models about atmospheric carbon.

Carbon residence times in forest ecosystems depend on the carbon fluxes between the atmosphere and the ecosystem, mainly photosynthesis and respiration. Both depend on carbon allocation within the ecosystem: photosynthesis depends on canopy leaf area, and mass-specific respiration on the component in question. Internal fluxes of carbon, especially allocation between fine roots and wood, which is an important trade-off determined by nutrient availability, and litter input from vegetation to the soil affect the carbon allocation. Litter input can be accelerated by increasing temperatures but also by increasing tree mortality caused by increasing rates of disturbance.

In this study, we aim to quantify the impacts of climate change on carbon residence time in boreal forests. We focus on making a distinction between the underlying impacts of long-term climate change on carbon residence time in the absence of disturbance versus the impacts with disturbances due to changes in extreme weather events, that are themselves also associated with changing climate. To accomplish this, we use a process-based stand growth model, PREBAS, combined with the Yasso soil carbon model to estimate the carbon residence times in boreal forests under climate change, considering climate and CO_2 impacts on process rates and including fire damage and bark beetle damage as examples of the impacts of increased disturbance rates. We analyse the relative impacts using Impact Response Surfaces (IRS) as a scenario-neutral tool for quantifying climate change effects. We also show how IRSs of carbon residence time can be evaluated with probabilistic projections of climate change derived from CMIP6 ensembles.

Changing disturbance regimes and forest landscapes in Fennoscandia

T1.7 Collaborating for boreal forests futures

Juha Honkaniemi[1]
Niko Kulha[1], Katharina Albrich[1], Clara Antón Fernández[2], Sören Wulff[3], Per Nilsson[3], Kari T. Korhonen[1], Cornelius Senf[4], Mikko Peltoniemi[1]
[1] Natural Resources Institute Finland (Luke), Finland
[2] Norwegian Institute of Bioeconomy Research (NIBIO), Norway
[3] Swedish University of Agricultural Sciences (SLU), Sweden
[4] Technical University of Munich (TUM), Germany

Abstract: Climate change, combined with past and present land-use, is altering the structure and composition of forests worldwide. In the boreal forests of Fennoscandia, forest management and past land-use practices have been the main disturbance agents influencing forest dynamics. In addition, the frequency, severity and size of natural disturbances are expected to change with climate warming. Here, we analyzed the past disturbance regimes and post-disturbance recovery using three different datasets. First, changes in pre-and post-disturbance forest dynamics were analyzed on regional scale using National Forest Inventory (NFI) data from Finland, Sweden and Norway. A 30-year time series of NFI was sampled by selecting plots identified as disturbed in the Landsat-derived European Disturbance Maps to analyze the post-disturbance reorganization of forest structure. Second, the dynamics of forest landscapes in Fennoscandia under different disturbance regimes were simulated using the landscape simulation model iLand. Specifically, we tested the effects of changing disturbance size and frequency on post-disturbance recovery in a changing climate using Neutral Landscape Models that controlled for landscape structure and environmental conditions. Third, the recovery and forest dynamics after large-scale disturbance events were studied by combining historical records, remote sensing data and field inventory data from case study sites in northern Finland, each with circa 20 000 ha of disturbance events in early 1960s. Here, the focus was on long-term recovery in different parts of the large, continuous disturbance area and the different natural disturbance interactions that followed these events. The results of the studies indicate that the recovery of forest structure is relatively fast towards pre-disturbance conditions in many parts of the boreal Fennoscandia due to intensive management. Natural disturbance regimes have historically been dominated by low-severity, high-frequency disturbance events, but this has changed with forest management and fire suppression. Site characteristics, climatic conditions, and recurring disturbances determine recovery time, rate and pathway, but the size and intensity of the initial disturbance also plays a role. Natural disturbance regimes have a major impact on forest dynamics, and accelerating climate change, together with forest management practices, will play a significant role in determining how boreal forest landscapes will look in the future.

Climate change adaption: Identifying climate refugia for retreating boreal forest species

T1.7 Collaborating for boreal forests futures

Jonathon Winnel[1, 2]
Kristoffer Hylander[1, 2], Johan Ehrlén[1, 2], Jonathan Lenoir[3], Caroline Greiser[1, 2]
[1] Department of Ecology, Environment and Plant Sciences, Stockholm University, Sweden.
[2] Bolin Centre for Climate Research, Sweden.
[3] Université de Picardie Jules Verne, France.

Abstract: Climate change is shifting species ranges. Cold-adapted species are predicted to contract poleward at their warm range edge under climate change. One potentially important climate adaptation tool is to identify and locate places in the forest landscape where populations of these species currently occur and can continue to occur under climate change. Such places are buffered from climate change and are called climate refugia. The identification and protection of climate refugia allows time for species to persist under climate change, adapt and disperse should the climate become suitable again. However there are still a number of knowledge gaps that hamper the implementation of this climate adaption tool. The overarching goal of this project then is to understand the premises of climate refugia and fill these knowledge gaps. We investigate how cold-adapted species are distributed in relation to different microclimate gradients, what is the role of interaction between cold-adapted retreating species and warm-adapted expanding species and what is the generality of these patterns across species and communities. To answer these questions, we use miniature microclimate loggers installed across large areas of Sweden in combination with observational and experimental field studies to investigate and model the effect of microclimate on cold-adapted boreal forest plants. This project aims to provide a solid knowledge base on how to identify and use climate refugia as potentially important climate adaption tool.

Combining Active and Passive Spaceborne Measurements to Estimate Circumboreal Forest Growth

[5] Max Planck Institute for Biogeochemistry
[6] University of Maryland

Abstract: Northern Hemisphere forests are currently subject to the most rapid warming on Earth from climate change. Since the last ice-age they have stored more atmospheric carbon than they have released, but their current fate is uncertain. Here, we estimate young boreal forest vertical growth as a baseline indicator of resilience to climate warming using ~49.7 million, 20 m height of canopy (hcan, 98% height profile) geo-segments collected at night from the Advanced Topographic Laser Altimeter System (ATLAS) onboard the Ice Cloud and Elevation Satellite 2 (ICESat-2) combined with Landsat stand age data from over 224,000 scenes spanning the period of 1985 – 2020 in a *space-for-time* substitution approach. Strong patterns of growth were apparent when calculated over a 0.5° × 0.5° grid. These empirically derived estimates provide a biome wide gridded reference to constrain estimates of boreal forest vertical growth which is important to provide a reference estimate of current above ground biomass accumulation.

Development of a Climate-Sensitive Matrix Growth Model for Larix gmelinii Mixed-Species Natural Forests and Prediction of Forest Dynamics

T1.7 Collaborating for boreal forests futures

YOUJUN HE[1]
Liang Zhang[1, 2], Jianjun Wang[1], Jinghui Meng[3]
[1] Research Institute of Forestry Policy and Information, Chinese Academy of Forestry
[2] China Inner Mongolia Forest Industry Group
[3] Research Center of Forest Management Engineering of National Forestry and Grassland Administration, Beijing Forestry University

Abstract: *Larix gmelinii* natural forests, which are of great ecological and economic importance, are mainly distributed in northeast China. Sustainable management of these forests play a vital role in ecological security in northeast China, especially in the context of climate change. Forest growth models, which support forest management decision-making, are lacking for *Larix gmelinii* natural forests, hampering the prescription of forest management strategies. In this study, we produced a climate-sensitive, transition-matrix model (CM) for *Larix gmelinii* natural forests. For comparison, a variable transition model without including climate change effects (NCM) and a fifixed-parameter model (FM) were also built. We examined the performance of the CM, NCM, and FM by conducting short- (5 years) and long-term (100 years) simulations. The results showed that for short-term prediction, no signifificant difference was observed among the three predictive models. However, the long-term prediction ability of the CM under the three different RCPs was superior to that of the FM and NCM. The number of trees and basal area were predicted to increase under climate change, which might result in natural disasters, such as snow break, windthrow, and forest fire. Silvicultural practices, such as reducing the intermediate thinning interval and the enrichment planting of slow growing trees, should be implemented to mitigate the deleterious effects of climate change.

How does forest fertilization influence tree productivity of different boreal forests? An analysis of data from commercial forestry across Sweden

T1.7 Collaborating for boreal forests futures

Margaux Boeraeve[1]
Gustaf Granath[2], Björn D. Lindahl[3], Karina E. Clemmensen[4], Joachim Strengbom[1]

[2] Department of Ecology and Genetics, EBC, Uppsala University, Uppsala, Sweden
[3] Department of Soil and Environment, Swedish University of Agricultural Sciences, Uppsala, Sweden
[4] Department of Forest Mycology and Plant Pathology, Swedish University of Agricultural Sciences, Uppsala, Sweden

Abstract: Forest fertilization is a forest management technique that is often claimed to be the most effective to increase productivity in boreal forests. It is however also costly, can have negative effects on biodiversity, and may increase nitrogen leaching from the soil. To underpin the development of more cost-efficient forest fertilization regimes that encompass the goals of improved productivity while simultaneously limiting the negative impact on the environment, we conducted a study to better understand under which conditions forest fertilization stimulates tree growth the most. We used a dataset containing data from 24 839 recently harvested stands from the largest forest owner in Sweden and assessed the effect of fertilization on standing tree volume at harvest and how it varied depending on stand characteristics (stand index, stem density), climatic conditions (temperature sum) and management (thinning, stand age at harvest). We found that fertilization improved productivity, but the efficacy of fertilization was highly context-dependent. In pine-dominated stands, fertilization did not increase tree volumes in the coldest areas and in the least productive stands. In spruce-dominated stands, fertilization generally increased tree volumes in unthinned stands, but no fertilizer effect was found in thinned stands. And while the difference between fertilized and ambient stands that we found in pine-dominated stands (on average 15.8 and 17.3 m^3 ha^{-1} in respectively thinned and unthinned stands) was in line with previously reported growth responses to fertilization (13-20 m^3 ha^{-1}), fertilization responses in unthinned, spruce-dominated stands were lower (11.4 m^3 ha^{-1}). Standing tree volumes at harvest did not differ between thinned and unthinned stands when they were dominated by spruce, suggesting that in these stands, stimulated growth after thinning and/or higher natural mortality in the unthinned stands compensated for the extracted volume. Although our results are largely in accordance with current fertilization recommendations, they indicate that current practices can have economic and ecological costs that may outweigh limited benefits. Updated recommendations could both benefit forest owners and reduce potential negative side effects.

How water moves in boreal forests from snow/rainfall to tree under changing seasonal precipitation: in-situ water isotope and water flux measurements

T1.7 Collaborating for boreal forests futures

Zuosinan Chen[1]
Pertti Ala-Aho[1], Hannu Marttila[1]
[1] Water, Energy and Environmental Engineering Research Unit, University of Oulu, Finland

Abstract: High latitude regions are warming more strongly than the global average with apparent changing precipitation seasonality. The latter includes warming-induced shifts from snowfall to rainfall, more frequent rain-on-snow events, and less summer rainfall. These do not only directly change the amount and the timing of regional water inputs by reduced winter snow and more variable summer rainfall, but could also alter how water goes through and exits boreal ecosystems, e.g., snowpack formation, sublimation, snowmelt, soil water movement, root water absorption, and tree water use. In boreal forests, c. 65% of the water being 'pumped' from soil to atmosphere (evapotranspiration) is done so through tree water use (transpiration). However, how boreal tree water use strategies and the affected northern ecohydrological processes respond to the ongoing rapid change in snow and rain is not well understood. Improving this understanding is critical as boreal forests are the second largest biome worldwide and have evolved under high precipitation seasonality. Currently, for tracing water movement and the water sources involved, the stable water isotope technique is the best tool available to researchers. Compared to the discrete, time-consuming, and destructive water isotope sampling method in snow, soils and plants, in-situ and high-resolution measurements are more needed than ever to investigate tree water use strategies, especially to understand the underlying mechanisms. Therefore, for the first time in northern environments, we are applying innovative in-situ continuous measurements of stable water isotopes (non-destructive Water Isotope Probes and Picarro L2140-i isotope analyzer) and water fluxes (bi-directional heat pulse sap flow sensors, soil water content, etc.) along the water movement pathway in boreal forests, i.e., snow (snowfall - snowpack - snowmelt), event-based rain (rainfall - throughfall), soil (vertical and horizontal), roots, and stems. These measurements are performed in typical boreal forests in Finland around the Arctic Circle (Oulanka Research Station and Pallas catchment).

Land-based Negative Emissions in the Boreal – Potentials and Challenges of Multi-Purpose Afforestation

T1.7 Collaborating for boreal forests futures

Abstract: Climate warming is considered the major problem to date. The Paris Agreement aims at maintaining global warming well below 2 deg C by the end of the century. In its 1.5 deg special report, the IPCC projects a very limited window of opportunity to live up to the Paris Agreement. In order to do so, in addition to reaching zero net emissions by 2050 on a global scale, negative emissions (NEs) in the dimension of 600 Gt might need to be created between – latest between 2050 and 2100. To date, several greenhouse gas removal technologies (GGRs) or negative emissions technologies (NETs) exist including Enhanced Weathering (EW), Bioenergy with Carbon Capture and Sequestration (BECCS), Direct Air Capture (DAC), Biochar and Afforestation/Reforestation/Restoration. However, relevant parameters including the effectiveness, (both for climate and technology), energy and water demand, land availability, environmental sustainability, and public acceptance, as well as ramp-up time (to name a few) of NETs are investigated and understood at different levels and intensities. Moreover, these parameters are also discussed rather controversially.

This study aims at identifying the potential net negative emission contribution that can be achieved by large-scale and multi-purpose afforestation/reforestation in the boreal Ecotone inter alia on abandoned agricultural land and area burned from wild land fires. A combined remote sensing/GIS approach coupled with biophysical forest and forest fire modeling will be applied to identify potential afforestation locations in boreal forests.

Northern Eurasian forests in the face of global change

T1.7 Collaborating for boreal forests futures

Anatoly Shvidenko[1]
Florian Kraxner[1], Dmitry Schepaschenko[1]
[1] International Institute for Applied Systems Analysis

Abstract: Climate changes make Northern Eurasia (NE, limited here to territories of the Russian Federation) a hotspot of global meaning concerning problems of adaptation of forest ecosystems to, and mitigation of, environmental change. The beginning of 21st century highlighted the risks and challenges related to this giant region of the Earth because *inter alia*: 1) the rate of warming in 1976-2020 was about 2.5 time faster here than the global one; 2) the observed increase of precipitation in vast regions is not able to compensate the increase of temperature; 3) the thawing of permafrost may provide an explosive increase of C emissions because C stock only in permafrost of high latitudes from Ural to Pacific exceeds 500 Pg C, mostly in form of methane; 5) variability of weather, the long and intensive heatwaves and droughts, lead to weakening the resilience of forests and explosive increase of natural disturbances. The disturbance regimes in forests substantially intensified in 2000-2020s: the area of wildfire increased at 3 time; outbreaks of dangerous insects are shifting towards the north at 200-300 km; and carbon sink of forests declined.

The future conditions for NE forests are homogeneous, but mostly not favorable, and in some large regions – critical, where forest likely will reach tipping point. The favorable conditions will be only in regions have satisfactory precipitations, and the fertilization effect of e[CO2] here is also very likely. The major part of NE forest zone will suffer from water stress, dramatic intensification of disturbance regimes, and direct impact of increased temperature. Particularly heavy conditions are expected in southern parts of mid-latitude NE ecotone where basic climatic scenarios promise future climates of dry steppe up to the 60th degree of NL.

The future climates will critically aggravate the problems which NE forests are facing now. There is an urgent need of development of a national strategic program of forest sector's transition to sustainable forest management resilient to future regime of disturbances. The presentation outlines major directions and components of such a program and discusses possibilities of its implementation.

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

A Measure of Structural Complexity: its Mathematical Properties and Regional Patterns

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Mark Ducey[1]
[1] University of New Hampshire

Abstract: In recent years, some authors have proposed using the ratio of the additive version of Reineke's Stand Density Index to the original version, or simple transformations of that ratio, as measures of stand structural complexity. We highlight some of the mathematical properties of this measure, including its relation to the shape parameters in a broad family of diameter distribution functions, and the connection with apparently dissimilar measures such as the coefficient of variation of the diameter distribution. The form of the complexity measure suggests that it could be generalized, within a family of similar measures that includes easier-to-calculate members. Finally, we illustrate the behavior and pattern of the structural complexity measure across the lower 48 United States. The results suggest that the measure does provide a useful, simple description of structural complexity. They also have strong implications for attempts to describe stand density quantitatively in landscapes where complex stands are surprisingly common.

Adapting production forests to climate change: The repercussions to biodiversity and ecosystem services of the resilience-path chosen

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Adam Felton[1]
Annika Felton[1], María Trinidad Torres García Torres-García[1], Magnus Löf[1]
[1] Southern Swedish Forest Research Centre, Swedish University of Agricultural Sciences, Sweden

Abstract: Production forests provide humanity with essential ecosystem services ranging from wood products and carbon sequestration, to environments for recreation. In many countries production forests also provide the majority of forest area for biodiversity. The ecosystem services and habitats provided by production forests are however increasingly threatened by the impacts of anthropogenic climate change, which are expected to fundamentally alter forest characteristics over the coming century. Ensuring that production forests retain their desired development state despite climate change is often framed in terms of enhancing their 'resilience'. Whereas resilience has many definitions in the environmental sciences, it is usefully defined as "the capacity of a system to absorb disturbance and reorganize while undergoing change so as to retain essentially the same function, structure, identity, and feedbacks" (Walker, 2004). In complex forests systems, the source of resilience is frequently linked to the ecological processes and feedbacks – so called 'ecological resilience' - that arise from biological diversity and the regulatory services that result. Production forests are however not just ecological systems, but social-ecological systems, for which anthropogenic sources of resilience – so called 'coerced resilience' (sensu Rist et al., 2014) – may also be tapped into. This often becomes a necessity, as the ecological character of production forests can be heavily altered by human actions, often in an attempt to standardize and simplify natural variability and thereby ensure the predictable delivery of forest biomass. In such cases, highly modified production forests can via anthropogenic efforts rather than ecological processes, return to a pre-disturbance state and thereby mimic the response of resilient complex natural systems. The availability of these two sources of resilience has created a choice when adapting production forests to climate change: A choice which readily equivocates between fundamentally different sources of resilience, and fundamentally different outcomes with respect to resultant forest complexity. Here we highlight important distinctions between these two climate change adaptation and forest complexity pathways, and their potential ramifications for biodiversity, ecosystem services, and the sustainability of production forests this century.

Analyzing spatial distribution of crop trees in spruce-birch mixed stands before precommercial thinning

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Lauri Männistö[1]
[1] Natural Resource Institute Finland (LUKE) Finland

Abstract: Mixed forests provide a wider range of ecosystem services and are in many cases more resilient compared to single species forests. Thus, mixed forests increase the diversity of forests and may mitigate the effects of climate change. The distribution of the mixture affects the development of the trees, the competition between trees and their resource allocation. In addition, the distribution of the trees delineates the possible structures of mature stands. When moving from the random distribution of species towards a clustered pattern, the forest structure begins to resemble a single species forest. Thus, the benefits of admixture might be lesser in clustered stands. Therefore the structure of mixed birch-spruce sapling stands was analyzed.

Measurements were conducted at 9 managed juvenile mixed spruce-birch stands located in Central and Southern Finland. All stands were planted with Norway spruce, and birch admixture had emerged naturally. 2 circular plots of 0,05 ha were established on all stands totaling 18 measured plots. In each plot, all crop trees were charted and measured. The distribution of trees was analyzed using Ripley's L-function and patterns of intermixing of species were analyzed using Ripley's L_{12}-function. The trees were distributed dispersedly on short observation distances, but as distance increased, the distribution shifted to random. When examining the tree species separately, such behavior was observed only on Norway spruce. The distribution of birch was random on all observation distances. When examining the intermingling of different tree species using L_{12}-function, no patterns were found.

Findings suggest that utilizing naturally regenerating birch as admixture on spruce stands creates mixed stands where no apparent gaps are present. Slight differences of distribution between tree species are most likely explained mostly by regeneration methods. There were no sings of different tree species being clustered, suggesting random tree wise mixture. There is need for further research on how different mixing patterns affect the development of the stand.

Assessing emerging changes in functional characteristics of European forests

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Marco Patacca[1, 2]

Abstract: European forests cover more than one third of the continent, providing intimate linkages with the climate system, water, soil and biodiversity, ultimately playing a crucial role for Europeans' well-being. The services that forest provides to Europeans directly depends on the forest composition and structure. The way tree communities organize themselves in response to environmental conditions ultimately lies in their functional strategies. Tree functional strategies are the evolutionary adaptations that species developed in the way they use available resources, influencing biogeochemical cycles, ultimately affecting ecosystem functioning and stability. There is extensive evidence that the effects of global warming, the observed increase of forest natural disturbances, and their interactions are causing disruptions of forest ecosystem functioning by prompting tree mortality, which is the main driver of changes in forest community functional assemblages. Although knowledge on species functional traits increased, a lack of comprehensive species-specific data and temporal trends is hampering the understanding of forest functional dynamics response to environmental changes and its application in management decisions. Here we tested how functional composition (assessed using synthetic indexes of hyperdimensional niche occupancy) changed in European forests over the past ~20 years. We used more than 120.000 georeferenced trait observations to train models to predict a wall-to-wall dataset of 20 important functional traits for 150 European tree species. We combined this trait data with a unique dataset of >210.000 remeasured National Forest Inventory (NFI) plots in 13 countries to assess the temporal changes. Using such wide, ground-measured datasets we were able to assess with high accuracy European forest's functional changes. Those results highlight the regions where functional changes happened in Europe in the last decades, both in a positive and negative way. Moreover our findings allow for assessing further what are the drivers of change (e.g. climate, disturbance or management?), paving the way to design management alternatives based on the most intimate linkage between trees and ecosystem functioning in the era of climate-change.

Challenging Assumptions: A Comparative Analysis of Handheld and Unmanned Laser Scanners for Accurate Tree Height Measurements in Mixed Forests

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Frederico Tupinambá-Simões[1]

[3] Forest Research Centre, School of Agriculture, University of Lisbon, Tapada da Ajuda, 1349-017 Lisbon, Portugal

Abstract: This research examines methods for tree height measurements in mixed forests, with a particular focus on comparing handheld laser scanner (HLS) and unmanned laser scanner (ULS) techniques. We experimented with several scanning approaches, starting with a handheld laser scanner (HLS) and subsequently employing an unmanned laser scanner (ULS) at four varying altitudes (50, 70, 90, 110 m), performed with different scan frequency (dual and triple-echo). The investigation features a case study involving data obtained from a 1-hectare marteloscope situated in a complex, terraced mixed forest region in Portugal. The paper offers a detailed analysis concerning a frequent assumption cited in various studies, which postulates that height measurements from ground-based sensors show a systematic underestimation of heights, due to occlusions created by leaves and crowns. We aimed to provide a differentiated understanding of the results associated with different flight altitudes and ULS return numbers and the potential need to harmonize the HLS and ULS point cloud data, with the data obtained from the HLS alone. Our findings indicate that neither the flight altitude nor the number of returns from ULS significantly influence the tree height measurements obtained. The fusion of data led to an average height increase of 20 cm per tree, but it's important to note that this increase does not indicate a reduction in HLS-associated errors. Instead, it could beassociated with an increase in noise and variations in the alignment among point clouds. Contrary to common belief, our results demonstrate that HLS does not underestimate tree heights in this type of forestFurthermore, the ULS can operate effectively at heights up to 110 meters, expanding the coverage area without affecting the quality of results. Additionally, it became evident that merging point cloud data does not necessarily improve height measurements. Therefore, the choice of the sensor should primarily be driven by the unique objectives of a study, as each sensor provides distinctive characteristics and results.

Abstract: Climate change and warming will potentially have profound effects on forest growth and yield. However, climate change is not only a threat, but also an opportunity for tree species to be more productive or colonize new territories where previously they were fragmented or absent.

European beech (*Fagus sylvatica* L.) is a dominant and very important tree species in European forests with a pronounced ability to grow on a great variety of sites and to form mixtures with other tree species due to its shade tolerance. Only a few studies have analysed its growth to changing climatic conditions outside its natural gradient to the north.

The aim of this study was to clarify the main growth patterns and tree ring formation characteristics of beech in mixed stands with Scots pine (*Pinus sylvestris* L.) located outside its natural gradient. Analyses were carried out in six two-layered Pine-beech stands in the western part of Lithuania. The total area of the forest stands made more than 10 hectares. After shelter wood cuttings as well as gap formation, we collected more than six hundred cross cuts of the beech. Cross cuts were taken above the root collar. After thoroughly polishing the disks' surfaces, we measured the tree-ring widths of the sample trees in two directions (North and East). Measurements were done with the "LINTAB 6" system and the program package "TSAP-Win 0.30". Accordingly, from the closest meteorology station, located in Šilute we collected and tested the impact of following climatic data to tree ring formation: annual precipitation, mean annual, absolute minimal and absolute maximal temperatures, as well as effects solar radiation amounts.

Analyses of the changes in monthly meteorological parameters and their effect on radial increment showed that increasing temperature trends of summer months together with decreasing precipitation during the vegetation period could have stronger negative consequences growth and survival of the species. Therefore, recent climatic changes are prospectively not in favour for European beech. However, trees of this species successfully grow in the western part of the country and produced additional 200 m^3 per hectare in stand structures like the analysed mixed pine-beech stand.

Comparing natural disturbance and forest management parameters as a reference for multi-functional silviculture in Europe

Abstract: In Europe, there has long been interest in natural dynamics silviculture (NDS) to provide a full spectrum of seral habitats and structural conditions required by forest biodiversity, including species that are poorly represented in intensively managed forests. NDS aims to emulate natural disturbance dynamics at stand and landscape scales through silvicultural manipulations of forest structure and landscape patterns. However, adoption of NDS has been limited by incomplete understanding of the ranges of variability in disturbance regimes, including frequencies, spatial attributes, and severities. Addressing this constraint in European forest management, we adapted a "comparability index" (CI) that was first developed in the US to compare natural disturbances and forest management effects. We extended the original concept that included spatial and temporal axes by adding disturbance severity (i.e. tree survivorship or retention) as a third dimension. We populated the model by compiling published data on disturbance dynamics for four major forest types (i.e. spruce, beech, oak, and pine-dominated). Data on silvicultural systems by country and

forest type were obtained through an expert-based process employing standardized estimation protocol. The data for both natural and harvest disturbances were visualized in three-dimensional plots indicating ranges for frequency, size, and severity. We developed an algorithim to calculate the index values for bivariate comparisons. The results indicated that natural disturbances are highly variable in size, frequency, and residual structure, but European forest management fails to encompass this complexity. The residual structure parameter proved crucial in the comparison of natural disturbances and silvicultural systems. The CI showed the highest congruence between uneven-aged silvicultural systems and key natural disturbance attributes. Even so, uneven-aged practices emulate only a portion of the complexity associated with natural disturbance effects. The remaining silvicultural systems perform poorly in terms of retention, especially, as compared to tree survivorship after natural disturbances. Our results and the CI will help European forest managers to expand their portfolio of silvicultural systems to manage for complexity and habitat diversity at multiple scales, while providing a broad array of ecosystem services. We suggest a holistic approach integrating natural dynamics silviculture with more conventional practices.

Comparison of horizontal forest structure between virgin and managed forests

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Andrej Bončina[1]
Christian Rosset[2], Vasilije Trifković[1]
[1] University of Ljubljana, Biotechnical Faculty, Department of Forestry and Renewable Forest Resources, Slovenia
[2] Bern University of Applied Sciences, School of Agricultural, Forest and Food Sciences, Switzerland

Abstract: Horizontal forest structure can be defined as the mosaic of forest patches. In virgin forests horizontal structure is as a result of i) processes of growth, regeneration, and tree mortality, and ii) natural disturbances influencing those processes. In managed forests patch pattern depends in great extent on the silvicultural system applied. Close-to-nature silviculture (CTNS) is characterized by natural regeneration and mimicking natural stand dynamics. The main aim of our study was to compare the horizontal structure of virgin forest (VF) and managed forest (MF) in which CTNS, combining elements of the irregular shelterwood and partly of the selection silvicultural system, has been applied for more than a century. We hypothesized that in the MF i) the patchiness and ii) vertical heterogeneity of patches are higher, iii) while the top height of patches in MF is lower in comparison to that in the VF. The study was performed in the Dinaric Mountains (Slovenia, the Rog areas, 22,776 ha, silver fir-European beech forest type with three virgin forest remnants). We used a TBk toolkit developed at the BFH to automate stand map creation based on LiDAR data. The objective delineation of stand patches enabled comparison of the size of patches and their structural characteristics (e.g. top height, coverage of four canopy layers, tree species composition) between the VF and MF. In the VF the average patch size is significantly larger, and top height of patches is significantly higher in comparison to that in the MF. In both objects small patches (0.05-0.5) prevail. However, the relative frequency of very small patches (<0.05 ha) and very large patches (>20.0 ha) is much larger in the VF, while the opposite is true for the medium sized patches (2-20 ha). In the final model of patch size, the variables describing coverage per canopy strata, dominant height of patches, index of vertical heterogeneity and the management treatment (VF, MF) – the latter as a dummy variable – were included. Current studies of horizontal structure were based on field mapping. The novel approach can contribute to the objective study of horizontal structure, enabling comparison of results between various forest types.

Dependence of broadleaf tree diversity on stand age and landscape structure: lesson from long-rotation and uneven-aged sugi plantations

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Satoshi Ito[1]
Chihiro Kawaguchi[1], Yuki Akaikie[1], Hiromi Yamagawa[2], Kiwamu Yamagishi[2], Ryoko Hirata[1]
[1] University of Miyazaki, Japan
[2] Kyushu Branch, Forestry and Forest Product Research Institute, Japan

Abstract: Conifer plantation forestry in Japan has partly been recommended to shift from short-rotation forestry (ca.40 years) of even-aged monoculture to uneven-aged forestry with small-scale clearcutting or long-rotation forestry for sustainable forest management. However, it is still unclear how these alternative forest management can contribute to promote the complexity of stand structure and the tree species diversity. We investigated broadleaf tree population in an old sugi plantation (137-year-old) and uneven-aged sugi (*Cryptomeria japonica*) plantations (including 4 to 80-year-old patches) in southern Japan, and evaluated the contributions and its limitations of long-rotation and small-scale clearcutting to the diversification of stand structure. The old sugi plantation had high richness of tree species equivalent to that of old-growth natural forests of the region. The size structure of broadleaf trees was also similar to the old-growth natural forests even growing beneath the sugi canopy layer, indicating that the canopy height as well as stand age is the key factor of promoting high structural diversity. However, species composition of the old plantation was not same as old-growth natural forests because of limited recolonization of trees with gravity-dispersal seeds (such as acorns) even under the canopy gaps created by natural disturbance. Uneven-aged patches also demonstrated a clear age dependence of the broadleaf trees colonizing in understory; older patches contain higher richness and abundance of trees those originally inhabit in natural forests rather than in disturbed sites. Forest edges created by small-scale logging mitigated the “stem exclusion” of colonized trees by improving the light condition under the thick canopy of the younger patches. Further, several shade tolerant species were thought to be maintained as metapopulations in the uneven-aged patch mosaics. However, the colonization of gravity-dispersed species was limited even in the older patches with improved light conditions. We concluded these case analyses that the long-rotation and uneven-aged forestry by small-scale clearcutting is effective for diversifying size structure and composition of broadleaf tree population in conifer plantations, and that the retention or restoration of effective seed sources at the landscape level is crucial for maintaining the population of gravity-dispersed trees even under in the uneven-aged forestry.

Does thinning intensity modify soil carbon stocks in a Mediterranean mixed forest?

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Ricardo Ruiz-Peinado[1]
Eduardo López-Senespleda[1], Javier Rodríguez[1], Jorge Aldea[1], Rafael Calama[1], Miren del Río[1]
[1] Instituto de Ciencias Forestales ICIFOR-INIA, CSIC, Ctra. A Coruña km 7.5, 28040 Madrid, Spain

Abstract: Mixed-species forests are reported to be more productive and can better provide ecosystem services than monocultures, which is of great importance for climate change mitigation. Management by thinning to reduce the stocking density is required to control competitive conditions and avoid the expected high mortality rates in mixed forests, while maintaining species proportion and the benefits of the admixing. Thinning is becoming one important measure for adapting forests to climate change, since it can mitigate the effect of extreme drought events. In this context, where soil carbon sequestration is one of the ecosystem services that may benefit from mixing due to the above and below-ground niche complementarity of tree species and their different type of litter inputs, practitioners should be clear about the effect of forest management. Thinning was expected to reduce the soil carbon stocks, with the most significant impacts in the forest floor and generally non-significant effects in the mineral soil, although the effects were usually dependent on forest and soil type, thinning intensity and time after treatment. In order to gain insight into the effects of forest management on soil carbon stocks, a thinning trial on a common Mediterranean mixture found in the Spanish mountains (Maritime pine – *Pinus pinaster* Ait.- and Pyrenean oak –*Quercus pyrenaica* Willd.-) was studied. In this trial, pine trees come from plantation in the 70's, while oak trees are sprouts from a previous coppice forest cleared in the soil preparation process. Two thinning intensities from below (moderate and heavy) and a control were compared. In 2010, thinning was applied only to pine trees. Forest floor were collected considering organic material until 2 cm of diameter, and mineral soil were sampled in the same place to a 30-cm depth. As main results, we didn't find any significant reduction in soil carbon stock at the mid-term after thinning, hypothesizing that since there was not a great stocking reduction, litter inputs have been recovered in a few years, and the modification of soil microclimate conditions or those soil affections by management were not so important to accelerate organic matter decomposition.

Does tree species mixture shift intra-annual growth response

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Sonja Vospernik[1]
[1] Boku, University of Natural Resources and Life Sciences

Abstract: Species mixture is frequently studied at the stand level and mixed stands have been reported to have a higher productivity, to reduce risk and to be beneficial for biodiversity and to be able to mitigate climate change impact. Species mixture is less frequently studied at the individual tree level and here studies of intra-annual growth have the highest temporal resolution and the closest relation to climate explaining most of the variation. Band dendrometer data of six tree species namely (*Picea abies* (L.) Karst., *Pinus sylvestris* L., *Larix decidua* Mill., *Abies alba* Mill., *Fagus sylvatica* L., *Quercus spp. (Quercus petrea* (Matt.) Liebl. *Quercus robur* L.) were sampled on five sites in mixture and in the respective pure stands for 6 to 10 years. The elevations of the sites varied between 400 and 1530 m above sea level, and the mean annual temperature of sites varied between 6.0 and 10.1 °Celsius, with annual precipitation sums of 490-1580 mm. Sites were not only very diverse in elevation and climate, but also with respect to soils and geology encompassing Planosols on flysch, Cambisols on granite and rendzic soils. Generalized additive mixed models were fit to the data encompassing a component for intra-annual growth, shrinkage and swelling and daily water uptake from the plant. The growing season was longer on the cooler and more humid sites and the highest growth rates were observed earlier for the deciduous species. Species effects however differed between years and so did mixture effects, which could be positive or negative. Mixture also shifted the seasonal growth pattern but only by few days.

Effects of forest structure on insect community assemblages in a large-scale experiment – a trait-based approach

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Ruth Pickert[1]
Jörg Müller[1, 2], Oliver Mitesser[1]
[1] University of Würzburg
[2] Nationalpark Bavarian Forest

Abstract: Structural diverse forests with the shading and buffering function of the canopy provide a heterogeneity of local microclimates, which is especially important for insects operating on small spatial scales and directly depending on external heat sources. However, forests shaped by human needs are usually focused on maximizing timber production and therefore very homogeneous in age, structure, and consequently microclimatic conditions. Trait-based approaches explaining the connection between functional traits and climatic parameters have earned attention in past decades. We aim to gain a more mechanistic understanding of how insect species assemble in and respond to variation in forest structure, which is essential in the context of ongoing loss of biodiversity. We tested the response of coleopteran, heteropteran and lepidopteran insect communities from 503 temperate forest sites throughout Germany to mean annual temperature, canopy openness and direct solar radiation. Further, we systematically enhanced the forest heterogeneity by creating gaps in four forestry regions in Germany and investigated their effects on nocturnal Lepidoptera in a large-scale experiment over two to four years. Subsequently, we analysed the whole moth community and also measured several individuals belonging to four species to also enlighten within-species responses to canopy openness, which is often neglected in the field of species community analyses. Linear mixed effect models reveal in forest insect communities a decrease in body size but an increase in colour lightness with increasing annual mean temperature. However, both traits decreased with increasing canopy openness. Further, there were no consistent coherences between the traits and canopy openness between moth families, which indicates that the composition of insect communities in forests is shaped by diverse processes. Our results indicate that canopy cover is strongly affecting insect communities by altering local climates. Influenced by climate change e.g., due to more frequent disturbance processes, canopy cover should seize more consideration in climate-biodiversity studies. Increased attention should be paid to forests' structural heterogeneity, for example by creating forest gaps, promoting forest biodiversity through an increased supply of resources and variability in microclimate.

Effects of neighbourhood tree species diversity and stand density on drought-induced mortality in European forests

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Julius Willig[1]
Benjamin Aldrich[1], Jürgen Bauhus[1]
[1] University of Freiburg, Chair of Silviculture

Abstract: Unprecedented tree mortality occurred in recent years (2018-2020) in Central European forests as a consequence of drought and heat waves. Forest scientists and practitioners are seeking for strategies to mitigate further mortality in existing forest stands. One frequently mentioned option is the promotion of tree species richness in forests. When compared to monocultures, mixing tree species can promote resistance and resilience of growth in relation to droughts. However, it is unclear if there is also a positive effect on tree survival.

Here, we investigated how plot and neighbourhood tree species richness, species composition and stand density affected tree mortality and also growth performance prior to death. For this purpose, we made use of the FunDivEurope exploratory platform, which consists of a plot network of mature forests in six European countries with diversity gradients from monocultures to six tree species, covering boreal, temperate and Mediterranean forest types. To reconstruct whether death occurred as a sudden event or was already indicated by a long period of declining growth performances, we analysed tree rings from dead trees and related the growth performance of dead individuals to their neighbourhood diversity and competition. Tree species richness, species composition and stand density served as main variables predicting mortality rate in our mixed model analysis.

The design of our study is suited to disentangle tree diversity and stand density effects on tree mortality. Accordingly, our results will allow us to elucidate how drought-induced mortality can be mediated by steering stand density in mixed forests. In addition, we provide information on which species combinations are most suitable to reduce drought-induced mortality in mature forests.

Enhancing tree species diversity in boreal forests: a large-scale simulation study in Sweden and Finland

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Abstract: Species diversification is an effective strategy to mitigate risks posed by climate change and natural disturbances as well as can benefit biodiversity. It can be implemented at both the stand level, where forest stands consist of multiple tree species, and at the landscape level, which includes mixed species stands and monocultures of different species. However, in boreal Sweden and Finland, there are limited options for native species with high biomass production potential. Scotch pine (*Pinus Sylvestris)* and Norway Spruce *(Picea Abies)* dominate the growing stock, followed by birch species *(Betula spp.)* in third place with a smaller share.

This study examines the potential for increasing species diversity by substantially increasing the share of birch both through monospecific plantations and mixed spruce-birch stands, as well as the share of mixed pine-spruce stands in Gävleborg and Västerbotten counties (Sweden) and Päijät-Häme and Kainuu regions (Finland). The Swedish Heureka and the Finnish Motti decision support systems are used to simulate forest development under various scenarios, including species diversification and different management intensities.

The study utilizes plot-based data from the National Forest Inventory of each country as the initial state. It focuses on the speed of species composition change and the impact on timber harvests, including species composition, total volume, and financial value. The results indicate that achieving substantial species composition change without premature harvesting requires a significant amount of time. The production and economic impacts show a moderate reduction in growth, harvests, and financial value. These negative impacts should be weighed against the multiple direct and indirect benefits of mixed forests, such as enhanced resilience and improved biodiversity conditions. In addition, future tree improvement programs are expected to enhance the growth of birch and its competitiveness compared to spruce.

Evaluation of growth models for mixed forests used in Swedish and Finnish decision support systems

Abstract: Interest in mixed forests is increasing since they could provide higher benefits and positive externalities compared to monocultures, although their management is more complex and silvicultural prescriptions for them are still scarce. Growth simulations are a powerful tool for developing useful guidelines for mixed stands. Heureka and Motti are two decision support systems commonly used for forest management in Sweden and Finland respectively. They were developed mostly with data from pure stands, so how they would perform in mixed stands is currently uncertain. We compiled a large and updated common database of well-replicated experimental research sites and monitoring networks composed by 218 and 1,160 plot-level observations of mixed stands from Sweden and Finland, respectively. We aimed to evaluated the accuracy of Heureka and Motti basal area growth models in those mixed-species stands and to detect any bias in their short-term predictions. Basal area growth simulations (excluding mortality models) were compared to observed stand-level values in a period-wise process with update of the start values in each period. The residual plots were visually examined for different stand mixtures: Norway spruce (*Picea abies* Karst.)-birch (*Betula* spp), Scots pine (*Pinus sylvestris* L.)-birch and Scots pine-Norway spruce. We observed that the basal area growth models in both decision support systems performed quite well for all mixtures regardless of the proportion of species. Motti simulations overestimated growth in Scots pine-Norway spruce mixtures by 0.063 $m^2 \cdot ha^{-1} \cdot year^{-1}$ which may be acceptable for practical use. Therefore, we corroborated that both decision support systems can be currently utilized for short-term forest growth simulation of mixed boreal forests.

Exploring complexity: Integrating experimental and observational infrastructures to enhance forests understanding and inform management strategies

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Felipe Bravo[1]
[1] Dpto. Producción Vegetal y Recursos Forestales, iuFOR (Instituto Universitario en Gestión Forestal Sostenible), E.T.S. de Ingenierías Agrarias, Universidad de Valladolid, Campus La Yutera, Avda. Madrid 50, 34071 Palencia, Spain

Abstract: Changes in forests are spatial and temporal dependent so a careful experimental and observational design is crucial in forest research. Long-term experimental and observational plots' networks provide unique insights into forest dynamics both in trends and quantitative level. Such research facilities provide information on forests stand that cannot obtained in small temporary plots. However, strategical, tactical, and operational forest inventories may effectively complement data from observational experiments collected over long time periods. The combination of the casual relationships uncovered with observational plots with experimental site generates key knowledge. Such insights under current global change situation are essential for understanding the long-term effects on stand dynamics and for developing adaptive forest management strategies at different spatial and temporal scales. Different challenges are faced by researchers that want to establish and maintain observational and experimental plots' networks to foster forest research. Examples of such challenges are (1) long term maintenance of plots' network securing enough funding, social engagement (stakeholders, public opinion,…) during long term periods, (2) use data from facilities deployed for old objectives and research question several years (if not decades) after its establishment, (3) effective collaboration with other scientists and data sharing policies development, (4) maintain representativeness of the facilities while environmental conditions and managerial schemas are changing. Different types of observational and experimental facilities have been used in the past. Examples of such facilities are plots (temporary, interval and permanent) networks across forest types, paired and triplet plots networks, Nelder wheels, structural modification (thinning and pruning) experiments, diversification plantations and natural regeneration experiments. Examples of observational and experimental facilities from different ecosystem types, research questions address, and managerial approaches are presented, and its trade-off discussed. Finally, challenges related with data analysis on these facilities on large spatial and temporal scales are discussed.

Exploring Intra- and Interspecific Interactions in Forest Ecosystems through Triplets: A Global Initiative

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

IRENE RUANO[1, 2]
FELIPE BRAVO[1, 2], HANS PRETZSCH[1, 2, 3]
[1] University Institute for Research in Sustainable Forest Management (iuFOR), University of Valladolid, Avda. Madrid 57, 34004 Palencia, Spain
[2] Department of Plant Production and Forest Resources, E.T.S. of Agriculture Engineering, Universidad de Valladolid, Palencia, Spain.
[3] Chair of Forest Growth and Yield Science, Department of Life Science Systems, TUM School of Life Sciences, Technical University of Munich, Freising, Germany

Abstract: Research on mixed forests vs monospecific species has consistently highlighted the importance of mixed forests in providing greater stability and higher productivity compared to pure stands. Different triplets' networks have been deployed in temperate forest ecosystems during the last decades for insight into mixture development. Based on our experience studying intra- and interspecific interactions in mixed stands using triplets' networks, we are currently developing a global triplet network. The plots within our triplets' networks are meticulously defined. In pure stands, the main species should account for a minimum of 80-90% of the basal area, while in mixed stands, one species should not exceed 70% and the other species should remain below 30%.

To expand the current knowledge and increase globally the awareness of developing and sustaining mixed forests we are analyzing intra and interspecific interactions in different forest ecosystems, based on species functional traits such as shade tolerance, wood density, or drought tolerance. Our network seeks to address key questions related to stand productivity, stress resilience, and the annual mixing effect. Currently, we have selected triplets of pure and mixed forests globally, consisting of shade tolerant and intolerant species. Triplets are in Europe, America, Africa and Asia covering different boreal, tropical and temperate forests. Triplets' data obtained are statics (no growth measurements) or dynamics (growth obtained by extracting increment cores or, in other cases, conducted multiple inventories over time)

We invite researchers to join our collaborative Triple Network aimed at investigating the dynamics of mixed and pure forest stands worldwide. By joining our Triple Network, researchers can contribute their expertise and contribute to a comprehensive understanding of the dynamics and ecological implications of mixed and pure forest stands.

From energy to species diversity: A mechanistic investigation

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Elizabeth Baach[1]
Carsten Dormann[1]
[1] University of Freiburg

Abstract: The distribution of species richness across the globe, particularly the gradient from the tropics to the poles, has been a longstanding interest of ecologists, especially concerning the mechanisms behind this distribution. This project focuses on the mechanisms relating to ecosystem energy availability and the corresponding abundance and species diversity at various trophic levels. We investigate the intermediate processes and patterns that contribute to the relationship between energy availability and species diversity at multiple trophic levels. To determine the constraints on energy flow between trophic levels, this project uses ecological efficiencies found from various literature sources to estimate the biomass potential for trophic guilds, following a bottom-up approach. Using an energy budget approach, we connect the estimated biomass values to richness estimates using species accumulation curves as well as determined correlations between richness at different trophic levels. In the process of creating this multitrophic energy and richness budget, this project collects and organizes data from numerous sources relating to trophic interactions of various organisms as well as quantified relationships between energy availability, abundance, and richness that will prove to be a useful compilation of data to researchers interested in investigating, modeling, and understanding complex forest trophic webs. This research also provides a quantitative approach to a theoretically dominated research field by using the theoretically developed pathways and relationships from species-energy theory approaches and overlaying values collected empirically to investigate and quantify these relationships.

Functionally dominant species and species richness mediate the effect of structural diversity on aboveground biomass in tropical forests

Abstract: Despite mounting empirical evidence regarding the positive effects of forest structural diversity (STR_{DIV}) on forest functioning, the underlying biotic mechanisms and controlling abiotic factors remain poorly understood. We provide the first assessment of the interactive effects of S_{DIV} and diversity in species and species functional traits on aboveground biomass (AGB) in various types of natural forests in West and East Africa. Using data from 276 plots and 7993 trees of 207 species distributed across major climatic zones of Africa and structural equation modeling, we evaluated how taxonomic and functional diversity attributes mediate the relationship between STR_{DIV} and AGB, while accounting for the effects of environmental covariates. We found that STR_{DIV} had a strong and positive effect on AGB. The positive effect of STR_{DIV} on AGB was underpinned by both the community-weighted mean of trait values (selection effects) and species richness (niche complementarity and competitive exclusion). Across floristically and environmentally homogenous forest units defined based on aridity index and stand development stage, STR_{DIV} primarily mediated the effects of CWM of traits and species richness on AGB. We also showed that water availability and soil fertility are crucial for maintaining positive STR_{DIV}–AGB relationships. Our findings highlight the importance of promoting high structural diversity to increase AGB production in tropical forests. Moreover, management and mitigation strategies aimed at fostering biomass production through increased STR_{DIV} should focus on maintaining high levels of functionally dominant species while also increasing tree species diversity.

Growth resilience of trees: Interactions between changing climatic conditions and the structural and trait composition of tree neighborhoods

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Jonas Glatthorn[1]
Jonas Stillhard[1], Martina Hobi[1]
[1] Swiss Federal Research Institute WSL

Abstract: Small scale disturbances in forest stands caused by humans through silvicultural interventions or by natural drivers such as windthrow, insects or pathogens are affecting the structure of the remaining stand. The growth response of the remaining trees to a sudden release event will largely determine the future development of a forest stand. We present results about the response of growth resilience of trees after disturbances to climatic conditions and the structural and trait composition of tree neighborhoods.

Trees that react with a growth increase due to reduced competition may contribute to the resilience of forest stands. However, older trees and tree species that have a low growth plasticity may react neutrally to release events or even with declined growth. Additional to effects of individual tree traits, the capacity of individual trees to respond to release events in a plastic way may be impaired in the future by changing climatic conditions. Structurally diverse tree neighborhoods with multiple species may increase resistance and resilience to disturbances than monospecific even-aged stands and thereby mitigate climate change impacts, whereas high competition pressure may lead to additional stress and a further decrease of forest resilience. Our objectives are to demonstrate driving factors of the growth response of different tree species to release events and how potential effects of a changing climate may be mediated or amplified by diverse tree neighborhoods and competition intensity.

We present results from the Swiss long-term forest growth monitoring network. Tree traits and coordinates from stands covering a broad range of Central European tree species, silvicultural management types and climatic conditions were monitored in 5-to-10-year intervals mostly since the 1980s, individual plots since the 1930s.

Our results are important for a better understanding of the biodiversity – ecosystem stability relationship in forests during climate change. For an adaptive management of forests, it is important to be aware about stand structural features that increase or decrease the resilience of trees and stands.

Higher tree water deficit under intra- vs. interspecific competition – insights from mature stands of European beech, Norway spruce and Douglas fir

Abstract: Mixed forests are, for multiple reasons, a promising option for forest management in Central Europe. However, it is not clear to what extent interspecific competition affects tree hydrological processes. High-resolution dendrometers capture sub-daily variations in stem diameter, presenting a valuable tool to monitor growth and water status of individual trees at the same time.

To evaluate the effect of intra- vs. interspecific neighborhood on tree growth and water status, we deployed >100 sensors in pure and mixed forest stands of European beech, Norway spruce and Douglas fir on four different sites in north-western Germany, measuring stem diameter at 10-minute resolution for a period of four years (2019-2022). Using normalized minimum tree water deficit as a daily indicator for water stress, we found that throughout the growing season, beech trees growing in pure stands exhibited higher water deficit than those in mixed stands. An exception was 2021, the wettest year of the study period, where all trees showed low water deficits, while the largest differences were observed during the driest year (2022).

We assume that these differences may arise from belowground complementarity in interspecific neighborhoods, since results from water stable isotope analysis on a subset of plots show small but consistent differences in water uptake depth of the tree species in the mixed stands, suggesting a broader access to belowground resources. Still, environmental variables (mainly VPD and soil matric potential) were the strongest predictors of tree water deficit, and annual growth was substantially impaired by drought on all plots.

Overall, our data suggests that mixed beech-conifer stands seem to be less affected by severe droughts than pure stands, making them indeed a valid option for the adaptation of forests to climate change.

Impacts of diversity across a range of scales: evidence of tree species diversity effects on the structure and function of forests in North America

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Abstract: This presentation highlights results from three studies of tree species and genetic diversity effects on forest function and structure. The first study is an experiment comparing the productivity of polyclonal and monoclonal plantings of *Populus spp.* plantations in southeastern US. The second study is observational, comparing monocultures and mixed-species structure and function in ~35-year-old plantation forests in the Pacific Northwest, US. The third study leverages national forest inventory plot data to assess regional impacts of species and functional diversity on forest productivity in the southern US. We synthesize results from these three studies and discuss how investigating impacts of tree species diversity at different scales can help advance our understanding of the biodiversity-ecosystem function relationship in forests. First, how short-rotation *Populus* plantations can serve as a model system for testing and developing hypotheses about diversity effects on ecosystem functions using approaches that would be infeasible in natural forests. As an example, I will highlight results from a study showing overyielding in polyclonal plantings is associated with differential expression of stress response genes, suggesting water and heat stress response as a possible underlying mechanism for increased productivity in mixtures. Second, field studies in plantation forests as found in the Pacific Northwest can provide semi-controlled conditions for observational studies to evaluate impacts of species composition at temporal and spatial scales larger than what is feasible for designed experiments. As an example, I will highlight results showing how tree-species composition affects productivity at the individual tree and plot level and may be explained by species characteristics that potentially contribute to increased canopy packing in mixtures. Third, these types of results help interpret large trends observed across regions, including how the positive relationship between tree species richness and productivity is mediated by stand density according to model results using national forest inventory data. In conclusion, generalizing trends, understanding specific mechanisms, and advancing ecological theory on biodiversity ecosystem function relationships in forests cannot be feasibly achieved by working at a single scale. Rather, integrated studies at multiple scales are needed.

Influence of different silvicultural practices on forest structure and genetic diversity of forest tree populations

Abstract: Genetic variation enables populations, species, and consecutively ecosystems to adapt to new environmental conditions. Functioning forest trees communities, also a consequence of their forest genetic resources, are key for the maintenance of biodiversity. However, forest genetic resources face a large number of increasing threats, such as climate change and unsuitable forest management practices, threatening future adaptive potential of forest trees and forest ecosystems. To assess an ecosystem's genetic resources and the system's ability to adapt, it is fundamental to analyze hypothetical changes in the population's genetic diversity and the consequences of these changes. Forest management can impact both structural characteristics and genetic variability of forests. Considering this, selection of suitable silvicultural practices is crucial for conservation of diverse genetic structure, including the maximization of population size and selection for specific adaptive characteristics. Different research results show that old-growth forests may have a more complex structure and higher genetic diversity than managed forests. Close(r)-to-nature forestry, that mimics natural processes in virgin and old growth forests, may positively impact biodiversity, including genetic diversity of forest tree populations and improve the adaptive potential of forests. The impact of different forest management practices on forest structure and spatial genetic diversity in 13 European forest types was analysed within the Life Systemic project. Species composition, stand density and age structure, site conditions, genetic structure, and soil biodiversity, as well as historical overview of the forest management practices, are being evaluated in 30 different sites across Italy, Croatia and Slovenia. These sites comprise different intensities of management, from unmanaged forest reserves to clear cutting management system, with the aim to evaluate the role of different forest management regimes to secure forest genetic structure important for the potential adaptability of forests to climate change in given European forest types.

Influence of tree species composition and of stand density on epiphytic diversity in mixed and pure pine and oak forests

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Marion GOSSELIN[1]
Yann DUMAS[1], Hilaire MARTIN[1]
[1] INRAE, UR1455 Ecosystèmes Forestiers, Domaine des Barres F-45290 Nogent-sur-Vernisson, France

Abstract: The effects of mixed stands on biodiversity are increasingly being studied. Nevertheless, among the few studies dealing with epiphyte taxa, even fewer compare mixed stands with the pure stands of each tree species. We evaluated the diversity of tree-dwelling cryptogamic communities (bryophytes, lichens) in mixed and pure oak-pine stands (Quercus petraea (Matt.) Liebl., Pinus sylvestris L.) in French lowland forests. The main explanatory variables were the phorophyte species and the stand type (pure versus mixed) at tree level, the stand composition (pure oak, pure pine and mixed) at plot level. In addition, we investigated the role of the stand density (low vs high). Data were analyzed using Generalized Linear Models under Bayesian statistics. Richness and abundance of cryptogams were significantly and strongly higher on oak. Pine cryptogamic diversity at tree level was higher in mixed compared to pure stands, whereas mixed stands did not enhance oak bryophyte richness. Epiphytic bryophyte richness decreased with increasing tree density, this was the only strong effect of tree density. Bryophytes and lichens showed similar relationships with the phorophyte tree species, the stand composition and density.

Influence of tree species diversity and competition on drought sensitivity of silver fir, Norway spruce and European beech in uneven-aged forests

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Mathieu Lévesque[1]
[1] Silviculture Group, Institute of Terrestrial Ecosystems, ETH Zürich, Switzerland

Abstract: Promoting tree species diversity and structural diversity are two commonly advocated forest management strategies for adapting forests to climate change and the projected increase in drought frequency and severity. Still, mixing and structural effects on the drought response of trees can vary substantially with site conditions and tree species identity. To investigate the influence of species-specific neighborhood environment (species richness, competition, stand structure) on the drought response of silver fir (*Abies alba*), Norway spruce (*Picea abies*) and European beech (*Fagus sylvatica*), we combined annually resolved tree-ring data with repeated forest inventory data spanning the past century at three long-term experimental plots in Switzerland. Our study focused on six drought events that occurred since the 1970s. Our findings indicate that neighborhood competition and tree species diversity effects are generally weak, with significant interspecific influences observed primarily in the growth resistance and recovery of European beech to drought. These effects, however, were overshadowed by the effects of tree age and size. While tree size consistently negatively affected all species, age effects depended on species identity. Our results highlight the fact that the effects of diversity can differ for each combination of species and vary along tree ontogeny, making it challenging to draw broad conclusions. This is because species interact through their specific traits, and interactions vary as trees' neighborhood structural complexity changes over time. Adaptive management strategies in mixed uneven-aged mountain forests are more likely to succeed if they promote drought-tolerant species and the reduction of stand density. Despite the lack of clear evidence supporting the advantage of tree diversity in enhancing drought resilience, the pursuit of species-rich forests still offers benefits such as risk distribution among multiple species and the provision of numerous ecosystem services.

Managing for Complexity in Western Coniferous Forests of North America

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Linda Nagel[1]
Courtney Peterson[2], Mike Battaglia[3]
[1] Utah State University, S.J. & Jessie E. Quinney College of Natural Resources, Utah, United States
[2] Colorado State University, Forest and Rangeland Stewardship Department, Colorado, United States
[3] USDA Forest Service, Rocky Mountain Research Station, Colorado, United States

Abstract: Managers and scientists are engaged in a collaborative effort to establish a series of experimental silvicultural trials across a network of different forest ecosystem types throughout the United States and Canada called the Adaptive Silviculture for Climate Change (ASCC) project. Partners in Colorado, USA have co-developed locally-specific adaptation actions for three complex, fire-adapted forest ecosystems across Rocky Mountain elevational gradients to research long-term ecosystem response to a range of climate change adaptation approaches, manage for changing fire regimes, and protect the valuable ecosystem services they provide. These three forest types include: 1) high-elevation, spruce-fir forests at the Colorado State Forest, which is the source of an estimated 75% of annual water in Colorado that flows to an array of downstream consumers from agriculture to municipalities, and crossing state lines; 2) lodgepole pine forests located in the north-central portion of the Taylor Basin of the Gunnison National Forest which are threatened by mountain pine beetle outbreaks and extreme fire and drought events; and 3) dry mixed-conifer forests on the San Juan National Forest established on Jackson Mountain in Southwestern Colorado, ranging in elevation from 2,250 to 2,620 meters and surrounded by communities in the wildland-urban interface.

To promote adaptive response of these forest ecosystems to drought, insects and disease, and changing wildfire regimes, treatments were developed to approximate a gradient of climate-adaptive management approaches including resistance, resilience, transition, and a no action control. Site-specific treatments were collaboratively designed by local managers and researchers using ecosystem vulnerability assessments. The range of treatments involve a combination of intermediate treatments, regeneration silviculture, forest assisted migration using natural and artificial regeneration, and increasing species and structural complexity and heterogeneity at the stand and landscape levels. This presentation will cover climate change impacts for these fire-adapted forests, key silvicultural considerations for achieving sustainable management of multiple species, forest structure and ecosystem services, and lessons learned from implementing adaptive silviculture treatments through this collaborative effort to steward forested watersheds and communities into the future under climate uncertainty.

Mixed pine forest effect on organic matter topsoil and their relation with understory vegetation.

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Abstract: The more efficient supply of ecosystem services by mixed *versus* monospecific forests has already been shown in many studies. But many of the mechanisms that implement this more efficient supply have yet to be discerned, especially when the mixtures combine two coniferous tree species. We assessed the effects of mixed *versus* monospecific stands of *Pinus sylvestris* and *P. pinaste*r on topsoil and their relationship whit under- and overstory in a triplet's essay in northern Spain Thus, in 180 plots [6 triplets x 3 forest stands (1 *P. sylvestris* monospecific stand + 1 *P. pinaster* monospecific stand + 1 Mixed stand if both *Pinus* species) x 10 plots/stand] were analyzed the quantity (Total organic carbon) and quality (C:N ratio) of topsoil organic matter, the % cover and richness of understory species and the % basal area of both *Pinus* species. *P. sylvestris* monospecific stands presented higher quantity and quality topsoil organic matter, in contrast to *P. pinaster* monospecific stands which presented lower quantity and quality topsoil organic matter. Mixed stands showed an intermediate quantity of topsoil organic matter but a quality of topsoil organic matter similar to *P. sylvestris* monospecific stand. We conclude that the similar species richness in mixtures to *P. sylvestris* monospecific stands is linked to the high quality of topsoil organic matter.

Quantifying maximum size-density relationships in mixed-species and monospecific stands of the southeastern United States

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Adam Polinko[1]
Maxwell Schrimpf[1]
[1] Department of Forestry, Mississippi State University

Abstract: Maximum size-density relationships have been quantified in single species stands for nearly a century. Quantifying size-density relationships in mixed-species stands, however, is a relatively new endeavor. Species specific functional traits and their interaction with climate have been demonstrated to influence maximum size-density relationships in mixed stands. However, these relationships have primarily been documented in temperate forests where at least one component of growing space is limiting. Mixed-species management is less common in the Southeast compared to other regions of the United States, however, the impact of climate change and a transition away from vertically integrated forest companies may increase the importance of mixed-species management in the future. Here, we evaluate maximum size density relationships across a range of monospecific and mixed-species stands in the southeastern United States. Specifically, we examine the role of functional traits and climate on maximum size-density relationships in a region characterized by long, warm, growing seasons and an abundance of precipitation. We used quantile regression to predict maximum size-density across 103,884 United States Department of Agriculture Forest Inventory and Analysis plot observations with 2,013,326 trees across 186 different species. Using the selected equation, we examined the role of climate, site, and species-level functional traits in predicting maximum size density for both monospecific and mixed-species stands. We will present results, discuss modelling challenges, and examine management implications. As climate change may already be altering maximum-size density relationships in the Southeast, understanding variation in maximum size-density relationships across a commercially and ecologically important region will allow for targeted management to optimize a wide range of ecosystem services.

Restoring complexity in plantations: mission impossible?

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Robert Schneider[1]

[3] Great Lakes Forestry Centre, Canadian Forest Service, Natural Resources Canada

Abstract: The importance of plantations in the landscape of the mixed forests of eastern Canada has increased over the last five decades. Although the plantations have some natural regeneration ingrowth (~ 40% in stocking), the biggest difference with pre-industrial forests are due to changes in the age structure, and to a lesser extent composition. The irregular and uneven-aged mixed wood stands have been replaced by even-aged stands, of which plantations can cover over 20% of a management unit. Over the last 15 years, efforts have been made to reintroduce complexity in some of these plantations by instigating a transition to irregular stands. But how is complexity measured? And how is it influenced by silvicultural treatments? These questions have been explored using the data from trials established in the last two decades. Within the trials, several thinning modalities were tested: thinning from below, neutral thinning and crop tree release. The latter is seen as the first step in converting the even-aged plantations to uneven-aged or irregular stands. Using traditional structural metrics, such as diameter distribution, plantations were found to be very resistant to anthropogenic disturbances. Even the spatial distribution of the trees in the stand changes only slightly after thinning unless gaps are created. We therefore hypothesized that canopy opening through partial harvesting may not influence the spatial and size distribution of the trees but could affect canopy and understory structure. Results from data obtained with a terrestrial laser scanner also showed that the structure of plantations is very resistant to thinnings, where even the "chainsaw effect" (i.e., the change between pre- and post-harvest conditions) is very limited. Understory composition, measured by specific and functional trait diversity, only changes when gaps are present. These results thus indicate that introducing complexity into plantations is a lengthy process and will mostly likely rest on the success of establishing natural regeneration. In this perspective, thinning, by opening the canopy, has increased the presence of natural regeneration under cover but not in the gaps. More fundamentally, silviculturists must ask the question: what is the time frame to restore complexity through silviculture in these plantations?

Silviculture of multi-aged temperate mixedwood forests in Eastern Canada

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Patricia Raymond[1]
Daniel Dumais[1], Emilie Champagne[1]
[1] Ministère des Ressources naturelles et des Forêts du Québec, Direction de la recherche forestière, 2700 rue Einstein, Québec, Qc, Canada, G1P 3W8

Abstract: The temperate mixedwood forest of Québec, Eastern Canada, has been used for decades for wood production, fishing, hunting and other recreational activities, given its proximity to inhabited areas. In this forest, temperate and boreal species coexist through complex interactions of light, moderate and severe disturbances that create diversified landscapes. Since 2010, ecosystem management is the main tool to achieve sustainable forest management on public land, because of its capacity to address multiple economical, ecological, and social objectives. Using natural forests as reference, ecosystem management aims at maintaining ecosystem functions and resilience by reducing the gap between managed and natural forests.

This talk will present the natural developmental model for yellow birch-conifer ecosystems and the associated ecological silviculture. Since natural dynamics for mixedwood ecosystems result in an increase of conifers, late-successional species, and structural complexity over time, silvicultural systems aim at enhancing these attributes. In young and intermediate age stands, the goal is to facilitate natural development by increasing the proportion of conifers and late-successional species. In mature and old-growth stands, actions aim at promoting diversity and structural complexity by ensuring the establishment of a regenerating cohort at each intervention, and by retaining biological legacies with silvicultural systems such as irregular shelterwood and hybrid selection cutting.

Even though ecological silviculture is based on past and current natural dynamics, the overall approach to promote structural complexity and species diversity can help fostering stand resistance and resilience, two adaptation strategies to help forests face climate change in a context of uncertainty.

Size heterogeneity – productivity relationship in pine forests across an environmental gradient

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

[3] Department of Natural Systems and Resources, School of Forest Engineering and Natural Resources, Universidad Politécnica de Madrid, Spain

Abstract: Structural complexity is a key characteristic of forests stands, as it is related to many forest functions and services. Many efforts have been done to identify the effects of species diversity on productivity, showing a general positive effect that is mediated by climate conditions. However, results on the effect of other structural traits such as size heterogeneity on productivity are less conclusive, with findings suggesting positive, neutral and negative effects. This relationship is driven by growth partitioning among trees, which depends on development phase, species composition and environmental conditions. For forest management, it is of great relevance to understand the relationships between size heterogeneity, growth partitioning and stand productivity, as size structure can be modified by silvicultural interventions.

Pinewoods occupy a large area of forest land in Spain, having a great importance from ecological and socio-economical point of view, including their role in carbon sequestration. In this study, we analyse the relationship between size heterogeneity, growth partitioning, and productivity in pine forest stands across an environmental gradient in Spain. We use the network of long-term experimental plots from the ICIFOR-INIA (CSIC), which covers stands of different pine species (*Pinus halepensis* Mill., *P. nigra* Arnold, *P. pinaster* Ait., and *P. sylvestris* L.), ages and site conditions. We select the plots and surveys that represent full growing stock (unthinned or slightly thinned plots). To describe environmental site conditions, we will use climatic and topographic variables, as well as site index derived from existing models for the different species. We estimate size heterogeneity through the Gini coefficient and the growth partitioning between trees in a stand through the growth dominance coefficient. For each species, we explore the effect of site conditions on size heterogeneity and growth partitioning, and their effect on stand productivity, taking also into account the possible effect of stand age. Finally, we compare and discuss the results of the different species and their implications for promoting complex structures through forest management.

Spatial pattern analysis of trees of Re-growth forest in International Institute of Tropical Agriculture, IITA, Nigeria

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Oladele Fisayo Falade[1]
Obonganwan Ernest Asuquo[1]
[1] Department of Forest Production and Products, University of Ibadan, Nigeria

Abstract: Inter-and intra-specific interaction contributes to coexistence of tree species alpha diversity. Exclusion and coexistence of tree species are dependent on competition intensity. However, failure of conservation efforts in most tropical natural forests is due to lack of understanding of relationship between competition and coexistence mechanisms among tree species. Therefore, the objective of this study was to quantify inter-tree spatial pattern in Re-growth forest of International Institute of Tropical Agriculture, IITA, Nigeria. Five (5) parallel line transects of 400m long and 50m width were demarcated in the IITA re-growth forest. Six (6) sample plots (30m x 30m) were demarcated alternatively with 30m intervals on a line transect of 400m long. A total of 30 sample plots (30m x 30m) were used for the study. Trees with diameter-at-breast height (dbh≥5cm) were enumerated and identified to species level and measured for stem circumference. Two reference trees maximum (Dominant) and minimum (Suppressed) dbh were selected in each plot. A circular sub-plot (Area=314.2 m^2; radius=10m) was demarcated around Dominant and Suppressed trees within a plot. Distances between reference and individual trees within a sub-plot were measured. Data collected were analysed using descriptive statistics, Correlation analysis, Clark-Evan index, C-E (Cluster stand <1.0, Regular stand; <2.14), diameter differentiation (D-D) and Mingling indices of dispersion. Dominant trees showed few significant negative correlations ($r = -0.873$; $n= 10$, $p \leq 0.027$) while Suppress expressed few significant positive and negative correlations ($r = 0.820$; $n=10$, $p \leq 0.013$) between sum of diameters of neighbouring trees and distances. Significant correlation occurred mostly at 7m to the reference trees. Ninety six percent of sub-plots expressed random pattern for communities of Suppress and Dominant trees, while three percent of sub-plots expressed cluster pattern for communities of Dominant and Suppress trees. Mingling index expressed J-shaped curve for tree communities of Dominant and Suppressed trees, respectively. Competition among trees was relatively weak and interference was more in tree communities of Suppressed than Dominant trees. Most trees were surrounded by neighbours of different species rather than same species. Spatial analysis should be limited to 7m around the reference trees.

Spatial Patterns of Eco-efficiency and Spillover Effects in the Life Community of Mountains-Rivers-Forests-Farmlands-Lakes-Grasslands Life Community

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Shaopeng Zhang[1]
Hongge Zhu[1], Yue Ren
[1] Northeast Forestry University

Abstract: Eco-efficiency as a measure of sustainability that can be improved is receiving increasingly widespread attention globally. Under the concept of integrated conservation and system governance in China, the measurement of eco-efficiency in mountains, water, forests, fields, lakes and grasses and the identification of the spatial distribution and spillover effects of eco-efficiency levels in a spatial and temporal pattern are of great significance in improving the quality and stability of China's ecosystems.Heilongjiang Province, situated in northeast China and serving as a significant natural ecological barrier in the region, encompasses diverse natural ecosystem features representative of the aforementioned systems.This study employs the super-efficiency Slacks-Based Measure (SBM) model to quantify the ecological efficiency of the Mountains-Rivers-Forests-Farmlands-Lakes-Grasslands Life Community in Heilongjiang Province from 2006 to 2019. The results indicate a relatively low overall ecological efficiency in Heilongjiang Province during the study period, classifying it as an inefficient ecological efficiency region. Spatial heterogeneity is observed among different cities within the study area.Moreover, this study utilizes GIS spatial tools and exploratory spatial econometric models to analyze the spatiotemporal patterns of ecological efficiency. The findings suggest a trade-off relationship between ecological efficiency and ecosystem services, rather than a synergistic one. Additionally, a significant negative spatial autocorrelation pattern is detected.

Structural Complexity is a Better Predictor than Single Habitat Attributes for Understory Bird Densities in Southern Andean Temperate Forests

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Abstract: The simplification of forest structural complexity, caused by anthropogenic land-use practices, is one of the main threats to understory specialist birds. We examined the association of forest habitat attributes and structural complexity with the density of four understory bird species in a Global Biodiversity Hotspot in South America. Between 2011 and 2013, we surveyed habitat attributes and conducted understory bird point counts in 505 plots in Andean temperate ecosystems in Chile. In each plot, we measured understory density, coarse woody debris (CWD) volume, number of snags, diameter at breast height (DBH) of trees, and litter depth. With these attributes, we developed an index of stand structural complexity (ISC). On average, old-growth forests had higher values for understory density, CWD volume, DBH, and litter depth than secondary forests and open fields. The density of understory species was positively correlated with the ISC for the Rhinocryptidae *Pteroptochos tarnii*, *Scelorchilus rubecula*, and *Scytalopus magellanicus*. We also found a positive association between understory density and litter depth with the density of the Furnariidae *Sylviorthorhynchus desmursii*. However, this latter species showed a negative association with the density of standing dead trees.

Our results suggest rhynocryptids as good indicators of structural complexity of temperate forest ecosystems. Also suggest the utility of an index of structural complexity, rather than single habitat attributes, for determining the density of understory specialist birds. We recommend that management plans should promote the retention of habitat legacies that contribute to the structural complexity of forest ecosystems.

Synergies between structural diversity and economic value in mixed forests of European beech with spruce and Douglas fir

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Abstract: Forest management in Germany is based on mixed forests with the underlying goal of providing several services and functions, both ecological and economical. This might be related to a more complex three-dimensional distribution pattern of tree elements, resulting in a higher overall structural diversity of mixtures. Structural diversity can present economic benefits over time, e.g. through income diversification; however, there is a lack of research on the relationships between structural diversity and economic outcomes in mixed forests. We hypothesize that there are synergies between economic value and structural stand complexity (from laser scanning data), while they differ between forest types (mixture or pure stands). We analyzed 40 plots of 0.25ha of pure and mixed stands of beech, Douglas fir and spruce throughout Lower Saxony, Germany. We scanned the plots using a mobile laser scanner with leaf-on conditions in July 2021. Scan data were processed with the Geoslam Hub software to produce 3D point clouds. The raw point cloud was first subsampled by removing points closer than 0.5 cm to each other. Then, we obtained the structural diversity indicators of box dimension, the effective number of layers (ENL) of dimensions 0, 1, and 2, and the vertical diversity ratio (VDR). As a simplified indicator of an economic value, we used the value of standing timber (stumpage value) based on inventory data. We modeled the relationships between the structural diversity indicators with economic value using either generalized linear mixed models or linear models. We noticed that the relationship between stumpage value and structural diversity was positive for most of the indicators, and this relationship is mediated by forest type in some of them (ENL0 and ENL1). In general, either Douglas fir or its mixtures with beech performed better in both structural diversity indicators and economic value. Thus, admixing beech forests with Douglas fir could be a nature-based solution to increase structural diversity as well as the economic value of the forests.

The illusion of heterogeneity: unveiling the impact on biodiversity and the need to embrace biodiversity as a dynamic process

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Carlos Miguel Landivar Albis[1, 2]
Carsten Dormann[1]
[1] Biometry and environmental system analysis, Uni Freiburg, Freiburg,Germany
[2] Bundesforschungszentrum für Wald, Vienna, Austria

Abstract: Forest management often aims to improve biodiversity by increasing forest structure heterogeneity using indicators such as tree species richness, deadwood diversity, and natural regeneration indices. However, existing research report contradictory results on how biodiversity responds to these variables, particularly at large spatial and temporal scales. Our study examined the effect of forest management on forest structure heterogeneity and its biodiversity implications in temperate forests. We performed a systematic review of peer-reviewed studies examining the impact of forest structure indicators on the species richness of four taxa (beetles, vegetation, fungi and lichens). Then, we evaluated the effect of forest management and local environmental conditions on forest structure heterogeneity in Germany's Black Forest using a Structural Equation Model (SEM). We also analyzed the effect of forest structures and heterogeneity on species diversity and community composition of seven taxa using Generalized Additive Models (GAM) in managed stands in Germany's Black Forest. Lastly, using a partition tree algorithm, we assessed the transition point for the biodiversity of three taxa (lichens, mosses and fungi) resulting from forest structure variables in protected Scandinavian areas. We found that management-influenced forest structures had no significant direct effect on species richness. While forest management actively shapes forest structure heterogeneity, the response of local environmental variables is taxa-specific, and we didn't find any clear pattern to suggest using a forest structure variable as a biodiversity indicator. Deadwood diversity significantly affected the biodiversity of lichens, mosses, and fungi in protected areas. Still, observed values were far from those that can be found in managed forests, making such transition points impractical for forest management. Our findings challenge the idea of using forest structures as biodiversity indicators and suggest a taxa-specific approach based on common triggers for conservation and management goals.

The trade-offs between timber production and forest grouse occupancy become harsher at larger spatial scale in the boreal production forests

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Abstract: Forest management affects the viability of forest biodiversity causing alterations to habitat quality. Sustainable forest management aims to find win-win solutions for economy and biodiversity, ensuring that timber flow is maintained while minimizing degradation of forest characteristics increasing habitat quality. As species are related to different forest characteristics at different spatial scales, the impact of forest management on their habitat can also be different. In this context, the aim of our study was analysing the spatial trade-offs between timber production and grouse occupancy at multiple spatial scales.

We simulated and optimized a Finnish forest holding for a typical rotation horizon under several management options with a forestry dynamics model. We compiled production possibility frontiers to reveal the tradeoff between the forest economic (Net Present Value of timber) and ecological value (grouse occupancy). Occupancy for four forest grouse species (hazel grouse, black grouse, capercaillie and willow grouse) was modeled using nationwide wildlife triangle census data with variables related to forest structure and composition at local (stand), home-range (1-km) and regional (5-km) scales.

Our results show that the trade-offs between timber production and forest grouse occupancy were species- and scale-specific. An increase in the economic value of the landscape highly reduced the landscape occupancy of capercaillie, related to undisturbed contiguous forests, intermediately for black grouse and hazel grouse, both preferring a mosaic of mixed young forests and marginally for willow grouse, related with open regeneration or poorly productive forests. The slope of the trade-off curves was steeper when species occupancy was estimated with predictors at regional than at local and home-range scales, as at this scale the explanatory power of the forest characteristics was larger and larger the impact of timber harvesting on grouse habitat.

In conclusion, our research demonstrates that the evaluation of the trade-offs between timber harvesting and species occupancy at multiple spatial scales can better inform forest managers about the species' potential use of the landscape and help target management at the relevant scale. The evidence that the conflicts are expected to be harsher at large spatial scales calls for better integration of forest planning among small forest owners.

Transformation methods of pine monocultures to mixed-species in the Mediterranean. The COMFOR network.

Abstract: The need to maintain and increase species- and structure-rich forests has increased in recent decades. This type of forest has positive effects on the regulation of biogeochemical cycles, the conservation of biodiversity and the mitigation of global warming. This need clashes with current forest landscape in many regions, which it is populated with monospecific and regular stands. With the turn of the century, the idea of increasing the area of structurally heterogeneous forests like mixed forests or the implementation of closer-to-nature management has been gaining attention. Although these principles have been recurrent in the history of forestry, almost since its origins (Gayer 1898), it is in the context of Global Change that a definitive move forward can be given to its large-scale implementation. Among the silvicultural options to maintain or increase structural complexity the irregular shelterwood system (ISS) has been proposed. This silvicultural system has been applied in boreal and temperate forests whereas, to our knowledge, its implementation on more semi-arid conditions, like the Mediterranean, is non-existing. Here, we present the first results of a broad scale implementation of the expanding gap variant of the irregular shelterwood system in southwest Europe. The implementation consisted of opening small and large gaps according to different site specific objectives. For example, in one of the sites the objective was to replace the monospecific pinewood plantation into a mixed oak Mediterranean forest. In this case, the gap size should prevent the establishment of pine seedlings while allow for a good development of planted Mediterranean oaks (*Quercus suber, Q. ilex and Q. faginea*). The analyses after three years of implementation showed that opening very small gaps (gap diameter = 0.5 times the dominant height) controlled the regeneration of *Pinus pinaster* (a light demanding species). However, larger gaps increased the survival rate of saplings indicating that a trade-off between controlling for pine regeneration and oak plantation performance must be considered. We discuss the appropriateness of the method and recommend guidelines for its correct implementation in Mediterranean forests.

Tree diversity increases forest temperature buffering

Abstract: The rising frequency and intensity of climate extremes make the stable provision of ecosystem functions and services a priority for forest management. One crucial but often overlooked forest function is the buffering of temperature extremes, that is, the cooling of hot and insulation against cold macroclimate temperatures beneath the tree canopy. Tree diversity may play a significant role in enhancing this temperature buffering, which may itself maintain forest biodiversity and functioning, for example, by stabilizing functions like photosynthesis that respond non-linearly to temperature. Despite its significance, the effect of tree diversity on temperature buffering remains largely unknown. Here, we leverage hourly measurements of microclimate temperatures over six years from a large-scale forest diversity experiment covering a species richness gradient of 1 to 24 tree species. We show that tree species richness consistently increased forest temperature buffering across daily, monthly, and annual time scales. We found that species richness strengthened both components of forest temperature buffering, the cooling of hot and the insulation against cold macroclimate temperatures, with the cooling effect being more pronounced. By disentangling the forest properties responsible for the buffering effect, we show that species richness effects are mediated by vegetation density and structural diversity, assessed as leaf area index and stand structural complexity, respectively. Our results demonstrate that forests with high diversity in tree species and structure have a stronger buffering effect on temperature fluctuations than forests with low tree diversity. This buffering effect of tree diversity may have important implications for temperature-sensitive forest functions, the diversity of forest-dwelling species, and

the thermal stress release humans experience in forests. Due to their temperature buffering capacity, species-rich and structurally diverse forests may foster the stable provision of ecosystem functions and services under global warming and climate extremes.

Tree Growth at Gap Edges. Insights From Long Term Research Plots in Mixed Mountain Forests

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Peter Biber[1]
Hans Pretzsch[1]
[1] Technical University of Munich, Chair for Forest Growth and Yield

Abstract: The structure and dynamics of Central Europe's forests are increasingly characterized by canopy gaps which either result from disturbances or from planned silvicultural actions. It remains, however, unclear, whether the neighborhood to a gap has effects on tree growth which cannot be sufficiently covered by existing standard models so far. In order to test for such effects, we used data from a series of long term experiments in Southern German mixed mountain forests, where silviculture has been traditionally working with gaps in order to steer forest structure and species shares. In parallel, we developed a method for an automatized detection of canopy gaps and gap edge trees given such data. We found that the basal area growth of such trees amounted to about 15–30% more compared to what could be covered by a classic spatial competition index, with a plausible ranking of the main species. Our results suggest, in addition, that an exposition to a gap has a longer lasting effect on tree growth, even after the gap has closed again. With regard to such long-term effects, we found that tree size at the first exposition matters, with strong species-specific differentiation. We concluded that gap exposition effects on tree growth, given their order of magnitude, require being included in tree growth models which are used for planning purposes.

Understanding the competition between different species in mixed forests: The impact of European Beech on the morphology of Scots Pine

T1.8 Complex forests: Understanding and management of multiple species, structures and ecosystem services.

Abstract: Mixed forests can have higher levels of resilience and resistance to environmental risk, and a more diverse portfolio of ecosystem services. The challenge now is to properly understand the interaction between species to adequately plan for future forests. Our research investigates how direct competition between European beech (Fagus sylvatica) affects the morphological characteristics of Scots pine (Pinus sylvestris L.). For this purpose, high-resolution terrestrial laser scanning (TLS) was performed, combined with quantitative structure modeling (QSM) allowed us to obtain an accurate and non-destructive representation of tree structures, especially at the thin branch level. This methodology allowed accurate estimates of tree structural parameters, such as crown and trunk variables, and to determine crown competition indices. Our study was conducted on two long-term permanent plots in the Bavarian region, examining 31 Scots pines, 14 of which were in direct competition with Beech. We obtained seventeen crown characteristics, four trunk variables, and the competition between individuals was defined by the KKL index at 60% of the height of the tree in question. The trees were felled, and measurements were validated on the ground. The findings indicated significant differences in the crown and trunk structures of Scots pine trees due to direct competition with European beech. As such, this study supports the value of using advanced technologies like TLS and QSM for understanding inter-species competition and managing complex forest structures in the context of climate change. Furthermore, the evidence provided emphasizes the need for a nuanced approach to forest management practices, taking into consideration the distinct responses of different species to competition.

Abstract: Mixed-species forests are common in natural environments, and recent findings of their benefits led to increased forest planting areas with mixed species worldwide. Recent studies suggest that mixed-species stands can overyield mono-specific stands. A more detailed understanding of how an inter-specific neighborhood affects tree growth, i.e., whether overyielding is mainly an effect of higher space-use-efficiency and packing density or higher efficiency of resource use (e.g., water, light, nutrient), may improve the knowledge-based design of resource-efficient forest ecosystems. For a common mixture in temperate forests (European beech (*Fagus sylvatica* L.) and Scots pine (*Pinus silvestris* L.)) for which overyielding have been reported, we here provide further insight into tree neighborhood diversity – crown structure - growth efficiency relationship. Based on 128 individual felled trees, we show that in mixed compared to mono-specific stands, (i) the tree crown and its components follow different allometric relationships, and (ii) the branch and leaf biomass allocation along the vertical structure are different, especially for E. beech. We (iii) show that an interspecific neighborhood can significantly increase the growth efficiency of E. beech. Our findings reveal that the overyielding in mixed stands is partially due to heightened space-use efficiency and packing density, attributed to distinct allometric relationships and biomass distribution within crowns. Furthermore, we posit that this overyielding is not solely dependent on spatial dynamics but is also enhanced by superior efficiency in resource use, with both effects coexisting. Our results are essential for individual tree modeling using potential-modifier approaches. They suggest that both potential growth and its reduction by local competition require an adjustment before models for mono-specific stands can be successfully applied to mixed stands.

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

400 years of fire history hidden at the bottom of our lakes

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

Abstract: Forest fires are getting more intense and frequent. In Canada, the surface burnt in the first 6 months of 2023 was 8 times greater than the mean of the last 30 years. Will this become our new reality? What does the future hold for our forests? To answer these questions and predict the fire dynamics under climate change, reconstructing past fire dynamics is essential. However, a major knowledge gap regarding past disturbance regimes in preindustrial forests remains, and past fire proxies are sparse, especially in Canadian boreal forests. So, how can we reconstruct fires?

At the beginning of forest exploitation, waterways were used as the main wood transportation. Since around 15% of log-driven logs sank during their transport, this accumulation of subfossil wood can serve as a proxy for reconstructing the fire dynamics of preindustrial forests. In Québec (Eastern Canada), eastern white pine stands used to dominate the landscape until 1800 and are now very sparse owing to intensive forest exploitation. Because of their high ecological and monetary value, efforts to preserve these stands and improve managing methods are necessary. However, little is known about the natural occurrence of fires in these stands and how it has changed with anthropization and climate.

The aim of this study was to reconstruct fire regimes in white pine stands of Eastern Canada forests from the preindustrial period to present using subfossil log-driven logs. We extracted 1000 logs from the bottom of lake Tee (Québec) and dated 90 fire scars.

We were able to reconstruct the fire dynamics of the last 400 years and revealed that surface fires occurred naturally in white pine stands. However, forest exploitation and climate change led to an increase in fire frequency (one fire every 10-50 years) since the middle of the 19th century. This study is the first to reconstruct fire regime of the preindustrial pine forests of Québec and demonstrates how human activities have interfered with this disturbance in the past. Our results are essential for the sustainable management of pine forests in Québec and to predict how fire regimes will be modified in a warming world.

Algorithms for multi-pith and tree-ring detections of stem images – a preliminary research on fresh stem discs

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

Abstract: Mixed forests have gained attention due to their better resistance to threats of climate change. To understand their growth patterns for in-depth ecological insights, dendrochronology is often used by analyzing stem cores and discs. However, stems in mixtures are often eccentric and may have multiple piths, so that the two directional cores typically extracted might not be sufficient to represent complex internal patterns.

In recent years, studies that employ automatic detections to reduce the burden of manual employments and produce reproducible measurements have emerged.

In this study, we have developed algorithms capable of extracting the pith and the tree ring data that are also able to handle detections under multi-pith and irregular discs conditions. Using X-ray images from 25 discs of conifer and broadleaf species, the hypothesis has been drawn that the application of our method on whole disc images can produce results that are identical to those detected manually.

The findings show that the algorithms obtained an average error of 4.0 and 1.57 pixels (equivalent to 0.60 mm and 0.24 mm) in comparison with human-eye detections for the pith and the tree ring detections, respectively. These offered sufficient multi-pith targeting capability, and considerably reduced the subjective error from manually determined ring width detection tracks.

The work offered insights into capturing irregular stem patterns and steps to reduce the burden of manual work. However, the distinguishment of the outer bark, a better edge detection method, and the trade-offs between the resolution and the computation difficulties remain open.

To conclude, the detection of ring patterns can help to extract precise patterns from irregular discs with relatively low manual efforts. Additionally, with this methodology, scientists can have access to more representative ring widths and growth patterns for a better analysis of structurally heterogeneous stands, such as the resilience to draught stress.

Assessing the growth response of silver birch (Betula pendula Roth.) to climate change

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

Lorna Zeoli[1]
Hugues Claessens[1], Tom De Mil[1]
[1] Forest Is Life, TERRA Teaching and Research Centre, Gembloux Agro-Bio Tech, University of Liège, Passage des déportés 2, 5030 Gembloux, Belgium

Abstract: In Europe, forest owners and managers have favoured a little number of species for a long time (e.g., Norway spruce, common beech), that are now threatened by the current extreme climatic events weakening trees and leading to forest dieback. This phenomenon raises the critical need for diversifying forests with a wider range of species to look towards a sustainable adaptive management.

Among the potential species, some native species were once neglected but should recover their rightful place in the forest ecosystem. In this context, silver birch (*Betula pendula* Roth.) could play a key role in the future forest diversification: its large ecological amplitude goes with a remarkable capacity to colonise diversified environments, even the most constraining.

Despite such interesting characteristics, the climatic sensitivity of silver birch has been barely studied in Europe. This issue has motivated my PhD project that combines complementary approaches, namely dendrometry, dendroecology and dendroanatomy.

The assessment of long-term growth response of silver birch to past climatic events will be performed at the regional scale of Wallonia (Belgium) through a dendroecological approach. Then, I will link tree structure to tree function by studying the impact of extreme climatic events on xylem anatomical traits and more specifically, the wood intra-density fluctuations using x-ray CT scan method and quantitative wood anatomy. Finally, the influence of soil water availability on growth daily variations will be assessed along contrasted forest sites using automatic radius dendrometers.

Biotic and abiotic factors in shaping variation of tree radial growth along topographic gradients in northwestern Yunnan, China

Abstract: Stem radial growth is known to be highly responsive to varying weather and offers a comprehensive record of tree inter-annual growth patterns. In mountain ecosystems, the diverse range of environmental conditions generated by topographic gradients provides an excellent opportunity to examine the influence of abiotic factors on tree radial growth. However, only 31 out of 110 articles reviewed, found significant relationship between tree radial growth and climate, meanwhile, only 16 of 31 studies found a significant relationship of radial growth with climate in elevation gradients (Cuapio-Hernández et al., 2023). This indicates other factors, e.g., biotic ones, and climate mutually influencing radial growth. Since specific influences of biotic factors, and their relative contributions with abiotic factors, in influencing the variation in tree radial growth, are not well understood. The aims of this research are to study how forest structure and composition, climatic conditions and soil nutrients in shaping tree radial growth variation along topographic gradients (elevation, mountain aspect and slope degree). We set inventory plot systematically in four cardinal directions at 100-m elevational intervals from one peak in the Hengduan Mountains, southwestern China. We measured and analyzed species composition, maximum height, basal area, number of trees per hectare, tree species richness, soil organic matter, soil nitrogen and soil phosphorus of each plot. We cored all trees with diameter at breast height larger than 10cm in the plots. We estimated the air temperature of each plot from 1958- 2021 based on the closest meteorological station and plot-based measurements for nearly a year. We calculated Standardized Precipitation Evapotranspiration Index (SPEI) of the closest meteorological station. We developed ring-width chronologies of each species in each plot, and analyzed the relationship between the radial growth with temperature, precipitation, SPEI, and soil nutrients change along topographic gradients. We also explored to what degree forest structure and species composition can explain tree radial growth, by examining the correlation between vegetation attributes with growth-climate/soil relationship. Our study will highlight the influences of biotic and abiotic factors in determining relationship between tree radial growth along topographic gradients and improve the comprehensive understanding of forests growth under climate change.

Carbon and oxygen dual-isotopes in tree rings indicate alternative physiological responses opted by European beech trees to survive drought stress

Abstract: Poor drought tolerance of European beech trees raised concerns in Europe. We hypothesized that beech could show an opposite physiological response to the same level of climatic drought with a change in edaphic drought. We performed a combined analysis of $\delta^{13}C$ and $\delta^{18}O$ in tree rings to reveal retrospective temporal physiological responses of trees to drought. The edaphic drought was assessed by quantifying the capacity of soil to store water in plots (classified as “dry” and “less-dry”) near the drought limit of the species in three near-natural oak-beech ecotones in Germany and Switzerland. Neighbourhood competition was quantified. A climatic drought index was calculated from meteorological records and related to the $\delta^{13}C$ and $\delta^{18}O$ values of the trees. Trees from dry plots showed a higher response to drought and climatic dependency than less-dry plots. Neighbourhood competetion increased $\delta^{18}O$ values significantly. Dual isotope analysis shows a tendency of greater stomatal resistance in dry plots and higher stomatal conductance in less-dry plots. We conclude that beech trees belonging to the same population under changing soil water availability can show different physiological responses under climatic drought stress. Our finding indicates the high plasticity of the beech trees to survive drought stress with varying site conditions.

Climate change effects on Mediterranean beech forests: new insight from dendro-ecological analysis and continuous monitoring system

Abstract: Forests provide an increasing array of ecosystem services to our society. At the same time, forest ecosystems are put under pressure by climate change with increasing trends in disturbance size, frequency, and severity. Although trees are able to survive the impact of extreme events thanks to their adaptive traits, is crucial to identify the most resilient species capable of countering future rates of climate change.

In this study we monitored two *Fagus sylvatica* stands located in the Matese Regional Park and subject to different microclimatic conditions, with the aim to unravel the responses of this widespread and important species to the environmental drivers and to climate stressors, such as drought. The adopted approach integrates dendroecological analysis with real-time monitoring data. Each monitored tree is equipped with a TreeTalker devices that transmit high-frequency data on the WEB cloud with a unique IoT identifier. Such technology has been demonstrated to be helpful in monitoring tree-level ecophysiological processes and their relation to environmental drivers.

Tree ring data and ^{13}C -derived intrinsic Water use efficiency (WUEi) of the two stands showed how the same species responds differently to microclimatic fluctuations, in terms of productivity and water use. The monitored trees during the 2021 and 2022 growing season, increased their transpiration with vapor pressure deficit (VPD) when the water deficit index was moderate, while the transpiration was lowered at high water deficit values, indicating a reduction in transpiration during the most droughty periods. In 2022 sap flux was generally lower, even if the response to VPD and water deficit appears to be the same. The contribution of incoming radiation was significant in 2022, while not in 2021. The transpiration of the Fagus trees in the beech forests appears to be limited by the low water availability, when in summer there is shortage of water resources.

We will discuss how our approach, showing the long-term trends in the hydraulic behaviour of Mediterranean *Fagus* forests and potential implications of it on the plant health and growth, help identifying proper "climate-smart" management strategies.

Climate effects on the growth of Pinus caribaea Morelet at the Intakin Silvicultural Research Station, Chiang Mai Province, Thailand

[3] Forestry Research Center, Faculty of Forestry, Kasetsart University. 50 Ngamwongwan Rd, Lat Yao, Chatuchak, Bangkok 10900, Thailand

Abstract: The relationship between the growth of *Pinus caribaea,* an exotic pine species in Thailand*,* and historical climatic variables was studied. Standard dendrochronological techniques were employed on a total of 40 core samples obtained from 20 trees to cross-date tree-ring width and establish the growth patterns of each sample. Over the period of 1985-2019, the calculated mean annual ring-width value was determined to be 1.008 cm per year. Additional statistical parameters derived from the COFECHA program, including mean series intercorrelation, average mean sensitivity, standard deviation, and autocorrelation, were found to be 0.679, 0.423, 3.534, and 0.585, respectively. An analysis of the relationship between the tree-ring widths of P. *caribaea* and climatic data indicated a strongly significant and negative correlation ($P<0.01$) with mean temperature in April ($r = -0.442$). The chronology also exhibited a significant and positive correlation ($P<0.05$) with mean relative humidity in April and rainfall in October ($r = 0.422$ and 0.370), respectively. Conversely, a negative correlation ($P<0.05$) was identified with the total rainfall in November ($r = -0.350$). Among the climatic factors analyzed, the temperature in April emerged as the main limiting factor for the growth of *P. caribaea* ($r^2=0.195$; $P<0.01$). This investigation emphasizes the significance of scrutinizing growth-restricting factors and establishing meaningful associations between climate variables and the growth of P. caribaea via the analysis of tree-ring widths using dendrochronology. These findings can be effectively employed to inform forest plantation management strategies and facilitate the identification of suitable areas for cultivating exotic pine species in Thailand.

Climate sensitivity of Norway spruce and Scots pine radial growth in a warming Norway, 1960-2020

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

[1] Norwegian Institute of Bioeconomy Research (NIBIO), Division of Forest and Forest Resources - Department Forest Management, Norway
[2] Norwegian Agriculture Agency (Landbruksdirektoratet), Department Ressources and Land - Section Forest, Norway

Abstract: Boreal forests are considered among the most vulnerable forest ecosystems to climate change, yet it is still unclear whether the warming trend of the past decades has triggered a change in the long-term growth dynamics. Since 1960, climate change has brought a mean temperature increase of 1.3°C during the growing season in the forested parts of Norway, accompanied with changes in precipitation patterns. Using the National Forest Inventory (NFI) plot network, we analysed the long-term relationship between radial growth and climate for the two dominant conifer species of Norway - Norway spruce and Scots pine - over a 60 years period (from 1960 to 2020). Despite the significant warming trend, the linear growth-climate relationship recorded in tree rings was relatively unchanged between the two sub-periods 1960-1990 and 1990-2020 in both species. We could confirm findings from earlier studies that shifts between temperature-limited and water-limited radial growth are tightly related to mean June temperature with water-limitation dominating under higher June temperatures. The temperature threshold between the two groups did not shift between the two 30-year periods. We subsequently examined growth-climate relationships at decadal time scales using moving windows. This analysis revealed important temporal shifts in the sensitivity of radial growth to temperature and water availability for spruce and pine. This study shows a relatively stable long-term relationship between growth and climate for Norway spruce and Scots pine based on the NFI network. However, it encourages discussion around updating drought indices to increase their relevance to boreal forests as well as additional tree-ring analysis, for example by including the specific response to individual climatic events.

Coherent but different climate responses of dominant and codominant trees in a Taiwan Cryptomeria japonica plantation

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

Ching-Chu Tsai[1]

[2] Experimental Forest, College of Bio-Resources and Agriculture, National Taiwan University

Abstract: Deciphering the climate signals embedded in trees is the first and pivotal step in assessing the impacts of climate change on forests. Trees record complex biotic and abiotic environmental signals, and different frequencies of radial growth variability may correspond to various climate factors. Extracting climatic signals embedded in radial growth is thus a crucial but nontrivial task. Furthermore, dominant and codominant trees may exhibit differential sensitivities to various climatic factors. This study analyzed tree-ring series of 37 dominant trees (DBH ³ 55 cm) and 26 trees codominant trees (DBH < 55 cm) from a 96-year-old *Cryptomeria japonica* plantation in central Taiwan. We used ensemble empirical mode decomposition to filter radial growth into different frequency bands. Between 1940 and 2020, radial growths were positively correlated with the growing season average daily minimum temperature (Tmin) and the early spring precipitation of the previous year, but negatively correlated with the annual average of daily sunshine hours (SSHr) and the diurnal temperature range (DTR). The detrended radial growth series were negatively correlated with the annual average of daily maximum temperature (Tmax) and the potential evapotranspiration (PET) in the early growing season. The highest frequency variations in radial growth were positively correlated with the average daily dew point temperature (DPT) of early spring between 1961 and 2021. The dominant and codominant trees responded coherently to various climate variables, although with differential sensitivities. The dominant trees responded stronger to Tmin, precipitation, and PET. In contrast, the codominant trees were more sensitive to Tmax, SSHr, and DPT. The study suggests that to understand how trees respond to climate using tree-ring analysis, we should include trees of different social statuses and separate radial growth variations into frequency bands. Otherwise, results may underestimate or overestimate the impacts of climate change, if not misleading.

Combining tree-ring growth and carbon isotope data enhances the understanding of climate sensitivity and physiological responses for Chinese fir

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

Aiguo Duan[1]

[1] State Key Laboratory of Efficient Production of Forest Resources, Key Laboratory of Tree Breeding and Cultivation of the State Forestry Administration, Research Institute of Forestry, Chinese Academy of Forestry, Beijing 100091, PR China

Abstract: Chinese fir(*Cunninghamia lanceolata* (Lamb.) Hook) is one of the most important forest tree species in China; hence possible adverse factors affecting its growth and physiology can have strong ecological and economic impacts. Hence, we investigated the tree growth and physiological response of 30 Chinese fir provenances in relation to changes in atmospheric CO_2 concentration(c_a) and climate in southern China during 1987-2013. Trees(a total of 354 trees) were sampled at a long-term common garden, encompassing the majority of Chinese fir's distribution range. Combined dendrochronology with carbon isotope analysis ($\delta^{13}C$), the 30 provenances were compared in terms of climate-growth relationships, growth trends and growth response to drought stress. The present analysis suggests that temperature and relative humidity is crucial for determining the growth and physiology of Chinese fir trees in our study. $\delta^{13}C$ in tree rings provide complementary information on eco-physiological responses to environmental changes and have been shown to be more sensitive to current growing-season climate than radial growth and wood density. We found that intrinsic water-use efficiency (iWUE) increased significantly over the last 27 year by 12.71 – 33.56%, but radial growth has significantly declined (--− 63.38% ~ − 88.93%). Strong growth decreases reflected increasing water stress as a result of drought events, which was not offset by greater iWUE. Our results highlight the important role of provenance temperature in growth rate and water use efficiency. Seed sources experiencing slightly warmer and more humid climates from the middle region grew faster and had higher water use efficiency (inferred from lower $\Delta^{13}C$) than provenances from drier climate conditions. However, provenances from drier climates had slower growth, higher wood density and higher carbon isotope discrimination ($\Delta^{13}C$) than those provenances. These results provide a better understanding of the climate sensitivity and physiological responses of Chinese fir under long-term drought conditions. Increasing the number of tree ring studies linked with eco-physiological parameters of tree growth is recommended to better visualize the level of stresses on the Chinese fir provenances.

Comparing methods for estimating gross primary production in a Norway spruce forest in SW Sweden

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

[3] Department of Biological and Environmental Sciences, University of Gothenburg, Sweden

Abstract: Forests are both affected by and affecting global climate change. In the Anthropocene, the era of human dominance on the Earth System, forests need to adapt to climate change, and at the same time, there is a need to optimize forest management for contributing to climate change mitigation by enhanced ecosystem carbon (C) storage.

Gross Primary Production (GPP) is a key flux in terrestrial ecosystems and roughly equivalent to stand level photosynthesis. We will present estimations of GPP for a 60-year-old Norway spruce forest at the SITES station Skogaryd Research Catchment comparing different approaches. First, we will use sap-flow measurements of transpiration conducted during 2015-21 combined with tree-ring isotope data ($\delta^{13}C$) at annual resolution from the rings to of the same trees. The GPP calculation is based on the well-established physiological relationship between GPP and transpiration, termed water use efficiency (WUE), the latter derived from the tree-ring $\delta^{13}C$. Second, GPP is assessed by eddy covariance (EC), the current state-of-the-art method. The EC approach is based on measurements of Net Ecosystem Production (NEP) and estimates for ecosystem respiration (Reco) and have been conducted since 2015, i.e. spanning the same years as approach one and including the drought year 2018, in which EC data suggest no change in GPP at the site.

In addition, we will present preliminary data on GPP estimates, stated in 2023, using a recently developed alternative method, which combines measurements of sap flow and the $\delta^{13}C$ of phloem, using the same physiological principles as above. Those measurements started immediately after a selection harvest and cover both, a selective cut stand and an un-harvested control. This method, in contrast to the EC approach, provides tree-scale information on GPP, which is critical to the assessment of selection harvest conducted at the site.

Coupling tree-rings and carbon isotope discrimination to forecast early warning of dieback on beech forest along a latitudinal gradient in Italy

[3] Department of Agriculture and Forest Sciences (DAFNAE), University of Tuscia, 01100 Viterbo, Italy
[4] National Biodiversity Future Center (NBFC), 90133 Palermo, Italy

Abstract: The impact of extreme climatic events such as dry spells accompanied by warmer temperatures has caused forest dieback and increased tree decline worldwide. Nonetheless, the physiological mechanisms to cope droughts and how forests will be able to survive under extreme climatic conditions are scarcely understood. In this study, we conducted a retrospective analysis of the period 1965-4, using tree-rings, basal area increment (BAI) trends, and ^{13}C derived intrinsic water use efficiency ($_i$WUE) to assess forest growth performance under droughts and disentangle the hydraulic strategies adopted by European beeches (*Fagus sylvatica* L.) by using generalized additive mixed models (GAMM). To investigate the temporal variations in forest resilience, we performed first-order autocorrelation (AR1) analysis, to detect any early warning signals of tree dieback, to identify sites that are more to withstands future extreme events.

We selected four stands of beech forest along a latitudinal gradient in Italy. The sites were: Trentino (TRE), Lazio (LAZ), Matese (MAT) and Calabria (CAL). The GAMM analysis revealed a drastic reduction in BAI trends in TRE, LAZ and CAL in the last decades, and this pattern was more noticeable in the northernmost site. On the contrary, MAT (the oldest site) exhibited a consistent increase of BAI.

The results of the AR1 indicated that TRE presented the highest increased in synchrony and autocorrelation following the drought event of 1995, indicating a reduction in resilience, thus more vulnerable to future droughts. Interestingly, $_i$WUE in TRE showed the highest increased over the last decades, suggesting that trees have responded closing their stomata to minimize water loss, reducing the photosynthesis rates, as observed by the decline in BAI.

Overall, multi-proxy, retrospective quantifications of tree-rings, BAI, iWUE and resilience assessments provide a robust and complementary tool for differentiate water use strategies and forecasting the growth decline and tree dieback, as well as identifying those that have the potential to survive in a hotter future and under drier conditions

Current and future drought vulnerability for three dominant boreal tree species

[3] Department of Forest Resource Management. Swedish University of Agricultural Sciences, 901 83, Umeå, Sweden

Abstract: Climate change is projected to increase the frequency and severity of droughts, possibly causing sudden and elevated tree mortality. Better understanding and predictions of forest responses to climate change are needed to efficiently adapt forest management. We used tree-ring width chronologies from the Swedish National Forest Inventory, sampled between 2010-2018, and a random forest machine-learning algorithm to identify the tree, stand and site variables that determine drought damage risk, and to predict their future spatial-temporal evolution. The dataset consisted of 16,455 tree cores of Norway spruce, Scots pine and birch from all over Sweden. The risk of drought damage was calculated as the probability of growth anomaly occurrence caused by past drought events during the period 1960-2010. We used the block cross validation method to compute model predictions for drought damage risk under current climate and climate predicted for 2041-2070 under the RCP.2.6, RCP.4.5 and RCP.8.5 emissions scenarios. We found local climatic variables to be the most important predictors, although stand competition also affects drought damage risk. Norway spruce is currently the most susceptible species to drought in southern Sweden. This species currently faces high vulnerability in 28% of the country and future increases in spring temperatures would greatly increase this area to almost half of the total area of Sweden. Warmer annual temperatures will also increase the current forested area where birch suffers from drought, especially in northern and central Sweden. In contrast, for Scots pine we were only able to identify drought damage associated with low early-spring temperatures. Consequently, the current area with high drought damage risk would decrease in a future warmer climate for Scots pine. We suggest an active selection of tree species, promoting mixtures and thinning to reduce tree competition as promising strategies for adapting northern-European forests to future droughts.

Dendroanatomy under an Eddy covariance tower. New perspectives for a better understanding of the link between climate, C uptake and biomass growth

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

Abstract: A better understanding of the forest carbon (C) cycle is essential to address climate change challenges. However, there is great uncertainty on the different effects of climate variability on photosynthesis (C uptake) and woody biomass growth (increment of C stock in long-term pool). Recent studies have investigated climate effects on both primary productivity (GPP) and biomass growth within the same site, evidencing different responses of C sink and C source to climate variability and, in most cases, scarce connections among them. Most of these studies have used ring width to estimate tree annual growth variability, and seasonal or annual eddy covariance (EC) measurements to estimate tree C uptake. We present different study cases in boreal, temperate and mountain conifer forests. Here, tree-ring quantitative wood anatomy (QWA) was used to assess intra- and inter-annual variability of woody biomass, and daily EC and climate data to investigate short-term variability of C uptake.

In *Pinus banksiana* boreal forest in Saskatchewan, Canada, and temperate *Pinus strobus* stand in Ontario, Canada, we observed complex associations between climate variability, C uptake and woody biomass growth. Our results warn against a simplified view of temperature limitation in boreal forests and drought limitation in temperate forests. Interestingly, strong correlations between GPP and cell and ring biomass suggest a direct linkage between C fluxes and the accumulation of carbon in woody biomass at the two pine stands. On the other hand, in a *Picea abies* stand in central Italian Alps, we found a clear influence of climate on xylem formation, but weak associations between C uptake and woody biomass production as compared to the pine stands.

Our study demonstrates that high-resolution of QWA data allows a deeper understanding of the mechanisms underlying the influence of climate on C uptake and biomass growth than the classical annual (tree-ring) approach. Integrating QWA with other sources of information operating at different scales can improve the understanding of the C cycle in forests.

Dendrochronological Potential of Native Species for Ecological Studies in Colombia

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

Jhoan Mateo Tobon Idrobo[1]

Abstract: Dendrochronology is the study of annual growth rings, which provides valuable insights into species growth and the environmental conditions they experience. Despite recent advances in dendrochronology in tropical regions, there is a need to expand the number of species with the potential to develop growth chronologies. At the Laboratory of Ecology and Forest Management of the Universidad del Cauca in Popayán, Colombia, we are assessing the feasibility of using dendrochronological methods for ecological studies in the northern tropical Andes. Our goal is to extend hydroclimatological records and establish growth models that enable the implementation of sustainable management practices for commonly harvested species. We are investigating the dendrochronological potential of *Retrophyllum rospigliosii* and *Podocarpus oleifolius*, which are native conifers of ecological importance in the Andean forests. These slow-growing species exhibit annual growth rings that allow cross-dating. Additionally, we are studying the dendrochronology of *Colombobalanus excelsa*, an endemic and endangered species of the Fagaceae family found on the eastern slope of the Andes due to its annual rings. We examined the growth patterns of commonly harvested timber species on the western slope of the Eastern Mountain Range of the Andes, including *Cedrelinga cateniformis*, *Erisma uncinatum*, and *Hymenaea* spp. Remarkably, we have identified individuals over 250 years old with annual growth rings among these species. Identifying tree rings in the Andes, particularly in the Colombian massif, will enable us to reconstruct and establish climate trends in an area that accounts for 70% of the country's freshwater supply. Additionally, the presence of growth rings in timber species will allow the development of growth models necessary for implementing measures aimed to their sustainable management and conservation. Overall, our study highlights the potential of dendrochronology in Colombia for ecological research and provides valuable insights into climate trends, species growth, and sustainable forest management practices.

Dendroecological demonstration of the adaptive value of phenotypic plasticity

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

[4] INRAE PIAF LIA FORESTIA, France

Abstract: Dendroecology allows to fit very efficiently response curves associating average time-series of annual tree-ring variables and of climatic variables. When applied on an individual basis, this method enables the adjustment of reaction norms, which are direct measures of phenotypic plasticity. The application of this approach to different annual ring variables and species demonstrates that phenotypic plasticity is not only highly variable between pairs of annual ring traits and environmental variables, but also is environmentally and genetically determined.

The application in common garden experiments is especially relevant in the frame of the climate change. The provenance trials installed in the second half of the 20th century experienced the full impact of climate change. The phenotypic plasticity estimated on these trees makes it possible to quantify, with a single value, several decades of response of an individual to local climate change.

Here we present results obtained from a common garden experiment of Douglas-fir provenances from Washington, Oregon and California (USA), planted in two sites in Southern France.

Our results show that the ability to estimate plasticity varies from almost 0% to over 90% from one ring variable to another. We also show that the ability to adjust reaction norms increases with the number of annual rings present in the time series. This is a direct consequence of the rise in statistical power that accompanies the increase in the number of rings.

But even in cases where the number of rings is as low as 20, we could sometimes estimate significant plasticity on more than 50% of the trees, which allow to comfortably use the statistical power of the common garden experiment.

In particular, we show that phenotypic plasticities associated with certain tree-ring variables are adaptive traits involved in resistance to drought: the provenances have evolved in their natural range under the effect of climatic pressures to become locally adapted.

The fact that the provenances in this common garden experiment have been established in regions hotter and drier than those in their natural range enables us to anticipate the effect of climate change when they are introduced into cooler, wetter regions.

Drought resilience in mixed forest plantations: interactive effects of functional trait diversity, tree size and competition

Abstract: Mixing tree species has been proposed as a potential solution to mitigate the impacts of rising drought stress in forest ecosystems while providing a wider range of ecosystem functions and services than dominant monocultures. However, it is still unclear how increasing tree diversity improves tree resilience to drought across different species and biotic and abiotic contexts (e.g. mixture composition, climate or degree of soil drought). Here, we investigated how the diversity of tree species and functional traits affects the drought responses of tree radial growth, wood density, and carbon isotope composition ($\Delta\delta^{13}C$, as a proxy for water use efficiency). We collected wood increment cores of 21 tree species growing in monocultures and mixtures (2- and 4-species) in nine experimental sites across Europe, belonging to the global network of forest biodiversity experiments (TreeDivNet). These experiments cover a wide gradient in climatic conditions, reflected in the forest types they represent (from boreal to temperate and Mediterranean). We determined the intensity of recent drought events based on the Standardized Precipitation Evapotranspiration Index (SPEI) and water availability outputs of the soil-plant-atmosphere hydraulic model SurEau. We obtained wood density and tree-ring width series using X-ray micro-Computed Tomography (μCT) and assessed the drought-induced responses of radial tree growth in terms of resistance, recovery, and resilience. We investigated how tree drought responses and water use efficiency varied depending on the tree species identity, the diversity of functional traits in the neighbourhood and the local climate. In addition, we analysed how the effect of tree diversity on the individual tree responses and community responses was mediated by drought intensity, tree size, and neighbourhood competition index. Our results indicate that selecting appropriate combinations of tree species is crucial for improving forest resilience to drought events. The identified mechanisms emphasize the importance

of increasing the diversity and complementarity of functional traits to adapt forests to drought risks and thus provide more robust restoration approaches in the face of climate change.

Effects of extreme weather scenarios on vitality and productivity of beech-, oak-, spruce and pine stands in northwest Germany

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

Anja Groening[1]
[1] Department of Forest Growth, Northwest German Forest Research Institute (NW-FVA), Goettingen, Germany

Abstract: Changing climatic conditions will increase extreme weather events in the future. Especially higher summer temperatures and decreased precipitation during the growing season, leading to more severe drought events, take their toll on forest vitality. Within the last years the national forest condition survey in Germany documented a decrease in vitality in all main tree species. Forest management now faces the task of developing a more climate adapted concept.

It is generally assumed that especially more frequent drought stress increases trees vulnerability on specific sites. This leads to a decrease in vitality, resulting in a reduced productivity and overall higher risk of other abiotic and biotic stressors. To establish tree specific drought limits as a reference for forest management we calculate the site water budget, being the sum of the climatic water availability in the growing season and the field capacity. On that basis tree specific thresholds for drought stress risk are defined based on literature, inventory assessments and expert knowledge.

In our project we evaluate the impact of extreme weather events of recent years on vitality and productivity on Forests in Northwest Germany through tree ring analysis (tree-ring width). We sample increment cores on plots of the forest condition survey, where concurrently soil survey data is available. To also evaluate the current drought risk thresholds for each tree species (European beech, Scots pine, Norway spruce, sessile oak and pedunculate oak) the plots were selected along a site water budget gradient. For each plot a comprehensive amount of data is available describing site and individual tree characteristics. In this study we correlate inventory data of 38 years, describing tree vitality with tree ring analysis on overall 672 sampled trees.

Our special interest is to combine growth reaction with climatic extreme events and vitality factors like defoliation and fructification to better understand tree species specific limits and to better advise forest management for the future.

Ensuring the sustainability of wood harvesting from Dry Afromontane forest in Ethiopia

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

Abstract: Accurate information on the structure, volume, and diameter growth rate of a tree is an essential element to ensure wood harvesting from a forest. Unfortunately, such information is lacking from Dry Afromontane forests in Ethiopia. Thus, in this study, we aimed to quantify the stand characteristics in the Chilimo Dry Afromontane forest and assess the sustainability of wood harvesting from *Juniperus procera* Hochst. ex Endl. trees. We established 163 plots (400 m^2) in the forest and collected vegetation data. We also conducted growth ring measurements on 12-disc samples. We determined the diameter growth rate, the current and mean annual increments, the minimum logging diameter, and the cutting cycle. We estimated the harvestable volume of wood by combining four minimum logging diameters and five cutting cycles using a stand projection table. The findings revealed that *J. procera* trees have an average density of 183 stems ha^{-1}, a total basal area of 12.1 m^2 ha^{-1}, and a standing volume of 98.9 m^3 ha^{-1}. The mean annual diameter growth rate ranges between 0.50 and 0.65 cm $year^{-1}$ with an overall mean of 0.59 cm $year^{-1}$. The population followed a reverse J-shape diameter distribution pattern. The current annual increment (CAI) occurred at 49 years, and trees reached 30 cm in diameter. The mean annual increment (MAI) occurred at 91 years. and trees attained 50 cm in diameter. Among the evaluated scenarios, the minimum logging diameter of 40 cm and a cutting cycle of 15 years provided the highest harvestable volume of wood (21 m^3 ha^{-1}) and volume increments (1.42 m^3 ha^{-1} $year^{-1}$). In addition, this scenario will enable us to preserve 82 % of the initial tree density and ensures the sustainable extraction of wood from the forest. We concluded that the forest is well stocked and has a substantial amount of harvestable volume of wood. This will enable Ethiopia to meet the growing wood demand. The study generated valuable information for policymakers to formulate a regulation for the sustainable harvesting of wood from *J. procera* trees from a well-stocked Dry Afromontane forest in Ethiopia.

Keywords: Logging, modeling, dendrochronology, cutting cycle, minimum logging diameter

Exploring the Influence of Climate and Soil Properties on Tree Ring Formation: Insights from a Multispecies Tree Ring Analysis in Central Europe

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

[2] Institute of Forest Growth, University of Natural Resources and Life Sciences BOKU, Vienna, Austria
[3] Institute of Wood Technology and Renewable Materials, University of Natural Resources and Life Sciences BOKU, Vienna, Austria

Abstract: Tree ring data is a valuable signal when it comes to growth reactions of trees due to varying environmental factors, in particular under a changing climate. Drought susceptibility and limits of different species has been the focus of many tree ring studies. However, the role of soil properties is not yet well understood due to limited data availability. To address this gap, we explored the influence of climate as well as soil compensating effects on tree ring formation.

We used a comprehensive dataset of 6 tree species (*Picea abies, Abies alba, Larix decidua, Pinus sylvestris, Fagus sylvatica, Quercus petrea* and *Quercus robur*) consisting of increment cores collected from mature stands at ~2,500 forest sites distributed over 2 Mio. hectares of forest in Austria with steep climatic and environmental gradients (mean annual temperature: 2.1°C to 11°C; mean annual precipitation: 450 mm to 2000 mm). The dataset includes detailed plot-specific climate, stand, and soil information. Soil data was obtained through a morphological description of 80 cm soil pits excavated at each forest site, laboratory analyses on a subset of ca. 20 % of the plots and upscaling of physical and chemical properties via pedo-transfer-functions for the remaining sites.

Generalized additive mixed models were fit to the data incorporating tree and stand attributes (e.g. age, competition), topographic factors (e.g. slope, aspect, irradiances), climatic factors (mean annual temperature, climatic water balance and drought indices) and detailed soil parameters (soil type, soil nutrients, plant available water capacity).

The model based on 2/3 of the data explains over 80 % of the variation in tree ring data and is currently being extended to include the climatically drier forest sites, where data collection was finished by the end of 2022. Tree growth depended on age, topographic factors, mean annual temperature, climatic water balance and plant available water capacity of the current and previous year and soil nutrient status and interactions thereof. Maximum growth was found on sites with sufficient soil moisture and nutrients and declined with a lack or surplus of water and nutrients. Species specific growth reaction were in line with the tree species auto-ecology.

Identifying proxies for drought tolerance in Sitka spruce to enhance forest resilience

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

Thomas Baer[1]
Domen Finzgar[1], Elspeth Macdonald[1], Richard Whittet[1], Rubén Manso[1]
[1] Forest Research, Northern Research Station, Roslin, Midlothian EH25 9SY, UK

Abstract: Extreme drought events across the UK are expected to increase in the future, both in intensity and frequency. Droughts can have an impact on tree growth and are a possible cause of wood defects in trees, causing cracking which can impact the structural integrity of timber. Wood density has been linked to predisposition to cracking and is also considered a potential heritable trait. Understanding the heritability of wood density and its link to drought resilience and resistance could make wood density an important proxy for resilience. With Sitka spruce (*Picea sitchensis* Bong. Carr.) being the most common and commercially important tree species in the UK, determining whether we can screen and select families of Sitka spruce showing higher resilience against drought would be of great value to tree breeding and forest management.

To answer this question, we measured tree-ring width and wood density in X-ray densitometry scans of samples taken from over 600 trees originating from 29 full-sibling Sitka spruce families growing on two sites in the UK. Individual nonlinear mixed-effects growth models were developed for both sites to remove non-climatic effects on growth. Drought events were identified using the standardised precipitation evapotranspiration index. The reaction of individual trees and families to a specific drought event (2003 to 2006) was measured using established resilience, resistance and recovery indices which compare growth before, during and after the drought event. Heritability calculations were performed to estimate the hereditary potential of the trait of wood density. Preliminary analysis suggests that although families do differ in resilience and mean density, their relative ranking in these traits is inconsistent between the two sites.

Life after recovery: post-drought compensatory growth and forest recovery dynamics

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

Thomas S Ovenden[1, 2]
Michael P Perks[2], Toni-Kim Clarke[2], Maurizio Mencuccini[3], Alistair S Jump[1]
[1] Biological and Environmental Sciences, University of Stirling, Stirling FK9 4LA, UK
[2] Forest Research, Northern Research Station, Roslin, EH25 9SY Midlothian, UK
[3] ICREA at CREAF, Campus de UAB, Cerdanyola del Vallés, Bellaterra, Barcelona, Spain

Abstract: Large scale losses in forest productivity and widespread tree mortality linked to extreme drought have now been documented on every forested continent on earth. With climate change set to increase the frequency, intensity, and duration of future extreme drought events, understanding the impact of drought on forest productivity and the post-drought recovery dynamics of these systems is increasingly important. However, the way we quantify the resistance, recovery, and resilience of tree growth to drought constrains and simplifies the temporal scale and resolution of our assessments. In turn, this limits our understanding of how forests respond and recover by partially obscuring a more complete understanding of drought legacies. To build on one of the most commonly used approaches to estimating resilience, we first demonstrated how our understanding of the drought resilience for *Pinus sylvestris* is dependent on the way in which resilience indices are calculated, using different pre- and post-drought time scales. We then developed an alternative approach using dynamic regression to capture each individual tree's relationship between climate and growth, which was then used to forecast tree growth annually for the drought year and nine subsequent years, in a scenario where no drought had occurred. This approach allowed us to increase the temporal scale and resolution of resilience assessment by comparing observed growth with forecasted growth in a 'no-drought' scenario and follow tree and stand level growth response throughout recovery and into a post-recovery phase, where we find evidence for significant compensatory growth. The existence of compensatory growth post-recovery reduced estimates of drought linked losses of radial growth, indicating that current approaches to quantifying drought impact risk underestimating tree and stand resilience and may overestimate losses in above-ground biomass. Our results have wide reaching implications for forest management targeted at increasing resilience, carbon budgeting and our understanding of drought legacy.

Long- and short-term impact of climatic conditions on mountain forest growth in the Alps along an elevation transect

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

Nikolaus Obojes[1]
[1] Institute for Alpine Environment, Eurac Research, Bozen/Bolzano, Italy

Abstract: Climate change is increasingly affecting mountain forests by an increasing frequency and intensity of extreme events such as drought or storms, but also by increasing growth conditions at high elevations due to higher temperatures and longer growing seasons. To investigate the long- and short-term growth responses of five conifer (*Larix decidua, Pinus cembra, Picea abies, Pinus nigra, Pinus sylvestris*) species to different and changing climate conditions, we combined tree ring analysis with dendrometer and sap-flow measurements starting in 2012 along an elevation gradient from the valley floor at 1000 m to the forest line at 2300 m above sea level within the LTSER platform Matsch|Mazia in the province of Bolzano/Bozen, Italy. We found a strong limitation of tree growth and transpiration by water availability at low elevations independent of species. At mid-elevations growth responses to precipitation were strongest for *Picea abies* and increasing in recent decades. Temperature responses at high elevation differed between *P. cembra* and *L. decidua* leading to growth increases of larch in recent decades. In a current project we are now adding xylogenesis and wood anatomy analysis to dig deeper into climatic impacts on wood formation and its influence on carbon storage and tree hydraulics. Given the location of the study area in the inner Alps and the resulting dry climate conditions, our measurements results could be a preview of conditions relevant to larger regions of the Alps in the future.

Pre-monsoon moisture sensitivity determines growth resilience of four Asian pine species

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

[3] Institute of Geography, University of Erlangen-Nürnberg, Erlangen 91058, Germany

Abstract: The increasing frequency of drought events poses a threat to forest stability, and the resilience of trees to extreme drought is directly related to trees and forests safety. However, the growth resilience of trees is affected by many factors, characteristic with regional and species specificity. Focusing on southwest China and Indochina Peninsula, this study used four widely distributed pine species (*Pinus densata, Pinus yunnanensis, Pinus kesiya, Pinus lattrei*) tree ring data, aiming to explore the resilience of trees to extreme drought events and reveal the influencing factors of growth resilience. The results showed that all species tree growth was markedly limited by pre-monsoon water conditions. We used pre-monsoon season 3-month standardized precipitation-evapotranspiration index (SPEI3) to identify the extreme drought events and then calculated resistance, recovery, and resilience for the quantification of tree growth resilience. We fund significant differences in drought resilience between species of our study pine, *P. densata* and *P. latteri* had highest resistance, *P. yunnanensis* had highest recovery. There was a tradeoff between resilience index, and growth recovery decreased with resistance increased, high resilience related to high recovery but was not relative to resistance. Trees growth rate and tree size effected growth resilience. Drought severity influenced trees recovery and resilience but not resistance. The sites which sensitive to pre-monsoon drought declined more in drought events but had higher recovery. However, there was no significant difference in the factors affecting drought resilience among different species. The results of our study will help to understand the adaptability of coniferous forest ecosystems to global climate change, and provide theoretical basis for management measures of coniferous forest resources in tropical and subtropical Southeast Asia regions.

Keywords: extreme drought, tree ring, growth resilience, pine, drought sensitivity

Quantifying drought impact on tree growth and wood formation: observations along an elevation transect in a dry alpine valley

T1.9 Dendroecology for Evidence- based solutions and Resilient Forest landscapes

Tamara Bibbò[1]
Patrick Fonti[2], Nikolaus Obojes[1]
[1] Institute for Alpine Environment, Eurac Research, Bolzano, Italy
[2] Swiss Federal Institute for Forest Snow and Landscape Research WSL, Zurcherstrasse 111, Research Unit Forest Dynamics, 8903 Birmensdorf, Switzerland

Abstract: Drought is increasingly affecting forest health and mortality, even in mountain areas. The Matsch valley (province of Bolzano/Bozen, Italy), one of the driest areas in the Alps, has been strongly affected by the 2015 and 2018 summer droughts and could be considered as an example of future scenario for larger areas in the Alps.

We expect drought to differently impact the timing and duration of wood formation processes along the elevation gradient and species. In particular, the lower elevation sites should be more affected by drought due to the combined effect of higher temperatures and lower precipitation. At lower elevation site, warm temperature in spring can lead to an earlier start of the wood formation process but then low water availability may lead to a premature cessation of xylogenesis or a dormant period. In contrast, climate warming can lead to a longer growing season at higher elevation due to earlier snow melt. We expect a difference between species as Pinus are less susceptible to drought than spruce and larch. Additionally, we hypothesize that deciduous larch might start xylogenesis later than evergreen spruce or pine.

Since 2012 we are monitoring tree growth along an elevational transect from 1160 to 2250 m a.s.l. that includes four plots with 4 species (40 trees total): 20 *Larix decidua* Mill., 10 *Pinus cembra* L., 5 *Pinus nigra* Arnold and 5 *Picea abies* L using dendrometers. These useful measurements to estimate both growth and water stress, have now been complemented by observations of wood formation (xylogenesis) by performing weekly micro-coring of xylem-cambium-phloem tissue during the growing season 2023. Xylogenetic analysis can directly determine climatic aspect on wood formation. Drought can impact the kinetics of wood formation, causing a lower number of cells produced, smaller and thinner cell walls and a longer duration of the formation phases.

To provide a better understanding of the impact of drought on wood formation, our contribution will provide original quantifications of the impact of drought on wood growth phenology of trees at different elevation and species within the Match valley monitored sites.

Rapid beech decline under recurrent drought stress. Findings & perspectives.

[4] Bavarian Office for Forest Genetics, Bavarian State Ministry of Food, Agriculture and Forestry (StMELF)

Abstract: During the summer of 2022, an acute drought once more afflicted central and southern Europe. This marked the third episode (after 2015 and 2018) of severe aridity in large parts of Germany within the last decade, leading to increased soil water depletion. Consequently, from July 2022 onward, European beech trees (*Fagus sylvatica* L.) exhibited early withering and pronounced premature defoliation. Nevertheless, crown defoliation exhibited substantial variation among trees within the same forest stands, prompting questions regarding the causal factors. In our study, we scrutinized twelve major drought-impacted, beech-dominated forest stands in northern Bavaria, arranged along a gradient of different nutrient regime levels (base-rich, intermediate, base-poor), with co-occurring vital (≤ 40% crown defoliation) and declining (≥ 60% crown defoliation) trees. Within each stand, we selected an equal number of vital and declining trees, culminating in a total of 332 target trees. Dendrochronological patterns were analysed to identify a potential timing of growth separation between vitality classes. Moreover, we used a Bayesian modelling framework to discern whether disparities in tree vitality hinged on competition, structure, small-scale differences in plant-available water, and competitor vitality. We further explored the factors influencing the magnitude of recent growth decline and how these were modulated by the site's nutrient regime. Our study unveiled that (i) vital and declining trees exhibited strikingly similar growth trajectories in the past, which underwent a drastic shift in recent years, indicating a potential for a rapid vitality and growth decline under recurrent severe drought stress; (ii) low and asymmetric competition bolstered tree vitality; (iii) declining trees were spatially aggregated; (iv) plant-available water emerged as a crucial determinant of tree vitality disparities within the same forest stand; (v) growth decline was most pronounced at base-poor sites. Our findings underscore the importance of accommodating small-scale differences in soil and stand characteristics and advocate for silvicultural guidance towards reduced stand densities in combination with a more heterogenous structure to mitigate European beech dieback in drought-prone forest stands.

Upscaling dendroecological studies at different spatial sampling designs: a case study on sessile oaks along a climatic gradient

[3] Institute of Forest Growth, University of Natural Resources and Life Sciences BOKU, Vienna, Austria

Abstract: Tree-rings provide the longest available quantitative records of tree and forest growth conditions, even in forests with extensive management history. Although dendroecological sampling designs are typically planned for local representativity without a comprehensive collection of tree cores along a greater region, the integration of different sampling designs could facilitate the upscaling of findings, conforming the information needs of large-scale forest planning.

Sessile oak (*Quercus petraea*) is an ecologically and economically important forest tree species in Central Europe, experiencing a potential renaissance of forest management interest, due to its wide but sometimes debated limits of drought tolerance. Within the frame of a forest site classification project in Northern and Eastern Austria over a forest area of ca. 800,000 ha, single tree core sampling at 1020 stratified sampling sites was carried out, with about a 25% share of oak stands significant for the region. In addition, seven monitoring sites have been established for the species with 15 trees sampled at each, spanning along a climatic gradient between 550 to 1250 mm annual precipitation and 7.7 to 10.8 ° C mean annual temperature. This gradient represents the entire climatic range of the species in Austria, while also approaching the xeric edge of its distribution.

Along this wide climatic gradient, the sensitivity of growth to the climatic drivers, drought induced growth anomalies, and the variability of individual tree response are tested in common multivariate statistical tools and machine learning algorithms at the different sampling scales. The statistical models are built and cross-validated on the complementing sampling designs. Mean climatological differences and other site and stand attributes are also included as predictors with lower frequency of temporal change to account for the (shifting) climatic gradient.

While previous data from similar single core sampling in the neighboring southern regions of Austria yielded promising results when modeling radial growth, the extension of the monitoring sites along the climatic gradient further reveals differences in growth patterns and their individual variability. This sets an interesting scene for the evaluation of findings at different scales, allowing also for a spatially explicit comparison of the climatic sensitivity of the selected species.

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Assessing adaptability and resilience of pure species and hybrid clones of Eucalyptus grandis and Eucalyptus camaldulensis in Kenya.

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Mitchel Akinyi Oluoch[1]
Joram Makaka Mbinga[1], Joyce Akinyi Okumu[2]
[1] Kenya Forestry Research Institute. Department of Forest Productivity Improvement, Kenya
[2] Kenya Forestry Research Institute. Department of Socio Economics Policy and Governance, Kenya

Abstract:
Hybrid crosses between the fast-growing *Eucalyptus grandis,* for high potential sites and *Eucalyptus camaldulensis*, for low potential sites are important for addressing challenges of commercial forest productivity brought about by climate change through adaptation initiatives. This study was initiated to demonstrate options for increasing productivity and quality of timber from planted forests amid the ravaging effects of climate change. The objective of the study was to determine the resilience of the Eucalyptus hybrid crosses and the pure species in terms of survival and growth in a medium potential site in Kenya. A Randomised Block designed (RBD), experiment was established with 34 treatments consisting of 15 clones of crosses between E. grandis and E. camaldulensis (GC), 18 pure E. grandis clones, all developed in South Africa, and one local E. grandis clone. Survival after establishment and growth parameters of height, and diameter at breast height (DBH) were assessed annually for seven years. Wood volume of the clones was determined from the growth parameters against weather components. Results show higher survival of pure species of *Eucalyptus grandis* clones with more than 50% trees surviving in each treatment. At age seven, the best performing clone showed growth in volume of 3,875.1m^3. Overall, there was a significant difference in volume growth among the clones, with hybrid clones consistently showing higher volumes compared to the germplasm of the pure species. The results confirms the potential of hybrid crosses as a viable option to increase productivity of forests in medium potential zones as well as a means of mitigating against the vagaries of climate change.

Key words: *Eucalyptus grandis* clones, Eucalyptus hybrids clones, resilience, climate adaptability.

Ecosystem Services Modelling of Ecologically Degraded Forested Wetland (Montreux Site)

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Shubham Kumar[1]
Laxmi Kant Sharma[1]
[1] Central University of Rajasthan

Abstract: Forested wetlands provide essential ecosystem services. Anthropogenic activities such as agriculture have increased the degradation and conversion of privately held wetland regions. The Montreux sites are the Ramsar sites of international importance where ecological changes have occurred, are occurring, or are projected to occur as a result of technological advancements, pollution, or other human influence. Ecosystem service valuation can guide restoration decisions. Therefore, the objective of the current study is to evaluate ecosystem services provided by ecologically degraded wetland ecosystems with a view to proper restoration and management practices. The study includes InVEST model for the valuation of ecosystem services. In this research, we discuss how such findings could influence local policy for environmentally responsible management and set a baseline for the vast wetlands networks. The study concluded that forested wetland plays a significant role even after the ecological conversion. The areas with high ecological degradation have shown low ecosystem services in terms of water storage, vegetation covers as well as carbon storage. These hotspot areas should be prioritized for the ecological restoration of the Montreux site. Keoladeo National Park, Montreux site, has recovered its ecological disturbances in several parts being a protected area. This is a positive sign for the study site that is an indication for its improving ecological condition.

Effects of forest harvesting technologies on the hydrology of compaction-prone soils

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

[9] Austrian Federal Forests, Purkersdorf, Austria

Abstract: Forest soils usually show high infiltration rates and thus, compared to other landuses, a quick recharge of the soil water storage, a reduced peak flow and a prolonged base flow.Soil structure is crucial for both, the infiltration rate as well as the plant available soil water storage capacity.

Different mechanical stresses caused by different harvesting technologies as well as biological remediation measures have, however, a short- and long-term impact on the infiltration rate and the water storage capacity of forest soils. Analysing the effects of fully and highly mechanized timber harvesting practices on the hydrology of compaction prone soilsis one of the objectives of a project, funded in the framework of the Austrian *Waldfonds*. The project focusses, in general, on how to secure the sustainability of forest soil functions in hardwood forests. In course of this project, water infiltration, surface runoff, water storage as well as water availability are being investigated on different scales, before and after the timber harvesting intervention using two harvester-forwarder (HF) configurations‘(w/wo bogie tracks) or cable-yarding with motor-manual-felling (CCM)‘. This includes rainfall simulation experiments and continuous as well as discontinuous soil moisture measurements.

Preliminary results, considering surface runoff, indicate a strong change in rainfall-runoff behaviour following timber harvesting operations. Rainfall events on recent, highly compacted skidtrails suggest a significant increase surface runoff. We further observe higher soil water content as a result of the lack of vegetation activity and the changed soil structure after harvesting. By linking the direct hydrological effects of timber harvesting with other affected soil functions, a holistic perspective is created, which will lead to recommendations for soil-conserving timber harvesting on soils at risk of compaction.

EFFECTS OF FOREST RESTORATION ON THE HYDROLOGICAL REGIME

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Nataly Foronda Ortega
Silvio Ferraz[1]
[1] Forest Hydrology Laboratory (LHF), Forest Sciences Department, University of Sao Paulo - Brazil

Abstract: Changes in land use has generated several consequences in ecosystem services and/or functions supported by forests, including water services. In this context, the United Nations Decade of Ecosystem Restoration 2021-2030 was established, and therefore more forest restoration projects worldwide have been occurring. The vegetation biomass affects the partition of precipitation in flow and evapotranspiration. Thus, the forest succession promoted by restoration also affects the quantity, quality, and regulation of the flow at the local scale. Despite this well-known relationship between forest and water, the implications of restoration forests in tropical region in water dynamics are an ongoing study and there are some knowledge gaps. In this study, the objective was to evaluate the effect of forest restoration on the hydrological dynamic at local scale using three paired catchments with 5- and 10-year-old restoration (RF10, RF5), and pastures (PA) considered the zero age in a semideciduous forest in the southeast of Brazil. Our results show that the base flow index (BFI) is higher in the catchment under PA (0.852), while the difference between the restoration catchments is low, with a BFI slightly higher in RF10 (0.655) than FR5 (0.503). The water yield was lower in the RF5 catchment (3.45%), which can be explained by the higher water consumption in the first years of establishment, while the RF10 and PA catchments had almost the same value (8.37% and 8.30%). In RF10, the higher value can be explained possibly due to the improvement in soil porosity, infiltration, and protection from the impact of rain. Regarding the flashness index, the RF5 catchment had the highest value (0.309) followed by RF10 (0.215), showing that with greater age of the vegetation, there is an improvement in the regulation of flows in the catchments, making them more stable; Contrary to expectations, PA (0.068) had the lowest value, with the most stable flow. We can conclude that even 5 and 10 years after the restoration, the establishment of vegetation can improve the flow regulation function, however, the water consumption throughout its development must be evaluated, in addition to studying better the soil properties in PA catchment.

Enhancing forest resilience for water-related ecosystem services in a changing environment

Enhancing water resources through restoring resilient forests in the U.S.

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Ge Sun[1]

[1] Southern Research Station, USDA Forest Service

Abstract: About 30% of the U.S. is covered by forests which provide a myriad of ecosystem services locally (e.g., clean water and air, aquatic habitat) and globally (timber supply and carbon sequestration). For example, it is estimated that 50% of the national total water yield is derived from forests and over 150 million or half of the US population benefit from forestlands for drinking water supply. However, these forests are increasingly stressed by climate change, urbanization, wildfire, biological invasion, and insects and disease outbreaks. For example, due to climate warming and fire suppression, the southern forests have experienced "mesophication" - forests have become too dense and plant species have shifted, resulting in decline in water yield and rise of wildfire risks even in a humid region. Similarly, meeting demands of timber productions during the past century in the region has favored fast growing pines (e.g., loblolly pine, *Pinus taeda*) have resulted in tremendous loss of 'open forest' ecosystems such as longleaf pine (*Pinus palustris*) forests. Restoring longleaf pine ecosystems with frequent prescribed fires is being considered as one approach towards enhancing regional forest resilience and improving water yield and other ecosystem services. This paper presents results from recent case studies that show forest management has the potential to improve forest ecosystem resilience and benefit ecosystem services in the U.S.

Forest disturbance thresholds for cumulative hydrological impacts in the Montane forests in British Columbia, Canada

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Yiping Hou
Xiaohua Wei[1], Jinyu Hui[1]
[1] University of British Columbia

Abstract: The forest disturbance threshold is defined as a critical disturbance level in forested landscapes above which cumulative and significant hydrological impacts are detected. Determining disturbance thresholds is critically important for supporting forest management to ensure sustaining of ecological and hydrological functions and services. However, there is no quantitative evaluation of forest disturbance thresholds regionally or globally. In this study, we applied the modified double mass curve, MDMC, to derive the long-term, continuous hydrological response curves and to quantify forest disturbance thresholds on annual streamflow in 42 Montane forested landscapes in British Columbia, Canada. We find that the average forest disturbance threshold for significant and cumulative hydrological impacts is 17.28% of cumulative equivalent clear-cut area (CECA) ranging from 7.20 to 51.67%. We also find that climate (inter-annual and intra-annual) and watershed properties exert critical controls on forest disturbance thresholds. Watersheds with greater snowfall proportions, more desynchronization of energy demand and water supply, lower ecosystem diversity, larger watershed sizes, lower water retention capacities, and steeper slopes have lower forest disturbance thresholds. These results have important implications for managing water supply and other hydrological functions under increasing forest disturbance and climate change impacts in the region.

Forest Landscape Restoration through multi-pronged approach in catchment of Yamuna river

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Dinesh Kumar[1]
Manisha Thapliyal[1]
[1] Silviculture and Forest Management division, ICFRE - Forest Research Institute, Dehradun, India

Abstract: Water and forests are intimately associated and dependent on each other as forests are important part of hydrological cycle. Majority of the areas that are facing severe water scarcity are those where forests and trees are currently scarce. The predicted shift in suitable climatic conditions for forest trees and ecosystems under climate change presents a challenge for large-scale restoration of deforested and degraded forest ecosystems. So the need is to evolve and practice climate-smart forestry to maintain a synergy between carbon sequestration and water usage by species. Under Indian government's programme on Greening India Mission and rejuvenation of the major Indian rivers, large-scale forest restoration activities alongwith soil and moisture conservation inputs are being taken up in degraded forest areas and river catchments. The study presents such approaches being practiced and envisaged for future, in the catchment of river Yamuna which is the largest tributary of the Ganga. The drainage basin of Yamuna is 366,223 km^2 in size which comprises areas of seven states, viz., Uttarakhand, Himachal Pradesh, Uttar Pradesh, Haryana, Delhi, Rajasthan and Madhya Pradesh. The major portion of the basin lies in semi-arid climatic region. Forest department regularly undertakes afforestation, soil and moisture conservation, wetland management and other forestry activities in the Yamuna basin.

The width of treatment zone (riverscape) was taken as 5 km on both sides of Yamuna and 2 km on both sides of its tributaries in plains. The entire catchment area of Yamuna was included in the riverscape in Uttarakhand and Himachal Pradesh, as well as untreated watershed area identified by Rajasthan forest department. The riverscape has three landscape classes viz. natural, agriculture and urban/peri-urban, and plantation activities are proposed for all. Activities commonly carried out in forest areas are planting of trees (oaks, fir, spruce, birch, maples, etc. in Himalayan area), shrubs, grasses, medicinal plants, enrichment plantation and low-cost soil and moisture conservation. In riverfront development, trees, shrubs and grasses have been planted to stabilize the riverbank and control soil erosion. Thus, with these measures it is hoped that forest landscape restoration in the river catchment will enhance its ecological and economic resilience.

Groundwater resource dynamics post plantation forestry in quaternary catchment K30C in the Southern Cape region of South Africa

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Tatenda Mapeto

Abstract: Intensively and sustainably managed plantation forests are an important land use in South Africa. They supply the bulk of the country's timber, fibre, pulp and paper requirements while generating local and export income, providing jobs and ensuring the conservation of natural landscapes that are mosaiced within plantations. These benefits of the commercial forestry sector are clear, yet they do come at considerable environmental costs, particularly the impact on water resources. Numerous studies have now conclusively indicated that plantations of introduced tree species consume more water than grasslands, shrublands or indigenous forests that they replace and thus they reduce water yield (stream flow) from afforested catchments. Additionally, while the hydrological cycle is well documented, the links between the interdependent components of ground water and surface water interactions as a function of land use and land use change are less understood. There are currently limited studies that have monitored groundwater resources during a rotation of plantation forestry stands and a few years after the formerly afforested land is cleared and currently in transition back to the natural or baseline vegetation landscape. This study quantified the groundwater resource dynamics after previously afforested land was fallowed and transitioned to natural vegetation within a mosaic of introduced species natural regeneration resulting from the seedbank of the previously planted introduced species stands. A comparative analysis of groundwater level dynamics monitored when the catchment had fully stocked plantation stands versus when the plantations have now been phased out is presented. The study therefore quantified, extrapolated, and compared groundwater resource dynamics in a quaternary catchment with stands that were previously afforested with introduced species and intensively managed for timber production. The work complements progressing scientific efforts to understand eco-hydrological patterns in tree production systems in a country where the best possible use of water is sought.

How light and atmospheric demand modulate tree transpiration in a mixed boreal forest

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Christina Hackmann[1, 2]
Klaus-Holger Knorr[1], Hjalmar Laudon[3], Jose Gutierrez Lopez[3]
[1] Ecohydrology & Biogeochemistry Group, University of Münster, Germany
[2] Department of Silviculture and Forest Ecology of the Temperate Zones, University of Göttingen, Germany
[3] Department of Forest Ecology and Management, Swedish University of Agricultural Sciences Umeå, Sweden

Abstract: Trees are pivotal regulators of water balance in boreal forests. Through evapotranspiration, they are key drivers of mass and energy transfer. Evapotranspiration can be partitioned into 50% evaporation (including interception) and 50% transpiration during the growing season. Yet, transpiration is a dynamic, species-specific process that can vary considerably according to climatic conditions and vegetation type. In general, trees at high latitudes experience contrasting light availability and temperature conditions during the growing season. Day length can be more than 20 h in summer and just above 10 h in early spring, and during this period temperatures can fluctuate from below freezing to 30°C. Under these circumstances, it is essential to make efficient use of the available resources, while responding promptly to the current environmental conditions.

Under non-limiting soil moisture conditions, the main environmental drivers for tree transpiration are light (Photosynthetically active radiation, PAR) and atmospheric demand (vapor pressure deficit, VPD). However, it is not clearly understood how tree transpiration responds to these factors throughout the season, and what the species-specific patterns are.

To elucidate this, we deployed sap flow sensors in a boreal forest in northern Sweden, on the three most dominant tree species: Scots pine (*Pinus sylvestris* L.), Norway spruce (*Picea abies* (L.) H. Karst), and Silver birch (*Betula pendula* Roth). For a period of three years (2019-2021), we monitored daily tree transpiration and environmental variables. We separately analyzed transpiration response to PAR and VPD to identify seasonal differences and species-specific patterns. Our data suggest that PAR and VPD are indeed strong drivers of transpiration, but the tree's response to them is not constant throughout the growing season.

Overall, light conditions tend to be set for a given latitude, however VPD and species composition in high-latitude boreal forests is projected to change in the upcoming decades. To estimate how the water and energy balances will be influenced, it is crucial to understand how the interaction between light and VPD can regulate tree and forest transpiration and evaporation rates.

Hydrological resilience indicator: understanding how forest management can mitigate water scarcity effects

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Lara Gabrielle Garcia[1]
Yhasmin Paiva Rody[1], Aline Aparecida Fransozi[2], **Silvio Frosini de Barros Ferraz**[3]
[1] Suzano S.A., Brazil
[2] Institute for Forest Research and Studies, Brazil
[3] University of Sao Paulo, ESALQ, Brazil

Abstract: Forest plantation areas are increasing in Brazil, reaching more than 9,9 million hectares. Suzano SA are an important part of this movement once the company has an important portion and a key role in the Brazilian forestry sector. The expansion frontier of forest plantation in Brazil has moving to humid subtropical and tropical climate, in a landscape predominantly covered by Savanna biome. Therefore, understanding forest-water relation is fundamental to enhance forest resilience and support water ecosystem services in this biome. In this context, the goal of our study is to understand the relation of climate effects on water supply in forest occupied catchments. Based on this knowledge, we established environmental indicators to determine the level of hydrological sensitivity in these catchments. Firstly, we delimited watershed boundaries for study area (Midwest of Brazil) and developed two indicators in each watershed: hydrological sensitivity indicator and forest management indicator. The hydrological sensitivity can be defined as local intrinsic hydrological characteristic and it was obtained as a function of four variables: water availability, annual precipitation seasonality, digital model of terrain and curve number (CN-SCS). The sum of these variables was further classified into five classes from lower to higher hydrological sensitivity. The indicator that represents forest management intensity is the sum of three variables: forest coverage percentage, forest plantation density and forest age mosaic. This indicator was classified into five classes from lower to higher management intensity. The ratio between watershed hydrological sensitivity and forest management intensity provided the hydrological resilience indicator, but they can be used separately to identify where the natural conditions afford management flexibility and where the best practices of management are essential. Our results showed that areas with higher hydrological sensitivity represents 6,2% of total watershed analyzed, trending to concentrate in Midwest of Brazil. The indicators allow us to understand which are the watersheds with highest hydrological sensitivity, where forest management can mitigate the effects of water scarcity, making forests more resilient, especially in the face of climate change.

Improving ecohydrological resilience of forest plantations in Brazil by landscape management

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Silvio Ferraz[1]
Aline Fransozi[2]
[1] University of São Paulo (USP)
[2] Institute of Forest Research (IPEF)

Abstract: Forest plantations in Brazil are increasing in last years reaching more than 9 million of hectares in 2022, due to internal and external demand growth for fiber and wood. Forest management plans are seeking environmental sustainability of those planted areas, guided by crescent restrictions enforced by government, environmental certification and society pressure. Landscape indicators commonly reflects environmental management, and the development of tools for landscape analysis and monitoring could be an opportunity to improve forest management in order to conserve biodiversity, water and ecological processes. Based on long-term stream monitoring data of several experimental catchments installed on forest plantation landscapes along Brazil and Uruguay, field data collection regarding biodiversity and insect damage, we analyzed the relationship between landscape indicators and ecosystem services related to biodiversity, water, soil and pest management. Landscape indicators were calculated based on climate, soil, terrain and landscape composition and structure related to different components of forest plantation ecosystem: eucalyptus plantations (genetic material diversity, age diversity, roads design, watershed composition) and natural areas (vegetal typology diversity, landscape proportion, edge density, proximity and core area). Data used for indicators calculation was extracted of land-use maps including forest stands, roads, and natural vegetation. Our results show that many field observations were related to landscape characteristics (natural or anthropogenic) like pest damage frequency, natural areas biodiversity, suspended sediments and stream flow regime. Based on results, we suggest a framework with landscape management alternatives to improve ecohydrological resilience on forest plantation ecosystem.

Landholders leverage over moisture flows and forest resilience in South America

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Chandrakant Singh[1, 2, 3]
Ingo Fetzer[1, 4], Arie Staal[5], Vivian Ribeiro[6], Sylvia Tramberend[3], Peter Greve[3, 7], Ruud van der Ent[8], Michael J. Lathuillière[6], Lan Wang-Erlandsson[1, 4]

[7] Helmholtz-Zentrum Hereon, GERICS, Hamburg, Germany
[8] Department of Water Management, Faculty of Civil Engineering and Geosciences, Delft University of Technology, Delft, The Netherlands

Abstract: Moisture originating (i.e., evaporation) from the Amazon rainforest contributes to the rainfall over the forest and human-influenced land systems in South America. However, the alarming rate of land-use change by landholders in the Amazon – mostly due to agricultural expansion – poses serious threats to regional water cycling. On the one hand, this loss of moisture over forests reduces their resilience to future hydroclimatic perturbations (e.g., droughts). Loss of moisture over human-influenced land systems, on the other, threatens rainfed agricultural yields. However, the leverage these landholders have over the downwind rainfall is uncertain. Understanding their influence will help us realise the potential of land-use-change impact on the regional water cycle. In this study, we analyse landholders' leverage over atmospheric moisture flows and the resilience of forest ecosystems in South America. Using the remotely sensed MapBiomas land-use dataset and the output of an atmospheric moisture tracking model - UTrack, we analyse moisture flows from different spatial explicit landholder-dominated regions to natural and anthropogenic land systems. We find that of all the moisture originating from small (3.0×10^3 $km^3\ yr^{-1}$), medium (0.6×10^3 $km^3\ yr^{-1}$) and large (4.7×10^3 $km^3\ yr^{-1}$) landholders, contributes to the rainfall over the forests. Furthermore, nearly half originates from the forests within these landholder-dominated regions. We also find that all landholders' equally influence the rainfall over nearby land systems and those situated further downwind. Among them, smallholders have a disproportionately larger influence over forests' rainfall (19-39% more than other landholders). Despite this, large landholders strongly influence forest resilience in South America, along with their disproportionately larger influence over the agricultural land systems (29-116% more than other landholders). The results from this study emphasise the need for more stringent forest policies to factor in the influence of deforestation on downwind landholders and promote effective ecosystem stewardship.

Light at the end of the tunnel or will-o‘-the-wisp? Best practices in integrated forest and water management in Germany beyond sector fragmentation

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Tanja Granzow[1]
Sabeth Häublein[1], Andy Selter[1]
[1] Chair of Forest and Environmental Policy, University of Freiburg, Germany

Abstract: The drought years in Germany since 2018 have highlighted the close relationship and interdependencies of forest and water resources and raised awareness about the negative effects of lacking precipitation and declining groundwater levels for forests. While water resources have turned into a prime concern on the agenda of forest actors, water resource management is only beginning to perceive forests as relevant for its area of responsibility. This fragmentation seems to prevail despite numerous disturbances affecting both forest and water resources and management. To successfully adapt to changing circumstances, however, joint efforts will be necessary in order to advance integrative management practices. These practices must aim at increasing water retention capacities to buffer droughts and floods, improving forest soil infiltration capacities and optimizing tree species composition to maintain forest cover under crisis conditions. In our research we contribute to both policy as well as management practices necessary to improve resilience of water forest ecosystems. Based on expert interviews and focus group discussions, we identify best practices in forest and water management, including the development of institutionalized policy integration across sectors. Data was collected in five highly affected local regions of Germany, which were selected according to maximum range sampling concerning type of disturbances and landscapes. Overall, our results contribute empirical evidence on best practices in integrated resource management policies and measures and their transferability to different regions and countries, while at the same time they provide valuable insights into the conditions for successful cooperation, the potential for integration and possible indications for limited benefit.

Management for forest multi-functionality with special emphasis on water

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Lars Högbom[1]
Kevin Bishop[2], Martyn Futter[2], Eva Ring[1], Nadeem Shah[3]
[1] the Forestry Research Institute of Sweden - Skogforsk
[2] Swedish University of Agricultural Science, Department of Aquatic Sciences and Assessment
[3] Forest Research, UK

Abstract: Forest management and forest operations have the potential to impose large negative effects both at the site in question and in neighbouring ecosystems. These effects can include abiotic as well as biotic disturbances and can vary depending on climate, soil properties, forest operation systems, and forest management strategies. Decisions on forest management should account for carbon balance, biodiversity, wood supply, and other ecosystem services, especially those related to hydrology and water quality.

This presentation will focus on the ways forest harvesting can affect both water quantity and water quality and will include aspects of forest management, technical solutions, and knowledge exchange/transfer to reduce forestry impacts. Some of the negative effects of forestry on water flows, water quality and aquatic ecology could be counteracted by improved management and logging planning, use of technical aids, and knowledge transfer between involved parties. The development of best management practices (BMPs) such as the use of forest buffers, protecting discharge areas, water sensitive driving and other low impact techniques could in some cases prevent impacts on water quality. Technical adjustments to machines, e.g., high flotation tires, use of extra bogie axle, lower inflation pressure, and use of steel flexibles tracks. Driving damage can be reduced using techniques to reduce soil compaction along the trails, e.g., brush mats, together with improved route planning. By implementing a small number of relatively low cost changes and adaptations, forestry can take greater concern for water related ecosystem services, which will contribute to more resilient forest ecosystems.

Managing forest hydrological services: Integration into forest management plans and applied implications in Aegean region

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Pinar Pamukcu-Albers[1]
Semiha Demirbas-Caglayan[2], Bilgehan Kaan Caliskan[2], Yildiray Lise[2], Ugur S. Zeydanli[2]

[2] Nature Conservation Centre, Ankara, Türkiye

Abstract: Forests act as natural sponges, absorbing rainfall and reducing surface runoff, thus preventing soil erosion and flooding downstream. The intricate root systems of trees enhance infiltration and groundwater recharge, ensuring a reliable water supply. However, forest management practices often face a conflict between erosion prevention and water provision. Logging and other forest activities can boost surface runoff, but also lead to soil erosion, water quality degradation, and harm groundwater. In some cases, in order to provide more water to dams, more trees are removed compared to standard silvicultural practices, and deciduous trees are more preferred over mixed or coniferous ones. Balancing and enhancing hydrological services for forest resilience and incorporating them into forest management require evaluating spatial information and local knowledge.

Our study focused on three dam watersheds in the Aegean region of Türkiye, assessing forest hydrological services beyond administrative district boundaries. We evaluated erosion prevention and quantified water yield by determining runoff coefficients for different land-uses, forest types, and hydrological soil groups, we modelled these services and validated through field surveys and stakeholder workshops. Slopes above 59% are considered severe in Türkiye. Forest conservation practices are carried out to prevent erosion with a slope of 60% to 79%, and to protect nature in forests with a slope of more than 80%. However, both models and field analyses have revealed that slopes starting from 40% are also significant for these services. For the study area, less than 35% of runoff occurs in forest stands, leading to soil loss below 0.5 tons/ha/year.

Collaborating with the General Directorate of Forestry in Türkiye, management practices have been developed for the forest management plans to enhance forest resilience, increase water efficiency, and minimize soil loss based on abovementioned thresholds for forest stands that fall outside the specified values. These practices involved different silvicultural options at the stand level. Our study serves as an example of successful integration of watershed considerations through water-related ecosystem services and multi-scale approach. It incorporates diverse mapping and modelling tools, proper monitoring, and the implementation of best management practices to minimize adverse impacts on these crucial ecosystem services.

Managing forests for water - lessons and challenges from implementation

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Sara Casallas Ramirez[1]

[1] Food and Agriculture Organization (FAO) of the UN

Abstract: This presentation will focus on the lessons and challenges during the implementation of projects that aim to improve the management of forests for water-related services as part of FAO's work. Over the past decade, FAO has been implementing projects, developing tools, advocating for and increasing the capacity of actors to improve the management of forests for water-related services, especially in the context of climate change. This presentation will include a brief overview of this work and will draw on examples from recent projects highlighting the lessons learned and challenges as well as the research gaps and priorities that have been identified. Examples will also cover different countries and geographies as well also allowing for discussion of governance considerations.

Managing forests for water-related ecosystem services under a changing environment

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Mingfang Zhang[1]

[1] School of Resource and Environment, University of Electronic Science and Technology of China, Chengdu611731, China

Abstract: Water-related ecosystem services such as water supply, flood control, flow regulation, soil erosion control, and climate regulation provided by forests are vital for human well-being. Frequent natural forest disturbances (e.g., wildfire, insect outbreak) and anthropogenic activities (e.g., deforestation, reforestation, and afforestation) can have profound impact on the provision of water-related ecosystem services by forests under a changing environment. This talk will share a world-wide synthesized work on the state of water-related ecosystem services of major forest ecosystems under changing climate, and the possible impacts of forest disturbances and anthropogenic activities on water-related ecosystem services of forested watersheds across different biomes. Forest management strategies for sustaining or improving water-related ecosystem services for different biomes will be recommended accordingly to mitigate negative impact of climate change and meet the growing human need for water-related ecosystem services of forests.

Mycorrhiza communities in a hybrid aspen plantation: first results

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Abstract: Mycorrhiza is a crucial for water and nutrient absorption and hence tree growth, particularly under widely intensifying drought conditions. Though, mycorrhizal communities vary locally, as well as depending on the host genotypes implying uneven efficiency of the symbiotic interactions. Furthermore, mycorrhizae are presumed to largely participate in plant communication, thus facilitating tree defense against pests and pathogens. Hybrid aspens, which are highly productive due to heterotic gene interactions favouring growth over defence, are sensitive to herbivores and, due to intensive similariton, also to water deficit and hence droughts. Though there are explicit clonal differences in growth and sensitivity. In this study, mycorrhizal communities on fine roots of two clones with contrasting productivity growing in a clonal trial established in 2008 on former agricultural land in the mid-part of Latvia were assessed using classical microbiological (isolation and propagation) and molecular genetic methods (genomic analysis; ITS sequencing and OTU identification). The clonal differences in mycorrhizal communities between clones considering the local variation were assessed using the permutational analysis of variance (ANOSIM) which compare difference with and between groups. The results are discussed in regarding the functional ecology of mycorrhiza species.

Keywords: Populus tremula × Populus tremuloides; fungal communities; functional ecology; diversity-productivity relationships.

Role of plantation forest in hydrology : a short review

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Christophe Oarzio[1]
Shirong Liu[2], Joanes Guillemot[3]
[1] IEFC
[2] CAF
[3] CIRAD

Abstract: This presentation is made on behalf of the IUFRO task force on planted forests, this will review publication related to plantation forest role on hydrology. Many aspects will be addressed, some of them are listed bellow.

- After the storm occurred in France in 1999, the reduction of forest areas induced a lower precipitation regime in the following years that has been recovered one forest has been replanted.

- In Portugal, the effect of afforestation with eucalyptus plantations compared with pine plantation did not show significant changes of fluxes in the mediterranean headwater catchment

- In FORSEE project, looking for indicator on water quality in relation to forest, scientists concluded on a very simple proxy to estimate water quality.

- In Bresil a study confirmed that depending on the management intensity, the dryness index and the ratio of eucalyptus in the landscape, we can evaluate eucalyptus plantation impact on water catchments.

The effect of forest disturbances on hydrology in karst aquifers

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Abstract: Forest disturbances are an essential component of forest ecosystem dynamics. The effects of rapid loss of forest cover and other changes in forest ecosystems are inextricably linked to hydrologic processes such as evapotranspiration, soil and recharge processes. Among all hydrogeological systems, karst aquifers are important because of their rich and unique biodiversity, heterogeneity, and drinking water resources. At the same time, they are characterised by specific hydrological processes that make them highly vulnerable to environmental changes.

The effects of large-scale forest disturbances in karst aquifers have been only marginally addressed, although evaporation of water from the soil and epikarst is recognized as an important process affecting the hydrologic cycle in karst regions. In this study we present a holistic approach to infiltration processes research in Dinaric silver fir – beech forest after ice storm in 2014. To better understand infiltration in different compartments of the karst aquifer, an *in-situ* environmental monitoring network of the atmosphere-vegetation-soil-unsaturated zone was designed. Special attention is given to the different stages of forest development following large-scale disturbances and to the morphology of the karst terrain. The amount of precipitation in the open, canopy interception in mature forest and in canopy gaps with different stages of forest development, soil moisture content, and soil temperature are measured at the surface and subsurface. These measurements are performed in the area of the eLTER site Postojna-Planina cave system, i.e., on the top and bottom of karst depressions, while in the underground water discharge, temperature, and electrical conductivity are measured in cave drips. By observing the time lag of the measured parameters to recharge events, the effective infiltration of precipitation into the aquifer is evaluated and quantified.

The results allow us to distinguish recharge conditions at different forest development stages following large-scale disturbances and under different geomorphologic conditions. In addition, vegetation-hydrologic modelling of recharge conditions is presented and further upscaling of the modelling results from the local scale to the catchment-wide scale is preformed to evaluate the effects of large-scale forest disturbance on the water balance of the entire karst aquifer system.

The effects of forests on precipitation

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Nadeem Shah[1]
[1] Forest Research, UK

Abstract: Whether forests influence precipitation patterns has been a matter of enquiry and debate for hundreds of years. A considerable body of conflicting research evidence has been presented by those who claim that forests do influence the amount and timing of rainfall, and those that think it does not. After a lull in scientific enquiry on the subject in the 20th Century, a revival has taken place partly driven by the intense interest generated by concerns over global warming and climate change. This renewed interest has led not only to new theories (e.g. the Biotic Pump) and ways of thinking about the subject (e.g. supply-side and demand-side), but also new research.

Recent studies have tried to shed light on the issue by utilising satellite data and long-term meteorological records, often combined with numerical models. These studies have been useful and many support the view that forests influence rainfall amounts, but empirical data is still lacking. This is partly due to the general increase in desk based studies relative to field based enquiry, but also some of the difficulties presented by the latter, such as the complexity of separating background climatic effects from the forest effect.

If forests do influence precipitation patterns there are wide-ranging implications for water supply, drought, ecological flows and flooding, to name but a few.

Here, we present some of the issues, knowledge gaps and solutions to addressing this key research question. We finish by introducing new research that aims to fill some of the knowledge gaps through both desk and field based approaches; the former utilises satellite and historical meteorological data whilst the latter is a field based empirical study.

Understanding the Relationship of Forest and Water Dynamics in a Changing Climate Regime: Insights from a Tropical Deciduous Watershed

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Manisha Singh[1, 2]

[3] National Institute of Hydrology, Bhopal, India

Abstract: Understanding the interlinkages between forest, water, and climate is vital for sustaining essential ecosystem services, ecological proliferation, and economic development. Furthermore, forests function as water and climate regulators while ensuring water security (quality and quantity), a major challenge globally. This necessitates the need for designing policies and strategies for effective management of forest and water resources. However, in the Indian context, policy and planning for natural resource management lack synergy and seldom consider the intricate feedback loops among forest, water and climate change. Forests in India (21.71%) are under pressure due to over-exploitation, climate change and deforestation, diluting the benefits and ecosystem services for forest-dependent communities (275 million rural and 88 million tribal people). India has the highest population (17.7% of the global population), with only 4% of the global freshwater resources, creating extremely high-water stress conditions (54%). The changing climate is catastrophic for both water security and ecosystem services linked to forests, especially water regulation, and there is a gap in research focusing on integration of climate variability with forest-water interlinkages in India. Our study attempts to understand the impact of climate change on forest disturbance and water quantity in the Dindori watershed (2313 km^2), a tropical deciduous forested watershed of the Narmada River in Madhya Pradesh. Long-term datasets of climate variables (rainfall, maximum and minimum temperature), observed streamflow, and land use & land cover change have been used as proxies for changing climate, water quantity and forest disturbance, respectively. Annual, monthly and seasonal trends for climate and water are assessed using time series analysis, non-parametric tests and change point detection. Multiple regression and sensitivity analysis is conducted to understand the integrated influence of climate on forest disturbance and water quantity. There has been a significant increase in minimum and maximum temperature, while rainfall patterns depicted no significant change from 1951 to 2020. Streamflow was more sensitive to changes in precipitation than LULC, as large watersheds are more resilient to forest disturbances. We further discuss the results in the context of existing forest-water policies and schemes for holistic forest-water management, focusing on ecosystem services and adaptation to climate change.

Water regulation on Amazonian streams depends on forest cover conservation

T1.10 Enhancing forest resilience for water-related ecosystem services in a changing environment

Raíza Precinoto[1]
Silvio Ferraz[2]
[1] Forest Resources Graduate Program, "Luiz de Queiroz" College of Agriculture, University of São Paulo (USP), Av. Pádua Dias, 11, Caixa Postal 9, 13418-900-Piracicaba, SP, Brazil

Abstract: The Amazon rainforest is crucial for climate regulation worldwide and water supply to South America. The intensification of deforestation in recent decades may have altered the hydrological dynamics of its rivers, but few studies address this issue. In this work, we assessed the influence of forest cover loss in Amazon basins over the last three decades on the regulation of water flow in their rivers. Four indicators were used: high flows (Q10), low flows (Q90), RB-Flashiness Index (RBI), and Base Flow Index (BFI). We compared these indicators from 1985 to 2018 in 12 intact forest watersheds and 12 deforested watersheds, using Mapbiomas Panamazonia data. Daily discharge and precipitation data came from the CAMELS-BR dataset. To test the effect of the dry season, we categorized basins as dry season absent (average monthly precipitation consistently above 100 mm) or present (other basins). Results showed that deforested watersheds had higher Q10, therefore the loss of forest cover leads to an increase in high flows, regardless of the dry season. In the same direction, the RBI was higher in deforested basins, meaning greater flow oscillations. So, deforestation increased Q10 and RBI in all deforested watersheds, threatening flood protection services regardless of climate. In addition, deforested basins had higher low flows (Q90), probably due to lower evapotranspiration or increased runoff. On the other hand, the lower BFI in deforested basins suggests decreased baseflow, probably due to lower infiltration. The most prominent effect of deforestation was in dry season watersheds, decreasing the base flow (BFI) and increasing flow fluctuations (RBI). Thus, our findings provide evidence that deforestation significantly impacts water regulation in the Amazon, potentially leading to detrimental effects on crucial water services, such as flood protection and water supply, particularly in watersheds experiencing both deforestation and the occurrence of the dry season. These results underscore the urgent need for proactive conservation measures as deforestation and climate change continue to pose significant threats to the Amazon's hydrological dynamics.

T1.11 Forest Fires in Mountain Regions

A comparative study on characteristics of the fuel flammability of forest ecosystems in the Alpine region

T1.11 Forest Fires in Mountain Regions

Mariana Silva Andrade[1]

[1] University of Natural Resources and Life Sciences (BOKU), Department of Forest- and Soil Sciences, Institute of Silviculture, Vienna, Austria

Abstract: As a consequence of drier and warmer conditions, the intensity and frequency of forest fires are increasing and is becoming a major threat for protective forests in Alpine regions. The long-term impacts result in a higher number of avalanches, rockfalls, erosion, carbon and smoke release putting human lives and infrastructures in danger. The suppression of fires in mountain areas are difficult and costly, due to steep terrains and high elevations. Therefore, it is crucial to understand the flammability of forest fuels in such mountain environments as one of the important components that influences fire ignition and fire behavior, in order to plan and perform preventive measures to reduce the fire risk. Fuel flammability describes how well a species burns (sustainability), how fast it burns (combustibility) and how long it burns (ignitability). The aim of this research has been to assess and compare flammability parameters of surface fuels collected between 2009 and 2023 in several study areas in Austria. More than 150 litter samples were collected during fuel measurements in the field, immediately oven-dried at 60°C for 48 hours in the lab, classified in 8 groups (needles, leaves, seeds and fruits, woody material < 6 mm, woody material from 6 -20mm, woody material > 20mm, bark and others) and weighed. Experimental burning was performed in a laboratory, under control conditions, using an indirect ignition source and three humidity levels. Our findings indicate that the variables 'time of ignition' and 'burning time' are positively correlated to fuel moisture content. The size and structure of the fuel has an important influence as well, as woody materials with larger diameter size took longer to ignite at all different levels of humidity in comparison to others. The findings will help to improve our knowledge about the assessment of the fire danger based on the fuel moisture of different fuel types in the early warning systems.

An integrated fire danger assessment system for mountain forests with high resolution vegetation data

T1.11 Forest Fires in Mountain Regions

Abstract: In the face of climate change, the European Alps experience higher temperatures, more heatwaves, and severe wildfires in recent years. Improved fire danger assessments become a key element of a holistic fire management strategy. An integrated fire danger assessment system was designed for the Alpine country of Austria considering i) daily fire weather index data, ii) high resolution topographic information, iii) a hazard map for fire ignition by human and lightning and iv) information about fuels, mainly regarding forest types. The expert-driven modelling approach was implemented as an online Web-GIS prototype, which produces daily forecasts of fire danger with a spatial resolution of 100 m x 100 m. To improve the information quality on fuel data, additional vegetation parameters were derived through field investigations, sampling of fuel data, by analysing high-resolution LiDAR data, aerial images, and by extracting information from Sentinel 2 data. Several new data layers were added to the online portal www.waldbrand.at, e.g. a map of forest gaps, a solar irradiance map, a layer on fire ladders, information about fuel loads and a classification of tree species. These layers were combined in order to improve the prediction quality of the ignition danger, fire spread and expected fire intensity based on vegetation parameters. In this contribution we demonstrate, how the inclusion of these new vegetation data in combination with topographical information and meteorological conditions can improve the daily fire danger assessments in mountainous areas.

Comparison of post-fire forest recovery and silvicultural interventions under different forest management regimes in the Western Himalayan Eco-region

T1.11 Forest Fires in Mountain Regions

Abstract: The Western Himalayan Eco-region (WHER) represents a complex, socio-environmentally vulnerable mountain landscape. Historically, human activities and socio-economic reforms have shaped the structure and quality of forests in the region. The middle Himalayan zone, spread between 800 - 2000 meters, is an acutely fire-prone zone due to current forest composition, topography, ongoing climate change, and anthropogenic disturbances. In the WHER, forest fire has historically been used to generate ecosystem services and support socio-economic and political goals. With the shifts in climate patterns, demography, agricultural practices, and values in forest management and conservation, the incidences of forest fires have been changing in the WHER. Often, controlled fires for resource management have spread to larger areas due to topographical, weather and poor fire management practices. The recovery and health of disturbed forest ecosystems can be impacted by various active and passive forest management approaches. The impact of different forest management approaches on the structural and functional attributes of forest and fire-focused silvicultural intervention is understudied in WHER. This study aims to explore and compare different fire-focused management interventions, post-fire vegetation structure, and ecosystem health in passively and actively managed fire-prone forests. The study will be focused in Uttarakhand, a fire-prone Indian state in the WHER. Forest management in Uttarakhand is governed by decentralized community forest management groups (*Van Panchayats*), forest, wildlife, and revenue departments, and private entities. Further, citizen groups and NGOs support these major forest stakeholders in managing forests for different socio-ecological goals. The sites will be identified based on remote sensing-based analysis of historical fire distribution and key-stakeholder interviews. The primary data will be collected through intensive ecological survey in the post-fire and fire season of the 2023 and 2024, respectively. First results are expected within June of 2024 and will reflect upon the existing condition of post-fire landscapes and fire-focused silvicultural treatments in Uttarakhand. The outcomes could provide recommendations for fire-focused forest management policies in the fragile mountain landscapes of the WHER.

Controlled or Uncontrolled; Effectiveness of Landscape Approach to Fire Management in Ghana.

T1.11 Forest Fires in Mountain Regions

Joseph Asante[1]
[1] Tropenbos Ghana, Kumasi – Ghana

Abstract: Evidence abounds on approaches to fire use and management in most parts of Sub-Saharan Africa, but often characterized as poor and less effective. In Ghana, fire use and management practices are less effective coupled with increasing warmer conditions; resulting in widespread wildfires, and associated risks. Landscape approach to fire management bridges this gap at scale by dwelling on locally owned, inclusive and participatory landscape governance for planning, and managing how best to live with fire within a given location. Though with marked potentials, effectiveness of landscape approach in addressing wildfire issues at scale, and sustenance of same especially in the tropics is least explored. This paper examined the nature and effectiveness of landscape approach to fire management, and to proffer options for improvements and upscale. This was done through extensive literature review and information gathering through interviews, focus group discussion, PRA techniques, etc. on landscape approach to fire management in the Juaboso-Bia/Sefwi Wiawso cocoa-forest landscape, and Kintampo/Atebubu landscape in the transition zone of Ghana. Indications are that, the approach addresses fire issues at scale by a composite of local actors, their resources, and interrelations that encompasses individual interests, sectors and activities; thus, making it comprehensive, and intersectoral. As a consequent, stakeholder inclusiveness and participation in fire discourse across the landscape is guaranteed which makes many fire users and actors more responsible towards effective fire use. Locals' leadership and ownership of processes at scale, enhanced capacity, improved sense of responsibility among stakeholders, adaptability and flexibility are key strengths of the approach. This imbues landscape actors with capacity to effectively engage and/or be engaged by other actors in fire use and management discourse, and have practically demonstrated this by successfully safeguarding some 252 hectares of restored forest lands, river buffers and agroforestry park lands. This hints that, with requisite capacity, resources and incentives, landscape actors can effectively and efficiently make use, and manage fires sustainably. This however requires enhanced capacity in contemporary fire management practices for all relevant actors, coupled with requisite policy and regulatory reforms that stresses multi-stakeholder inclusiveness in fire management at scale.

Disturbances and ecosystem carbon in a fire-prone human-impacted mountain in northwestern Yunnan, China

T1.11 Forest Fires in Mountain Regions

Zhongqian Cheng[1, 2]
Tuomas Aakala[2], Markku Larjavaara[3]
[1] Institute of Ecology and Key Laboratory for Earth Surface Processes of the Ministry of Education, College of Urban and Environmental Sciences, Peking University, Beijing 100871, China
[2] Faculty of Science and Forestry, School of Forest Sciences, University of Eastern Finland, Joensuu 80101, Finland
[3] Department of Forest Sciences, Faculty of Agriculture and Forestry, University of Helsinki, Helsinki 00014, Finland

Abstract: Ecosystem carbon is largely determined by climate, soil and past disturbances. In a human-impacted mountain ecosystem, the disturbance regimes are largely influenced by people. Feedbacks between woody vegetation attributes and disturbance regimes are critical for shaping ecosystem carbon along topographic gradients in mountain ecosystem. The aim of this research was to explore the effects of disturbances, especially fire, on ecosystem carbon in a fire-prone human-impacted mountain. We set woody vegetation and soil inventory plots systematically in four cardinal directions at 100-m elevational intervals from a 4200m peak in the Hengduan mountains in northwestern Yunnan, China. We used records from local authorities, interviews with villagers, remotely sensed data and dendrochronological wood samples to describe past disturbances. Based on these, we (1) quantified the effects of these disturbance regimes on woody vegetation structure, composition, and on tree species richness and radial growth, and then (2) established links between disturbance regimes and ecosystem carbon. This research is crucial for advancing our understanding of how disturbances affect carbon stocks in fire-prone human-impacted subtropical highland forests.

Effects of thinning and prescribed burning on future forest productivity and composition in southwest US

T1.11 Forest Fires in Mountain Regions

Cecile Remy[1, 2]
Dan Krofcheck[2], Alisa Keyser[2, 3], Marcy Litvak[2], Scott Collins[2], Matthew Hurteau[2]
[1] Institute of Geography, Augsburg University, Augsburg, Germany
[2] Department of Biology, University of New Mexico, Albuquerque, New Mexico, USA
[3] Natural Resource Ecology Laboratory, Colorado State University, Fort Collins, Colorado, USA

Abstract: In the southwestern US mountains, ongoing climate change is exacerbating a legacy of fire-exclusion that has altered forest structure and increased high-severity wildfire risk. Management can mitigate this risk by reducing forest density and restoring frequent surface fires, but at which cost in terms of carbon stocks and habitat diversity? We sought to quantify the impact of management on the carbon storage capacity and potential tree composition changes along an elevation gradient comprising pinyon-juniper woodlands, ponderosa pine forests, and mixed-conifer forests. We simulated carbon and vegetation dynamics under projected climate and wildfires with and without management scenario. This scenario involved thinning and prescribed burning in areas with high probability of high-severity wildfires. At multidecadal scale, management significantly increased net photosynthesis relative to no-management, especially in ponderosa pine and mixed-conifer forests. Furthermore, management allowed to better maintain tree species diversity. Given the increasing climatic and disturbance pressures impacting southwestern US mountains, management will play a critical ensuring the continued provision of ecosystem services.

Engaging citizen science in gathering data related to forest fire risk in mountain regions: A case study in Central Vietnam

T1.11 Forest Fires in Mountain Regions

The Trung Hoang[1]
Mortimer Müller[1], Mariana Silva Andrade[1], Philipp Hummer[2], Florian Heigl[3], Harald Vacik[1]
[1] Institute of Silviculture, University of Natural Resources and Life Sciences, Vienna, Austria
[2] SPOTTERON Gmbh, Faßziehergasse 5, 1070 Vienna, Austria
[3] Institute of Zoology, University of Natural Resources and Life Sciences, Vienna, Austria

Abstract: Negative consequences from forest fires are becoming increasingly severe for human life, destroying natural ecosystems and bringing enormous economic losses. Fire management planning requires regularly updated data about forest fuels and forest fires to adapt the plans and mitigate related risks. However, the current methods to collect such empirical information have limitations in terms of workforce, real-time and related costs, especially in mountainous areas.

This study aims to explore the potential of engaging citizen science in providing data on forest fires and fuels in mountain regions, leveraging a mobile phone application as a tool for data collection, and evaluating the suitability of the voluntarily collected data from citizens. Through a citizen science approach, different representatives of authorities, action forces, and scientists were engaged in discussing an initial set of questions for collecting forest fire data in a workshop in the study area of Hue province, Vietnam. The workshop outcome provided feedback on the questions and helped to ensure a user-friendly design of a mobile application for the collection of forest fire-related data suitable for the needs and capabilities of volunteers. For example, the mobile app can automatically record the date, time, and coordinates of each observation, and the volunteers can answer the question about forest fuel, including uploading photos of the observation, estimating surface vegetation conditions and continuity of large woody debris as well as the probability of fire ignitions of the observation.

The study outcomes reveal that citizen science might close the gap in needing more real-time information on forest fuel data to facilitate an assessment of ignition potential. In addition, a key aspect identified through this collaborative process was providing and integrating comprehensive information into documents on forest fire events is crucial in reducing forest fire risk and improving fire prevention measures in mountainous areas.

Furthermore, the research findings are promising for future exploration and application of citizen science projects, including ensuring reliable quality data generated. These are expected to strengthen community involvement, raise public awareness, and enhance and mitigate forest fire impacts in mountain regions.

Exploring the Potential of using Sentinel-2 Satellite Data in Mapping Burn Severity in Aberdare Ranges Afromontane Forest, Kenya

T1.11 Forest Fires in Mountain Regions

John Kigomo[1]
Dennis Kimeli[2], Bernard Kirui[3], Gilbert Obwoyere[3]
[1] Kenya Forestry Research Institute; Central Highlands Eco-Region Research Programme
[2] Jomo Kenyatta University of Agriculture and Technology, Kenya; Geomatics Engineering and Geospatial Information Systems
[3] Egerton University, Kenya; Department of Natural Resources

Abstract: In Kenya, most of the reported wildfires in mountains and ranges mostly occurs in inaccessible areas with difficult terrain causing high destruction of water catchment and biodiversity. Studies using moderate or high-resolution satellite images to understand the spatial and temporal occurrence in mountains covered with Afromontane forests are limited. This study aimed to evaluate commonly used Normalized Burn Ratio (NBR) and Burned Area Index for sentinel-2 (BAIS2) in mapping burn severity using sentinel-2 satellite data and to compare the relationships of Field Based Index (FBI) and sentinel derived severity indices. The study was carried out in Aberdare Ranges, which represent tropical Eastern Afromontane forests and also a designated world heritage site with a rich diversity of fauna and flora but frequently affected by wildfires. The sentinel data during the 2022 fire season was processed for NBR and BAIS2 using Google earth engine. After processing the burn severity classes, a separability index (M) was used to estimate the effectiveness of spectral indices to discriminate among the burn severity classes. Fifty-nine plots distributed in high (21), moderate (9), and low (15) burn severity classes and unburnt areas (14) were established about 2-3 weeks after the wildfires to develop FBI guided by affected ground vegetation. Our results indicated that NBR performed better with a mean separability index (M) of 1.10 compared to BAIS2 (M=0.75) in all severity classes. Separability index for NBR was good during discriminating low and moderate severity classes (M=1.31) but rather weak between moderate and high severity classes (M=0.84). The separability index for BAIS2 was good when discriminating low severity and unburnt areas (M=1.13) but poor in all other burn severity classes. The best model to explain the relationship between the sentinel derived spectral indices and the FBI was best described by a nonlinear equation for NBR (R^2= 0.89) and BAIS2 (R^2=0.62). Our studies demonstrates the usefulness of sentinel-2 satellite images and the superiority of NBR spectral indices in mapping burn severity within Afromontane forests. We recommend further studies in various vegetation types of Kenya to support wildfire management.

Key words; Wildfires, Sentinel-2, Burn severity, Aberdares, Afromontane forests.

Forest fire management and post fire forest restoration in mountainous part of Slovenia

T1.11 Forest Fires in Mountain Regions

Andreja Nève Repe[1]
Marija Kolšek[1], Jurij Rozman[1], Aleš Poljanec[1, 2]
[1] Slovenia Forest Service
[2] University of Ljubljana, Biotechnical Faculty, Department of Forestry and Renewable Forest Resources

Abstract: In recent decades, fires do not significantly disturb the development of forests in the mountainous parts of Slovenia. However, with upcoming climate change reflecting in further rising of average annual temperatures, unevenly distributed annual precipitation, lengthening of spring and summer draughts period the fire risk in the mountainous parts of Slovenia will increase. Knowledge of the occurrence and severity of forest fires as well as impact of fires on mountain forest ecosystems is therefore important for the successful management of fires and rehabilitation of burnt areas. In this contribution, the dataset on forest fire occurrence and severity will be analysed for the period 1995-2022. Furthermore, efficiency of fire intervention and the role of public forest service will be assessed analysing selected case studies. In addition, the impact of fire on forest ecosystem and efficiency of post fire regeneration measures will be analysed using restoration plans and dataset on realized regeneration measures. The results shows that most of the forest fires accrued in the period 1995-2022 are small (burned area is smaller than one ha). In this period, nine large fires (burned area > 100 ha) accrued with about fifth of the total burned area of that time spam. Humans cause the vast majority of fires; a natural phenomenon (lightening) is very rarely the cause of a fire. The fires are followed by cascading events, which is mainly manifested in the reduced protective role of forests, greater exposure of forest soils to erosion processes, may affect forest productivity, biodiversity and water retention capacity. Large burned areas also negatively effects social functions such as recreation and tourism. The public forestry service is formally involved in the fire management, cooperates with planning and supervision of fire preventing and protection measures. In the case of intervention places on disposal at the Intervention headquarters' forestry maps with the delineation of all forest roads. It helps individual fire-fighting unit with its spatial orientation, and directs them on the firebreaks and forest roads. In conclusion, the fire resilient forest management will be discussed, as well as improvements of forest fire management and post fire forest restoration actions.

Forest Fuel Load Monitoring in the Himalayan Region Using Earth Observation Satellite Data and Machine Learning Methods

T1.11 Forest Fires in Mountain Regions

Konica Bhandari[1]
Gulab Singh[1]
[1] Indian Institute of Technology Bombay

Abstract:
Wildfires in forested areas are vital for ecosystem development and succession, but as cities expand and climate changes, their detrimental impacts have increased. The sensitive Himalayan region is particularly vulnerable to forest fires, posing threats to ecosystems, nearby human settlements, air quality, and climate. Managing these recurring fires requires understanding and managing fuel load, which refers to the amount of combustible biomass available for burning and plays a crucial role in mitigating wildfire risks.

This study emphasizes the importance of quantifying fuel load for effective fire management. Accurate fuel load information enables fire managers to assess fire risk levels and prioritize fuel reduction treatments. Proactive strategies, such as prescribed burns, fuel breaks, and fuel management programs, can be developed based on timely and precise fuel load data to minimize the likelihood and severity of wildfires.

Traditional fuel load estimation methods, such as destructive sampling, provide accurate ground-level information but are impractical for global-scale applications. Satellite-based spatial earth observation data offer a promising solution, providing comprehensive coverage of forest fuel load at a global scale. Optical, synthetic aperture radar (SAR), and light detection and ranging (LiDAR) datasets, with their distinct imaging mechanisms, can be leveraged to map fuel load accurately. Optical data captures leaf and canopy characteristics, while SAR and LiDAR data enable the determination of forest vertical structure.

In this study, an integrated approach for forest fuel load estimation is presented, establishing a relationship between in-situ measurements and earth observation satellite data. Correlations between different fuel load types and optical and SAR data are analysed. Machine learning techniques, including Random Forest and Support Vector Machines (SVM), are employed to develop fuel load estimation models using data from the study area and variables derived from optical and SAR datasets. The focus of the study is on the unique terrain challenges and opportunities in the Himalayan region. Accurate fuel load estimation based on multi-sensor remote sensing data can facilitate proactive fire management strategies, thereby minimizing the impacts of wildfires on ecosystems, human settlements, and the environment.

Fueled by Data – impacts of data type on wildfire modeling outputs

T1.11 Forest Fires in Mountain Regions

Shelby Corning[1]
Andrey Krasovskiy[1], Florian Kraxner[1]
[1] Agriculture, Forestry, and Ecosystem Services (AFE) Group, Biodiversity and Natural Resources (BNR) Program, International Institute for Applied Systems Analysis (IIASA)

Abstract: Wildfire prediction models require the same base data to function: climate, fuel, topography, and in some cases population. Historically, data has been taken from the ground, but technological advancements in the field of remote sensing have led to more models being fueled purely by satellite-derived data. As the trend to use only satellite data grows, it is essential to understand how and if data source and type affect model outcomes. In this comparative study, we analyze and explore how two different data sources and types impact the modeling of wildfire probability and spread in Sardinia, Italy at a scale of $1km^2$. The wildFire cLimate impacts and Adaptation Model (FLAM), developed at the International Institute for Applied Systems Analysis (IIASA) for modeling wildfire dynamics, incorporates climate, population and biomass data, and human activities to model historic wildfires as well as predict future fire probability and spread under different climate and forest management scenarios. Using different data sources for the input components, we calibrate and validate FLAM to assess how and if model outputs of wildfire probability, frequencies, and burned area are significantly altered based on the input source. The impact of monthly vs yearly calibration is shown, alongside final model results from both datasets. Further, the influence of different population density scales is explored and discussed, especially in the context of mountainous and coastal regions, where high-density cities may be located next to vast low-to-no-population areas – emphasizing the necessity to consider how density variables are expressed and used in models. Our results will provide insight into how and if ground-based data is still necessary for wildfire models and in what contexts, which is essential to ensure reliable modeling and for accurate future projections under climate warming scenarios.

HOT SPOTS MONITORING OF PROTECTED AREAS IN PARAGUAY

T1.11 Forest Fires in Mountain Regions

Marcelo Orrabali[1]
Larissa Rejalaga[1]
[1] Universidad Nacional de Asunción

Abstract: The monitoring of active hot spots can become essential in the day to day because the biggest problems are found in the fires produced by third parties in protected areas, the objective of this work is to observe and monitor the way in which the active hot spots are presented and generate maps of national interest in the months of May and June with respect to them, the methodology consists of four steps; The methodology consists of four steps: "location of the study area" focusing on the protected areas which are distributed at the country level in the eastern and western region, which are divided into departments and the points of interest are expanded in each one of them; "pre process" which is performed by vectors that are downloaded from EarthData and then transported to a GIS to perform the corresponding analysis; "process" that goes from a geographic information system where the shapefiles of the border of Paraguay and the polygons of the respective protected areas are located to obtaining the data in a qualitative manner; This post-process helps us to obtain quantitative data through numbers generated within the same GIS where a comparative statistic is produced per day of all the protected areas to later send them to the PySinLlamas platform, As a result, the days with the highest number of fire outbreaks were May 24, 2022 with 24 hot spots and June 15 with 62 hot spots, giving us the tool to know the protected areas with the highest risk of fires, which are the Tinfunque National Park and the Mbaracayu National Forest Reserve. Once the statistics are generated, they are of great importance at a national level and help in decision making, remaining as a database within the aforementioned platform, leaving high level comparisons in risk management and decision making, where its potential use is freely accessible to all persons, entities, companies, etc. that wish to visit the aforementioned platform.

Hybrid Forest Fire Prediction Modelling by Transferring Human Domain Knowledge into Artificial Intelligence

T1.11 Forest Fires in Mountain Regions

Hyun-Woo Jo[1]
Andrey Krasovskiy[2], Florian Kraxner[2], Woo-Kyun Lee[1]
[1] Korea University, Department of Environmental Science and Ecological Engineering, South Korea
[2] International Institute for Applied Systems Analysis (IIASA), Agriculture, Forestry, and Ecosystem Services (AFE), Austria

Abstract: Due to the combination of increasing climate change-induced heat waves and densely forested areas adjacent to highly populated urban areas, the dynamics of forest fires in South Korea are influenced by a complex interplay of biophysical and anthropogenic factors, posing a significant challenge to response systems. In response to this challenge, various forest fire models have been developed, each with its own strengths and weaknesses: process-based model has high interpretability relying on human domain knowledge but requires substantial efforts for optimization, whereas the machine learning based model automatically identifies features but has limited interpretability. To exploit the strengths of both models, this study aimed to transfer human domain knowledge for interpreting forest fire dynamics into a machine learning process. The algorithms of IIASA's wildfire cLimate impacts and Adaptation Model (FLAM)—a processed-based model integrating biophysical and human impacts—was developed as a neural network, named FLAM-Net. The development of FLAM-Net included enhancing the backpropagation properties of the transferred algorithm to optimize it for the given environment, as well as introducing new algorithms for interpreting national-specific forest fire patterns of South Kora. The FLAM-Net was applied to multiple scales and were integrated through U-Net-based deep neural networks, named Deep Neural FLAM (DN-FLAM), to produce downscaled prediction. The study successfully optimized FLAM-Net for the forest fire dynamics of South Korea, which exhibited spatial concentration near metropolitan cities and the east coastal area, with temporal concentration in spring. Integration of the multi-scale features through DN-FLAM yielded the most optimal performance with Pearson's r values of 0.943, 0.840, and 0.641 for temporal, spatial, and spatio-temporal dimensions, respectively. Projecting future scenarios based on the Shared Socioeconomic Pathways (SSP) climate change scenarios revealed an increase in forest fires until 2050, with a more pronounced spatio-temporal concentration, followed by a decrease due to increased precipitation. This study highlights the advantages of combining process-based models and artificial intelligence as a hybrid model, such as FLAM-Net and DN-FLAM, in terms of interpretability, accuracy, and efficient optimization. These models provide scientific evidence for local-specific climate resilience strategies that can be expanded globally, thereby enhancing worldwide climate resilience with context-specific approaches.

Insolation drives ecosytem resilience after stand-replacing forest fires on South- and North-exposed slopes in a dry central-Alpine valley

T1.11 Forest Fires in Mountain Regions

Thomas Wohlgemuth[1]
Barbara Moser[1], Jürgen Dengler[2], Céline Gauye[3], Pascal Vittoz[4], Daniel Scherrer[1]

[4] Institut des dynamiques de la surface terrestre, University of Lausanne, Switzerland

Abstract: With ongoing climate change, the risk for extreme forest fires is projected to considerably increase. Beyond the foreseeable economic consequences of stand replacing fires for forestry, questions on the effects on ecosystem resilience regarding the recolonization of plant and animal species are of utmost interest. In mountain forests in densely populated regions such as the European Alps, post-fire tree regeneration is an important concern, particularly in protection forests. To answer questions of post-fire changes of vascular plant species composition and the speed of tree species regeneration, we monitored the revegetation process on two forest fire patches in the Alps (Valais, Switzerland: Leuk 2003 with 300 ha, from 850 to 2100 m asl; Visp 2011 with 160 ha, from 700 to 1500 m asl) that rank among the largest stand-replacing burns since 1900 in that region. The original forests consisted mainly of conifers, with *Pinus sylvestris* at low elevations and *Picea abies*, *Abies alba* and *Larix decidua* at higher elevations.

As an effect of the highly diverse forest and open land patchwork, plant species richness rapidly increased, with considerable amounts of ruderals, grassland and mountain species. In this early stage of succession that lasted 10 years, the average plot richness exceeded the one of ancestral forest plots by 30%.

Post-fire tree regeneration is dominated by pioneers (*Populus* spp., *Salix* spp., *Betula pendula*) that recolonized the burns rapidly and have since dominated the vegetation. Stem numbers 10 years post-fire strongly differ between south and north exposed slopes, with less than 1000 stems per hectare on the south-exposed site and more than 10’000 stems per hectare on the north-exposed slope. On the south-exposed slope, a trees species switch from *Pinus sylvestris* to *Quercus pubescens* can be observed.

The post-fire dynamics on the monitored burns are discussed in the light of diaspore dynamics and climate change.

Landscape-wide loss of threatened temperate Nothofagus forests in the costal range of central Chile: Synergism among fire, land use and climate change

T1.11 Forest Fires in Mountain Regions

Mauro Gonzalez[1, 2]
Mauricio Galleguillos[3], Javier Lopatin[3], Claudia Leal[4], Constanza Becerra-Rodas[4], Antonio Lara[2], Nicole Burger[4]

[3] Universidad Adolfo Ibañez, Facultad de Ingeniería y Ciencias, Santiago, Chile
[4] Universidad Austral de Chile, Graduate School, Faculty of Forest Sciences and Natural Resources, Valdivia, Chile

Abstract: Since 2010, forest fire activity has increased in south-central Chile due to climate change. We assessed the effects of fire severity, invasion by the exotic fire-prone *Pinus radiata*, and land-cover composition and configuration of the landscape on the resilience of fragments of *Nothofagus* forests (*N. glauca* and *N. alessandrii*) after a megafire in 2017. We used remote sensing data to estimate land-use classes and cover, fire severity and invasion cover of *P. radiata*. Following the megafire, over 80% of *Nothofagus* forests were moderately or severely burnt. Extreme wildfires favoured by intense drought, heat waves and widespread exotic pine plantations, increased the ability of fire-adapted invasive species to colonize *Nothofagus* forest remnants. The propagation and severity of fire was amplified by the exotic pines located along the edges of, or inside, the *Nothofagus* remnant forests and the highly flammable pine plantations surrounding these fragments. *Pinus radiata*, a fire-adapted pioneer species, showed strong post-fire recruitment within the *Nothofagus* fragments, especially those severely burnt, which reduce the resilience of these forests to fire. Positive feedback between climate change (i.e. droughts and heat waves), wildfires and pine invasions is driving *Nothofagus glauca* and *N. alessandrii* forests into an undesirable and probably irreversible state (i.e. a landscape trap). A large-scale restoration programme to design a diverse and less flammable landscape is needed to avoid the loss of these highly threatened forest ecosystems.

Modeling risks of climate-driven wildfires in protective forests in mountain areas: the FLAM approach

T1.11 Forest Fires in Mountain Regions

Andrey Krasovskiy[1]
Shelby Corning[1], Florian Kraxner[1]
[1] International Institute for Applied Systems Analysis (IIASA), Laxenburg, Austria

Abstract: Forest fires pose significant threats in various forests worldwide, with mountain areas becoming increasingly vulnerable. The unique characteristics of mountain regions, such as decreased suppression efficiency mainly due to difficult access and/or steep slopes and specific management requirements of protective forests contribute to their heightened susceptibility. Additionally, human activities in seeking recreation can serve as ignition sources, requiring specific consideration, particularly during periods of drought. This study introduces the wildFire cLimate impacts and Adaptation Model (FLAM) developed at the International Institute for Applied Systems Analysis (IIASA) for modeling wildfire dynamics. FLAM utilizes mechanistic algorithms to evaluate the influences of climate, human activities, and fuel availability on wildfire probabilities, frequencies, and burned areas, operating on a daily time step. The model undergoes validation using GIS and remote sensing data to ensure its accuracy and reliability. Future projections are conducted under different climate change scenarios at various scales and resolutions, focusing on protective forests in mountain areas. The presentation of modeling results encompasses fire-related factors specific to mountain regions, simulation of burned areas, adaptation options, and projections of burned areas until 2100. We identify unique factors that increase ignition probability or decrease suppression efficiency in mountainous regions, such as forest road location and density, fire management stations and supplies, and average response times. Our findings align with international analyses that climate change will likely escalate the frequency, size and impact of wildland fires in the mountains in the forthcoming decades, further highlighting the significance of safeguarding protective forests in mountain areas.

Modeling the interaction between bark beetle outbreaks and wildland fire behavior: new perspective for Italian forests affected by the storm Vaia

T1.11 Forest Fires in Mountain Regions

Luca Mauri[1]
Flavio Taccaliti[1], Emanuele Lingua[1]
[1] Department of Land, Environment, Agriculture and Forestry, University of Padova, Legnaro (PD), Italy

Abstract: Among the most common natural disturbances affecting Mediterranean mountain regions, forest fires, windstorms and bark beetle outbreaks jointly represent a relevant issue for European forests in geomorphological, ecological and social terms. In this regard, local stakeholders and authorities are nowadays facing critical circumstances, concerning the identification and implementation of efficient silvicultural management of forest stands affected by such issues. The storm Vaia occurred in 2018 in northeastern Italy, creating an unprecedented scenario for Italian Alps. Following the windthrow produced by the storm, bark beetles proliferated first on the downed logs, and later moved to the neighbour standing forest, modifying the quantity and availability of forest fuel. In this context, the development of remote sensing and photogrammetric techniques such as Light Detection and Ranging (LiDAR) and Unmanned Aerial Vehicle (UAV), as well as fire behaviour models, allow researchers to perform detailed terrain reconstruction and estimation of forest fuel, necessary to simulate fire behaviour over disturbed forested areas. Predicting key factors related to wildfire risk (e.g., fire type, rate of spread, flames length) is useful in estimating fire behaviour in windthrown areas affected by bark beetles outbreaks. At the same time models output reliability is principally limited by input data estimation, specifically concerning troubles in retrieving precise data such as fuel characteristics and fire behaviour fuel models in such disturbed areas. Therefore, new methods able to overcome these limitations in forest fire simulations are nowadays needed. The project RETURN aims to improve the implementation of fire behaviour modeling in forested areas affected by similar natural disturbances, enhancing spatial mapping of input layers for fire simulators in the Alpine region. In this research, the joint interaction between bark beetle outbreaks and wildland fire dynamics is investigated by coupling extensive field data collection and fire behaviour models with high-resolution LiDAR and UAV-based analysis. Results could enrich the information available for the local administration of the Alpine region to find effective interventions and management options for the areas affected by similar natural disturbances over time.

Modelling post-fire regeneration patterns under different restoration scenarios to improve forest recovery in degraded ecosystems

T1.11 Forest Fires in Mountain Regions

[2] University of Padova

Abstract: Changes in disturbance regimes triggered by land-use and climate change can significantly alter forest ecosystems by modifying the distribution of some species and hindering post-disturbance regeneration dynamics. Applied nucleation (AN) can be a valuable active restoration approach for promoting natural regeneration in forest ecosystems affected by extreme disturbance events since it improves seed availability and microsite conditions. Still, AN has been mostly applied in tropical forests, but it has the potential to be applied in Mediterranean mountain forests given the increase in extreme disturbance events in the area. The research aimed to investigate the potential outcomes of a set of AN scenarios in a mountain forest ecosystem of the Northwestern Italian Alps dominated by Scots pine. The area was affected by a large stand-replacing wildfire in 2005 and post-fire salvage logging operations that increased ecosystem degradation and dampened natural regeneration. We assessed the main drivers affecting post-fire natural recovery and identified suitable sites for regeneration through a machine learning correlative model (Bayesian Additive Regression Tree, BART), using the occurrence of natural regeneration as the response variable and several environmental variables as predictors. We predicted the probability of regeneration presence across the landscape under the current situation and a set of AN scenarios characterized by an increase in *nuclei* density, since distance from seed trees emerged as the most important driver for natural regeneration. These predictions made it possible to assess the most efficient active management scenario in terms of regeneration processes. The simulations showed the positive effects of AN and the importance of site selection for tree planting, proving that AN is a promising post-fire management technique for facilitating natural regeneration while minimizing human interventions and their associated economic and ecological costs. To our knowledge, this work is the first AN simulation in temperate mountain ecosystems. The selection of suitable sites can be further improved by identifying favourable microsites at a fine scale through field experiments and cross-scale integration.

Settlers in the aftermath: early regeneration in burnt artificial Pinus nigra forests through an altitudinal and latitudinal gradient

T1.11 Forest Fires in Mountain Regions

[4] University of Ljubljana, Biotechnical Faculty, Department of Forestry and Renewable Forest Resources

Abstract: Forest fires appear as a destructive phenomenon, consuming years of vegetation growth in a little timespan. In addition, forest fires change the environmental conditions for years to come, sometimes permanently. On the other hand, fire has been present in some biomes for ages, and it will be surely a natural disturbance of tomorrow forests.
Scientific knowledge has accumulated on forest fires and post-fire forest dynamics, but it is still difficult to predict what will happen to a burnt forest, especially today and in Europe: climate change is shifting the ground regarding forests dynamics, and information on long term post-fire forest dynamics are scant in Europe, due to the strong and long-lasting anthropic footprint. Increasing our understanding of post-fire forest dynamics is a first step to reduce disruptions in the provision of forest ecosystem services.
The simplest way to study post-fire forest dynamics is to sample post-disturbance natural regeneration. Especially where fire burns with high severity (primary succession) species that arrive first will probably impose the forest composition for the next decades. Information on this dynamic is particularly relevant for artificial secondary forests, because little or no record may be available regarding their response to forest fires.
In our study, post-fire natural regeneration was sampled in three artificial *Pinus nigra* J.F.Arnold forests burnt with high severity in 2012, 2017, and 2022, respectively. This species was extensively used for afforestation in Southern Europe, and nowadays black pine forests show similar dynamics and a high proneness to fires across all its areal. The three forests differ in altitude, latitude and climate, but have common traits, such as bedrock type, natural regeneration species and potential natural forest composition (nearby stands).
Results show a clear transition from pine to broadleaves forests after fire, mainly due to resprouting. Black pine regeneration is present, but only where severity is low. Common trends across sites hint that general indications may be drawn, although the main intended contribution of our study is to propose an approach to study post-fire forest dynamics in areas with relatively short records of forest fires, such as artificial conifer forests in European mountains.

THE EXIGENCIES OF FOREST FIRE: EXPLORING THE ECOLOGICAL AND SOCIAL IMPACTS OF FOREST FIRES IN THE MAJESTIC HIMALAYAS

T1.11 Forest Fires in Mountain Regions

Aditi Mishra[1, 2, 3]

[1] Aditi Mishra, Govind Ballabh Pant National Institute of Himalayan Environment, Almora, India

[2] K.C. Sekar, Govind Ballabh Pant National Institute of Himalayan Environment, Garhwal Regional Centre, India

[3] Harshit Pant Jugran, Govind Ballabh Pant National Institute of Himalayan Environment, Almora, India

Abstract: The Himalayas harbour a remarkable diversity of vegetation, ranging from tropical dry deciduous forests in the foothills to alpine meadows above the timberline. With their vast natural resources and unique geographic features, Himalayas sustain local communities in numerous ways, ensuring their livelihood, well-being and holistic development. The Himalayas being economically less explored and being the most densely populated mountain ecosystem, are highly vulnerable to environmental changes. Forest fires are a devastating disaster in the Himalayas posing significant challenges to the biodiversity and local communities. Fire is widely recognized as a significant factor contributing to forest degradation in India. As a result of the ongoing global climate crisis, forest fire regimes have been constantly changing in the Himalayas and have become a phenomenon of regular occurrence, posing threats to community's resilience and well-being.

This study is conducted in Almora district of Uttarakhand, a Himalayan state. Overall, 22.27% of the forest cover in India is prone to forest fire while in Uttarakhand. A total of 54801 ha forest area has been burnt between January 2000 and April 2023 due to forest fires as per Forest Survey of India (FSI). In this study, the evaluation of forest fire is carried out by examining factors including Elevation, NDVI using ArcGIS and QGIS software. Further analysis of the potential impacts of forest fire on vegetation and its soil has been carried out using primary data collection through the quadrat method and phytosociological study of the fire-affected forest patch.

Additionally, this study also measured the social impacts on community livelihood and well-being. By combining field observations, data analysis, and community feedback, this research provides valuable insights into the ecological and social implications of forest fires in Uttarakhand. The findings from this study can be useful for decision-making for targeted interventions and developing management strategies to mitigate the detrimental effects of forest fires, preserve biodiversity, and safeguard the well-being of the affected mountain communities. It is expected that insights gained will contribute to a more sustainable and resilient approach to forest fire management in Uttarakhand and at the national level.

Keywords: Forest Fire, Himalayas, Community perception, livelihood.

Unravelling the local dynamics of increasing fires in community forests of mid-hills Nepal

T1.11 Forest Fires in Mountain Regions

Sarada Tiwari[1]
Naya Sharma Paudel[1], Jocelyne Sze[2], Rahul Karki[1]
[1] ForestAction Nepal
[2] University of Sheffield, Sheffield, UK

Abstract: Forest fire is a global phenomenon and is having unprecedented impacts across continents. Nepal is not an exception to the increasing impacts, where hundreds of acres of forests is lost, or damaged, to forest fire. The severity of forest fire is on the rise in recent decades, wherein community forests have witnessed effects of the calamity over the recent years. This paper investigates the local factors behind the increasing frequency and severity of forest fires in mid-hills of Nepal. The paper draws on three separate cases from the research sites, involving five years of 'Enhancing Livelihoods from Improved Forest Management in Nepal (EnLiFT2)' project's team observations in Bhumlu rural municipality and Chautara Sangachokgadhi municipality of Kavrepalanchok and Sindhupalchok district respectively. This is complemented by informant interviews taken with 25 individuals. The paper primarily examines forest-people-fire relationship to demonstrate the weakening collective actions among the community forest user groups (CFUGs) as an important factor for increasing forest fires in the mid-hills of Nepal. We found the changing forest-people relationship, weakening CFUG governance, and increasing regulatory impositions as important factors driving the alienation of users from the forest thus, undermining collective action in forest management. We argue that strengthening collective action on better forest management to prevent forest fire is crucial over adopting mitigation techniques. The alienation of forest user groups from their forest in the changing socio-economic and forest management context can be addressed to strengthening the collective action for better forest management and ultimately to forest fire prevention and management.

Keywords: Collective actions, forest fire, forest management, forest-people-fire relationship

Vertical characterization of vegetation stratas in a mountainous region with Atlantic climate for incorporation into a fire-risk decision-making tool.

T1.11 Forest Fires in Mountain Regions

SANDRA SÁNCHEZ-GARCÍA[1]
ELENA CANGA[2], **Covadonga Prendes**[2]
[1] Technological and Business Pole of the Biomass of Asturias (PTEBi). El Lugarín, Ujo. Mieres, Asturias. Spain.
[2] Fundación CETEMAS (Forestry and Wood Technology Research Center), Spain

Abstract: The determination of the vertical structure of the forest is key for various issues such as the maintenance of biodiversity and the determination of fire risk due to vertical fuel continuity. The accurate description of fuel properties is thus critical to improving fire danger assessment and fire behavior modeling. In this sense, the ability of airborne LiDAR (Light Detection And Ranging) sensor to penetrate the tree canopy makes this technology suitable for analyzing this variable.

This study analyzed the capacity of low-resolution LiDAR data in the vertical characterization of the different vegetation strata, selecting the LiDAR metrics, or combination of metrics, that best represent the vegetation stratification for the development of regional mapping. With the aim of mapping the characterization of forest fuel maps at the regional level (pixel size of 25 meters), the metrics selected were included in an algorithm able to automatically generate the number of strata per pixel and the relationship of this with vertical continuity as well as with other variables that describe existing forest fuels, such as height and coverage of tree- and shrub strata, fuel type and topographic variables such as slope.

The results were evaluated under several scenarios according to the type of vegetation involved, with the intention of guiding its application in fire prevention and extinction tasks. Automation, scaling, updating, and dissemination of the results were built in a open source programming language and through the construction of an open data medium that can be consulted and/or exploited through an entity's own Spatial Data Infrastructure (IDE). This provides a channel to facilitate the management of spatial data, metadata and visualization services in accordance with the European INSPIRE Directive and the OGC (Open Geospatial Consortium).

Wildfire Hot Spot Mapping in the Alps - Austria Fire Futures

T1.11 Forest Fires in Mountain Regions

Florian Kraxner[1]
Andrey Krasovskiy[1], Shelby Corning[1], Dmitry Shchepashchenko[1], Anatoly Shvidenko[1], Harald Vacik[2], Mathias Neumann[2], Mortimer Mueller[2], Arne Arnberger[2], Herbert Formayer[2], Tobias Schadauer[3], Susanne Karel[3], Christoph Bauerhansl[3]
[1] International Institute for Applied Systems Analysis (IIASA); Agriculture, Forestry, and Ecosystem Services (AFE)
[2] BOKU University, Vienna
[3] Bundesforschungszentrum fuer Wald, Vienna, Austria

Abstract: The main objective of the Austria Fire Futures study is to develop a unique and innovative concept containing new sets of fire risk hotspot maps at highest spatial resolution under various climate change scenarios and integrate novel insights on local fuel types into forest and forest fire risk models, including new mountain-specific variables such as morphology and recreational activities. To generate such maps on a local scale, fire hazard modeling is necessary to identify endangered forest types in combination with topographic effects. Furthermore, recent fire events in the Austrian Alps show that social aspects, particularly the hiking tourism, are paid too little attention to.
Based on the above motivation, we believe that an innovative and improved fire risk hotspot mapping is the fundament for all further forest- and wildfire prevention and hence needs to be seen as an indispensable tool for an integrated fire management (prevention, suppression, post fire measures) while substantially contributing to mitigating climate change as well as minimizing damage to ecosystems, their services, and people.
The study will improve our understanding of fire-vulnerable forest areas in the Alpine Space that may shift over time and space given the underlying climate and fuel assumptions. This will allow experts, practitioners, and the interested public to take a look into the future in order to comprehend and derive solid short-/medium-/and long-term recommendations for fire resilient and sustainable forest management and fire emergency planning.

T1.12 Forest genetics tools to improve forest resilience to climate change and forest health

A Decade of European Ash Breeding: Advancements in Resistance against Ash Dieback

T1.12 Forest genetics tools to improve forest resilience to climate change and forest health

Mateusz Liziniewicz[1]
Beatrice Tolio[1, 2], Michelle Cleary[2]
[1] Skogforsk, Ekebo 2250, 268 95 Svalöv, Sweden
[2] Swedish University of Agricultural Sciences, Southern Swedish Forest Research Centre, Alnarp, Sweden

Abstract: European ash (*Fraxinus excelsior*) populations across Europe are facing a significant threat from the invasive fungal pathogen *Hymenoscyphus fraxineus*, causing ash dieback and resulting in the extensive decline of ash forests. The consequent reduction in the ash population has led to habitat degradation for numerous organisms relying on ash substrates.

Conventional breeding for resistance has been considered as a counter measure to develop a more resistant ash population that will be ready to use in operational forestry and for the restoration of ash habitats. In Sweden, the first attempts to establish a new resistant breeding population was initiated in 2013. The high genotypic variation in resistance was shown in clonal seed orchards that were established before the first report of disease in Sweden selected on the basis of growth and quality traits. The number of clones showing high resistance was around 10 out of 106 tested.

However, this limited number of resistant clones fails to ensure sufficient genetic diversity within the population. Consequently, four new trials were conducted between 2016 and 2022, involving over 200 additional clones. These new clones were derived from trees classified as resistant in the field, sourced from remaining ash stands, ash alleys, and parks. The trials were annually monitored to assess resistance against ash dieback.

Additionally, a parallel approach involved propagating numerous progenies from the most promising female trees identified after six years of seed-orchard monitoring. These progenies were planted in seven trials, implementing a "strong forward selection" strategy. The objective was to leverage the high within-family variation and select resistant genotypes within each tested family.

Here, we present the results of quantitative genetic analysis and provides a descriptive overview of the experiments. The findings demonstrate the feasibility of obtaining resistant ash populations in Sweden, highlighting advancements in breeding for ash dieback resistance.

A Multi-omics Approach to Study Disease Resistance in North American Pines

T1.12 Forest genetics tools to improve forest resilience to climate change and forest health

Amanda De La Torre[1]
Laura Figueroa Corona[1], Jill Wegrzyn[2], Richard Sniezko[3], Aleksey Zimin[4]
[1] Northern Arizona University, Flagstaff, Arizona, USA
[2] University of Connecticut, Storrs, Connecticut, USA
[3] US Forest Service, Cottage Grove, Oregon, USA
[4] Johns Hopkins University, Baltimore, Maryland, USA

Abstract: White pine blister rust caused by the fungal pathogen *Cronartium ribicola* is a devastating disease affecting all five-needle (*Strobus*) pines in North America. Warming climates bring significant challenges to the management, breeding, and conservation of these economically and ecologically important pine species. In this study, we use a multi-omics approach that includes genomics (Whole-genome re-sequencing, GWAS), transcriptomics (differential expression at 3 infection times), and epigenomics (differentially methylated sites at 2 infection times) to understand the processes and mechanisms of disease resistance and how to ensure health resilience under climate change. In addition, we have developed several resources for public use such as a *de novo* transcriptome, a high-density linkage map and a new, chromosome-scale 32-Gigabase genome assembly for sugar pine (*Pinus lambertiana*).

Adapting Abies pinsapo to Climate Change: Forest Genomics as a Key to Resilience and Restoration

T1.12 Forest genetics tools to improve forest resilience to climate change and forest health

Irene Victoria Blanca-Reyes[1]
Concepción Ávila[1], Victor Lechuga[2], Jose Antonio Carreira[2], Francisco M. Cánovas[1], **Vanessa Castro-Rodriguez**[1]
[1] University of Malaga, Department of Molecular Biology and Biochemistry, Spain
[2] University of Jaen, Department of Animal Biology and Vegetal Biology and Ecology, Spain

Abstract: Forest ecosystems are vital for carbon fixation, biodiversity preservation, and economic value, making their resilience to climate change crucial. However, the increasing threats from pathogens, pests, and environmental disturbances pose significant challenges to forest health. *Abies pinsapo*, commonly known as Spanish fir, is a relict species with a limited distribution in the southern mountains of the Iberian Peninsula. This species plays a critical ecological role, providing habitat for numerous plant and animal species and contributing to the maintenance of biodiversity. Additionally, *Abies pinsapo* forests are essential for ecosystem services, including soil erosion prevention, water regulation, and carbon sequestration. The conservation and sustainable management of this species are of paramount importance to maintain the ecological balance and functioning of these forest ecosystems. This species is highly susceptible to climate-driven changes, including rising temperatures, droughts, and pathogen attacks. Trying to mitigate these threats and ensure the long-term survival of *Abies pinsapo*, an integrative and interdisciplinary approach is underway including molecular and ecophysiological strategies.

The main objective of our project is to gain a comprehensive understanding of the adaptive capacity of *Abies pinsapo* and develop strategies to enhance its resilience to biotic and abiotic stresses. Through the use of state-of-the-art molecular and genomic techniques, we aim to unravel the molecular basis of key adaptive traits and identify potential targets for genetic engineering and breeding programs. The anticipated outcomes of this research project include the generation of valuable genomic resources, the identification of genetic markers associated with stress tolerance, and the development of molecular tools for selective breeding and assisted migration programs. These advancements will contribute to the conservation and sustainable management of *Abies pinsapo* forests, as well as provide valuable insights into the adaptation mechanisms of other coniferous species facing climate-related challenges. We aim to unlock the adaptive potential of *Abies pinsapo* and pave the way for innovative strategies in forest management and conservation.

Advanced tools for optimizing the selection and deployment of genetically improved loblolly pine resistant to fusiform rust

T1.12 Forest genetics tools to improve forest resilience to climate change and forest health

Abstract: Fusiform rust, caused by *Cronartium quercuum* f. sp. *fusiforme*, is one of the most damaging fungal diseases of loblolly pine (*Pinus taeda*) and the leading cause of product loss for timber growers in the southeastern United States. The most effective management strategy against fusiform rust is the use of host genetic resistance, which requires an integrated approach that involves both breeding resistant families of loblolly pine and the identification of high-risk areas where the use of improved families is justified and ultimately convenient. And while this approach has been successfully deployed in the last decades, there is still room for optimization, especially now that new cost-effective technologies and improved computational approaches are available. The classification of phenotypes in resistance breeding programs, for instance, currently relies upon the visual detection of symptoms, which is lengthy, prone to human error, and dependent on local disease pressure, which might vary in different years. To optimize the selection process, we developed an approach that combines near-infrared (NIR) spectroscopy with multivariate statistics to identify chemical patterns associated with resistance phenotypes. Using machine learning, we trained our algorithm on spectra collected from 35 families with a handheld device and achieved predictive models that can correctly classify highly resistant or susceptible trees with up to 78% accuracy. To optimize deployment, we improved the current fusiform rust hazard maps by incorporating the effects of both the host genetics and environmental factors on disease incidence. Using data collected over multiple years and progeny tests across the region, we first used a Least Absolute Shrinkage and Selection Operator (LASSO) regression to identify relevant predictor variables and then modeled them using Generalized Additive Models (GAMs) for a non-improved and an improved genetic line of loblolly pine. Finally, we spatially interpolated the disease risk for both families and were able to explain up to 89.2% and 94.3% of the deviance for the non-improved and improved lines, respectively. In summary, by using innovative technological and computational tools, we optimized both the selection and deployment of genetically improved loblolly pine families and hence provided advanced solutions to the management of fusiform rust.

Ash in Distress: results from a large experimental field trial on ash dieback in Austria

T1.12 Forest genetics tools to improve forest resilience to climate change and forest health

Abstract: Common ash (*Fraxinus excelsior*) is a highly valuable broadleaved species, whose survival is threatened by the alien invasive ash dieback pathogen *Hymenoscyphus fraxineus*. Studies have provided evidence that ash dieback tolerance has a polygenic basis and identified tolerance-associated genetic loci (Stocks et al., 2019). Here, we report on one of the largest field trials to date aimed at identifying and characterizing ash dieback tolerant genotypes, while capturing the genetic diversity of common ash in Austria. The overall goal of the project "Ash in Distress" is the selection of highly disease-tolerant clones and in consequence the establishment of seed orchards to provide forest owners with improved reproductive material. In detail, seeds were collected from 715 disease-tolerant female trees in 2015 and 2017, resulting in more than 35,000 progeny raised in a community garden. Disease incidence and severity was assessed on all seedlings for three consecutive years. Eventually, approximately 20% of the offspring evaluated remained disease free, providing a broad base for further selection. We observed that susceptibility in juveniles can strongly increase during the first three years following germination, whereas trees showing no disease symptoms towards the end of the third vegetation period are likely to remain symptomless or become only slightly damaged over the following years. Genotype-tolerance association analyses were carried out on over 1,000 individual trees, including a susceptible and a putative tolerant progeny of tolerant mothers, using the 4TREE array (Guilbaud et al., in prep) targeting 13,407 single nucleotide polymorphisms (SNPs). Overall, our genotype-tolerance association analyses did not reveal any candidate loci that could be used for future genotype-informed breeding. Nevertheless, the array is proving to be a powerful tool for studying genetic structure and detecting introgression from closely related species, as well as exploring associations with environmental variables and other traits of interest.

Aspen mosaic-associated virus populations of Populus tremula in Finland and Sweden

T1.12 Forest genetics tools to improve forest resilience to climate change and forest health

Abstract: A new *Emaravirus*, aspen mosaic-associated virus (AsMaV), was identified as the causal agent of the mosaic disease in *Populus tremula*. The genome of AsMaV consists of five negative-sense single-stranded RNA (-ssRNA) molecules. The RNA1 (7.1 kb) encodes for the viral RNA-dependent RNA polymerase (RdRP, 268.2 kDa), RNA2 (2.3 kb), RNA3 (1.6 kb), RNA4 (1.6kb) and RNA5 (1.3kb) encode for the glycoprotein precursor (GPP, 73.5 kDa), viral nucleocapsid protein (N, 35.6 kDa), a putative movement protein (MP, 41.0 kDa) and a protein of unknown function (P28, 28.1 kDa), respectively. Different regions of the virus genome were used to investigate genetic diversity and population genetic parameters. To do this, full-length AsMaV-RNA3, -RNA4, and partial -RNA1 were amplified via RT-PCR with specific primer pairs. Subsequently, the amplicons were investigated by RT-PCR-RFLP and selected variants were subjected to sequencing. The results showed that AsMaV has a conserved genome, however, Finland isolates and Sweden isolates are belonging to different phylogenic groups and probably belong to different populations. RT-PCR-RFLP developed in this study, could detect the locations with the highest number of haplotypes.

Association Mapping in Forestry Tree Crops: Scope, Feasibility Test & Conditions and Models

T1.12 Forest genetics tools to improve forest resilience to climate change and forest health
